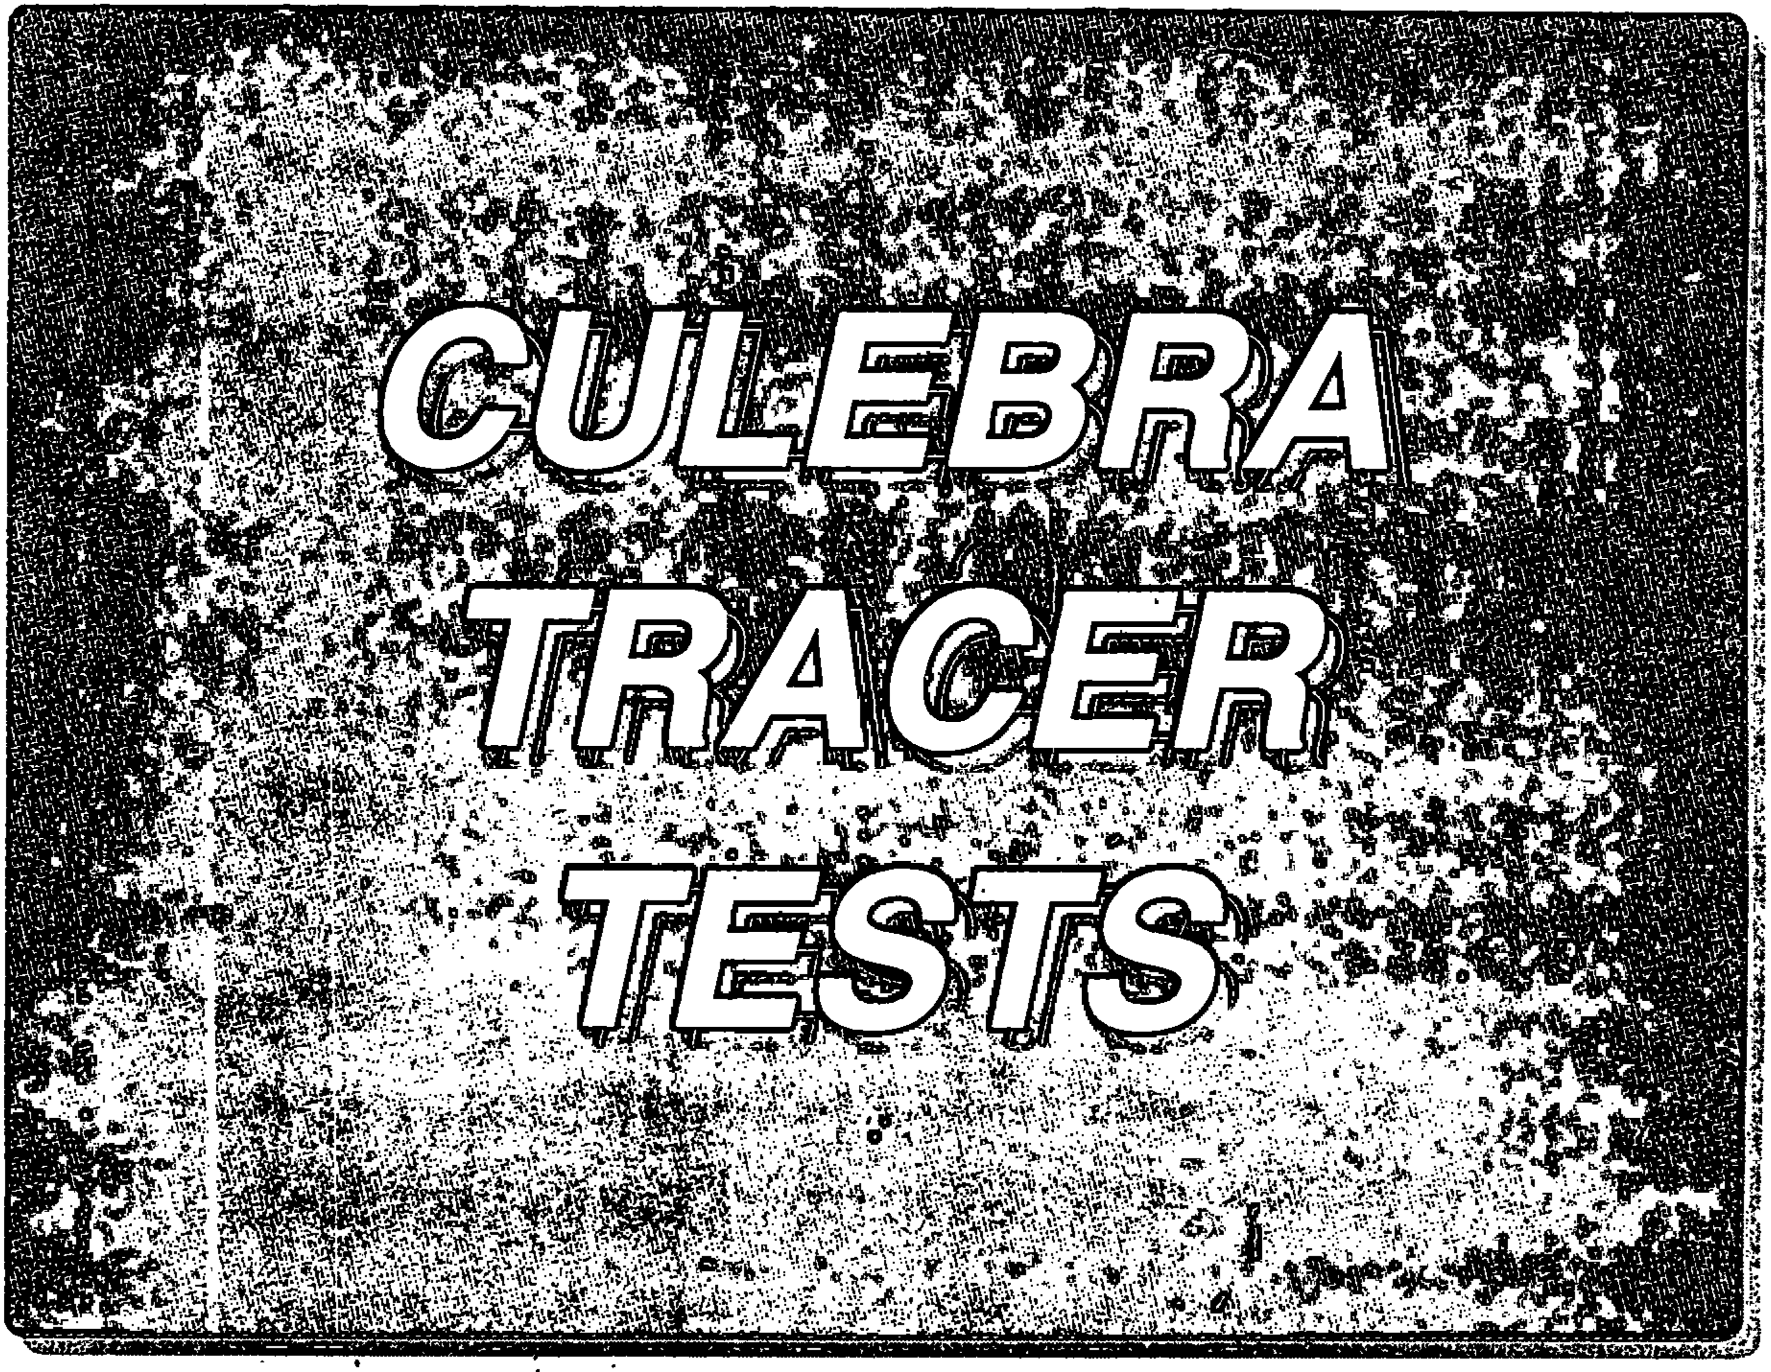
CULEBRA TRACER TESTS



Objectives of Tracer Tests

- Descriminate between conceptual models of flow and transport in the Culebra (e.g. single-porosity (fracture-only) vs. double-porosity).
- Evaluate the effects of heterogeneity, anisotropy, scale and possibly layering on transport.
- Provide quantitative parameter estimates.
- Evaluate the slug method of tracer injection (comparison to passive-injection).

Brief Outline of Tracer Test Plans

- Drilling of wells at new 7-well hydropad (H-19)
- Logging and hydraulic testing of wells.
- Single-well tracer test in central well.
- Multi-well tracer test (non-sorbing tracers).

Summary of Physical Transport Issues for Performance Assessment Compliance Calculations (Part 1 of 2)

- Transport Conceptual Model:
  - Fracture-only transport (no physical or chemical retardation) effectively eliminates the Culebra as a barrier to radionuclide transport to the accessible environment.
  - Double-porosity transport (i.e. matrix diffusion) has the capacity for significant physical retardation of radionuclide transport (one to several orders of magnitude shift of the CCDF).
  - Matrix diffusion in double-porosity transport significantly reduces uncertainty in the availability of sorption sites for chemical retardation; chemical retardation in the matrix has the capacity for another several orders of magnitude shift of the CCDF.

Summary of Physical Transport Issues for Performance Assessment Compliance Calculations (Part 2 of 2)

- **Parameter Uncertainty in the Double-Porosity Model:**
  - Both deterministic and stochastic parameter uncertainty analyses indicate that the physical transport parameter fracture spacing (matrix block size) has a very large impact on double-porosity transport.
  - Fracture spacing interpreted from existing tracer tests indicate values ranging from 0.06 to 1.2 meters; wider range (up to 8 meters) in current PA parameter distribution reflects convergent flow tracer test uncertainties due to questions about tracer injection technique and incomplete constraint on flow geometry.
  - 1992 Performance Assessment calculations indicate that the combined impact of fracture spacing less than approximately 1 meter and matrix chemical retardation results in ***no significant release*** through the Culebra (i.e. the Culebra is effectively a complete barrier to significant radionuclide transport).

Plans for Upcoming Conservative Tracer Tests

1) Complete pumping well and three tracer-injection wells 120° apart and 15 m from pumping well at new location (H-19 hydropad)

2) After each of the wells is completed, perform short pumping test, fluid logging, and televiewer and/or video logging to gain preliminary information on conductive features and hydraulic properties.

3) After all four wells are completed, perform a preliminary convergent-flow tracer test to identify which of the three tested flow paths provides the fastest transport.

4) Based on the preliminary tracer test results and hydraulic interpretation of anisotropy, locate last three wells diametrically opposed to first three tracer-injection wells, at greatest distances feasible for obtaining interpretable breakthrough curves.

5) Perform cross-hole, multi-layer hydraulic tests among all wells to characterize fracture interconnections.

6) Inject three slugs of tracer into central well for single-well test, pause overnight.

7) Begin pumping central well at low rate, recovering tracers and creating converging flow field.

8) After ~ steady-state gradients have been established, inject tracers in three 15-m wells, using two different tracer-injection techniques.

9) After breakthrough curves are defined, double pumping rate.

10) Inject tracers in all six wells, using two different tracer-injection techniques and, in some cases, tracers with different free-water diffusion coefficients.

Methods to Demonstrate and Evaluate the Magnitude of Diffusion into the Matrix

- Single-well tracer test.
- Double pumping rate (evaluate effects for 3 different flow paths).
- Use tracers with different free-water diffusion coefficients (for most wells inject benzoic acids, one well also inject deuterium and bromide).
- Possible continuous passive-'injection' of helium and neon (for a close well).

Non-Sorbing Tracer Tests - Phase I Single-Well Tests

- **Objectives:**
  - Focus on conceptual model differentiation between fracture-only transport (with channeling) and double-porosity (with matrix diffusion).
  - The strength of this test is its ability to focus on transport mechanism by elimination flow geometry factors; the limitation of this test is that it does not provide the flow geometry information required for quantification of key transport parameters (i.e. fracture spacing).
  - A technical challenge is elimination regional flow (drift) effects that could mask the difference between fracture-only channeling and matrix diffusion under double-porosity conditions.

- **Procedure:**
  - Inject three 250-gallon slugs, each containing a different tracer
  - Pause 16 hours to allow matrix diffusion to occur
  - Pump for 2-3 weeks, monitoring tracer recovery
  - Compare tracer-recovery curves to predication made using double-porosity models and fracture-only (channeling) models

Non-Sorbing Tracer Tests - Phase II Multi-Well Test (Part 1 of 2)

- Objectives:
  - ⇨ Focus on well constrained quantification of physical-transport parameter values to reduce parameter uncertainty.
  - ⇨ Provides additional information on uniqueness of transport conceptual model.
  - ⇨ Strength of this test is its thorough characterization of flow geometry and elimination of tracer injection uncertainty.
  - ⇨ This test will allow rigorous interpretation of fracture spacing and other key physical-transport parameters; will also provide basis for evaluation of previous tracer tests.

Non-Sorbing Tracer Tests - Phase II Multi-Well Test (Part 2 of 2)

- **Procedure:**
  - Establish new 7-well test location (H-19) along expected flow path to site boundary.
  - Define permeable layers within Culebra (fluid density logging) and correlate these layers/fractures among wells (to aid definition of flow geometry).
  - Performance cross-hole hydraulic tests to identify any relatively high permeability connections.
  - Perform convergent-flow tracer test by pumping central well and injecting conservative tracers at the three 50 foot wells.
  - After breakthrough, increase pumping rate and inject different tracers in all six surrounding wells.
  - Test passive versus slug tracer injection techniques.
  - Apply different modeling approaches to test conceptual models and perform quantitative interpretation of transport parameters.

GROUND WATER BUREAU

Mr. Client Marshall, Geologist III
New Mexico Environment Department
Ground Water Bureau
P. O. Box 26110
1190 St. Francis Drive
Santa Fe, New Mexico 87502

Subject: REQUEST FOR CONCURRENCE THAT A DISCHARGE PLAN IS NOT REQUIRED FOR THE WASTE ISOLATION PILOT PLANT CULEBRA TRACER INJECTION TEST PROGRAM - ADDITIONAL POTENTIAL TRACER CHEMICALS

Dear Mr. Marshall:

The U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) is requesting written concurrence that a Part 3-100 Discharge Plan will not be required for the proposed Culebra Transport Test Programs under development by Sandia National Laboratories at the Waste Isolation Pilot Plant (WIPP). The Culebra Transport Test Program is designed to collect additional hydrogeologic characterization data from the Culebra, and perhaps Rustler formation, to test hydrological models for the WIPP Performance Assessment.

To accomplish this, Sandia National Laboratories proposed to establish up to 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Most of the new test wells will be located on the new H-19 hydropad. Three existing wells in the vicinity of the H-19 hydropad and several new wells strategically located around H-19 will be used to monitor pressure responses associated with the hydrologic tracer tests being conducted at the H-19 hydropad.

The DOE-CAO believes that this project should be exempted from the discharge plan requirements because the existing concentration of ground water in adjacent wells exceeds 10,000 mg/l Total Dissolved Solids (TDS). Additionally, none of the proposed tracer chemicals are listed in the New Mexico Water Quality Control Regulations, Part 1-101(UU), *Toxic Pollutants*, or Part 3-103, *Standards for Ground Water of 10,000 mg/l TDS Concentration or Less*.

A list of additional potential tracer chemicals and Material Safety Data Sheets (MSDS) are attached to support our request for concurrence that a Discharge Plan is not required for the Tracer Test project.

If you have any questions about this proposed project or require any additional information, please contact Mr. J. R. Hollen at (505) 234-8271.

Sincerely,

L. R. Fitch, Manager
Environment, Safety, Health and Regulatory Compliance

SECTION 2 COMPOSITION/INFORMATION ON INGREDIENTS

COMPONENT : SODIUM HYDROXIDE
CAS NUMBER: 1310-73-2
PERCENTAGE: 100

OTHER CONTAMINANTS: NONE

SECTION 3 HAZARDS IDENTIFICATION

CERCLA RATINGS (SCALE 0-3): HEALTH=3 FIRE=0 REACTIVITY=1 PERSISTENCE=0
NFPA RATINGS (SCALE 0-4): HEALTH=3 FIRE=0 REACTIVITY=1

EMERGENCY OVERVIEW:
Odorless, white or off-white hygroscopic solid.
Harmful if swallowed. Causes severe burns to mucous membranes. Causes respiratory tract, skin and eye burns. May cause blindness. May affect the heart. May damage the lungs. May react with water.
Do not breathe dust. Do not get in eyes, on skin, or on clothing. Do not allow water to get in container. Keep container tightly closed. Wash thoroughly after handling. Use only with adequate ventilation. Handle with caution.

POTENTIAL HEALTH EFFECTS:
INHALATION:
SHORT TERM EFFECTS: May cause irritation, possibly severe. Additional effects may include coughing, difficulty breathing, lung damage and shock.
LONG TERM EFFECTS: May cause effects as in short term exposure. Additional effects may include sores, diarrhea, nervousness and lung effects.
SKIN CONTACT:
SHORT TERM EFFECTS: May cause burns. Additional effects may include sores.
LONG TERM EFFECTS: Same effects as short term exposure.
EYE CONTACT:
SHORT TERM EFFECTS: May cause burns. Additional effects may include sores and blindness.
LONG TERM EFFECTS: Same effects as short term exposure.
INGESTION:
SHORT TERM EFFECTS: May cause burns. Additional effects may include paleness, diarrhea, stomach pain, bloody vomit, blood in the stool, suffocation, shock, coma and heart failure.
LONG TERM EFFECTS: Same effects as short term exposure.

CARCINOGEN STATUS:
OSHA: N
NTP: N
IARC: N

SECTION 4 FIRST AID MEASURES

INHALATION:
FIRST AID- Remove from exposure area to fresh air immediately. If breathing has stopped, give artificial respiration. Maintain airway and blood pressure and administer oxygen if available. Keep affected person warm and at rest. Treat symptomatically and supportively. Administration of oxygen should be performed by qualified personnel. Get medical attention immediately.

SKIN CONTACT:
FIRST AID- Remove contaminated clothing and shoes immediately. Wash affected area with soap or mild detergent and large amounts of water until no evidence of chemical remains (at least 15-20 minutes). In case of chemical burns, cover area with sterile, dry dressing. Bandage securely, but not too tightly. Get medical attention immediately.

EYE CONTACT:
FIRST AID- Wash eyes immediately with large amounts of water, occasionally lifting upper and lower lids, until no evidence of chemical remains (at least 15-20 minutes). Continue irrigating with normal saline until the pH has returned to normal (30-60 minutes). Cover with sterile bandages. Get medical attention immediately.

INGESTION:
FIRST AID- Do not use gastric lavage or emesis. Dilute the alkali by giving Water or milk to drink immediately and allowing vomiting to occur. As soon as possible, have qualified medical personnel do esophagoscopy and

irrigate injured areas with 1% acetic acid until the alkali is completely neutralized. (Dreisbach, Handbook of Poisoning, 11th Edition). Get medical attention immediately.

NOTE TO PHYSICIAN
ANTIDOTE:
No specific antidote. Treat symptomatically and supportively.

SECTION 5 FIRE FIGHTING MEASURES

FIRE AND EXPLOSION HAZARD:
Negligible fire hazard when exposed to heat or flame.

EXTINGUISHING MEDIA:
Dry chemical, carbon dioxide, water spray or regular foam (1990 Emergency Response Guidebook, DOT P 5800.5).

For larger fires, use water spray, fog or regular foam (1990 Emergency Response Guidebook, DOT P 5800.5).

FIREFIGHTING:
Move container from fire area if you can do it without risk. Apply cooling water to sides of containers that are exposed to flames until well after fire is out. Stay away from ends of tanks (1990 Emergency Response Guidebook, DOT P 5800.5, Guide Page 60).

Use agent suitable for type of fire. Use water in flooding quantities as fog. Apply water from as far a distance as possible.

HAZARDOUS COMBUSTION PRODUCTS:
Thermal decomposition may release toxic fumes of sodium oxide.

SECTION 6 ACCIDENTAL RELEASE MEASURES

OCCUPATIONAL SPILL:
Do not touch spilled material. Stop leak if you can do it without risk. For small spills, take up with sand or other absorbent material and place into containers for later disposal. For small dry spills, with clean shovel place material into clean, dry container and cover. Move containers from spill area. For larger spills, dike far ahead of spill for later disposal. Keep unnecessary people away. Isolate hazard area and deny entry.

Reportable Quantity (RQ): 1000 pounds
The Superfund Amendments and Reauthorization Act (SARA) Section 304 requires that a release equal to or greater than the reportable quantity for this substance be immediately reported to the local emergency planning committee and the state emergency response commission (40 CFR 355.40). If the release of this substance is reportable under CERCLA Section 103, the National Response Center must be notified immediately at (800) 424-8802 or (202) 426-2675 in the metropolitan Washington, D.C. area (40 CFR 302.6).

SOIL SPILL:

Dig holding area such as lagoon, pond or pit for containment.

Use protective cover such as a plastic sheet to prevent material from dissolving in fire extinguishing water or rain.

WATER SPILL:
Add suitable agent to neutralize spilled material to pH-7.

SECTION 7 HANDLING AND STORAGE

Observe all federal, state and local regulations when storing this substance.

Store in a cool, dry, well-ventilated location. Separate from acids, water, metals. Immediately remove and properly dispose of any spilled material. (NFPA 49, Hazardous Chemicals Data, 1991)

Store away from incompatible substances.

SECTION 8 EXPOSURE CONTROLS/PERSONAL PROTECTION

EXPOSURE LIMITS:
SODIUM HYDROXIDE:
2 mg/m3 OSHA ceiling
2 mg/m3 ACGIH ceiling
2 mg/m3 NIOSH recommended ceiling
2 mg/m3 DFG MAK TWA (total dust);
4 mg/m3 DFG MAK 5 minute peak, momentary value, 8 times/shift

Measurement method: Particulate filter; hydrochloric acid; titration; (NIOSH Vol. III # 7401, Alkaline Dusts).

1000 pounds CERCLA Section 103 Reportable Quantity

OSHA revoked the final rule limits of January 19, 1989 in response to the 11th Circuit Court of Appeals decision (AFL-CIO v. OSHA) effective June 30, 1993. See 29 CFR 1910.1000 (58 FR 35338)

VENTILATION:
Provide local exhaust ventilation system to meet published exposure limits.

EYE PROTECTION:
Employee must wear splash-proof or dust-resistant safety goggles and a faceshield to prevent contact with this substance.

Emergency wash facilities:
Where there is any possibility that an employee's eyes and/or skin may be exposed to this substance, the employer should provide an eye wash fountain and quick drench shower within the immediate work area for emergency use.

CLOTHING:
Employee must wear appropriate protective (impervious) clothing and equipment to prevent any possibility of skin contact with this substance.

GLOVES:
Employee must wear appropriate protective gloves to prevent contact with this substance.

RESPIRATOR:
The following respirators and maximum use concentrations are recommendations by the U.S. Department of Health and Human Services, NIOSH Pocket Guide to Chemical Hazards; NIOSH criteria documents or by the U.S. Department of Labor, 29 CFR 1910 Subpart Z.
The specific respirator selected must be based on contamination levels found in the work place, must not exceed the working limits of the respirator and be jointly approved by the National Institute for Occupational Safety and Health and the Mine Safety and Health Administration (NIOSH-MSHA).

SODIUM HYDROXIDE:

50 mg/m3- Any powered air-purifying respirator with a dust and mist filter.
Any supplied-air respirator operated in a continuous flow mode.

100 mg/m3- Any self-contained breathing apparatus with a full facepiece.
Any supplied-air respirator with a full facepiece.
Any air-purifying full facepiece respirator with a high efficiency particulate filter.

250 mg/m3- Any supplied-air respirator with a full facepiece and operated in a pressure-demand or other positive pressure mode.

Escape- Any air-purifying full facepiece respirator with a high efficiency particulate filter.
Any appropriate escape-type self-contained breathing apparatus.

FOR FIREFIGHTING AND OTHER IMMEDIATELY DANGEROUS TO LIFE OR HEALTH CONDITIONS:

Any self-contained breathing apparatus that has a full facepiece and is operated in a pressure-demand or other positive-pressure mode.

Any supplied-air respirator that has a full facepiece and is operated in a pressure-demand or other positive-pressure mode in combination with an auxiliary self-contained breathing apparatus operated in pressure-demand or other positive-pressure mode.

SECTION 9 PHYSICAL AND CHEMICAL PROPERTIES

DESCRIPTION: Odorless, white or off-white hygroscopic solid.
MOLECULAR WEIGHT: 40.00
MOLECULAR FORMULA: NA-O-H
BOILING POINT: 2534 F (1390 C)
MELTING POINT: 604 F (318 C)
VAPOR PRESSURE: 100 mmHg @ 1111 C
SPECIFIC GRAVITY: 2.130
WATER SOLUBILITY: soluble
PH: 14 @ 5% solution

SOLVENT SOLUBILITY: Soluble in alcohol, glycerol; insoluble acetone, ether.

SECTION 10 STABILITY AND REACTIVITY

REACTIVITY:
Reacts exothermically with water.

CONDITIONS TO AVOID:
May burn but does not ignite readily. Flammable, poisonous gases may accumulate in tanks and hopper cars. May ignite combustibles (wood, paper, oil, etc.).

INCOMPATIBILITIES:
SODIUM HYDROXIDE:
ACETALDEHYDE: May result in violent polymerization.
ACETIC ACID: Mixing in closed container increases temperature and pressure.
ACETIC ANHYDRIDE: Mixing in a closed container increases temperature and pressure.
ACIDS: May react violently.
ACROLEIN: May result in an extremely violent polymerization.
ACRYLONITRILE: May cause violent polymerization.
ALLYL ALCOHOL + BENZENE SULFONYL CHLORIDE: Possible explosion hazard.
ALLYL CHLORIDE: Hydrolyzes.
ALUMINUM: Vigorous reaction.
ALUMINUM, ARSENIC TRIOXIDE, SODIUM ARSENATE: May generate flammable hydrogen gas.
AMMONIA + SILVER NITRATE: Precipitation of explosive silver nitride may occur.
AMMONIUM SALTS: May react violently evolving ammonia gas.
BENZENE-1,4-DIOL: Exothermic reaction.
N,N'-BIS(TRINITROETHYL)UREA: Formation of explosive compound.
BROMINE: Possible explosion if not stirred continously.
CHLORINE TRIFLUORIDE: May cause violent reaction.
CHLOROFORM + METHYL ALCOHOL: Exothermic reaction.
CHLOROHYDRIN: Mixing in a closed container causes an increase in temperature and pressure.
4-CHLORO-2-METHYLPHENOL: Possible ignition.
CHLORONITROTOLUENES: Possible explosion.
CHLOROPICRIN: May cause violent reaction.
CHLOROSULFONIC ACID: Mixing in a closed container causes an increase in temperature and pressure.
CINNAMALDEHYDE: Exothermic reaction.
COATINGS: May be attacked.
COPPER: Solutions may slowly corrode.
CYANOGEN AZIDE: May form sodium 5-azidotetrazolide, which is explosive if isolated.
2,2-DICHLORO-3,3-DIMETHYLBUTANE: Hazardous reaction.
1,2-DICHLOROETHYLENE: May form spontaneously flammable monochloroacetylene.
DIBORANE AND OCTANAL OXIME: Exothermic reaction.
ETHYLENE CYANOHYDRIN: Mixing in a closed container causes an increase in temperature and pressure.
FLAMMABLE LIQUIDS: Fire and explosion hazard.
GLYCOLS: May cause exothermic decomposition with evolution of hydrogen gas.

GLYOXAL: Mixing in a closed container increases temperature and pressure.
HALOGENATED HYDROCARBONS: Violent reaction.
HYDROCHLORIC ACID: Mixing in a closed container causes an increase in temperature and pressure.
HYDROFLUORIC ACID: Mixing in a closed container causes an increase in temperature and pressure.
HYDROQUINONE: Rapid decomposition of hydroquinone with evolution of heat.
IRON: Solutions may slowly corrode.
LEAD: May be attacked; flammable hydrogen gas may be liberated.
LEATHER: May be attacked.
MALEIC ANHYDRIDE: Explosive decomposition.
METALS: Corrodes metals, reacting to form flammable hydrogen gas.
4-METHYL-2-NITROPHENOL: Exothermic reaction.
NITRIC ACID: Mixing in closed container increases temperature and pressure.
NITROBENZENE: Possibly explosive reaction upon heating in presence of water.
NITROETHANE: Forms an explosive salt.
NITROMETHANE: Forms an explosive salt.
NITROPARAFFINS: The nitroparaffins, in the presence of water, form dry salts with organic bases. The dry salts are explosive.
NITROPROPANE: Forms an explosive salt.
O-NITROTOLUENE: Possible explosion.
OLEUM: Mixing in a closed container causes an increase in temperature and pressure.
ORGANIC PEROXIDES: Incompatible.
PENTOL (3-METHYL-2-PENTENE-4-YN-1-OL): Possible explosion.
PHOSPHORUS: May form mixed phosphines which may ignite spontaneously in air.
PHOSPHORUS PENTOXIDE: May react violently when heated.
PLASTICS: May be attacked.
B-PROPIOLACTONE: Mixing in a closed container causes an increase in temperature and pressure.
PROPYLENE OXIDE: Ignition or explosion may occur.
RUBBER: May be attacked.
SODIUM TETRAHYDROBORATE: Dry mixtures with sodium hydroxide containing 15-40% of tetrahydroborate liberate hydrogen explosively at 230-270 C.
SULFURIC ACID: Mixing in a closed container causes an increase in temperaure and pressure.
1,2,4,5-TETRACHLOROBENZENE: Violent reaction.
TETRACHLOROBENZENE + METHYL ALCOHOL: Possible explosion.
TETRACHLOROETHYLENE: Possible explosion.
TETRAHYDROFURAN: Serious explosions can occur.
TIN: Evolution of hydrogen gas which may form an explosive mixture.
1,1,1-TRICHLOROETHANOL: Explosion may occur.
TRICHLOROETHYLENE: Formation of explosive mixtures of dichloroacetylene.
TRICHLORONITROMETHANE + METHANOL: May cause violent reaction.
WOOL: May be attacked.
ZINC (DUST): Fire and explosion hazard.
ZIRCONIUM: May cause explosive reaction upon heating.

HAZARDOUS DECOMPOSITION:
Thermal decomposition may release toxic fumes of sodium oxide.

POLYMERIZATION:
Hazardous polymerization has not been reported to occur under normal

temperatures and pressures.

SECTION 11 TOXICOLOGY INFORMATION

SODIUM HYDROXIDE:
IRRITATION DATA: 500 mg/24 hours skin-rabbit severe; 1% eye-rabbit severe; 50 ug/24 hours eye-rabbit severe; 1 mg/24 hours eye-rabbit severe; 400 ug eye-rabbit mild; 1 mg/30 seconds rinsed eye-rabbit severe; 1%/24 hours eye-monkey severe.
TOXICITY DATA: 1350 mg/kg skin-rabbit LD50 (Van Waters & Rogers Inc. MSDS); 500 mg/kg oral-rabbit LDLo; 104-340 mg/kg oral-rat LD50 (Van Waters & Rogers Inc. MSDS); 40 mg/kg intraperitoneal-mouse LD50; mutagenic data (RTECS).
CARCINOGEN STATUS: None.
LOCAL EFFECTS: Corrosive- inhalation, skin, eye, ingestion.
ACUTE TOXICITY LEVEL: Toxic by ingestion; moderately toxic by dermal absorption.
TARGET EFFECTS: No data available.
AT INCREASED RISK FROM EXPOSURE: Persons with pre-existing skin and eye conditions.

HEALTH EFFECTS
INHALATION:
SODIUM HYDROXIDE:
CORROSIVE. 250 mg/m3 Immediately Dangerous to Life or Health.
ACUTE EXPOSURE- Effects due to inhalation of dusts or mist may vary from mild irritation of the nose at 2 mg/m3 to severe pneumonitis depending on the severity of exposure. Low concentrations may cause mucous membrane irritation with sore throat, coughing, and dyspnea. Intense exposures may result in destruction of mucous membranes and delayed pulmonary edema or pneumonitis. Shock may occur.
CHRONIC EXPOSURE- Prolonged exposures to high concentrations of dusts or mists may cause discomfort and ulceration of the nasal passages. Repeated exposures of 5000 mg/L were harmless to rats, but 10,000 mg/L led to nervousness, sore eyes, diarrhea and retarded growth. Rats exposed 30 minutes/day to unmeasured concentrations of sodium hydroxide aerosols suffered pulmonary damage after 2-3 months. Death occurred in 2 of 10 rats exposed to an aerosol of 40% aqueous sodium hydroxide for 30 minutes, twice a week for 3 weeks. Histopathological examination showed mostly normal lung tissue with foci of enlarged alveolar septae, emphysema, bronchial ulceration, and enlarged lymph adenoidal tissues. An epidemiologic study of 291 workers chronically exposed to caustic dusts for 30 years or more found no significant increase in mortality in relation to duration or intensity of such exposures.

SKIN CONTACT:
SODIUM HYDROXIDE:
CORROSIVE.
ACUTE EXPOSURE- Upon contact with the skin, damage including redness, cutaneous burns, skin fissures and white eschars may occur without immediate pain. Exposure to solutions as weak as 0.03 N (0.12%) for 1 hour has caused injury to healthy skin. Solutions of 25-50% caused no sensation of irritation within 3 minutes in human subjects. With solutions of 0.4-4%, irritation does not occur until after several hours.

Skin biopsies from human subjects having 1 N sodium hydroxide applied to their arms for 15 to 180 minutes showed progressive changes beginning with dissolution of the cells in the horny layer and progressing through edema to total destruction of the epidermis in 60 minutes. A 5% aqueous solution caused severe necrosis to the skin of rabbits when applied for 4 hours. Alkalies penetrate the skin slowly. The extent of injury depends on the duration of contact. If sodium hydroxide is not removed from the skin, severe burns with deep ulceration may occur. Exposure to the dust or mist may cause multiple small burns and temporary loss of hair. Pathologic findings due to alkalies may include gelatinous, necrotic areas at the site of contact.

CHRONIC EXPOSURE- Effects are dependent upon concentration and duration of exposure. Dermatitis or effects similar to those for acute exposure may occur.

EYE CONTACT:
SODIUM HYDROXIDE:
CORROSIVE.

ACUTE EXPOSURE- Contact may cause disintegration and sloughing of conjunctival and corneal epithelium, corneal opacification, marked edema and ulceration. After 7 to 13 days either gradual recovery begins or there is progression of ulceration and corneal opacification. Complications of severe eye burns are symblepharon with overgrowth of the cornea by a vascularized membrane, progressive or recurrent corneal ulceration and permanent corneal opacification. Blindness may occur.

CHRONIC EXPOSURE- Effects are dependent upon concentration and duration of exposure. Conjunctivitis or effects similar to those for acute exposure may occur.

INGESTION:
SODIUM HYDROXIDE:
CORROSIVE/TOXIC.

ACUTE EXPOSURE- The reported lethal dose in rats is 140-340 mg/kg. Ingestion may cause a burning sensation in the mouth, corrosion of the lips, mouth, tongue and pharynx, and severe esophageal and abdominal pain, vomiting of blood and large pieces of mucosa, and bloody diarrhea. Asphyxia can occur from swelling of the throat. Mediastinitis, alkalemia, pallor, weak, slow pulse, cardiovascular collapse, shock, coma and death may occur. Perforation of the alimentary tract and constrictive scarring may result. Esophageal stricture may occur weeks, months, or even years later to make swallowing difficult. The estimated fatal dose in man is 5 grams. Cases of squamous cell carcinoma of the esophagus have occurred with latent periods of 12 to 42 years after ingestion. These cancers were believed to be sequela of tissue destruction and possibly scar formation rather than the result of direct carcinogenic action of sodium hydroxide.

CHRONIC EXPOSURE- Depending on the concentration, repeated ingestion of alkaline substances may result in inflammatory and ulcerative effects on the oral mucous membranes and other effects as with acute ingestion.

SECTION 12 ECOLOGICAL INFORMATION

ENVIRONMENTAL IMPACT RATING (0-4): no data available

ACUTE AQUATIC TOXICITY: no data available

DEGRADABILITY: no data available

LOG BIOCONCENTRATION FACTOR (BCF): no data available

LOG OCTANOL/WATER PARTITION COEFFICIENT: no data available

SECTION 13 DISPOSAL INFORMATION

Observe all federal, state and local regulations when disposing of this substance.

Disposal must be in accordance with standards applicable to generators of hazardous waste, 40 CFR 262. EPA Hazardous Waste Number D002.
100 pound CERCLA Section 103 Reportable Quantity.

SECTION 14 TRANSPORTATION INFORMATION

U.S. DEPARTMENT OF TRANSPORTATION SHIPPING NAME-ID NUMBER, 49 CFR 172.101:
Sodium hydroxide, solid-UN 1823

U.S. DEPARTMENT OF TRANSPORTATION HAZARD CLASS OR DIVISION, 49 CFR 172.101:
8 - Corrosive material

U.S. DEPARTMENT OF TRANSPORTATION PACKING GROUP, 49 CFR 172.101:
PG II

U.S. DEPARTMENT OF TRANSPORTATION LABELING REQUIREMENTS, 49 CFR 172.101 AND SUBPART E:
Corrosive

U.S. DEPARTMENT OF TRANSPORTATION PACKAGING AUTHORIZATIONS:
EXCEPTIONS: 49 CFR 173.154
NON-BULK PACKAGING: 49 CFR 173.212
BULK PACKAGING: 49 CFR 173.240

U.S. DEPARTMENT OF TRANSPORTATION QUANTITY LIMITATIONS 49 CFR 172.101:
PASSENGER AIRCRAFT OR RAILCAR: 15 kg
CARGO AIRCRAFT ONLY: 50 kg

SECTION 15 REGULATORY INFORMATION

OVER EXPOSURE EFFECTS... NO APPLICABLE INFORMATION WAS FOUND CONCERNING ANY ADVERSE ACUTE/CHRONIC HEALTH EFFECTS RESULTING FROM OVEREXPOSURE TO THIS PRODUCT.

FIRST AID PROCEDURES....

EMERGENCY FIRST AID

INHALATION:
IF LARGE AMOUNTS ARE INHALED, REMOVE TO FRESH AIR IF NOT BREATHING, GIVE ARTIFICIAL RESPIRATION, PREFERABLY MOUTH-TO-MOUTH. IF BREATHING IS DIFFICULT GIVE OXYGEN, AND CALL A PHYSICIAN.

SKIN CONTACT:
FLUSH SKIN WITH PLENTY OF WATER AFTER EXCESSIVE CONTACT. WASH THOROUGHLY WITH HANDCREAM OR HANDCLEANER.

EYE CONTACT:
FLUSH EYES IMMEDIATELY WITH PLENTY OF WATER FOR AT LEAST 15 MINUTES. CALL A PHYSICIAN.

INGESTION:
INDUCE VOMITING IMMEDIATELY BY GIVING TWO GLASSES OF WATER. GET MEDICAL ATTENTION. NEVER GIVE FLUIDS TO AN UNCONSCIOUS PERSON.

SECTION VI - REACTIVITY DATA

CHEMICAL STABILITY...... STABLE
CONDITIONS TO AVOID..... NONE
INCOMPATIBLE MATERIALS.. OXIDIZING AND REDUCING AGENTS MAY DESTROY COLOR.
DECOMPOSITION PRODUCTS.. CO,CO2,OXIDES OF NITROGEN, SULFUR, AND OTHER POTENTIALLY TOXIC FUMES.
HAZARDOUS POLYMERIZATION
POLYMERIZATION AVOID.... NONE EXPECTED

SECTION VII - SPILL OR LEAK PROCEDURE

FOR SPILL............... SPILLS SHOULD BE SWEPT UP AND PLACED IN CONTAINERS. SPILL AREAS CAN BE WASHED WITH WATER; COLLECT WASTE WATER FOR APPROVED DISPOSAL.

WASTE DISPOSAL METHOD... WASTE DISPOSAL SHOULD BE IN ACCORDANCE WITH EXISTING FEDERAL, STATE AND LOCAL ENVIRONMENTAL REGULATIONS.

CERTIFIED MAIL - RETURN RECEIPT REQUESTED

January 31, 1995

E. K. Hunter, Chief
DOE - WIPP Site Branch
P.O. Box 3090
Carlsbad, NM 88221

RE: WIPP - Culebra Transport Test Program

Dear Mr. Hunter:

The New Mexico Environment Department (NMED) has received your letter for the Culebra Transport Test Program at the Waste Isolation Pilot Plant (WIPP) in accordance with Section 1-201. of the NM Water Quality Control Commission (WQCC) Regulations. The facility is located approximately 30 miles east of Carlsbad in Section 29, T22S, R31E, Eddy County. The application satisfies the requirements of Section 1-201 of the WQCC Regulations.

Based on the presently available information in your letter, a discharge plan is not being required for this discharge as long as the discharge is as described in your letter of October 21, 1994.

A discharge plan is not being required because it appears that the discharge conforms to the numerical ground water standards and does not contain any toxic pollutants as defined in WQCC Reg.1-101.ZZ, and therefore is exempt from the discharge plan requirement under WQCC Reg.3-105.A.

The exempt discharge is briefly described as follows:

Tracer solutions will be injected into the Culebra Formation at the H-19 well at the WIPP site hydropad. Movement of the tracers will be achieved by pumping approximately 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Monitoring will take place in seven additional wells at the site. Among the list of constituents submitted as possible tracers for the tests, Trifluoroacetic Acid-d will be excluded because it may possibly degrade to one or more of the contaminants listed in WQCC Regulation 1-101.ZZ.

Although a discharge plan is not being required for this discharge, you are not relieved of liability should your operation result in actual pollution of surface or ground waters. Further, this decision by the NMED does not relieve you of your responsibility to comply with any other applicable federal, state, and/or local laws and regulations, such as zoning requirements, plumbing codes and nuisance ordinances.

If at some time in the future you intend to change the amount, the character, or location of your discharge so that it will not be as described, or if observation or monitoring shows that the discharge is not as described, you must file a new request for exemption with the Ground Water Section.

If you have any questions, please contact either Clint Marshall of the Ground Water Section staff at 827-0027 or the Program Manager of the Ground Water Section at 827-2900.

Sincerely,

Marcy Leavitt, Chief
Ground Water Protection &
Remediation Bureau

Subject: REQUEST FOR CONCURRENCE THAT A DISCHARGE PLAN IS NOT REQUIRED FOR THE WASTE ISOLATION PILOT PLANT CULEBRA TRACER INJECTION TEST PROGRAM

Dear Mr. Marshall:

The U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) is requesting written concurrence that a Part 3-100 Discharge Plan will not be required for the proposed Culebra Transport Test Programs under development by Sandia National Laboratories at the Waste Isolation Pilot Plant (WIPP).. The Culebra Transport Test Program is designed to collect additional hydrogeologic characterization data from the Culebra, and perhaps Rustler formation, to test hydrological models for the WIPP Performance Assessment.

To accomplish this, Sandia National Laboratories proposed to establish up to 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Most of the new test wells will be located on the new H-19 hydropad. Three existing wells in the vicinity of the H-19 hydropad and several new wells strategically located around H-19 will be used to monitor pressure responses associated with the hydrologic tracer tests being conducted at the H-19 hydropad.

The DOE-CAO believes that this project should be exempted from the discharge plan requirements because the existing concentration of ground water in adjacent wells exceeds 10,000 mg/l Total Dissolved Solids (TDS). Additionally, none of the proposed tracer chemicals are listed in the New Mexico Water Quality Control Regulations, Part 1-101(UU), *Toxic Pollutants*, or Part 3-103, *Standards for Ground Water of 10,000 mg/l TDS Concentration or Less*.

A copy of water quality data from two existing wells located within one-half mile of the H-19 hydropad, and a list of proposed tracer chemicals are enclosed to support our request for concurrence that a Discharge Plan is not required for the Tracer Test project.

printed on recycled paper

If you have any questions about this proposed project or require any additional information, please contact Ms. M. E. Bennington at (505) 234-8132.

Sincerely,

E. K. Hunter

Thus, up to 17 wells are involved; ten test wells along the principal Culebra flow path, and seven monitoring wells which may or may not lie along this flow path.

Additional Monitoring and Required Coordination With Westinghouse

Additional fluid level monitoring for these tests could be carried on at any of the existing wells monitored by the Environmental Monitoring Group of the Westinghouse Waste Isolation Division (WID). Such monitoring and indeed many phases of this activity will require coordination and consent of many groups within the Waste Isolation Division, Environmental Monitoring Group, Regulatory Group, and Industrial Safety and Radiation Safety Group.

Further Details on the Proposed Hydropad and Monitoring Wells

The proposed hydrologic testing or monitoring wells will be drilled to an approximate depth of 800 ft. The wells will be constructed with a smaller (compared to oil field rigs) diamond core/wireline coring/minerals industry rig, a sonic rig, or an environmental drilling rig. The other types of rigs are about 1/3 the size of an oil field rig rated to the same depth. The volume of their drilling fluid systems is about 1/5 that of an oil field rig rated to the same depth. These smaller rigs and their drilling fluid system have a much smaller environmental impact/"footprint" than standard oil field rigs common to the Permian Basin. While the exact well design has not been determined, the wells, with one exception, will be similar in construction to H-18, shown in Figure 2a. Core, 3.5-inch o.d., will be taken from the Culebra in these wells. However, 6-inch o.d. core from the Culebra will be required from one well on the H-19 hydropad in addition to the 3.5-inch core from the top to the Culebra; a preliminary well design for this well is shown in Figure 2b. Figure 5 shows a possible hole configuration for a Convergent-Flow Tracer Test. The large well (Figure 2b) will be the pumping well. The other wells on H-19 will be tracer-injection wells.

Reentry Into Additional Wells Not Annotated In Earlier Culebra Transport Program Checklist

Prior to the construction of the H-19 hydropad and the drilling of the hydrologic testing wells on that pad, the drilling of additional new monitoring wells, and the possible deepening of the H-3d well, certain wells at the H-3 hydropad and the H-11 hydropad will be reentered, and may be cleaned out and worked over. The reentry into any H-3 and H-11 wells, with associated geophysical logging operations, was approved on an earlier National Environmental Policy Act (NEPA) checklist for the Culebra Transport Program, dated June/July 1993. Some work is already underway on the H-11 hydropad under that earlier checklist.

Potential Tracers for Use in the Culebra Transport Test Program

CAS Number	Chemical Names
433-97-6	Ortho-Trifluoromethy Benzoic Acid
454-92-2	A,A,A-Trifluoro-Meta-Toluic Acid

WASTE ISOLATION PILOT PLANT
WIPP

Authorization to Discharge Unpermitted, Non-Hazardous Effluent into the WIPP Sewage Treatment Facility

Name: DAN ROBERTSON

Signature: [signature]

Date: 10/11/94

Department/Section: ENVIRONMENTAL COMPLIANCE AND SUPPORT

Origin of Effluent: FORMATION FLOW AND SALT DEBRIS PUMPED FROM THE WIPP WASTE SHAFT SUMP. EFFLUENT CONTAINS 10-20% SOLIDS. REQUEST NMED GROUND WATER BUREAU PERMISSION TO DISCHARGE EFFLUENT TO THE WIPP SALT PILE EVAPORATION POND. THIS POND WAS FORMERLY PERMITTED FOR SUMP EFFLUENT DISCHARGES

Type of Effluent: WATER, DIRT & SALT DEBRIS
(In gallons)

Restrictions on Discharge:

- [x] Effluent has been characterized and the generation process has not changed: (Attach analytical results to the discharge form and submit to Environmental Compliance and Support for signature.) (SEE ATTACHED ANALYSES)
- [ ] Effluent Characterization is Required: (Attach sampling results to the discharge request form and return to Environmental Compliance and Support for submittal to NMED for discharge authorization signature.)

Authorization Signatures:

1. Authorization Signature: [signature] Date: 10/11/94
   (Environmental Compliance and Support (EC&S))
2. Authorization Signature: Mary E. [signature] Date: 10/11/94

COMMENTS:

STATE OF NEW MEXICO
ENVIRONMENT DEPARTMENT

September 16, 1993

Mr. Arlen E. Hunt, Manager
Waste Isolation Pilot Plant
P.O. Box 3090
Carlsbad, NM 88221

RE: 60-Day Extension for Brine Discharge at WIPP, DP-831

Dear Mr. Hunt:

Pursuant to Water Quality Control Commission (WQCC) Reg. 3-109, the proposed 60 day extension to discharge nonhazardous brine water into the existing salt pile evaporation pond at the Waste Isolation Pilot Plant (WIPP), is hereby approved. The facility is located approximately 30 miles east of Carlsbad in Section 29.142, T22S, R31E, Eddy County. In approving this extension, the New Mexico Environment Department has determined that the requirements of WQCC Reg. 3-109.C have been met.

The proposed discharge is briefly described as follows: Up to 1500 gallons per day of nonhazardous brine water will be discharged into the salt pile evaporation pond for a period not to exceed 60 days from the date of this letter. The original time period of 18 months is stated as a specific requirement of discharge plan #831 as approved on January 16, 1992. This condition was included to allow time for the construction of the proposed new evaporation lagoons.

This approval is contingent on your discharging as described in your discharge plan application received by our office on November 14, 1991.

This approval does not relieve you of your responsibility to comply with any other applicable federal, state, and/or local laws and regulations, such as zoning requirements and nuisance ordinances. Also this approval does not relieve you of liability should your operation result in actual pollution of surface or ground waters.

Dear Concerned Citizen:

Enclosed is a fact sheet regarding the New Mexico hazardous waste draft permit that the New Mexico Environment Department (NMED) and the Hazardous And Solid Waste Amendments of 1984 (HSWA) draft permit that the Environmental Protection Agency (EPA) propose to issue for the Waste Isolation Pilot Plant (WIPP).

The U.S. Department of Energy and the Waste Isolation Division of the Westinghouse Electric Corporation have requested a hazardous waste permit from the State of New Mexico to receive and manage hazardous waste at the WIPP site located approximately 26 miles east of the City of Carlsbad.

The HSWA permit proposed by the EPA implements the requirements imposed by the HSWA, such as hazardous waste minimization, hazardous waste process vents and corrective action to investigate possible releases from Solid Waste Management Units (SWMUs).

Copies of the proposed permits are available for review from August 30, 1993 through November 1, 1993 at the office of the NMED Hazardous and Radioactive Bureau (HRMB), 525 Camino De Los Marquez, Suite 4, P.O. Box 26110, Santa Fe, New Mexico 87502, during the hours of 8:00 A.M. to 5:00 P.M. and at the locations listed below:

Subject Discharge Form -
30 (or 60) day extension of brine discharge

Discussion I told Dan and Beth that the form for miscellaneous discharge into the sewage lagoon would be fine. ~~[illegible]~~ Each time a form is transmitted, I will follow it up with a confirmation letter.

Asked them ~~[illegible]~~ if 30 day extension of brine disposal into the salt stock runoff pond would be enough. They said 60 days would be better. I said no problem.

Conclusions Write up 60 day extension approval letter.

FACT SHEET

Intent to Issue Permits for the Operation of
A Hazardous Waste Storage Facility under the
New Mexico Hazardous Waste Act (NMHWA)
and the Hazardous and Solid Waste Amendments of 1984 (HSWA)

Waste Isolation Pilot Plant (WIPP)
Carlsbad, New Mexico

Facility Name:	Waste Isolation Pilot Plant (WIPP)
EPA ID Number:	NM4890139088
Location:	The facility is located north of Jal Highway (State Highway 128) in Eddy County, New Mexico. The facility consists of 16 sections of federal land in Township 22 South, Range 31 East. The WIPP site is located approximately 20 miles east of Loving, and 26 miles east of Carlsbad.
Landowner:	U.S. Department of Energy (DOE)
Operator:	Westinghouse Electric Corporation Waste Isolation Division

Introduction of Facility and Purpose of Permit:

The U.S. Department of Energy (DOE) and the Waste Isolation Division (WID) of the Westinghouse Electric Corporation have requested permits from the State of New Mexico and the Environmental Protection Agency (EPA) to receive and manage hazardous waste at the Waste Isolation Pilot Plant (WIPP). The WIPP is located in southeastern New Mexico, approximately 26 miles east of the city of Carlsbad. In 1980, Congress authorized WIPP "for the express purpose of providing a research and development facility to demonstrate the safe disposal of radioactive waste resulting from the defense activities and programs of the United States." This research will be conducted during a "test phase," during which various tests or experiments will be performed to assess WIPP's viability for long-term disposal. DOE has indicated that it must manage TRU-mixed waste within the WIPP during the test phase. The waste will be transferred to WIPP from only two sites, the Idaho National Engineering Laboratory (INEL) and the Rocky Flats Plant (RFP) in Colorado. TRU-mixed waste contains both transuranic radioactive and a hazardous waste component(s), and the hazardous waste component is regulated under the New Mexico Hazardous Waste Regulations (HWMR-7). Since the WIPP will receive hazardous waste from off-site facilities, a permit to operate a hazardous waste storage facility in accordance with HWMR-7 is required for any area of the WIPP where waste will be stored.

The WIPP facility consists of surface buildings and structures, an underground network of subsurface mined openings and vertical shafts which connect the surface and subsurface areas. The New Mexico Environment Department (NMED) received a permit application from DOE and WID which requested a permit to operate a hazardous waste container storage area in the Waste Handling Building and to operate two miscellaneous hazardous waste management (Subpart X) units within a portion of the subsurface mined openings. The NMED has reviewed the permit application and determined that the application, as modified by the conditions of the draft permit, adequately addresses the requirements of the New Mexico Hazardous Waste Act and the New Mexico Hazardous Waste Management Regulations.

The State permit to operate the hazardous waste management units at the WIPP will be issued to both the owner and operator of the WIPP. The permit will allow the owner and operator to store hazardous waste within the Waste Handling Building and within Bin Scale Test Rooms 1 and 3 of Panel 1 in the underground mined openings, under specific conditions cited within the permit. The permit will be issued for storage of waste during the test phase only, and the term of the permit will be 10 years. The permit will only allow the owner and operator to receive contact handled (CH) TRU-mixed waste. The permit will not allow disposal of TRU-mixed waste and will require the complete removal of hazardous waste and hazardous waste constituents from the facility prior to the expiration of the permit, unless a new or revised permit is issued.

The NMED has based the State draft permit on Revision 3 of the RCRA Part B permit application submitted by DOE and WID, as well as associated attachments and clarifying information submitted by the Permittees. In addition to NMED HWMR-7 requirements and EPA HSWA requirements, WIPP must meet additional requirements of a number of other agencies and statues which have jurisdiction or regulatory authority over operations at the WIPP facility. The DOE and WID have and will continue to generate plans and procedures documents in response to requirements of these other agencies or statutes. The NMED understands that many of these documents will discuss issues related both directly and indirectly to topics/etc. addressed within the State draft permit. Issues discussed in documents prepared to meet requirements of other regulations include the types and quantities of TRU-mixed waste, the types of subsurface rooms used for testing, and the number and types of containers that DOE and WID would like to use for test phase experiments at the WIPP. However, the conditions of the permit issued to DOE and WID by the NMED will supersede all other documents with regard to storage and management of TRU-mixed waste. For example, if the DOE and WID desire to add to the types of TRU-mixed waste, the type of subsurface rooms used for experiments, or the number or type of containers which are used to manage TRU-mixed waste beyond that set forth in the draft permit, then DOE and WID must submit a request for permit modification to the NMED. Any TRU-mixed waste management activity described in a document that is not reflected in the draft permit shall not be allowed unless DOE or WID requests a permit modification. That request shall be subject to public notice and hearing.

There are a number of operational and waste handling activity issues concerning the WIPP which are not within the purview of the draft permit or that NMED does not have statutory or regulatory authority under the New Mexico Hazardous Waste Act or Hazardous Management Waste Regulations. Examples of these issues include: transportation of waste to and from the WIPP, handling and management of radioactive materials and the radioactive component of the TRU-mixed waste; the types of experiments to be conducted at WIPP (except to ensure that the experiments will not result in a release of hazardous waste or constituents); and compliance with regulations enforced by other agencies, such as the Mine Safety and Health Administration.

Description of the Permit:

Joint hazardous waste permits will be issued by both the New Mexico Environment Department (NMED) and the U.S. Environmental Protection Agency. The NMED and the U.S. EPA both must issue permits to the facility in order for WIPP to have a full Resource Conservation and Recovery Act (RCRA) permit to operate.

The permit proposed by the New Mexico Environment Department (NMED), which is found in draft permit modules I through V,under the NMHWA describes the structures, equipment, and procedures WIPP is required to comply with in order to store hazardous mixed waste. Hazardous mixed waste will be stored in specially designed containers in both above- and below-ground locations which are further described in the remainder of the fact sheet.

The permit proposed by the U.S. Environmental Protection Agency (EPA), which is found in draft permit module VI, implements the requirements imposed by the federal Hazardous and Solid Waste Amendments of 1984 (HSWA), such as hazardous waste minimization, hazardous waste land disposal restrictions, air emission standards for hazardous waste process vents, and corrective action to investigate possible releases from Solid Waste Management Units (SWMUs).

Waste to be Managed:

The types of waste to be managed during the Test Phase experiments at the site will be limited to Group I, contact handled (CH), Transuranic (TRU) mixed waste. The TRU-mixed waste designation refers to waste which contains both a transuranic radioactive and a hazardous waste component. TRU-mixed waste accepted at the site will be classified as contact handled waste, which is defined as TRU waste whose external surface (container) dose rate does not exceed 200 mrem per hour. The Group I designation refers to the type of TRU-mixed waste which will be placed into the container, and includes such items as clothing (boots, overalls, gloves etc.), lead shielding, glassware, paper, debris, etc., which are contaminated with hazardous constituents and radioactive components. A more complete definition of the type of waste can be found in Permit Attachment II-1, the Waste Analysis Plan. The State permit also allows the storage of derived wastes, which are mixed wastes generated from on-site operations with the experimental TRU-mixed waste.

Units to be Permitted:

The DOE and WID have requested a hazardous waste permit from the State to operate three hazardous waste management units at the WIPP site. The first unit is a hazardous waste container storage area which will be located above ground within the Waste Handling Building (WHB), which is facility Building #411. The second and third units are miscellaneous hazardous waste management units, which consist of Bin Scale Test Rooms (BSTRs) 1 and 3 located within Panel 1 of the underground mined openings.

Waste Handling Building

The Waste Handling Building (WHB) consists of a totally enclosed area of approximately 84,000 square feet. Of that 84,000 square feet, approximately 36,000 square feet will be permitted to store and manage TRU-mixed waste. The hazardous waste container storage area of the WHB will consist of three distinct interconnected rooms which will manage the waste. The rooms are: (1) Inventory and Preparation Area (IPA), approximately 27,000 square feet; (2) the Site Generated Waste Room (SGWR), approximately 5,250 square feet; and (3) the Overpack and Repair Room (OPRR), approximately 3,750 square feet. These rooms will be used to store TRU-mixed waste consisting of the test phase experiment wastes and "derived" wastes which are generated during the Test Phase and during closure.

The concrete floor, floor trenches and sump of the IPA, SGWR, and OPRR will be covered with an impermeable coating. The WHB ventilation system will be operated in such a manner that the interior of the WHB will be maintained at a lower atmospheric pressure than the outside of the building, thus mitigating potential contaminant release to the atmosphere through openings or air leakage points. The exhaust from the WHB ventilation system will be filtered prior to discharge to the atmosphere. The three areas of the WHB will be permitted to store a total of 172 test bin containers and four 55-gallon drums of derived wastes. It is anticipated that some of the 172 test bins that may be stored will be empty test bins.

During closure of the facility, the IPA room will be permitted to store up to 500, 55-gallon drums of derived waste. Complete decontamination of the two subsurface BSTRs and the WHB could generate relatively significant quantities of waste, necessitating the maximum 500 drum storage capacity during closure. In addition, up to 12 spent activated carbon canisters could be stored in the WHB during closure.

Bin Scale Test Rooms (BSTRs)

The BSTRs 1 and 3 are located within Panel 1 of the subsurface mined openings. The BSTRs are classified as miscellaneous hazardous waste management units since hazardous waste will be stored in units which do not have specific technical standards under New Mexico HWMR-7. The BSTRs are located within the bedded salt of the Salado Formation, and are approximately 2150 feet below the surface. BSTRs 1 and 3 have nominal dimensions of 13 feet high, 33 feet wide and 300 feet long, with an approximate floor area of 9,900 square feet. The two BSTRs will store TRU-mixed waste during test phase experiments as well as "derived" waste which is generated during the test phase. Test bins are carbon steel and polyethylene lined, with a nominal volume of 330 gallons. Each test bin will be completely enclosed in a carbon steel standard waste box/radiological control boundary (SWB/RCB) that has an approximate volume of 410 gallons. The SWB/RCB will also act as secondary containment for the test bin.

Derived waste will be stored in standard 55-gallon steel drums with polyethylene liners. Secondary containment is provided by either over packing four drums into a SWB or placing the drums on a steel portable containment tray.

The capacity of BSTR 1 is 68 test bins to store TRU-mixed waste, 8 empty baseline bins, 16 drums of derived waste within 4 SWBs, and 2 drums on a portable containment tray. BSTR 1 may also store up to 12 spent carbon canisters. The capacity of BSTR 3 is 104 test bins (inside RCBs) and 2 drums of derived waste on a portable containment tray.

Both of the BSTRs have been equipped with an engineering feature which consists of 10-foot long rock bolts, which are designed to enhance room stability. In addition, BSTR 1 has been equipped with a supplementary roof support system consisting of roof bolts, steel channel sets, and a wire rope/wire mesh lacing system to enhance the roof stability. The system is discussed further in Module IV and Permit Attachments III-1, IV-5, and IV-6. The permit application submitted by DOE and WID did not specify that a similar system would be used in BSTR 3. Therefore, the draft permit, under permit conditions IV.B.6 and I.J.1, requires the Permittees to demonstrate to NMED that a supplementary support system which can achieve the same degree of safety as the existing BSTR 1 supplementary system will be in place prior to acceptance of waste in BSTR 3.

Each of the BSTRs is also equipped with a geomechanical monitoring system which allows measurements to be taken to determine the nature and amount of wall, floor and ceiling movements within the BSTR. Analyses of the slat movement around the BSTR will provide advance warning of potential roof stability problems and allow for safe retrieval of waste if required. This system is described more fully in Module IV, and Permit Attachments III-1, IV-5, and IV-6.

Each test bin stored in a BSTR will be connected to an air emission collection, control, and monitoring system designed to prevent the release of volatile organic hazardous constituents to the atmosphere. In addition, the air entering and exiting each BSTR will be monitored on a regular basis to ensure that releases of volatile organic hazardous constituents have not occurred. These systems are more fully addressed in the unit description contained in Module IV, and in Permit Attachments III-1, IV-1, IV-2, and IV-3.

Organization of the Draft Permit:

The WIPP draft permit generally follows the format specified by NMED and used by the Department for other New Mexico permits. The draft permit also incorporates the format specified in the EPA guidance entitled the "Model RCRA Permit for Hazardous Waste Management Facilities," Office of Solid Waste, U.S. Environmental Protection Agency, September, 1988.

The WIPP draft permit is divided into six modules, each which will be briefly described in this fact sheet. The first two modules, Modules I and II, are entitled "General Permit Conditions" and "General Facility Conditions," respectively, and are generally applicable (included within) to all RCRA permits. Module I addresses such issues as permit expiration date, and the Department's authorization to inspect and obtain samples. Module II establishes permit conditions for such issues as security, training, waste analysis, and waste characterization. Module II also addresses emergency procedures (contingency plan) and general closure requirements.

Module III addresses the engineering design and operations of the above ground hazardous waste container storage area referred to as the Waste Handling Building. For example, this module describes the design requirements for the building, the secondary containment system, and the containers used to manage waste. The module also specifies the maximum number of waste containers which can be managed in the unit and how the containers will be managed, stored and inspected to minimize the potential for release of hazardous constituents to the environment. Module IV addresses the same issues concerning the design and operation of the Bin Scale Test Rooms (BSTRs) which are located in the subsurface mined openings. Module V addresses the groundwater monitoring program requirements for the WIPP facility. Module VI contains permit conditions that are required by the Hazardous and Solid Waste Amendments of 1984 (HSWA) under EPA authority.

Draft Permit Issues:

This section of the fact sheet addresses conditions within the permit which may be of widespread public interest or that may raise issues of concern. In order to facilitate public review, issues and conditions are discussed by permit module.

Module I

Module I of the draft permit contains a compliance schedule which is included as permit conditions I.J.1 through I.J.13. Under HWMR-7, pt. IX and 40 CFR 270.33, a permit may include a schedule of compliance which requires the facility to submit certain information or documents within a specified time period. The draft permit contains several compliance schedules which may be of interest to the public. The first is that by December 31, 1996, the Permittees must identify the name and location of the off-site, out-of-state interim storage facility(s) which will receive all of the TRU-mixed waste managed at the WIPP at the time of closure. In a related compliance schedule, the Permittees must identify, within a year of permit issuance, the name and location of the off-site facility to which TRU-mixed waste from the WIPP will be shipped if waste removal is required prior to identification of an interim storage facility. The second compliance schedule of interest requires the Permittees to submit detailed design plans for the proposed roof support and geomechanical monitoring systems in BSTR 3 to NMED for approval prior to managing waste in BSTR 3. Another compliance schedule issue requires the Permittees to provide a sampling and analysis plan and obtain samples in accordance with that plan to determine natural background levels (if any) of hazardous waste constituents in the below-ground salt formation prior to accepting waste at the facility. This information will be used to help demonstrate that all hazardous waste and hazardous constituents have been removed from the BSTRs at closure.

Module II

Module II addresses waste characterization and waste analysis plan requirements, as well as facility security, general inspection requirements, personnel training, preparedness and prevention, the facility contingency plan, and general closure requirements. Relative to waste characterization, a number of issues may be of interest to the public, including waste acceptance criteria. The draft permit limits WIPP to accepting waste only from INEL and RFP, while imposing waste acceptance criteria that are similar to those currently in place at WIPP, including restrictions on accepting explosive/flammable wastes and reactive wastes, free liquid limitations to <1%, and visual waste examination requirements.

Waste which may be managed in WIPP during the test phase have also been identified as an issue of concern to the public. The draft permit restricts WIPP to accepting only contact handled Group I TRU-mixed wastes, which is a waste grouping that includes waste categories such as combustibles and noncombustibles, benelex and plexiglass, firebrick and ceramic crucibles, graphite, filters, glass supercompacted waste, leaded rubber and metal wastes which have been contaminated with hazardous and TRU radioactive components. Combining of waste categories within a given bin is allowed because compatibility has been demonstrated.

Permit conditions within Module II require that Group I waste be characterized at the generator site via headspace gas analysis (in accordance with previously determined EPA requirements), process knowledge, real-time radiography (RTR), and visual examination. Chemical analysis of Group I wastes beyond headspace gas analysis is not required, although reporting of tentatively identified compounds detected during headspace gas analyses is dictated within draft permit conditions. The combination of process knowledge, visual examination, RTR, and headspace gas analysis provides sufficient information to ensure that Group I wastes are characterized and can be managed appropriately in accordance with RCRA requirements.

Although DOE requested that they be able to manage Group II and III wastes, acceptance of these waste Groups--which include solidified organic and inorganic sludges and pyrochemical salts, and combinations of sludges and Group I wastes--shall not be allowed because the application did not contain sufficient sampling and analysis information to ensure adequate waste characterization.

Characterization of on-site generated waste may also be of concern to the public. Wastes would be generated on-site, for example, if a small spill was cleaned up with an absorbent. On-site generated (derived) waste and retrieved waste shall be characterized via process knowledge, but if NMED questions waste contents, additional sampling and analysis may be required by NMED. Because characterization of Group I wastes prior to acceptance at WIPP is satisfactorily stringent, chemical characterization of a spill is not immediately required. DOE and WID are required to perform detailed waste shipment screening and verification and to follow prescribed quality assurance methodologies presented in Attachment II-2 of the permit. In response to public concerns regarding accuracy of generator-site bin loading and waste characterization, the draft permit requires DOE and WID to perform generator-site audits to verify that waste characterization as required under the permit are being satisfactorily performed, and to report all nonconformances and reject bins which have not met audit requirements unless the generators can demonstrate compliance with waste characterization requirements. Management of simulated (non-hazardous) wastes within the WIPP is allowed, but cannot interfere with the safe management of TRU-mixed waste management activities. If the simulated waste at some point generates a hazardous waste, management of this waste must be in accordance with all conditions of the permit.

Quarterly reports are also required within the draft permit to transmit information to NMED that is not included in annual reports, and to keep NMED informed throughout the waste characterization process. These reports shall include waste profile forms and bin case reports, visual and RTR examination reports, results of headspace gas analysis (for both drums prior to loading, and bins after loading, including TICs), results of generator site audits, an assessment of how visual, headspace gas, and RTR results compare with those anticipated via process knowledge, copies of manifests, and any additional information as acquired.

Module III

Module III provides permit conditions for the design and operation of the Waste Handling Building (WHB) hazardous waste container storage area. Several of the permit conditions may be of particular interest to the public. First, the Permittees will be limited to the use of only Type 1 dry and Type 1 humid test bins for managing experimental TRU-mixed waste. A permit modification request must be submitted and approved before the Permittees would be allowed to manage experimental TRU-mixed waste in Type 1 inundated test bins or Type 2 (pressurized) test bins. Additional public notice and comment opportunity would be required before such a modification could be approved. Second, the Permittees shall not be allowed to accept for storage any containers of TRU-mixed waste which contain greater than 1% free liquid by volume. Secondary containment for containers of TRU-mixed waste stored in the WHB will be provided either by the concrete floor and the fire suppression water trench/sump system, or by a supplementary secondary containment system such as a portable steel tray. Test bins stored in the WHB will be enclosed in standard waste boxes (RCBs) except when the bins are being prepared for Test Phase experiments or for shipping off-site. While test bin containers managing TRU-mixed waste are stored in the WHB, the Permittees will be required to conduct sampling, analysis, and purging of head space gases in the test bins at a frequency which ensures that the mixture of potentially flammable gases within the headspace remains at concentrations no more than one-half of the lower explosive limit.

Module IV

Module IV provides permit conditions for the design and operation of Bin-Scale Test Rooms (BSTRs) 1 and 3 within the subsurface. The use of subsurface mined openings called Alcoves for experiments using TRU-mixed waste is not included in this permit. As discussed under Module III, the draft permit will limit the Permittees to the use of only Type 1 dry and Type 1 humid test bins for conducting

Test Phase experiments with TRU-mixed waste. Test Bin containers will not be accepted for storage if they contain greater than 1% liquid by volume. However, the Permittees will be allowed to adjust the humidity of the atmosphere inside the test bins while they are stored in the BSTRs. Humidification of the atmosphere in a bin will be accomplished by recirculating the air in the bin over a reservoir of salt brine. The volume of liquid evaporated from the reservoir into the test bin atmosphere will be carefully measured to ensure that the total amount of free liquid (including moisture in the test bin at the time of receipt and moisture added during humidification) shall not be allowed to exceed 1% of the volume of the test bin. Secondary containment for containers of TRU-mixed waste stored in the WHB will be provided either by the RCB for test bins, or by a portable secondary containment tray or an SWB for derived waste containers. While test bin containers managing TRU-mixed waste are stored in the BSTRs, the Permittees will be required to conduct sampling, analysis, and purging of head space gases in the test bins at a frequency which ensures that the mixture of potentially flammable gases within the headspace remains at concentrations no more than one-half of the lower explosive limit.

Several of the permit conditions related to the management of TRU-mixed waste in the BSTRs may be of particular interest to the public. The first is the installation, monitoring and maintenance of the existing and proposed roof support systems. The conditions of Module IV require the Permittees to maintain the existing roof support, roof support monitoring, and geotechnical monitoring systems in good operating order. The conditions also require the Permittees to submit designs and plans for NMED approval if any proposed roof support or monitoring systems for BSTR 3 are different from the existing systems in BSTR 1. The Permittees are required to monitor the condition of the BSTRs and the supplementary roof support systems using the monitoring equipment described above. Corrective action, maintenance, and possibly waste retrieval, will be required if the monitoring indicates that deterioration of the roof or support system is occurring.

Another set of permit conditions in Module IV requires the Permittees to manage volatile organic compound (VOC) emissions from test bin containers in storage in the BSTRs to prevent releases to the atmosphere. This will be accomplished by connecting the test bin outlets to a manifold collection system which includes an activated carbon filter capable of removing at least 95% of the test bin VOC emissions. The Permittees will be required to monitor the outlet of the manifold collection system(s) as well as the outlets from the BSTRs themselves on a regular basis to ensure that significant releases of VOCs to the atmosphere are not occurring.

Module V

The permit does not require DOE and WID to perform groundwater monitoring during the term of the permit. This determination was made because the Waste Handling Building (WHB), Bin Scale Test Rooms (BSTRs), and waste container designs are such that release from the units to the uppermost aquifer is not likely. Site hydrogeologic conditions were also evaluated by examining hydrogeologic data included within the permit application and associated references. These site-specific hydrogeologic data, such as depth to groundwater, groundwater flow rates, and rock permeability, indicate that contaminant introduction to, or migration within the uppermost aquifer below the WHB or BSTRs during the permit period is highly unlikely. However, should conditions change within the Waste Handling Building (WHB) or Bin Scale Test Rooms (BSTRs), such that the potential for a release to the uppermost aquifer below the WHB or BSTR could occur, NMED can require groundwater monitoring.

Module VI

The permit proposed by the U.S. Environmental Protection Agency (EPA) is located in Module VI and implements the requirements imposed by the Hazardous and Solid Waste Amendments of 1984 (HSWA) to the federal Solid Waste Act. Conditions include requirements for hazardous waste minimization, hazardous waste land disposal restrictions, air emission standards for hazardous waste process vents, and corrective action to investigate possible releases from Solid Waste Management Units (SWMUs).

SWMUs are waste units that contain hazardous waste constituents, such as lead, benzene, xylene, etc. The facility must find the full extent of contamination for each SWMU identified in the permit. Some SWMUs may require cleanup/remediation. In addition, the permit requires the Permittees to notify EPA of newly identified SWMUs and newly identified releases from SWMUs at the WIPP.

Availability of the Draft Permits:

The draft permits are available for public review at the New Mexico Environment Department's Hazardous and Radioactive Materials Bureau, 525 Camino de Los Marquez, Suite 4 in Santa Fe, New Mexico 87502, Monday through Friday from 8:00 A.M. until 5:00 P.M., and at the library of the U.S. Environmental Protection Agency, (U.S. EPA), Region 6, 1445 Ross Avenue in Dallas, Texas 75202. Copies are also available for public review at the following locations:

Comment Period and Regulatory Contacts:

For the RCRA hazardous waste permit:

Hazardous and Radioactive Materials Bureau
New Mexico Environment Department
P.O. Box 26110
Santa Fe, New Mexico 87502
Attention: Ms. Barbara Hoditschek
(505) 827-4308

For the HSWA hazardous waste permit:

Mr. Bill Honker, Chief
Hazardous Waste (RCRA) Permits Branch
1445 Ross Avenue
Dallas, Texas 75202
(214) 655-6770

Comments on either draft permit must be received by November 1, 1993, in order to be considered.

Permit Decision:

All comments submitted concerning the NMED hazardous waste draft permit will be considered in formulating the NMED permit decision. The Secretary of the NMED may propose a modified draft permit based on comments received during this comment period. After public hearings the Secretary of the NMED may either approve the permit as written, modify the permit, or deny the permit in whole or in part. Public hearings will be held before any NMED permit decision is made.

In order to store TRU-mixed wastes at the WIPP, the Permittees must obtain permits from both the NMED and the U.S. EPA. All comments submitted concerning the EPA draft permit will be considered in formulating the EPA permit decision. The Regional Administrator of the U.S. EPA, Region 6 may either issue the permit as proposed or modify the permit based on the comments received. EPA may participate in the public hearings that will be scheduled by the NMED.

If the permits are issued, they will become the facility operating conditions, in conjunction with all applicable regulations promulgated in the New Mexico or federal Hazardous Waste Regulations for hazardous waste management at the facility. The NMED and the U.S. EPA will notify DOE and Westinghouse of the final permit decision and each person who submits written comments during the public comment period and who provides a forwarding address.

Subject Correspondance between WIPP and NMED concerning permission to despose of certain wastes waters into the sewage lagoon; permission to continue disposal of brine into evap pond.

Discussion WIPP wants to use a new form to expediate approval of certain waste waters coming from various parts of the plant to be discharged into the sewage lagoon. We said we would review the form and let them know. WIPP also wants to continue to dichange brine from the air intake shaft into the evap. pond instead of the sewage lagoon because it will only be happening for one more month. Emergency temp. approval is currently in effect and granted thru the language of the permit (not the formal 120 day extension). We said probably no problem - will let them know.

Conclusions Review form to see if it is adequate for approval correspondance (Will we have to follow it up with a letter of our own?). Review plan language to see if we can allow brine dischange into evap. pond for one more month.

DAN ROBERTSON to BOB GARCIA
887-8240

Subject OP-831 WIPP SEWAGE ponds

Discussion DAN plans to dispose 4-55 gallon drums of laboratory rinse water into the sewage evaporation lagoons. DAN sampled the water and faxed the results to me on 4/16/93. After reviewing the data and discussing this with MARCY, we decided to allow this because WQCC Section 3-103.A water quality standards were not exceeded.

Conclusions Mr. Robertson can proceed with his plan to dispose of this water in the sewage evaporation ponds.

Santa Fe, New Mexico 87503

Dear Ms. Levitt:

The Department of Energy (DOE) requests an extension for the submittal of the first discharge monitoring report (DMR) for the Waste Isolation Pilot Plant (WIPP) sewage system until construction of the facility has been completed. The DOE requests that the submittal of the initial DMR be delayed 90 days. Construction delays were caused by difficulties with material procurement, and the completion of the competitive construction, and liner installation bids. The DOE is confident that the construction will be completed before June 30, 1993.

The DOE appreciates the assistance Mr. Garcia has provided in helping the WIPP with design suggestions for the facility. We appreciate your consideration of these requests. If you have any questions concerning this matter please feel free to contact Ms. M. E. Bennington of my staff at (505) 887-8132.

Sincerely,

Arlen Hunt, Manager

RE: DP-831; Sewage system discharge monitoring report(DMR)

Dear Mr. Hunt:

The New Mexico Environment Department (NMED), Ground Water Section (GWS) has reviewed your March 22, 1993 letter requesting an extension for submittal of the first DMR.

Because of the reasons stated in your letter (construction delays, material procurement, liner bids, etc.) your request to delay submittal of the monitor requirements for the soon-to-be lined evaporation lagoons is hereby approved. However, you must submit the remaining information required as part of your approved discharge plan no later than May 3, 1993.

If you have any questions please call Bob Garcia at 827-0027 or myself at 827-2900.

Sincerely,

Marcy Leavitt, Manager
Ground Water Section

RE: Waste water/Sludge Disposal, DP - 831

Dear Mr. Hunt:

The New Mexico Environment Department (NMED), Ground Water Section is in receipt of your August 13, 1992 notification of waste water/sludge disposal and is in agreement with the procedures as outlined therein as pertains to the conditions and requirements of your approved discharge plan, referenced above.

If you have any questions or desire further information, please contact me at 827-2703. Your discharge plan has been assigned to me and I look forward to a mutually rewarding association.

Sincerely,

Phillis Stevens

Mr. Robert J. Garcia, P.E.
Environmental Engineer Specialist
Ground Water Section
New Mexico Environment Department
1190 St. Francis Drive
Santa Fe, NM 87502

Dear Mr. Garcia:

This letter is to reiterate your telephone discussions with the Waste Isolation Pilot Plant (WIPP) today concerning the water collected in a chiller water pipe trench. The Department of Energy (DOE) would like to pump the water collected in the chiller water pipe trench into the WIPP sewage lagoon. The pipe trench is designed to provide maintenance access to insulated chiller piping which runs below the surface. Storm water has collected in the trench over the past eight years and has the potential to rust out the chiller piping.

As was discussed, analysis has shown that contaminant levels in this water are below state and federal regulatory limits. However, the sediments at the bottom of the trench exceed state groundwater regulatory limits for arsenic, barium, and possibly, selenium. Copies of the analyses for both the water (Enclosure 1) and sediments (Enclosure 2) are enclosed.

The DOE proposes to pump the non-regulated water to the WIPP sewage lagoon, leaving several inches of water in the trench so that the underlying sediments will not be disturbed. The DOE will then use a sump pump to transfer the sediments into drums. Those drums which meet Department of Transportation standards will subsequently be sent off-site for disposal at a licensed landfill in accordance with the applicable regulations.

AUG 1 3 1992

The DOE is requesting the New Mexico Environment Department's Groundwater Bureau provide confirmation that the disposal of the above referenced waters into the sewage lagoon is allowed under the provisions of the discharge plan for the WIPP sewage lagoon (DP-831).

If you have any questions regarding this proposal, please feel free to contact Hart M. Greenwood at (505) 887-8107.

Sincerely,

Arlen Hunt

Department of Energy
Albuquerque Operations Office
Waste Isolation Pilot Plant Project Office
P. O. Box 3090
Carlsbad, New Mexico 88221

APR 10 1992

RECEIVED
APR 13 1992
GROUND WATER BUREAU

Mr. Robert J. Garcia, P.E.
Environmental Engineering Specialist
Ground Water Protection and Remediation Bureau
New Mexico Environment Department
1190 St. Francis Drive
Santa Fe, NM 87502

Dear Mr. Garcia:

On March 26, 1992, the Waste Isolation Pilot Plant (WIPP) Project Site Office (WPSO) requested approval from the New Mexico Environment Department (NMED) to dispose nonhazardous brines, generated by the cleaning of WIPP observation wells, through discharge into the WIPP salt pile evaporation basin. NMED approved the disposal in its March 27, 1992, letter under the provisions of WIPP Discharge Plan DP-831. In the approval letter, NMED requested the following documentation at the end of the disposal activity: (1) a copy of the analysis of the waters discharged, (2) the amount of disposed brines, and (3) the date(s) of disposal.

Results of the March 24, 1992, WIPP laboratory analysis of a composite sample of the subject brines are enclosed. Prior to discharge, the subject brines were stored in steam-cleaned frac tanks. A total of 46,578 gallons of brine were hauled by truck to the evaporation basin for disposal. On March 31, 1992, 25,368 gallons were hauled to the evaporation pond. On April 3, 1992, 21,210 gallons were hauled to the evaporation pond.

If you have any questions or require any additional information, please contact Hart M. Greenwood at 887-8107.

Sincerely,

for Arlen Hunt
Project Site Manager

Environmental Monitoring
Waste Isolation Pilot Project

April 6, 1992

Larry,

As per request of the New Mexico Environmental Department letter dated March 27, 1992 the dates and quantities of water disposed of in the WIPP salt pile evaporation pond are as follows.

On March 24, 1992 a sample of waters to be disposed were taken and analyzed in the WIPP environmental on site laboratory. The results were TDS 49,300, Specific Gravity 1.0466, Specific Conductivity 71,800 and total Iron 3.84 mg/l. A copy of the laboratory analysis work sheet is attached.

On March 31, 1992 Rowland trucking disposed of 604 barrels (42 gallons per barrel) and again on April 3, 1992 Rowland trucking Disposed of 505 barrels. Both discharges were made to the WIPP salt evaporation pond and in each instance the tank used to transport the water from the well site to the evaporation pond was steamed cleaned prior to transporting the water. Affidavits of steam cleaning for the trucks are also attached.

Sincerely

Ron Richardson

Re: DP-831

Dear Mr. Hunt:

On March 23, 1992 NMED was contacted by your staff requesting permission to dispose of circulation waters used in the cleaning of the observation well casings at the WIPP. This request was followed in writing with your March 26, 1992 letter. Your letter stated analysis results indicate that no applicable standard will be approached or exceeded, with only slight elevations in Total Suspended Solids (TSS), Chloride (CL), and Iron (Fe). This discharge with slight elevations of TSS, CL, and Fe, should not pose a problem with the existing salt pile evaporation pond. Accordingly, your request is acceptable and approved.

For our files please submit a copy of the analysis of this water, the amount and the dates this water is disposed of in the WIPP salt pile evaporation pond.

If you have any questions please call me or Phillis Stevens at 827-2919 or 827-2703.

Sincerely,

Robt M. Gallegos

Mr. Robert J. Garcia, P.E.
Environmental Engineer Specialist
Ground Water Section
New Mexico Environment Department
P. O. Box 26110
Santa Fe, NM 87502

Dear Mr. Garcia:

As my staff recently discussed with you, the Waste Isolation Pilot Plant (WIPP) requests permission to discharge circulation waters generated from the cleaning of observation well casings at the WIPP. The accumulation of solids on the walls of the well casings makes it impossible to obtain a seal with well packers used to sample water from different levels in our observation wells. Therefore, the well casings have been cleaned, resulting in production of associated circulation waters which are presently being stored in a truck-borne tank. The WIPP proposes to dispose of these circulation waters in the WIPP salt pile evaporation pond. Analysis results indicate that no applicable standard will be approached or exceeded, with only slight elevations in Total Suspended Solids (TSS), Chloride (Cl), and Iron (Fe) from this one-time procedure.

If you have any questions regarding this procedure, please feel free to contact Trey Greenwood of my staff at 887-8107. Thank you for your consideration on this matter.

Sincerely,

for Arlen Hunt

RE: Discharge Plan Approval, DP-831

Dear [illegible]nt:

Pursuant to Water Quality Control Commission (WQCC) Reg. 3-109, the discharge plan application for DP-831, submitted by the U.S. Department of Energy, Waste Isolation Pilot Plant (WIPP) Project Site Office for the discharge of 23,000 gallons per day (GPD) of sewage effluent and up to 1500 GPD of nonhazardous brine water from the Waste Isolation Pilot Plant is hereby approved, subject to any conditions listed below. The facility is located approximately 30 miles east of Carlsbad in the NE1/4, SE1/4, NW1/4 of Section 29, T22S, R31E, Eddy County. In approving this discharge plan, the New Mexico Environment Department (NMED) has determined that the requirements of WQCC Reg. 3-109.C have been met.

The approved WIPP sewage treatment is briefly described as follows:

An average of 23,000 GPD of sewage effluent is being discharged into an existing lagoon system. The existing sewage facilities at the WIPP site are made up of two settling and polishing cells, operated in parallel, and a single evaporation lagoon. The present system is approximately 3.9 surface acres, or 12.59 acre/feet in size. The proposed evaporation lagoon expansion will enlarge the facility by approximately 1.5 surface acres, or 5.25 acre/feet. These new lagoons will be lined with a 30-mil synthetic liner. A maximum of 1500 GPD of nonhazardous brine water will be hauled by tank truck and pumped into the existing Salt Pile evaporation pond, until the proposed new evaporation lagoons are constructed. After the new lagoons are completed, flow from the existing lagoon system will be diverted to the new lagoons. The existing North Cell evaporation lagoon will be lined prior to being brought back into service.

Harold Runnels Building • 1190 St. Francis Drive • P O Box 26110 • Santa Fe, New Mexico 87502
(505) 827-2850 FAX (505) 827-2836

The approved discharge plan consists of the materials submitted by Westinghouse Electric Corporation dated November 14, 1991 and January 8, 1992. However, approval of this discharge plan does not relieve you of your responsibility to comply with any other applicable local laws and regulations, such as zoning requirements and nuisance ordinances.

SPECIFIC REQUIREMENTS

The terms and conditions of this approval contain specific requirements which are summarized below.

1. The applicant shall monitor the quantity of brine water pumped into the evaporation ponds monthly and submit a quarterly report to the Ground Water Section's office.

2. A Water Quality analysis of the inflow to the lagoon system shall be submitted with the quarterly report mentioned above. This report shall include the analysis for Nitrate, TKN, Radium 226 & 228. (See attached Discharge Plan Listing and Summary).

3. Each evaporation lagoon shall be sampled for TDS quarterly and the results submitted in the quarterly report.

4. Berms protecting the lagoon system shall be maintained to protect from precipitation runoff and runon.

5. The applicant has 18 months from date of approval to complete construction of the proposed evaporation ponds. The applicant can discharge brine waters into the existing Salt Pile evaporation pond until the new evaporation ponds are completed.

GENERAL DISCHARGE PLAN REQUIREMENTS

In addition to any other requirements provided by law, the approval of DP-831 is subject to the following general requirements:

Monitoring and Reporting

Monitoring and reporting shall be as specified in the discharge plan and supplements thereto. These requirements are summarized on the attached sheet(s). Any inadvertent omissions from this summary of a discharge plan monitoring or reporting requirement shall not relieve you of responsibility for compliance with that requirement.

Record Keeping

1. The discharger shall maintain at the facility, a written record of ground water and wastewater quality analyses.

The following information shall be recorded and shall be made available to the NMED upon request.

a. The dates, exact place and times of sampling or field measurements.

b. The name and job title of the individuals who performed the sampling or measurements.

c. The dates the analyses were performed.

d. The name and job title of the individuals who performed the analyses.

e. The analytical techniques or methods used.

f. The results of such analyses, and

g. The results of any split sampling, spikes or repeat sampling.

2. The discharger shall maintain a written record of any spills, seeps, and/or leaks of effluent, leachate and/or process fluids not authorized by this discharge plan.

3. The discharger shall maintain a written record of the operation, maintenance and repair of facilities/equipment used to treat, store and/or dispose of wastewater; to measure flow rates; and/or to monitor water quality. This will include repairs, replacement or calibration of flow meters or repairs or replacement of pond liners.

Inspection and Entry

In accordance with Sections 74-6-9.B & E NMSA 1978 and WQCC Reg. 3-107.D., the discharger shall allow the Secretary or her authorized representative, upon the presentation of credentials, to:

1. Enter at regular business hours or at other reasonable times upon the discharger's premises or where records must be kept under the conditions of this discharge plan.

2. Inspect and copy, during regular business hours or at other reasonable times, any records required to be kept under the conditions of the discharge plan.

3. Inspect, at regular business hours or at other reasonable times, any facility, equipment (including monitoring, and control equipment), practices or operations regulated or required under this discharge plan.

4. Sample or monitor, at reasonable times for the purpose of assuring discharge plan compliance or as otherwise authorized by the New Mexico Water Quality Act, any effluent at any location before or after discharge.

Duty to Provide Information

In accordance with Section 74-6-9.B NMSA 1978 and WQCC Reg. 3-107.D., the discharger shall furnish to the NMED, within a reasonable time frame specified by NMED, any relevant information which it may request to determine whether cause exists for modifying, terminating and/or renewing this discharge plan or to determine compliance with this plan. The discharger shall furnish to the NMED, upon request, copies of records required to be kept by this discharge plan.

Spills, Leaks and Other Unauthorized Discharges

This approval authorizes only those discharges specified in the discharge plan. Any unauthorized discharges violate WQCC Reg. 3-104, and must be reported to the NMED and remediated as required by WQCC Reg. 1-203. This requirement applies to all seeps, spills, and/or leaks discovered from the sewage lagoons or that may directly or indirectly leave the boundaries of the WIPP site.

Retention of Records

The discharger shall retain records of all monitoring information, including all calibration and maintenance records, copies of all reports required by this discharge plan, and records of all data used to complete the application for this discharge plan, for a period of at least five years from the date of the sample collection, measurement, report or application. This period may be extended by request of the Secretary at any time. This requirement does not supercede any other requirements for records retention.

Enforcement

Failure to grant the Secretary or her authorized representative access to the records required to be kept by this discharge plan or to allow an inspection of the discharge facilities or to the collection of samples is a violation of this discharge plan and the WQCC Regulations. Such violations as well as other violations of the discharge plan, may subject the discharger to civil penalties and injunctive relief pursuant to Sections 74-6-5.P and 74-6-10 NMSA 1978, and/or modification or termination of this discharge plan pursuant to Section 74-6-5.J NMSA 1978. In addition, anyone who knowingly makes any false statement, representation or certification in any record, report or other document required to be kept by this discharge plan shall, upon conviction, be punished by a fine of not less than $300 or more than $10,000 per day or by imprisonment for not more than one year or both, pursuant to Section 74-6-5.O NMSA 1978.

Modifications and/or Amendments

The discharger shall notify NMED, pursuant to WQCC Regs. 3-107.C, of any modifications or additions to the applicant's wastewater disposal system, including any increase in wastewater flow rate and wastewater storage and disposal management changes to the system as approved under this discharge plan. The discharger shall obtain NMED's approval, as a discharge plan modification, prior to any increase in the quantity or concentration of constituents in the waste water above those approved in this plan. Please note that WQCC Regs. 3-109.E and F provide for possible future amendment of the plan.

Other Requirements

Please be advised that the approval of this plan does not relieve WIPP of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

RIGHT TO APPEAL

If the applicant is dissatisfied with this action taken by NMED, the applicant may file a petition for hearing before the WQCC. This petition shall be in writing to the Secretary of NMED at:

P.O. Box 26110 - Runnels Bldg.
1190 St. Francis Drive
Santa Fe, NM 87502

within thirty (30) days of the receipt of this letter. Unless a timely request for hearing is made, the decision of the NMED shall be final.

PERIOD OF APPROVAL

This approval is good for five years and will expire on January 16, 1997.

We would like to thank Mr. Dan Robertson for his cooperation throughout this discharge plan review and approval process.

Sincerely,

Steven J. Cary, Chief
Ground Water Protection &
Remediation Bureau

Department of Energy
Albuquerque Operations Office
Waste Isolation Pilot Plant Project Office
P. O. Box 3090
Carlsbad, New Mexico 88221

JAN 07 1992

Dr. Ernest C. Rebuck, Program Manager
Groundwater Bureau
New Mexico Environment Department
1190 St. Francis Dr.
Santa Fe, New Mexico 87503

Dear Dr. Rebuck:

Please find enclosed the revised Discharge Plan Application, and the engineering design drawings for the expansion of the sewage lagoon system at the Waste Isolation Pilot Plant (WIPP). In addition, please find enclosed the five year discharge permit fee ($1,150). Please note that the WIPP Project Site Office (WPSO) is submitting the engineering design drawings by January 6, 1992, as required by the New Mexico Environment Department (NMED). In addition, the WPSO is submitting a revised Discharge Plan Application as requested by Robert J. Garcia of your staff on December 18, 1991. The original Discharge Plan Application was submitted on November 14, 1991. The WPSO understands that this submittal completes the permit application package requirements for a NMED groundwater discharge permit.

The expansion of the sewage lagoon will include the construction of a new, lined, evaporation lagoon, to be located "downstream" from the existing sewage lagoon, and the installation of a liner in the existing sewage lagoon. The liner for the existing sewage lagoon will be installed after the new lagoon is put "on-line".

The new lagoon will store and evaporate sewage effluent flowing from the existing sewage lagoon. In addition, the new lagoon will store and evaporate brine waters generated from mine dewatering activities and the pumping of groundwater observation wells around the site. A truck will be used to transport the brine to the new lagoon. It is important to note that brine waters will only be introduced into the north cell of the new sewage lagoon.

The WPSO will submit the certified "as-built" engineering drawings upon completion of the expansion of the sewage lagoon. These drawings will detail the "as-built" berms, fence, and synthetic liner construction. The sewage lagoon expansion will begin after the NMED groundwater discharge permit has been received, and after the National Environmental Policy Act (NEPA) requirements have been met.

If you have any questions regarding this submittal, please contact James A. Mewhinney at (505) 887-8143.

Sincerely,

For Arlen Hunt
Project Manager

UNITED STATES
DEPARTMENT OF THE INTERIOR
FISH AND WILDLIFE SERVICE
Ecological Services
Suite D, 3530 Pan American Highway, NE
Albuquerque, New Mexico 87107

December 23, 1991

Mr. Ernest Rebuck
Ground Water Section
New Mexico Environment Department
P.O. Box 26110
Santa Fe, New Mexico 87502

Dear Mr. Rebuck:

This responds to the Public Notice dated November 25, 1991, regarding the effects of granting State of New Mexico groundwater discharge permits on fish, shellfish, and wildlife resources in New Mexico.

The U.S. Fish and Wildlife Service (Service) has determined there is no wetland or other environmentally sensitive habitat that will be adversely affected by the following discharge plans.

> **DP-48 Karler Packing Company**, 10 miles south of Albuquerque, Bernalillo County, New Mexico.

> **DP-213 Chino Mines Company**, Santa Rita and Hurley, Grant County, New Mexico.

The Service is providing the following comments regarding these additional permit applications.

> **DP-831 Waste Isolation Pilot Plant - Sewage Lagoon**, 30 miles east of Carlsbad, Eddy County, New Mexico. Two sewage ponds are proposed to be added to five existing ponds to treat sewage effluent, brine waters generated from mine dewatering activities, and groundwater pumped from observation wells around the site. The Service recommends that steps be taken to preclude migratory bird access to the ponds such as the installation of netting or screens over the ponds.

> **DP-832 Olex Spice, Inc.**, 2 miles east of Radium Springs, Dona Ana County, New Mexico, plans to store effluent composed of recovered condensed steam (water) and hexane in a poured concrete lagoon for evaporation of hexane and reuse in the operation or for irrigation of landscape areas at the plant. The Service also recommends such measures as the installation of netting or screens over the lagoon to preclude migratory bird contact with the effluents. Furthermore, the potential for groundwater contamination exists if recovered water with residual hexane is applied to the ground during irrigation procedures. Tests should be performed before application to ensure no hexane remains in any water to be used for this purpose.

Section 703 of the Migratory Bird Treaty Act (Act) prohibits anyone at any time or in any manner to capture, transport, or kill any migratory birds unless permitted by regulations promulgated under it. If migratory birds become exposed and/or accumulate harmful levels of contaminants, this may constitute "take" under the Act. The courts have stated the Act can be constitutionally applied to impose penalties to persons, associations, partnerships, or corporations which did not intend to "kill" migratory birds, and that the Act includes poisoning by any means. The unlawful killing of even one migratory bird is an offense.

If we can be of further assistance, please leave a message for Todd Adornato or phone Richard Roy at (505) 883-7877.

Sincerely,

Jennifer Fowler-Propst

December 2, 1991

The Honorable Bob Forrest
Mayor
City of Carlsbad
P.O. Box 1569
Carlsbad, NM 88220

Dear Mayor Forrest:

Enclosed is a copy of the public notice which includes notice of a proposed discharge plan(s) for one or more operations in or near your city which is being published by the New Mexico Environment Department in a newspaper of general circulation.

If you have any questions, please do not hesitate to contact me at the address listed below or at 827-2900.

Sincerely,

Ernest C. Rebuck
Program Manager
Ground Water Section

PUBLIC NOTICE

NEW MEXICO ENVIRONMENT DEPARTMENT

Notice is hereby given that, pursuant to New Mexico Water Quality Control Commission Regulations, the following proposed discharge plans have been submitted for approval to the New Mexico Environment Department. The information in this notice generally has been supplied by the applicant and may or may not have been confirmed by the Environment Department.

DP-48 KARLER PACKING COMPANY, Jess Karler, President, P.O. Box 1005, Albuquerque, NM 87103, proposes to renew its discharge plan for the discharge of 60,000 gallons per day of meat processing waste water to a concrete lagoon followed by land application. The facility is located 10 miles south of Albuquerque in Section 31, T9N, R3E, Bernalillo County. The meat processing waste water is routed to a concrete lagoon for preliminary treatment. The waste water is then trucked to the west mesa for land application. Ground water below the site is at a depth greater than 100 feet and has a total dissolved solids concentration of approximately 500 milligrams per liter.

DP-213 CHINO MINES COMPANY, D.P. Milovich, Manager, Hurley, NM 88043, proposes to modify its discharge plan for its copper and molybdenum concentrator facility located at Santa Rita, NM and pipelines associated with the concentrator. The concentrator has a capacity of 50,000 tons of ore per day. The concentrator is connected to the tailings area at Hurley by a set of three buried pipelines which traverse the seven mile distance. There is also a concentrate slurry line and a process water return line associated with the concentrator. The concentrator and pipelines are located in T17S, R12W; T18S, R12W; T18S, R13W; T19S, R12W and T19S, R13W. The concentrator is located at Santa Rita, NM and the pipelines are between Santa Rita and Hurley, NM, Grant County. The modification proposes methods to improve leak detection of pipeline ruptures and proposes corrective actions for addressing tailings spills. Ground water below the site is at a depth of approximately 19 to approximately 100 feet and has a total dissolved solids concentration of approximately 375 to 3,630 milligrams per liter.

DP-831 WASTE ISOLATION PILOT PLANT - SEWAGE LAGOON, Mr. Arlen E. Hunt, P.O. Box 2078, Jal Highway, Carlsbad, NM 88220, proposes to discharge about 23,000 gallons per day of sewage effluent and about 1,500 gallons per day of brine water into lined evaporation ponds. The facility is located approximately 30 miles east of Carlsbad in the SE 1/4, NE 1/4, NW 1/4 of Section 29, T22S, R31E, Eddy County. Lined lagoons will be used to treat sewage effluent, brine waters generated from mine detwatering activities and ground water pumped from observation wells around the site. Ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 10,500 milligrams per liter.

DP-832 OLEX SPICE, INC., Lloyd Anderson, Star Route Box 314, Rincon, NM 87940, proposes to discharge 2,800 gallons per day of condensate containing a maximum of five pounds of hexane per hour from an Oleo resin extraction plant. The facility is located approximately two miles due east of Radium Springs in the E 1/2, NW 1/4, SW 1/4 of Section 12, T21S, R1W, Dona Ana County. Effluent is to be stored in a poured concrete lagoon for evaporation of hexane and reuse in the operation or for irrigation of landscape areas at the plant. Ground water below the site is at a depth of approximately 65 feet and has a total dissolved solids concentration of approximately 2,160 milligrams per liter.

Any interested person may obtain further information from the Ground Water Section of the Environment Department, telephone (505) 827-2900, and may submit written comments to the Ground Water Section, Environment Department, P.O. Box 26110, Santa Fe, NM 87502. Prior to ruling on any proposed discharge plan or its modification, the Environment Department will allow thirty (30) days after the date of publication of this notice to receive written comments and during which a public hearing may be requested by any interested person. Requests for public hearing shall set forth the reasons why the hearing should be held. A hearing will be held if the Environment Department determines that there is significant public interest.

GROUND WATER BUREAU

Dr. Ernest C. Rebuck, Program Manager
Groundwater Bureau
New Mexico Environment Department
1190 St. Francis Dr.
Santa Fe, New Mexico 87503

Dear Dr. Rebuck:

Please find enclosed the completed Discharge Plan Application for the expansion of the sewage lagoon system at the Waste Isolation Pilot Plant (WIPP). The expansion includes the construction of a new, lined, evaporation lagoon, to be located "downstream" from the existing sewage lagoon, and the installation of a liner in the existing sewage lagoon. The liner for the existing sewage lagoon will be installed after the new lagoon is put "on-line."

The new lagoon is designed to store and evaporate brine waters generated from mine dewatering activities and the pumping of groundwater observation wells around the site. The new lagoon will also be used as an additional storage and evaporation basin for sewage effluent flowing from the existing sewage lagoon. A truck will be used to transport the brine to the new lagoon. It is important to note that brine waters will not be introduced into the other cells of the existing sewage lagoon system.

This discharge plan application is being submitted as part of the requirements of the New Mexico Environment Department (NMED) temporary 120-day discharge permit for the disposal of brine waters in the salt pile evaporation pond. The WIPP Project Office understands that the NMED must receive the final engineering design drawings and construction cost estimates by January 6, 1992. This January submittal will complete the permit application package.

If you have any questions regarding this submittal, please contact James A. Mewhinney at 887-8143.

Sincerely,

Thomas J. Reese
for Arlen Hunt
Project Manager

PUBLIC NOTICE

NEW MEXICO ENVIRONMENT DEPARTMENT

Notice is hereby given that, pursuant to New Mexico Water Quality Control Commission Regulations, the following proposed discharge plans have been submitted for approval to the New Mexico Environment Department. The information in this notice generally has been supplied by the applicant and may or may not have been confirmed by the Environment Department.

DP-831 WASTE ISOLATION PILOT PLANT - SEWAGE LAGOON, Mr. Arlen E. Hunt, P.O. Box 2078, Jal Highway, Carlsbad, NM 88220, proposes to discharge about 23,000 gallons per day of sewage effluent and about 1,500 gallons per day of brine water into lined evaporation ponds. The facility is located approximately 30 miles east of Carlsbad in the SE 1/4, NE 1/4, NW 1/4 of Section 29, T22S, R31E, Eddy County. Lined lagoons will be used to treat sewage effluent, brine waters generated from mine detwatering activities and ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 10,500 milligrams per liter.

Any interested person may obtain further information from the Ground Water Section of the Environment Department, telephone (505) 827-2900, and may submit written comments to the Ground Water Section, Environment Department, P.O. Box 26110, Santa Fe, NM 87502. Prior to ruling on any proposed discharge plan or its modification, the Environment Department will allow thirty (30) days after the date of publication of this notice to receive written comments and during which a public hearing shall set forth the reasons why the hearing should be held. A hearing will be held if the Environment Department determines that there is significant public interest.

CERTIFIED MAIL - RETURN RECEIPT REQUESTED

September 18, 1991

James A. Mewhinney
Program Manager, Environment,
Safety and Health
Waste Isolation Pilot Project Office
Dept. of Energy, Albuquerque Operations O.
P. O. Box 3090
Carlsbad, NM 88221

RE: Temporary Permission for Disposal of Brine Waters

Dear Mr. Mewhinney:

Your letter dated August 22, 1991 requested permission to temporarily discharge approximately 1500 gallons per day of brine waters from mine dewatering and the pumping of monitor wells to an unlined one-acre basin. The basin is located within the Waste Isolation Pilot Plant site and is approximately 26 miles east of Loving in the SE 1/4 of Section 20, T22S, R31E, Eddy County.

Pursuant to Section 3-106. B. of the NM Water Quality Control Commission (WQCC) Regulations, the above referenced discharge hereby is allowed without an approved discharge plan until January 16, 1992.

This approval is contingent on your discharging as described in your letter of August 22, 1991 and the following condition:

> A discharge plan application will be submitted to the NM Environment Department (NMED), Ground Water Section within 60 days of the date of this letter. A blank application form is enclosed.

New Mexico DRUG FREE It's a State of Mind!

The reason for this requirement is that the temporary permission is restricted by the WQCC Regulations to a maximum of 120 days. Any discharges after the 120 days must be pursuant to an approved discharge plan, and the NMED requires 60 days in order to process a discharge plan application.

Further, this approval does not relieve you of your responsibility to comply with any other applicable local laws and regulations, such as zoning requirements and nuisance ordinances.

Also this approval does not relieve you of liability should your operation result in actual pollution of surface or ground waters which may be actionable under other laws and/or regulations.

If you have any questions, please contact Ernest Rebuck of the Ground Water Section at the above address or phone 827-2900.

Sincerely,

/S/

RE: Temporary Permission for Disp[...]
Waters

Dear Mr. Mewhinney:

Your letter dated August 22, 1991 requested permission to temporarily discharge approximately 1500 gallons per day of brine waters from mine dewatering and the pumping of monitor wells to an unlined one-acre basin. The basin is located within the Waste Isolation Pilot Plant site and is approximately 26 miles east of Loving in the SE 1/4 of Section 20, T22S, R31E, Eddy County.

Pursuant to Section 3-106. B. of the NM Water Quality Control Commission (WQCC) Regulations, the above referenced discharge hereby is allowed without an approved discharge plan until January 16, 1992.

This approval is contingent on your discharging as described in your letter of August 22, 1991 and the following condition:

> A discharge plan application will be submitted to the NM Environment Department (NMED), Ground Water Section within 60 days of the date of this letter. A blank application form is enclosed.

The reason for this requirement is that the temporary permission is restricted by the WQCC Regulations to a maximum of 120 days. Any discharges after the 120 days must be pursuant to an approved discharge plan, and the NMED requires 60 days in order to process a discharge plan application.

Further, this approval does not relieve you of your responsibility to comply with any other applicable local laws and regulations, such as zoning requirements and nuisance ordinances.

Also this approval does not relieve you of liability should your operation result in actual pollution of surface or ground waters which may be actionable under other laws and/or regulations.

If you have any questions, please contact Ernest Rebuck of the Ground Water Section at the above address or phone 827-2900.

Sincerely,

Kathleen M. Sisneros

Ernest C. Rebuck, Ph.D.
Program Manager, Ground Water Bureau
New Mexico Environment Department
1190 St. Francis Drive
Santa Fe, N.M. 87504

Dear Dr. Rebuck,

The purpose of this letter is to request an emergency permit to temporarily dispose of brine waters generated by mine dewatering and observation well pumping activities at the Waste Isolation Pilot Plant (WIPP). On August 13, 1991, the trucking and disposal contractors responsible for off-site brine water disposal at the WIPP announced that they could no longer honor their contract to haul brines from the WIPP.

Loss of service resulted when the Oil Conservation Department (OCD) conducted a review of permits issued to regional trucking companies. This review found that the permits issued to the hauling and disposal companies contracted to the WIPP, allowed for the disposal of waste waters generated by oil and gas exploration and production (e&p) only. Waters from WIPP shaft dewatering and observation well pumping are not classifed as E&P waste waters.

This announcement has put the WIPP in a difficult position of finding a properly permitted alternative disposal site or to immediately develop and obtain a permit for an on-site brine disposal facilities. The WIPP is presently developing plans for an on-site lined evaporation pond. Additionally, the WIPP is preparing to conduct due diligence at several off-site disposal facilities. However, the time required to complete either of these activities far exceeds the time it will take to fill the WIPP brine storage tank.

Mine dewatering produces approximately 21,000 gallons of brine waters every 14 calendar days. The storage capacity of the WIPP brine tank is 21,000 gallons; it will be filled by August 27, 1991. Arrangements are underway to obtain additional storage tanks. However, until permanent solutions are found, the WIPP requests an emergency permit to dispose of brine waters in the WIPP salt pile rainwater catchment/evaporation basin. This one-acre basin is unlined but sits on top of a compacted caliche pad. The depth to the nearest water-bearing stratum is approximately 800 feet. The evaporation rate at the site is 12 inches per year; thus, any potential for brines to impact ground water is essentially zero.

To assist with an emergency permit application, I have enclosed representative copies of sampling analysis results which are representative of WIPP brines, a copy of the WIPP site plan, and a drawing of the salt pile evaporation basin. If a temporary permit is granted, the WIPP will provide New Mexico Environment Department (NMED) with analyses of brine waters as part of our routine sampling program.

The WIPP is presently evaluating long term disposal options. The WIPP will keep your office apprised of its decision to obtain a permit for a permanent on-site evaporation facility, issue a contract for off-site injection well disposal, or determine if it is possible to sell process brine waters as an alternative to disposal.

We appreciate your quick attention on this matter. If you require any further information regarding this request, please contact Mr. Dan Robertson at 887-8240.

Sincerely,

James A. Mewhinney

Dear Dr. Rebuck,

The purpose of this letter is to request an emergency permit to temporarily dispose of brine waters generated by mine dewatering and observation well pumping activities at the Waste Isolation Pilot Plant (WIPP). On August 13, 1991, the trucking and disposal contractors responsible for off-site brine water disposal at the WIPP announced that they could no longer honor their contract to haul brines from the WIPP.

Loss of service resulted when the Oil Conservation Department (OCD) conducted a review of permits issued to regional trucking companies. This review found that the permits issued to the hauling and disposal companies contracted to the WIPP, allowed for the disposal of waste waters generated by oil and gas exploration and production (e&p) only. Waters from WIPP shaft dewatering and observation well pumping are not classifed as E&P waste waters.

This announcement has put the WIPP in a difficult position of finding a properly permitted alternative disposal site or to immediately develop and obtain a permit for an on-site brine disposal facilities. The WIPP is presently developing plans for an on-site lined evaporation pond. Additionally, the WIPP is preparing to conduct due diligence at several off-site disposal facilities. However, the time required to complete either of these activities far exceeds the time it will take to fill the WIPP brine storage tank.

Mine dewatering produces approximately 21,000 gallons of brine waters every 14 calendar days. The storage capacity of the WIPP brine tank is 21,000 gallons; it will be filled by August 27, 1991. Arrangements are underway to obtain additional storage tanks. However, until permanent solutions are found, the WIPP requests an emergency permit to dispose of brine waters in the WIPP salt pile rainwater catchment/evaporation basin. This one-acre basin is unlined but sits on top of a compacted caliche pad. The depth to the nearest water-bearing stratum is approximately 800 feet. The evaporation rate at the site is 12 inches per year; thus, any potential for brines to impact ground water is essentially zero.

To assist with an emergency permit application, I have enclosed representative copies of sampling analysis results which are representative of WIPP brines, a copy of the WIPP site plan, and a drawing of the salt pile evaporation basin. If a temporary permit is granted, the WIPP will provide New Mexico Environment Department (NMED) with analyses of brine waters as part of our routine sampling program.

The WIPP is presently evaluating long term disposal options. The WIPP will keep your office apprised of its decision to obtain a permit for a permanent on-site evaporation facility, issue a contract for off-site injection well disposal, or determine if it is possible to sell process brine waters as an alternative to disposal.

We appreciate your quick attention on this matter. If you require any further information regarding this request, please contact Mr. Dan Robertson at 887-8240.

Sincerely,

James A. Mewhinney

MEMORANDUM

TO: Stuart P. Castle, Bureau Chief, Ground Water Bureau

FROM: Ernest C. Rebuck, Program Manager, Ground Water Section

DATE: June 15, 1990

SUBJ: WIPP WWTP Discharge Plan Application

As per your request I've reviewed the discharge plan file referenced above. I support the type of letter which has been drafted; however, I recommend that the second paragraph be revised to include specific questions on the geology of the site, with no mention that we are considering exempting the facility from having to obtain a discharge plan. I find the information in the file at present to be extremely brief in regard to the underlying hydrogeology. I believe that it would be very helpful to meet with the WIPP technical staff and review the geology/hydrogeology with them.

Another alternative would be to quickly draft a policy memorandum for Richard Mitzelfelt's signature stating that where background water quality is demonstrated to exceed 10,000 mg/l, the facility is exempt from discharge plan requirements. In practice we would require that such facilities only register with EID via an NOI, however there would be no discharge plan.

The WQCC regulations exempt facilities from having to meet standards if the background water quality exceeds 10,000 mg/l, but the regulations stop short of exempting such from the discharge plan process itself. The intent seems to be that we automatically approve such discharge plans, which does seem terribly logical. The end result would be a discharge plan approval without EID being unable to take any enforcement action. Not only would the recommended poilicy be appropriate to WIPP, but it would a reasomable regulation change for all other facilities where background water quality exceeds 10,000 mg/l.

RE: Discharge Plan DP - ____ or NOI

Dear Gary:

Enclosed is a copy of the latest notice of intent which the EID Ground Water Section has received for your district. It is for US DOE WIPP sewage effluent pond.

Please call me at 827-2900 if you would like additional information on this facility.

Sincerely,

Ernest C. Rebuck
Program Manager
Ground Water Section

GROUND WATER BUREAU

Mr. Ernest Rebuck
Groundwater Bureau
New Mexico Environmental Improvement Division
P.O. Box 968
Santa Fe, NM 87504

Dear Mr. Rebuck:

The purpose of this letter is to transmit the enclosed Notice of Intent. The U.S. Department of Energy seeks approval for the discharge of approximately 500,000 gallons of treated sewage effluent from the sewage effluent drying pond at the Waste Isolation Pilot Plant in Carlsbad. Analytical results for samples taken from the pond are included with the notice.

The three samples taken from the evaporation pond were analyzed for volatile organics, semi-volatile organics, and metals. All parameters tested for were below the detection limits, except for Barium (0.5 mg/L) and Mercury (0.0007mg/L). These two metals are below the human standards for groundwater as identified in part 3 of the New Mexico Water Quality Control Commission Regulations.

If you have any questions concerning this matter, please contact Tom Lukow of my staff at 887-8108.

Sincerely,

for Jack B. Tillman
Project Manager

Ground Water Section
Environmental Improvement Division
P. O. Box 968
Santa Fe, NM 87504

Dear Mr. Rebuck:

The purpose of this letter is to transmit the enclosed Notice of Intent. This Notice is being filed for discharge of sanitary sewage effluent to the sewage lagoon system at the Waste Isolation Pilot Plant in Carlsbad. The sewage lagoon system consists of two Hypalon-lined stabilization ponds, two Hypalon-lined polishing ponds, a chlorinator, and an unlined evaporation pond.

Based on previous communications with the Ground Water Section, it was believed that it was not necessary to file a Notice of Intent to discharge to the sewage lagoon (Attachment 1). However, based on a recent review of this matter with Greg Lewis of your section, the U.S. Department of Energy has decided to file a Notice of Intent for discharge of effluent to the sewage lagoon system (Attachment 2).

Copies of analytical results for samples recently taken from each of three operating ponds have been enclosed for your information. Please note that although the sample taken from the lined stabilization pond exceeds the 10 mg/l limit for nitrates, the sample taken from the unlined evaporation pond is well below the limit.

Please advise us as soon as possible if a discharge plan is required.

If you have any questions concerning this matter, please contact Tom Lukow of my staff at 887-8108.

Sincerely,

Jack B. Tillman
Project Manager

Dr. Robert Eastmond
Waste Isolation Pilot Project
PO Box 2078
Carlsbad, NM 88221

Dear Dr. Eastmond:

In response to your telephoned request on June 27th for a confirmation that a discharge plan is not required for the sewage disposal activities at the WIPP site, I enclose copies of several letters:

1) A memorandum from EID scientific staff recommending that a discharge plan not be required for construction at the WIPP site;

2) A letter from the then-director of EID, Russell Rhoades, advising the WIPP Project Manager that a discharge plan was not required;

3) A letter from the WIPP Project Manager to EID, referring EID to portions of the plans and specs of the Waste Handling Building which related to sewage disposal.

According to Maxine Goad, when those plans and specs were received she simply forwarded them to the District Engineer for review, since it had been determined earlier that no discharge plan would be required. The final enclosure, ---

4) --- is a letter from Percy Blair, District Engineer, indicating that the plans appeared satisfactory.

I hope that these materials satisfy your concerns. Thank you for being so scrupulous in complying with the State ground water protection regulations.

Sincerely,

Paige Grant Morgan

WATER POLLUTION CONTROL BUREAU

M E M O R A N D U M

RECEIVED
AUG 07 1989
GROUND WATER BUREAU

TO: Charlie Nylander, Chief, WPCB

THROUGH: Bruce Gallaher and Randy Hicks

FROM: Dennis McQuillan D. McQ.

SUBJECT: U.S. Department of Energy (USDOE), Notice of Intent to Discharge for Construction Activities at the Waste Isolation Pilot Plant (WIPP)

DATE: May 11, 1983

We have reviewed the USDOE document WTSD-TME-005, Notice of Intent to Discharge Water Contaminants, WIPP, which was sent to R.F. Rhoades in a letter from J.M. McGough dated April 20, 1983. This Notice addresses construction-related discharges only; geohydrologic issues pertaining to the operation of the proposed repository are being dealt with by the Environmental Evaluation Group.

In term of specific discharges of water contaminants, this proposal is not very different from the Site and Preliminary Design Validation program. However, one difference is that a larger quantity of salt will be removed from the Salado Formation and stored at the surface. Potential discharges covered by this Notice include salt-pile runoff and possibly 26,000 gallons of a brine-based drilling fluid.

Based upon Mercer 1983, page 67, the shallowest saturated zone at the site is in lenticular Dewey Lake sandstone at depths on the order of 185 feet. These "minor" saturated zones do not appear to be continuous or capable of producing enough water to be considered an aquifer. In any case, Figure 2 of Register 1980 indicates that surface discharges would have to penetrate more than 100 feet of the Dewey Lake Redbeds (predominantly siltstone and claystone) to reach a 185-foot-deep saturated zone. Therefore, we recommend that a ground-water discharge plan not be required for the proposed construction activities.

Mr. J. M. McGough
Project Manager
WIPP Project Office
Department of Energy
Albuquerque Operations Office
P. O. Box 5400
Albuquerque, NM 87115

Dear Mr. McGough:

Please be advised that this Division has received and reviewed both your air quality permit application and Notice of Intent to Discharge for the second phase of the Waste Isolation Pilot Plant which is located approximately 26 miles east of Carlsbad, T22S, R31E, in Eddy County, New Mexico.

We have determined that neither an air quality permit for construction nor a ground water discharge plan is required for the proposed activities. If at sometime in the future you intend to change the amount, the character or the location of either air pollution emission levels or water discharges, or if observation and monitoring indicate the situation is not as described, you should notify this office.

We appreciate your cooperation in following State procedures in regard to your project. If you should have any questions, please contact this office.

Sincerely,

Russell F. Rhoades
Director

Mr. Charles Nylander
Chief, Water Pollution Control Bureau
Environmental Improvement Division
P. O. Box 968
Santa Fe, NM 87504

Dear Mr. Nylander:

In his letter of May 16, 1983, Mr. Russell Rhoades advised the Department of Energy that a ground water discharge plan would not be required for construction of the Waste Isolation Pilot Plant (WIPP) facilities near Carlsbad, NM. However, in a March 1983 meeting with you and Ms. Maxine Goad, we agreed to make the plans and specifications for the WIPP Waste Handling Building [Construction Contract Package 14 (CCP-14)] available to your office when they were completed.

Please be advised that plans and specifications for the Waste Handling Building are now complete. Copies of the plans and specifications have been forwarded to Mr. Robert Neill, Director of the WIPP Environmental Evaluation Group (EEG) in Santa Fe for their review in accordance with the terms of the Consultation and Cooperation Agreement. Because the CCP-14 design package is quite large and only a portion is of specific interest to the EID, we request that you coordinate your review with that of the EEG. Mr. Neill may be reached at 827-8280.

In regard to the containment and handling of any contaminated liquids in the Waste Handling Building, we suggest that you review the following drawings in particular:

1. 41-F-087 Revision 5, Page 2-205

2. 41-E-003 Revision 4, Page 2-27

3. 41-E-005 Revision 4, Page 2-28

Please contact us if you have any questions or comments or if we can provide any assistance during your review.

Sincerely,

Roger Dentons

GROUNDWATER BUREAU

Ms. Dale Doremus
Ground Water Quality Bureau
New Mexico Environment Department
P.O. Box 26110
Santa Fe, New Mexico 87502

Dear Ms. Doremus:

This responds to the New Mexico Environment Department's (Department) public notice dated January 15, 1997, proposing to approve discharge plans for the applicants listed below. The U.S. Fish and Wildlife Service (Service) has provided technical comments to assist the Department in developing permit stipulations and conditions to assure protection of fish and wildlife resources in New Mexico.

Permit #	Applicant	County / Location NMPM
DP- 27	Phelps Dodge Tyrone, Inc.	Grant/Sections 18-20, T18S R15W
DP- 362	Quivira Ambrosia Lake Old Stope	McKinley/various sections, T14N, R10W
DP- 375	Artesia Golf and Country Club	Eddy / Section 12, T17S, R25E
DP- 408	Truog Dairy	Chaves/Section 15&16, T14S, R25E
DP- 519	Inhalation Toxicology Res. Institute	Bernalillo / Section 3, T8N, R4E
DP- 831	Waste Isolation Pilot Plant	Eddy/Sections 28&29, T22S, R31E
DP-1051	Rhino Environmental Services	Otero / Section 22, T26S, R6E
DP-1078	Santa Fe Southern Railway Wetland	Santa Fe / Section 10, T15N, R10E
DP-1129	DLD Resources	Lea / Section 35, T19S, R36E
DP-1140	McAnally Enterprises, Inc.	Doña Ana / Section 3, T26S, R3E

Discharge plans that use lagoons, ponds, or constructed wetlands for disposal of waste waters should not create an attractive nuisance that is harmful to any threatened or endangered species or migratory birds. The Service is primarily concerned with the quality of the ponded water, because inevitably, migratory birds are attracted to these lagoons, ponds, and constructed wetlands to drink, rest, and perhaps feed on the algae and invertebrates associated with these ponded waste waters. Lagoons, ponds, and constructed wetlands might contain water, sediment, and biota with the potential for elevated concentrations of trace elements, nutrients, heavy metals, organic chemicals, antibiotics, veterinary chemicals, and even pathogenic microorganisms that may pose a risk to the health of migratory birds and other wildlife. We recommend that the applicant demonstrate that any pond, lagoon, or constructed wetland will be "bird safe" (e.g., meets New Mexico general water quality standards 1102B, 1102F, and 3101K or 3101L). Where necessary, we recommend the use of wildlife exclusion technology (e.g., nets, fences, enclosed tanks) to prevent migratory birds and other wildlife from reaching any ponds or lagoons that contain toxic chemicals. In the discharge plan (DP-831) for the Waste Isolation Pilot Project, not only should toxic chemicals be considered, but also the evaporation and accumulation of excess salts, as these pose risks to the waterfowl in this region.

Our intent is to inform and intercede before any migratory bird deaths occur as migratory birds are beneficial (e.g., they hold pest populations in check) and are protected by law. The Migratory Bird Treaty Act (MBTA) makes it unlawful for anyone at anytime or in any manner to take (i.e., pursue, hunt, take, capture, kill, transport, or possess) any migratory bird unless authorized by a permit issued by the Department of the Interior. The courts have interpreted "illegal take" to include accidental poisoning or accumulation of harmful concentrations of contaminants by migratory birds, even if the contamination event was accidental or the perpetrator was unaware of the fact that his or her actions (or failure to take action) could ultimately prove harmful to migratory birds. Therefore, if the creation and operation of a pond or lagoon results in migratory bird deaths and the problems are not addressed, the operators may be held liable under the enforcement provisions of the MBTA. If migratory birds are dying around a lagoon, pond, or wetland, please contact either the Service (800-299-0196) or the New Mexico Department of Game and Fish.

In the discharge plan (DP-27) for Phelps Dodge Tyrone in Silver City, the applicant proposes the combination of remediating hydrocarbon-contaminated soils for use as a soil substitute or tailing cover. If this is a pilot project, additional monitoring should be carried out to learn the success of this remediation strategy. Does the mine's reclamation plan need to be amended to include this new procedure for obtaining a soil substitute? One concern we have is that during precipitation events, ponding may occur in the concrete-lined tailings thickeners, which could present a potentially hydrocarbon-contaminated drinking water source to migratory birds.

In discharge plans DP-1051 and DP-1129, the applicants have recommended large expanses of land be used for the disposal of hydrocarbon-contaminated soils and to pivot-spray wastewater from a hydrochloric acid plant of a pH of 4. These discharge plans have the potential to affect many wildlife species (e.g., reptiles, cacti, prairie dog towns, predators, and migratory birds) of the Plains and Chihuahuan Desert Ecosystems. Spraying an acidic solution on 39 acres of rangeland certainly has the potential to have the same type of adverse effects to the environment as does acid rain and has the potential to injure plants and animals directly. We suggest you contact the New Mexico Department of Game and Fish and the New Mexico Energy, Minerals, and Natural Resources Department, Forestry and Resources Conservation Division for information concerning fish, wildlife, and plants of State concern in these areas before approval of these discharge plans.

In the discharge plan DP-1140, the applicant proposed to discharge chicken manure and process water to the alluvium in the Rio Grande Valley. Over time, this may present groundwater concerns. Perhaps these nutrient-rich waters can be delivered through irrigation canals during peak flow to agricultural businesses in order to supplement their reliance on fertilizers.

If you have any questions about these comments, please contact Joel D. Lusk at (505) 761-4525.

Sincerely,

Sonja Jahrsdoerfer

TO BE PUBLISHED ON OR BEFORE JANUARY 15, 1996

PUBLIC NOTICE

NEW MEXICO ENVIRONMENT DEPARTMENT

Notice is hereby given that, pursuant to New Mexico Water Quality Control Commission Regulations, the following proposed discharge plans have been submitted for approval to the New Mexico Environment Department. The information in this notice generally has been supplied by the applicant and may or may not have been confirmed by the NM Environment Department.

DP-27, PHELPS DODGE TYRONE, INC., H.M. Conger, President, proposes to modify its discharge plan to landfarm approximately 25 cubic yards per month of hydrocarbon contaminated soils at the existing tailings thickeners at the inactive mill facility and dispose of remediated soil on the No. 3 Tailings Impoundment. The landfarm facility and tailings impoundment are located approximately 10 miles southwest of Silver City in Sections 18, 19, and 20, T18S, R15W and Section 11, T19S, R15W, Grant County. Contaminated soils resulting from minor spills of kerosene and organic product at the SX/EW plant and of diesel, motor oil, and gasoline at the Tyrone Mine fuel docks, lube shop, and truck stop will be treated by bioremediation in the concrete-lined tailings thickeners. Remediated soil will be placed on the No. 3 Tailings Impoundment for site closure purposes. Ground water below the site is at a depth of approximately 50 to 70 feet and has a total dissolved solids concentration of approximately 200 to 400 milligrams per liter.

DP-362, QUIVIRA AMBROSIA LAKE OLD STOPE, LEACHING, Peter Luthiger, Supervisor Radiation Safety, and Environmental Affairs, proposes to renew and modify its discharge plan which currently allows the injection of up to 1,440,000 gallons per day of lixiviant into the workings of 8 underground uranium mines. The facility is located in the Amborosia Lake area approximately 15 miles north of Grants. Lixiviant injection is currently approved for underground uranium mines located in Sections 17, 19, 30, 30W, 33, and 35, T14N, R9W, and Sections 22 and 24, T14N, R10W, McKinley Co. The modification will allow lixiviant injection into 4 additional mines located in Sections 13, 15, 23, and 25, T14N, R10W, McKinley County. Up to 1,440,000 gallons per day of lixiviant composed of ground water fortified with sodium bicarbonate and/or sulfuric acid and recirculated mine water will be injected into 12 underground uranium mines for secondary recovery of uranium. Injectate is collected in the mine workings via drains and pumped to Quivira's Ambrosia Lake Uranium Mill for processing. Ground water below the land surface is at a depth of approximately 800 feet and has a total dissolved solids concentration approximately 1,200 milligrams per liter.

DP-375, ARTESIA GOLF AND COUNTRY CLUB, Mr. Joe Smith, Facility Representative, proposes to renew its discharge plan which allows the land application of 126,000 gallons per day of treated domestic wastewater effluent to the Artesia Golf and Country Club grounds. The facility is located approximately one mile northwest of Artesia in the NE 1/4 of Section 12, T17S, R25E, Eddy County. Treated wastewater effluent from the wastewater treatment plant is discharged to four bentonite-lined storage lagoons (one main storage reservoir and ponds) at the golf and country club. Stored wastewater is used as needed to irrigate the golf course grounds. Ground water below the site is at a depth of approximately 165 feet and has a total dissolved solids concentration of approximately 764 milligrams per liter.

DP-408, TRUOG DAIRY, Arlene Truog, Owner, proposes to modify its discharge plan to discharge up to 40,000 gallons per day of dairy washwater from the Truog Dairy facility. The facility is located four miles west of Hagerman, NM, in Sections 15 & 16, T14S, R25E, Chaves County. Truog Dairy had previously been approved to discharge up to 24,000 gallons per day. Effluent is discharged to a solids separator, then to a lined concrete tank where it is discharged to irrigation ditches, mixed with irrigation water and used to irrigate 540 acres of cropland. Ground water below the site is at a depth of 170 feet and has a total dissolved solids concentration of approximately 608 milligrams per liter.

DP-519, INHALATION TOXICOLOGY RESEARCH INSTITUTE, Joe Mauderly, proposes to renew its discharge plan to oversee closure and post-closure monitoring of the former lagoon site. The facility is located in Section 3, T8N, R4E, Bernalillo County. Ground water below the site is at a depth of approximately 100 feet and has a total dissolved solids concentration of approximately 1,600 milligrams per liter.

DP-831, WASTE ISOLATION PILOT PLANT (WIPP), Mr. George Dials, Manager, U.S. Department of Energy, proposes to renew and modify its discharge plan for the discharge of 32,000 gallons per day of sewage effluent and brine waters from a nuclear waste storage facility. The facility is located 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. Up to 23,000 gallons per day of sewage effluent is discharged to a series of synthetically lined ponds for settling and evaporation. Up to 2,000 gallons per day of non-hazardous brine is discharged to a synthetically lined evaporation cell. The modification consists of discharging up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells and from other non-hazardous sources to a synthetically lined evaporation pond. Ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration from approximately 3,920 to 218,000 milligrams per liter.

DP-1051 RHINO ENVIRONMENTAL SERVICES-OTERO II, Mr. Steve Dyer, President, proposes to modify the volume and location for treatment of hydrocarbon contaminated soils derived from leaking underground storage tanks and/or spills at the Otero II facility. The facility is located approximately 1 mile NW of Newman, New Mexico in Section 22, T26S, R6E, Otero County. Rhino proposes to increase the total volume of soil treated at any one time from 12,090 cubic yards to 80,804 cubic yards. Area of the treatment site will increase from Section 22.3, T26S, R6E, to the entire Section 22, T26S, R6E. Contaminated soils are spread in six inch layers and rotated to maximize aeration and volatilization of contaminants. Ground water below the site is at a depth of approximately 350 feet and has a total dissolved solids concentration of approximately 1,000 milligrams per liter.

DP-1078, SANTA FE SOUTHERN RAILWAY WETLAND, Robert A. Sarr, proposes to modify its discharge permit to include use of treated wastewater for fire control. The facility is located in Lamy in Section 10, T15N, R10E, Santa Fe County. The modification consists of allowing treated wastewater from the lined holding pond to be used in fire control as long as the fecal coliform count in the wastewater meets 200 counts/100 milliliters of water. Ground water below the site is at a depth of approximately 30 feet and has a total dissolved solids concentration of approximately 750 milligrams per liter.

DP-1129, DLD RESOURCES, Mr. Darrel Bearden, President, proposes to discharge up to 144,000 gallons per day of neutralized acid production wastewater from a hydrochloric acid production plant. The facility is located 1 mile west of Monument, NM in Section 35, T19S, R36E, Lea County. DLD Resources will discharge up to 144,000 gallons per day of acid production effluent that has been neutralized to at least a pH of 4 to a pivot spray irrigation system irrigating 39 acres of range land. Ground water below the site is at a depth of approximately 50 feet and has a total dissolved solids concentration ranging from 1500 milligrams per liter to 60,000 milligrams per liter.

DP-1140, MCANALLY ENTERPRISES, INC., Carlton R. Lofgren, proposes to discharge up to 2,188 gallons per day of process water and up to 112.5 tons per day of chicken manure from the McAnally Enterprises egg production facility. The facility is located in Section 3, T26S, R3E, Dona Ana County. Up to 2,188 gallons per day of process water from the egg production plant will be discharged to a septic tank/leachfield system. Up to 112.5 gallons per day of chicken manure will be discharged to a 900,000 square foot unlined pad where it is dried, stacked and then sold as fertilizer. Ground water below the site is at a depth of approximately 54 feet and has a total dissolved solids concentration of approximately 633 milligrams per liter.

Any interested person may obtain further information from the Ground Water Pollution Prevention Section of the NM Environment Department, telephone (505) 827-2900, and may submit written comments to the Ground Water Section, NM Environment Department, P.O. Box 26110, Santa Fe, NM 87502. Prior to ruling on any proposed discharge plan or its modification, the NM Environment Department will allow thirty (30) days after the date of publication of this notice to receive written comments and during which a public hearing may be requested by any interested person. Requests for public hearing shall set forth the reasons why the hearing should be held. A hearing will be held if the NM Environment Department determines that there is significant public interest.

Subject: RENEWAL AND MODIFICATION OF DISCHARGE PLAN – DP-831

Dear Mr. Doremus:

Enclosed are three (3) copies of the completed Discharge Plan Application and $50.00 filing fee for the renewal and modification of Discharge Plan DP–831 for the Waste Isolation Pilot Plant (WIPP).

The volumes and character of the discharges to the existing sewage lagoon facilities described in DP–831 remain the same. The modification to DP–831 is the addition of a separate evaporation pond to be used for the storage and evaporation of non–hazardous brine waters generated at the WIPP. The additional evaporation pond, known as the H–19 Evaporation Pond, was originally used as part of the Culebra Transport Test Program conducted by Sandia National Laboratories for the U. S. Department of Energy at the WIPP. The pond was used to store and evaporate returned drilling fluids and brines produced from construction and hydrologic testing for the Culebra Transport Test Program. A Notice of Intent to discharge drilling fluids and brines from hydrologic testing was submitted to your office on May 18, 1995. Your response on June 16, 1995, was that a discharge plan was not required. At this time we are requesting the H–19 Evaporation Pond be included in our discharge plan.

With the completion of the test program, the H–19 Evaporation Pond will be used to store and evaporate non–hazardous waters generated at the WIPP. These waters include brine waters generated from mine dewatering activities, pumping of groundwater observation wells, and from miscellaneous non-hazardous sources.

If you have any questions or comments please contact Mr. Jim Hollen at (505) 234–8271.

Sincerely,

K. S. Donovan

1. **Type of facility or operation (dairy, municipality, mining, etc.):**

   The Waste Isolation Pilot Plant (WIPP) is designed to permanently dispose of transuranic waste left from the research and production of nuclear weapons. Located in southeastern New Mexico, 26 miles east of Carlsbad, project facilities included disposal items contaminated with trace amounts of radioactive elements mostly plutonium. The WIPP is scheduled to open for waste receipt in November 1997.

   The WIPP employs a facultative lagoon system for waste water treatment and a series of evaporation ponds for storage and evaporation of various waters generated at the site.

   The WIPP proposes to renew its Discharge Plan, DP-831, with a modification that will expand the storage and evaporation capabilities for various non-hazardous waters generated at the site.

The sewage and evaporation facilities (Attachment 1) currently permitted under DP-831 will remain the same with regard to the physical description, volumes, and character of the discharges as described in DP-831.

The proposed permit modification is to expand our storage and evaporation facilities by including the H-19 Evaporation Pond in our current discharge plan (Attachments 2 and 2a). The addition of the H-19 Evaporation Pond will reduce the load on the currently permitted sewage lagoon evaporation pond thus extending the life of the facility.

2. **Proposed method(s) of treatment, storage, and/or disposal of effluent or leachate (Package plant - lagoon - leachfield, wetlands - infiltration gallery, air stripper - injection well, etc.):**

The H-19 Evaporation Pond facility was constructed in July, 1995, for the storage and evaporation of returned drilling fluids and brines produced from hydrologic testing for the Culebra Transport Test Program. The test program was conducted by Sandia National Laboratories for the WIPP. A Notice of Intent to discharge to the H-19 Evaporation Pond was submitted to the Ground Water Protection and Remediation Bureau of the New Mexico Environment Department (NMED) on May 18, 1995. Response from the NMED on June 16, 1995, was that a discharge plan was not required. The Culebra Transport Test Program was completed in April, 1996. The H-19 Evaporation Pond was sampled on August 7, 1996. The analysis results (Attachment 3) indicate the pond contains no hazardous constituents from the previous use.

The H-19 Evaporation Pond will be used for the storage and evaporation of various non-hazardous waters generated at the WIPP. These waters include brine waters generated from mine dewatering activities, pumping of ground water observation wells, and from miscellaneous non-hazardous sources. These represent the same waters currently permitted for disposal into the existing synthetically lined domestic wastewater lagoons.

Discharge Characteristics

3. **Quantity:**

   a. **Design discharge rate in gallons per day (gpd):**

   The existing sewage lagoon and evaporation facility are currently permitted for 23,000 gpd sewage effluent and 2,000 gpd non-hazardous brine discharged to the north evaporation cell.

   Up to 8,000 gpd of brine waters generated from mine dewatering activities, pumping of ground water observation wells, and from miscellaneous non-hazardous sources may be discharged into the H-19 Evaporation Pond. These waters will be transported by truck or portable tank to the H-19 facility.

b. Gallons per day computed on an annual basis:

Sewage Lagoon - 8,395,000 gallons
(365 days per year x 23,000 gpd)

North Evaporation Cell - 520,000 gallons
(260 days per year [5 days/week] x 2,000 gpd)

H-19 Evaporation Pond - 2,080,000 gallons
(260 days per year [5 days/week] x 8,000 gpd)

c. Number of days per year facility will be discharging:

Sewage Lagoon - 365 days per year

North Evaporation Cell - 260 days per year (5 days per week)

H-19 Evaporation Pond - 260 days per year (5 days per week)

4. Method used to meter or calculate the discharge rate:

Sewage Lagoon - The discharge volume is approximately equal to the total WIPP facility domestic water usage. Water flow into the site is metered.

North Evaporation Cell - The requested volume of waters to be discharged to the North Evaporation Cell is 2,000 gallons per day. Volumes are calculated by a time/volume method or by volumetric measurement in the portable tanks used to transport the water from the point of generation to the North Evaporation Cell. Small volumes of water may also be estimated. For example, ½ of a 55 gallon drum ≈ 25 gallons.

H-19 Evaporation Pond - The requested volume of waters to be discharged to the H-19 Evaporation Pond is 8,000 gallons per day. Volumes are calculated by a time/volume method or by volumetric measurement in the portable tanks used to transport the water from the point of generation to the H-19 Evaporation Pond. Small volumes of water may also be estimated. For example, ½ of a 55 gallon drum ≈ 25 gallons.

5. Flow characteristics. Describe if flow is:

a. Daily (five or seven days per week) or seasonal (give months):

Sewage Lagoon - Daily, seven days per week, 365 days per year.

North Evaporation Cell - Daily, five days per week, Monday through Friday, 260 days per year.

H-19 Evaporation Pond - Daily, five days per week, Monday through Friday, 260 days per year.

b. **Continuous or intermittent:**

Sewage Lagoon - Continuous.

North Evaporation Cell - Intermittent.

H-19 Evaporation Pond - Intermittent.

6. **Discharge Quality. List the concentrations of contaminants and toxic pollutants generally associated with the type of facility or operation. The contaminants of concern are those listed in Section 3-103 of the NM Water Quality Control Commission (WQCC) Regulations and total nitrogen (nitrate + total Kjeldahl nitrogen). The toxic pollutants are listed in WQCC Regulations 1-101-1.UU.**

Attached is Discharge Monitoring Report Number 11 for the third quarter of 1996 as was reported to the Ground Water Section of the NMED on September 27, 1996. This represents the latest analytical data required by the current DP-831. (Attachment 4)

Attached are the analytical data from the H-19 Evaporation Pond. The data indicates no hazardous constituents are present in the evaporation pond. (Attachment 3)

Each discharge to the evaporation ponds is characterized and determined to be non-hazardous prior to discharge approval. This process is controlled by WIPP Procedure *WP 02-EM1001 Sewage System Discharge Monitoring and Compliance*. (Attachment 5)

Location Information

7. **Location of discharge site:**

County: Eddy

Township: 22S Range: 31E Section: 29

Latitude/Longitude: 32.22.30N Latitude, 103.47.30W Longitude

Please provide a copy of a State of New Mexico road map with the property clearly outline. (Attachment 6)

8. **Location of any water supply wells, injection wells, seeps, springs, bodies of water or water courses within one mile of the outside perimeter of the discharge site. These items must be plotted on a copy of the pertinent USGS topographic map(s) or an aerial photograph. Include the name(s) of the USGS topographic map(s).**

There are no water supply wells, injection wells, seeps, springs, bodies of water, or water courses within one mile of the outside perimeter of the discharge site. The nearest water supply well is located at the Mills Ranch. This windmill produces water of marginal quality, and is used for livestock watering. The windmill is located approximately 3¼ miles from the WIPP site and approximately five miles from the H-19 Evaporation Pond.

9. **Give the location of any proposed or existing wells to be used for monitoring the ground water quality.**

WQSP-6a	22S	31E	29

The Water Quality Sampling Program (WQSP) well locations are shown in Attachment 2.

Ground Water Conditions

10. **a. The depth (feet) to ground water below the discharge site:**

The approximate depth is 608 feet.

b. The flow direction of ground water below the site:

The flow direction is generally North to South.

c. The gradient of the ground water below the site:

The gradient of the ground water below the site is approximately 0.00013°. This is based upon water level elevation readings taken at the DOE-1 well and the H-11 well. These wells are approximately one mile apart and in line with the H-19 Evaporation Pond. The calculation is done with the assumption that the water densities are the same at both wells.

d. Reference or source of information for 10. a, b, c, above:

The information was gathered during the Culebra Transport Test Program conducted at the H-19 Hydropad. The test program report has yet to be issued by Sandia National Laboratories.

11. a. The Total Dissolved Solids (TDS) concentration (mg/l) of the ground water:

TDS ranges are from 3,920 mg/l found at the WQSP-6a well, to 218,000 mg/l found at the WQSP-3 well.

b. Reference or source of information:

The WIPP water quality sampling program. Analysis of the WQSP wells. (Attachment 7).

Flooding Potential

12. Describe the flooding potential of the discharge site based on the latest Federal Emergency Management Agency flood plain information or site specific analysis:

The 1996 WIPP Safety Analysis Report (DOE/WIPP-2065, Rev. 1) page 4-1 states: "The WIPP facility does not lie within a 100-year floodplain. There are no major surface-water bodies within 5 mi. (8 km) of the site, and the nearest river, the Pecos River, is approximately 12 mi. (19 km) away. The general ground elevation in the vicinity of the surface facilities (approximately 3,400 ft. [1,036m]) above mean sea level is about 500 ft. (152 m) above the riverbed and 400 ft. (122 m) above the 100-year floodplain." The potential for flash flooding is minimal around the facility because the site is constructed on the sand dunes of the Los Medaños plateau. Considering this information, the flooding potential is minimal.

13. Describe the methods used to control flooding of the discharge site (berms, diversion channel, etc.):

If flash flooding was to occur in the immediate area of the sewage facility and the North Evaporation Pond, flooding is controlled by a series of diversion berms that surround the facility. The berms are constructed to divert a WIPP site maximum storm event of 5.9 in. which is greater in magnitude than the site 100-year/24-hour storm event of 4.9 in. Details of diversion berms and outflow channels are provided in Attachment 8.

The H-19 Evaporation Pond is constructed on a raised crushed caliche pad. The pond berm walls are approximately 1 ft. 6 in. above the caliche pad. Given the topography, the raised pad and the height of the pond walls, the flood potential of the facility is minimal.

Soil and Geologic Information

14. Attach a copy of the USDA Soil Conservation Service soil survey map and descriptive information for soil(s) associated with the discharge site:

Attached is a copy of the USDA Soil Conservation Service soil survey aerial and associated soil contour maps Number 122 for Eddy Area, New Mexico. (Attachment 9)

The 1996 WIPP Safety Analysis Report (DOE/WIPP-2065, Rev. 1) page 2-41 described the soil in the central dune plains as "...deep and sandy."

15. Describe the lithology and thickness of each geologic unit below the discharge site. Please indicate which units are water bearing. This information may be obtained from driller's logs or geologic reports.

Thickness (feet)	Description
0 - 78	Surficial Deposits / Santa Rosa Formation
78 - 588	Dewey Lake Redbeds *(water bearing)*
588 - 652	Forty-Niner Member of the Rustler Formation
652 - 672	Magenta Member of the Rustler Formation *(water bearing)*
672 - 770	Tamarisk Member of the Rustler Formation
770 - 790	Culebra Member of the Rustler Formation *(water bearing)*
790 - 802 (partial)	Lower unnamed member of the Rustler Formation (partial)

This information was obtained from the Basic Data Report for the WQSP wells (DOE/WIPP-95-2154). Specifically, WQSP-4 well which is adjacent to the discharge site. (Attachment 10)

Attachments 11 and 11a show generalized site stratigraphy and is obtained from the WIPP Safety Analysis Report (DOE/WIPP-2065).

Operational Plan

16. An operational plan must be attached which describes how the system(s) for the collection, treatment, distribution, and disposal of waste waters or other discharges will be operated and maintained.

WIPP Procedure *WP 02-EM1001, Sewage System Discharge Monitoring and Compliance.* (Attachment 5)

Contingency Plan

17. A contingency plan must be attached which describes actions to be taken in the event that spills or failures occur or ground water standards are threatened.

A visible inspection for damaged liners is conducted daily. In the event of a significant tear in a liner that results in a release to the environment, an effluent spill or unauthorized discharge of hazardous constituents, the Ground Water Section of the NMED will be notified. The WIPP Environmental Compliance and Support Section and the Operations Department will asses damages and attempt to isolate any discharge. Samples will be taken to determine the extent and severity of contamination. A remediation plan will be developed based on sampling data and communications with the NMED Ground Water Section.

Monitoring Plan

18. A monitoring plan must be attached which outlines the proposed sampling point locations (monitoring wells, outfalls, etc.), sampling protocols (bailers, pumps, etc.), sampling frequency (monthly, yearly, etc.), chemical parameters to be analyzed for (TDS, nitrate, etc.), static water levels, discharge rates (gpd), etc.

a. The quantity of waters discharged to the evaporation ponds will be monitored and that quantity will be submitted in a quarterly report to the Ground Water Section of the NMED.

b. A water quality analysis of the inflow to the lagoon system will be submitted in the quarterly report. The report will include analysis for Nitrate, total Kjeldahl nitrogen (TKN), and Radium 226 and 228.

c. Each evaporation pond will be sampled for total dissolved solids (TDS) quarterly and the results submitted in the quarterly report.

Closure Plan

19. A closure plan must be attached for system components that are likely to be discontinued during the term of the permit. The closure plan must address the reclamation and post-operational monitoring of ground water at the site, as appropriate. Also the plan shall provide for plugging and abandonment of all monitoring wells, after ground water quality meets the WQCC Regulations.

At the time the WIPP facility is decommissioned, the sewage facility and the evaporation ponds will be closed using closure plans discussed in the *Waste Isolation Pilot Plant (WIPP), Final Supplement Environmental Impact Statement (SEIS)* (DOE/EIS 0026-FS, January, 1990). Although a detailed closure plan has not been completed, the SEIS states that all surface facilities will be decommissioned, all hazardous materials removed from the site, surface soils will be re-contoured to approximate original features, and native vegetation will be planted.

Closure plans for the sewage facility and evaporation ponds will specifically require that all lagoons and ponds will be pumped or evaporated and that all sludges be sampled to determine if hazardous constituents exist as defined by the Resource Conservation and Recovery Act (RCRA - 40 CFR 261). If hazardous constituents are detected, the sludges will be managed accordingly.

Signature(s)

20.a. I certify that I am the legal owner of the property in which all discharges will occur.

RECEIVED
DEC 12 1996
GROUND WATER BUREAU

Dear Stakeholder:

I am pleased to provide you with the enclosed *Citizens' Guide to the Compliance Certification Application.* As you may know, the Carlsbad Area Office (CAO) submitted the Compliance Certification Application to the Environmental Protection Agency at the end of October 1996. We know this 21-volume, 24,000-page document is a formidable reading task; thus, we have prepared a "reader friendly" *Citizens' Guide* so that stakeholders can understand what the application is about, ask questions, and seek further information.

The *Citizens' Guide* provides newcomers to the Waste Isolation Pilot Plant (WIPP) with an overview of the national problem of transuranic waste storage at Department of Energy (DOE) facilities nationwide, the solution that the WIPP provides to this problem, and a review of regulatory and oversight agencies that have monitored the Carlsbad Area Office's activities and will continue to do so. This document summarizes the four key requirements the CAO must meet so that the EPA can certify that the WIPP complies with environmental regulations. Finally, the document provides an overview of the next steps in the process, the role citizens play, and sources for additional information. In the document's margins, we have provided a brief summary of chapters in the application relevant to the sections in the *Citizens' Guide* -- in case you would like to read parts of the application for more detail.

Please call our Information Center at 1-800-336-WIPP (9477) if you have any questions or comments about the *Citizens' Guide* or our progress towards disposal operations at the WIPP.

Sincerely,

George E. Dials

RE: Response to Notice of Intent to discharge an additional tracer chemical and increased alcohol usage at the WIPP Site

Dear Mr. Donovan:

The New Mexico Environment Department (NMED) has received your Notice of Intent for the discharge of an additional tracer chemical and to increase alcohol usage for the Culebra Transport Test Program at the Waste Isolation Pilot Plant in accordance with Section 1201. of the NM Water Quality Control Commission (WQCC) Regulations. The facility is located approximately 30 miles east of Carlsbad in Section 29, T22S, R31E, Eddy County. The application satisfies the requirements of Section 1201 of the WQCC Regulations.

Based on the presently available information in your letter, dated December 27, 1995, a discharge plan is not being required for this discharge as long as the discharge is as described.

A discharge plan is not being required because it appears that the discharge conforms to the numerical ground water standards in WQCC Reg. 3103 and does not contain any toxic pollutants as defined in WQCC Reg. 1101.TT, and therefore is exempt from the discharge plan requirement under WQCC Reg. 3105.A.

The exempt discharge is briefly described as follows:

NMED issued three letters dated January 31, 1995, June 12, 1995 and November 16, 1995 stating that a discharge plan was not required for a group of chemical tracers and alcohols to be used in the Culebra Transport Test Program. Since that time, the discharger has submitted another request for an additional chemical constituent to be added to the original group and to increase the quantity of alcohols used in the test.

The Culebra Transport Test Program consists of injecting tracer solutions into the Culebra Formation at the H-19 well at the WIPP site hydropad. Movement of the tracers will be achieved by pumping approximately 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Monitoring will take place in seven additional wells at the site.

In addition to the constituents approved in the letters dated January 31, 1995, June 12, 1995 and November 16, 1995, as possible tracers for the tests, the following tracer chemical has been added:

2,3,5-TRIFLUOROBENZOIC ACID

Quantities of the following alcohols will be increased from a combined total of 7 liters to no more than 100 liters for any one approved alcohol, or a combined total not to exceed 180 liters.

METHANOL
ETHANOL
ISOPROPYL ALCOHOL

Although a discharge plan is not being required for this discharge, you are not relieved of liability should your operation result in actual pollution of surface or ground waters. Further, this decision by the NMED does not relieve you of your responsibility to comply with any other applicable federal, state, and/or local laws and regulations, such as zoning requirements, plumbing codes and nuisance ordinances.

If at some time in the future you intend to change the amount, the character, or location of your discharge so that it will not be as described, or if observation or monitoring shows that the discharge is not as described, you must file a new request for exemption with the Ground Water Section.

If you have any questions, please contact either Clint Marshall of the Ground Water Section staff at 827-0027 or the Program Manager of the Ground Water Section at 827-2900.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

December 27, 1995

RECEIVED
JAN 02 1996
GROUND WATER BUREAU

Mr. Clint L. Marshall, Geologist III
New Mexico Environment Department
Ground Water Bureau
P. O. Box 26110
1190 St. Francis Drive
Santa Fe, New Mexico 87502

Subject: REQUEST FOR USE OF ADDITIONAL TRACER CHEMICAL AND INCREASED ALCOHOL USAGE

Dear Mr. Marshall:

The Westinghouse Waste Isolation Division (WID) requests your approval for the use of the following tracer chemical in the Culebra Transport Test Programs under development by Sandia National Laboratories at the Waste Isolation Pilot Plant. Material Safety Data Sheets are attached.

- 2,3,5-Trifluorobenzoic acid - CAS Number 654-87-5

The amount of 2,3,5-Trifluorobenzoic acid used through the remainder of the Culebra Transport Test Program is approximately five kilograms.

The WID also requests an increase in the quantity of alcohols that may be injected as part of the Culebra Transport Test Program. The alcohols previously approved by you are methanol, ethanol and isopropyl alcohol, in combined total of seven liters. The amount now requested for injection is no more than 100 liters of any one approved alcohol, and no more than 180 liters combined total for all three approved alcohols. The increase in alcohol use is required because it is necessary to dissolve some approved tracer compounds in water soluble organic solvents.

Additionally, the U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) is requesting written concurrence that a Discharge Plan will not be required for the proposed Culebra Transport Test Programs. The Culebra Transport Test Program is designed to collect additional hydrogeologic characterization data from the Culebra aquifer to test hydrological models for the WIPP Performance Assessment.

The DOE-CAO believes that this project should be exempted from the discharge plan requirements because the existing concentration of Total Dissolved Solids (TDS) in ground water in adjacent wells exceeds 10,000 mg/l. Additionally, neither the proposed tracer nor the chemical solvents are listed in Title 20, Chapter 6, Part 2, Subpart I, Section 1101, *Toxic Pollutants*, or Section 3103; *Standards for Ground Water of 10,000 mg/l TDS Concentration or Less*.

If you have any questions about this proposed project or require any additional information, please contact Mr. Jim Hollen at (505) 234-8271.

Sincerely,

Kurt Donovan

Safety Data Sheet

Date of issue November 14, 1995

2,3,5-Trifluorobenzoic acid

1. Identification of the substance/preparation and company

2,3,5-Trifluorobenzoic acid

2. Composition/Information on ingredients

2,3,5-Trifluorobenzoic acid

CAS No.: 654-87-5 — Hazard symbol: XR

EINECS No.: *** — R-phrases: 36/37/38

3. Hazards identification

Irritating to eyes, respiratory system and skin

4. First-aid measures

Skin contact: Remove all contaminated clothing and wash affected skin immediately with plenty of soap and water

Eye contact: Wash eyes thoroughly with water for ten minutes with the eyelids held open. Obtain medical advice immediately.

Ingestion: If chemical is confined to mouth give large quantities of water as mouth wash. Ensure mouth wash is not swallowed. If chemical has been swallowed drink plenty of water immediately, and then again at frequent intervals. Rinse the mouth with plenty of water. DO NOT induce vomiting. Obtain medical advice

Inhalation: After inhalation move patient to uncontaminated area for fresh air, keep patient calm and warm. If the casualty is unconscious place in a face downwards position and watch to see if breathing stops. If breathing has stopped apply artificial respiration. Obtain medical advice.

5. Fire-fighting measures

Extinguishing media: CO_2, foam, dry powder; in event of larger fires, water spray should be used. Never use direct water jet.

Fire-fighters should wear self contained breathing apparatus

6. Accidental release measures

Wear suitable protective clothing. Transfer to labelled container and arrange for disposal observing all local regulations.

7. Handling and storage

Avoid contact with skin, eyes and clothing. Use only in adequately ventilated fume hood, and ensure this material is handled only by suitably trained personnel.

When not in use keep original container closed and store in a cool, dry well ventilated place.

8. Exposure controls/personal protection

Respiratory protection: Use suitable dust mask. For larger releases a self-contained breathing apparatus should be used.

Eye protection: Use closely fitting goggles.

Hand protection: Wear suitable chemical resistant gloves (e.g. nitrile rubber).

Other protective equipment: Wear protective clothing.

Avoid contact with skin and eyes and the inhalation of vapour. Take off immediately all contaminated clothing. Keep working clothes separate. Wash hands before breaks and at end of work.

9. Physical and chemical properties

Appearance:	White powder or crystalline solid
Odour	***
Melting Point:	***
Boiling Point:	***
Flash Point:	***
Auto-ignition temperature:	***
Solubility:	Soluble in most organic solvents. Soluble in basic aqueous solutions. Sparingly soluble in water and petrol.

10. Stability and reactivity

Thermal decomposition:	No thermal decomposition when stored and used correctly
Hazardous decomposition products:	May evolve carbon monoxide, carbon dioxide, hydrogen fluoride and other toxic gases in case of fire or during thermal decomposition
Hazardous reactions.	No hazardous reaction when used as directed Reacts vigorously with strong base May react with oxidising materials

11. Toxicological information

No information is available but risk assessment should be based on data for other fluorinated benzoic acids.

12. Ecological information

Do not allow to escape into waters, wastewater or soil.
Ecological data not yet available.

13. Disposal considerations

Observe all local toxic waste regulations. Contaminated empty containers should be treated in the same way as the contents. When contaminated empty containers are passed on, the recipient must be informed of the possible risks. Where large quantities are involved consult the supplier

14. Transport information

UN No.: NR
Class ***
PG: ***
RID/ADR: ***
ICAO/IATA: ***

Declaration for land shipment.	2,3,5-TRIFLUOROBENZOIC ACID
Declaration for sea shipment:	2,3,5-TRIFLUOROBENZOIC ACID
Declaration for air shipment.	2,3,5-TRIFLUOROBENZOIC ACID

Other information:
Keep dry. Keep away from foodstuffs.

15. Regulatory information

Classification and labelling for supply in accordance with the Chemicals (Hazard Information and Packaging for Supply) Regulations 1994 (CHIP 2) in line with European Community Directive. 93/21/EEC.

Symbol	NR
Hazard description:	NR

2,3,5-Trifluorobenzoic acid
Caution! Substance not yet fully tested.

Safety Data Sheet

Date of is: November 14, 1995

2,3,5-Trifluorobenzoic acid

15. Regulatory information (Continued)

R 36/37/38:	Irritating to eyes, respiratory system and skin.
S 26	In case of contact with eyes, rinse immediately with plenty of water and seek medical advice
S 37/39:	Wear suitable gloves and eye/face protection.

The current Health and Safety at Work etc. Act (HSWA) and Control of Substances Hazardous to Health Regulations (COSHH) must be observed when handling this material. Relevant overseas legislation must be observed where appropriate.

16. Other Information

Prepared in accordance with Directives 91/155/EEC & 93/12/EC

The information given here is based on current knowledge and experience. The purpose of this Safety Data Sheet is to describe the product in terms of its safety requirements. It does not signify warranty with regard to the product's properties or use to which it may be put.

RE: Response to Notice of Intent to discha
and alcohols at the WIPP Site

Dear Mr. Donovan:

The New Mexico Environment Department (NMED) has received your Notice of Intent for the discharge of an additional tracer chemical and alcohols to be used for the Culebra Transport Test Program at the Waste Isolation Pilot Plant in accordance with Section 1-201. of the NM Water Quality Control Commission (WQCC) Regulations. The facility is located approximately 30 miles east of Carlsbad in Section 29, T22S, R31E, Eddy County. The application satisfies the requirements of Section 1-201 of the WQCC Regulations.

Based on the presently available information in your letter, dated October 11, 1995, a discharge plan is not being required for this discharge as long as the discharge is as described.

A discharge plan is not being required because it appears that the discharge conforms to the numerical ground water standards in WQCC Reg. 3-103 and does not contain any toxic pollutants as defined in WQCC Reg.1-101.ZZ, and therefore is exempt from the discharge plan requirement under WQCC Reg.3-105.A.

The exempt discharge is briefly described as follows:

NMED issued two letters dated January 31, 1995 and June 12, 1995, stating that a discharge plan was not required for a group of chemical tracers to be used in the Culebra Transport Test Program. Since that time, the discharger has submitted another request for an additional chemical constituent to be added to the original group as well as three alcohols.

The Culebra Transport Test Program consists of injecting tracer solutions into the Culebra Formation at the H-19 well at the WIPP site hydropad. Movement of the tracers will be achieved by pumping approximately 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Monitoring will take place in seven additional wells at the site.

In addition to the constituents approved in the letters, dated January 31, 1995 and June 12, 1995, as possible tracers for the tests, the following tracer chemical and alcohols have been added:

POTASSIUM IODIDE

METHANOL
ETHANOL
ISOPROPYL ALCOHOL

Although a discharge plan is not being required for this discharge, you are not relieved of liability should your operation result in actual pollution of surface or ground waters. Further, this decision by the NMED does not relieve you of your responsibility to comply with any other applicable federal, state, and/or local laws and regulations, such as zoning requirements, plumbing codes and nuisance ordinances.

If at some time in the future you intend to change the amount, the character, or location of your discharge so that it will not be as described, or if observation or monitoring shows that the discharge is not as described, you must file a new request for exemption with the Ground Water Section.

If you have any questions, please contact either Clint Marshall of the Ground Water Section staff at 827-0027 or the Program Manager of the Ground Water Section at 827-2900.

Sincerely,

Marcy Leavitt, Chief
Ground Water Protection &
Remediation Bureau

October 11, 1995

Mr. Clint Marshall, Geologist III
New Mexico Environment Department
Ground Water Bureau
P. O. Box 26110
1190 St. Francis Drive
Santa Fe, New Mexico 87502

Subject: REQUEST FOR USE OF ADDITIONAL TRACER CHEMICALS

Dear Mr. Marshall:

Approval is requested for the use of the following tracer chemical in the Culebra Transport Test Programs under development by Sandia National Laboratories at the Waste Isolation Pilot Plant (WIPP). Material Safety Data Sheets (MSDS) are attached.

Potassium Iodide - CAS Number 7681-11-0

The amount of potassium iodide used through the remainder of the Culebra Transport Test Program is approximately six kilograms.

Approval is also requested for the following alcohols:

Methanol - CAS Number 67-56-1
Ethanol - CAS Number 64-17-5
Isopropyl Alcohol - CAS Number 67-63-0

These may be deployed to enhance the solubility of other previously approved tracer chemicals. The combined total amount of these alcohols would not exceed seven liters.

As with our previous requests, the U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) is requesting written concurrence that a Part 3-100 Discharge Plan will not be required for the proposed Culebra Transport Test Programs. The Culebra Transport Test Program is designed to collect additional hydrogeologic characterization data from the Culebra aquifer to test hydrological models for the WIPP Performance Assessment.

The DOE-CAO believes that this project should be exempted from the discharge plan requirements because the existing concentration of ground water in adjacent wells exceeds 10,000 mg/l Total Dissolved Solids (TDS). Additionally, neither the proposed tracer nor the alcohols are listed in the New Mexico Water Quality Control Regulations, Part 1-101(2ZZ), *Toxic Pollutants*, or Part 3-103, *Standards for Ground Water of 10,000 mg/l TDS Concentration or Less*.

If you have any questions about this proposed project or require any additional information, please contact Mr. J. R. Hollen at (505) 234-8271.

Sincerely,

Chuan-Fu Wu for

K. S. Donovan, Manager
Environment, Safety, and Health

************************* EXTINGUISHING MEDIA ********************************

USE WATER SPRAY, DRY CHEMICAL, CO2, OR ALCOHOL FOAM. DO NOT USE A DIRECT WATER STREAM.

********************** SPECIAL FIRE FIGHTING PROCEDURES **********************

FIRE FIGHTERS SHOULD WEAR SELF-CONTAINED BREATHING APPARATUS AND FULL PROTECTIVE CLOTHING. USE WATER SPRAY TO COOL NEARBY CONTAINERS AND STRUCTURES EXPOSED TO FIRE.

******************** UNUSUAL FIRE AND EXPLOSION HAZARDS ********************

EXTINGUISH ALL NEARBY SOURCES OF IGNITION. THIS PRODUCT MAY BURN WITH A FLAME WHICH IS INVISIBLE IN DAYLIGHT. MIXTURES WITH WATER AND AS LITTLE AS 21% METHANOL ARE FLAMMABLE. VAPORS FORMED FROM THIS PRODUCT ARE HEAVIER THAN AIR AND MAY TRAVEL ALONG THE SURFACE TO A DISTANT SOURCE OF IGNITION AND FLASHBACK. EXPLOSIVE VAPOR-AIR MIXTURES MAY BE FORMED ABOVE THE FLASH POINT OR BETWEEN THE LOWER AND UPPER FLAMMABLE LIMITS.

SECTION IV FIRE & EXPLOSION HAZARD DATA is continued on the next page.

SECTION IV FIRE & EXPLOSION HAZARD DATA is continued from the previous page.

SECTION V REACTIVITY DATA

Stability? PRODUCT IS STABLE

Avoid: CONDITIONS TO AVOID: HEAT, SPARKS, AND OPEN FLAMES.

******************** INCOMPATIBILITY (Materials to Avoid) ********************

STRONG OXIDIZING AGENTS, ALUMINUM, ZINC, ANY METAL THAT DISPLACES HYDROGEN, ACIDS, AND ALKALIS.

******************** HAZARDOUS DECOMPOSITION OR BY-PRODUCTS ******************

MAY LIBERATE CARBON MONOXIDE, CARBON DIOXIDE, FORMALDEHYDE AND UNIDENTIFIED ORGANIC COMPOUNDS IN BLACK SMOKE.

Hazardous Polymerization? POLYMERIZATION: WILL NOT OCCUR.

Avoid: CONDITIONS TO AVOID: HEAT, SPARKS, AND OPEN FLAMES.

SECTION VI HEALTH HAZARD DATA

****************************** ROUTES OF ENTRY *********************************

Inhalation? YES
Skin? YES
Ingestion? YES
Eyes? YES

**************************** ADDITIONAL INFORMATION ****************************

PRIMARY ROUTES OF EXPOSURE: SWALLOWING, SKIN OR EYE CONTACT, INHALATION.

TOXICITY DATA:

ORAL: HUMAN LDLO = 340 MG/KG; RAT LD50 = 5628 MG/KG
DERMAL: RABBIT LD50 = 20 G/KG
INHALATION: HUMAN TCLO = 86 G/M3 (IRRITATION); RAT LC50 = 64,000 PPM/4H

OTHER DATA: NONE

SECTION VI HEALTH HAZARD DATA is continued on the next page.

SECTION VI HEALTH HAZARD DATA is continued from the previous page.

******************************** CARCINOGENICITY ********************************

NTP? NO IARC? NO OSHA? NO

***************** ADDITIONAL INFORMATION (CARCINOGENICITY) *******************

CARCINOGENICITY: THIS MATERIAL IS NOT CONSIDERED TO BE A CARCINOGEN BY THE NATIONAL TOXICOLOGY PROGRAM, THE INTERNATIONAL AGENCY FOR RESEARCH ON CANCER, OR THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION.

********************** ACUTE AND CHRONIC HEALTH HAZARDS **********************

CHRONIC EFFECTS OF EXPOSURE: PROLONGED OR REPEATED EXPOSURE MAY RESULT IN CNS DAMAGE, BLINDNESS, DAMAGE TO PANCREAS, OR DEATH.

********************** SIGNS AND SYMPTOMS OF EXPOSURE *************************

INHALATION: PROLONGED OR REPEATED EXPOSURE OR BREATHING VERY HIGH CONCENTRATIONS MAY CAUSE HEADACHES, NAUSEA, VOMITING, DIZZINESS, VISUAL DISTURBANCES, GIDDINESS, INTOXICATION, SLEEPINESS, UNCONSCIOUSNESS, AND DEATH. INITIAL SYMPTOMS OF INHALATION MAY ONLY BE MILD INTOXICATION BUT MAY BECOME MORE SEVERE AFTER 12-18 HOURS. TOXIC EFFECTS ARE EXERTED ON THE CENTRAL NERVOUS SYSTEM, ESPECIALLY THE OPTIC NERVE.

EYE CONTACT: VAPORS WILL IRRITATE THE EYES. LIQUID AND MISTS WILL IRRITATE AND MAY BURN THE EYES.

SKIN CONTACT: BRIEF CONTACT MAY DRY THE SKIN. PROLONGED OR REPEATED CONTACT MAY IRRITATE THE SKIN, CAUSING DERMATITIS. METHANOL MAY BE ABSORBED THROUGH INTACT SKIN TO PRODUCE SYSTEMIC EFFECTS.

SWALLOWED: SWALLOWING 100-250 ML OF METHANOL CAN BE FATAL. SWALLOWING LESSER QUANTITIES CAN CAUSE BLINDNESS, DIZZINESS, HEADACHES, OR NAUSEA. ABSORPTION OF METHANOL IS RAPID BUT EXCERTION IS SLOW, RESULTING IN DELAYED EFFECTS OR COMPOUNDING EFFECTS OF REPEATED EXPOSURE. INITIAL SYMPTOMS MAY ONLY BE MILD INTOXICATION BUT THESE MAY BECOME MORE SEVERE 12-18 HOURS LATER. TOXIC EFFECTS ARE EXERTED ON THE CENTRAL NERVOUS SYSTEM, ESPECIALLY THE OPTIC NERVE.

************* MEDICAL CONDITIONS GENERALLY AGGRAVATED BY EXPOSURE *************

PRE-EXISTING EYE, SKIN OR RESPIRATORY DISORDERS MAY BE AGGRAVATED OR IMPAIRED LIVER OR KIDNEY FUNCTION MAY BE MORE SUSCEPTIBLE TO THE EFFECT OF THE SUBSTANCE.

SECTION VI HEALTH HAZARD DATA is continued on the next page.

SECTION VI HEALTH HAZARD DATA is continued from the previous page.

******************** EMERGENCY AND FIRST AID PROCEDURES ***********************

IF INHALED: REMOVE TO FRESH AIR. GIVE ARTIFICIAL RESPIRATION IF NOT BREATHING. GET IMMEDIATE MEDICAL ATTENTION.

IN CASE OF EYE CONTACT: IMMEDIATELY FLUSH EYES WITH LOTS OF RUNNING WATER FOR 15 MINUTES, LIFTING THE UPPER AND LOWER EYELIDS OCCASIONALLY. GET IMMEDIATE MEDICAL ATTENTION.

IN CASE OF SKIN CONTACT: IMMEDIATELY WASH SKIN WITH LOTS OF SOAP AND WATER. REMOVE CONTAMINATED CLOTHING AND SHOES; WASH BEFORE REUSE. GET MEDICAL ATTENTION IF IRRITATION PERSISTS AFTER WASHING.

IF SWALLOWED: IF CONSCIOUS, IMMEDIATELY INDUCE VOMITING BY GIVING 2 GLASSES OF WATER AND STICKING A FINGER DOWN THE THROAT. GET IMMEDIATE MEDICAL ATTENTION. AFTER PATIENT HAS VOMITED HAVE PATIENT DRINK MILK, WATER, OR SOLUTION OF SODIUM BICARBONATE IN WATER (1 TSP/1 QT). DO NOT GIVE ANYTHING TO AN UNCONSCIOUS OR CONVULSING PERSON.

SECTION VII PRECAUTIONS FOR SAFE HANDLING AND USE

DOT Classification: NO DATA SUPPLIED

********* STEPS TO BE TAKEN IN CASE MATERIAL IS RELEASED OR SPILLED *********

ACTION TO TAKE FOR SPILLS OR LEAKS:
WEAR PROTECTIVE EQUIPMENT INCLUDING RUBBER BOOTS, RUBBER GLOVES, RUBBER APRON, AND A SELF-CONTAINED BREATHING APPARATUS IN THE PRESSURE DEMAND MODE OR A SUPPLIED-AIR RESPIRATOR. IN ANY EVENT, ALWAYS WEAR EYE PROTECTION. EXTINGUISH ALL IGNITION SOURCES AND ENSURE THAT ALL HANDLING EQUIPMENT IS ELECTRICALLY GROUNDED. FOR SMALL SPILLS OR DRIPS, MOP OR WIPE UP AND DISPOSE OF IN DOT-APPROVED WASTE CONTAINERS. FOR LARGE SPILLS, CONTAIN BY DIKING WITH SOIL OR OTHER NON-COMBUSTIBLE ABSORBENT MATERIALS AND THEN PUMP INTO DOT-APPROVED WASTE CONTAINERS; OR ABSORB WITH NON-COMBUSTIBLE ABSORBENT MATERIAL, PLACE RESIDUE IN DOT-APPROVED WASTE CONTAINERS. KEEP OUT OF SEWERS, STORM DRAINS, SURFACE WATERS, AND SOIL.
COMPLY WITH ALL APPLICABLE GOVERNMENTAL REGULATIONS ON SPILL REPORTING, AND HANDLING AND DISPOSAL OF WASTE.

*************************** WASTE DISPOSAL METHOD *****************************

DISPOSE OF CONTAMINATED PRODUCT AND MATERIALS USED IN CLEANING UP SPILLS OR LEAKS IN A MANNER APPROVED FOR THIS MATERIAL. CONSULT APPROPRIATE FEDERAL, STATE AND LOCAL REGULATORY AGENCIES TO ASCERTAIN PROPER DISPOSAL PROCEDURES. NOTE: EMPTY CONTAINERS CAN HAVE RESIDUES, GASES AND MISTS AND ARE SUBJECT TO

SECTION VII SAFE HANDLING AND USE is continued on the next page.

SECTION VII SAFE HANDLING AND USE is continued from the previous page.

PROPER WASTE DISPOSAL AS ABOVE.

****** PRECAUTIONS TO BE TAKEN IN HANDLING AND STORAGE/REGULATORY DATA ******

KEEP AWAY FROM HEAT, SPARKS, AND FLAMES. STORE IN A COOL, DRY, WELL-VENTILATED PLACE AWAY FORM INCOMPATIBLE MATERIALS. VENT CONTAINER FREQUENTLY, AND MORE OFTEN IN WARM WEATHER, TO RELIEVE PRESSURE. ELECTRICALLY GROUND ALL EQUIPMENT WHEN HANDLING THIS PRODUCT AND USE ONLY NON-SPARKING TOOLS. KEEP CONTAINER TIGHTLY CLOSED WHEN NOT IN USE. DO NOT USE PRESSURE TO EMPTY CONTAINER. WASH THOROUGHLY AFTER HANDLING. DO NOT GET IN EYES, ON SKIN, OR ON CLOTHING.

REPAIR AND MAINTENANCE PRECAUTIONS: DO NOT CUT, GRIND, WELD, OR DRILL ON OR NEAR THIS CONTAINER.

OTHER REGULATORY INFORMATION:

DO NOT DETACH THIS SECTION FROM THE MSDS AND BE SURE TO INCLUDE THIS SECTION WHEN COPYING THE MSDS.

THIS PRODUCT CONTAINS THE FOLLOWING TOXIC CHEMICAL(S) SUBJECT TO THE REPORTING REQUIREMENTS OF SECTION 313 OF TITLE III OF THE SUPERFUND AMENDMENTS AND REAUTHORIZATION ACT OF 1986 AND 40 CFR PART 372:

NAME	CAS NO.	% WT
METHANOL	67-56-1	> 99%

THIS PRODUCT CONTAINS THE FOLLOWING CHEMICAL(S) CONSIDERED BY THE STATE OF CALIFORNIA'S SAFE DRINKING WATER AND TOXIC ENFORCEMENT ACT OF 1986 (PROPOSITION 65) AS CAUSING CANCER OR REPRODUCTIVE TOXICITY AND FOR WHICH WARNINGS ARE NOW REQUIRED:

CHEMICAL	CAS NO.	% WT.
HEAVY METALS		0.2 PPM
LEAD	7439-92-1	0.01 PPM
CADMIUM	7440-43-9	1.0 PPM
CHROMIUM	7440-47-3	0.5 PPM
NICKEL	7440-02-0	0.1 PPM

THE COMPONENTS OF THIS PRODUCT ARE ON THE TSCA INVENTORY OF CHEMICAL SUBSTANCES.

UNDER MASSACHUSETTS RIGHT-TO-KNOW LAW, HAZARDOUS SUBSTANCES AND EXTRORDINARILY HAZARDOUS SUBSTANCES COMPONENTS PRESENT IN THIS PRODUCT WHICH REQUIRE REPORTING ARE:

NTP? NO IARC? NO OSHA? NO

**************** ADDITIONAL INFORMATION (CARCINOGENICITY) *******************

CARCINOGENICITY: THIS MATERIAL IS NOT CONSIDERED TO BE A CARCINOGEN BY THE NATIONAL TOXICOLOGY PROGRAM, THE INTERNATIONAL AGENCY FOR RESEARCH ON CANCER,

SECTION VI HEALTH HAZARD DATA is continued on the next page.

SECTION VI HEALTH HAZARD DATA is continued from the previous page.

OR THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION.

********************** ACUTE AND CHRONIC HEALTH HAZARDS **********************

CHRONIC EFFECTS OF EXPOSURE:
NO SPECIFIC INFORMATION AVAILABLE.

********************** SIGNS AND SYMPTOMS OF EXPOSURE ************************

INHALATION:
VAPORS AND MISTS IRRITATE THE NOSE AND THROAT. INHALATION OF HIGHER CONCENTRATIONS MAY CAUSE HEADACHES, NAUSEA, VOMITING, AND COMA. INHALATION OF VERY HIGH CONCENTRATIONS OR PROLONGED EXPOSURE MAY CAUSE UNCONSCIOUSNESS OR DEATH.

EYE CONTACT:
VAPORS WILL IRRITATE THE EYES. LIQUID AND MISTS WILL IRRITATE AND MAY BURN THE EYES.

SKIN CONTACT:
BRIEF CONTACT MAY DRY THE SKIN. PROLONGED OR REPEATED CONTACT MAY IRRITATE THE SKIN, CAUSING DERMATITIS.

SWALLOWED:
SWALLOWING LARGE QUANTITIES CAUSES DRUNKENESS FOLLOWED BY SEVERE SYSTEMIC ILLNESS, AND PERHAPS BLINDNESS AND DEATH. BASED ON METHYL ISOBUTYL KETONE, INGESTION MAY PRODUCE CNS DEPRESSION AND LIVER DAMAGE.

************ MEDICAL CONDITIONS GENERALLY AGGRAVATED BY EXPOSURE *************

PRE-EXISTING EYE, SKIN, AND RESPIRATORY DISORDERS MAY BE AGGRAVATED BY EXPOSURE TO THIS PRODUCT. IMPAIRED LIVER FUNCTION FROM PRE-EXISTING DISORDERS MAY BE AGGRAVATED BY EXPOSURE TO THIS PRODUCT. PERSONS ON DISULFIRAM (ANTABUSE*) THERAPY, SHOULD BE AWARE THAT THE ETHYL ALCOHOL IN THIS PRODUCT IS HAZARDOUS TO THEM JUST AS IS ALCOHOL FROM ANY SOURCE. DISULFIRAM REACTIONS (VOMITING, HEADACHE AND EVEN COLLAPSE) MAY FOLLOW SMALL AMOUNTS OF ALCOHOL BY INGESTION, AND HAVE BEEN DESCRIBED FROM SKIN CONTACT.

STUDIES IN LABORATORY ANIMALS INVOLVING PROLONGED AND REPEATED EXPOSURES TO ETHYL ALCOHOL, HAVE RESULTED IN SUCH EFFECTS AS LIVER DAMAGE, EMBRYO-TOXICITY, FETOTOXICITY, AND TERATOGEENICITY(SIC). A TRANSIENT MUTAGENIC EFFECT HAS BEEN REPORTED IN RATS.

ALTHOUGH THE SIGNIFICANCE TO HUMANS IS UNKNOWN, IN MALE RATS EXPOSED BY INHALATION TO MIBK VAPORS (UP TO 1000 PPM) FOR 90 DAYS, EVIDENCE OF SLIGHT KIDNEY DAMAGE WAS OBSERVED.

*DATA ENTRY NOTE:

SECTION VI HEALTH HAZARD DATA is continued on the next page.

SECTION VI HEALTH HAZARD DATA is continued from the previous page.

ANTABUSE IS A REGISTERED TRADEMARK

******************** EMERGENCY AND FIRST AID PROCEDURES ***********************

IF INHALED:
REMOVE TO FRESH AIR. GIVE ARTIFICIAL RESPIRATION IF NOT BREATHING. GET IMMEDIATE MEDICAL ATTENTION.

IN CASE OF EYE CONTACT:
IMMEDIATELY FLUSH EYES WITH LOTS OF RUNNING WATER FOR 15 MINUTES, LIFTING THE UPPER AND LOWER EYELIDS OCCASIONALLY. GET IMMEDIATE MEDICAL ATTENTION.

IN CASE OF SKIN CONTACT:
IMMEDIATELY WASH SKIN WITH LOTS OF SOAP AND WATER. REMOVE CONTAMINATED CLOTHING AND SHOES; WASH BEFORE REUSE. GET MEDICAL ATTENTION IF IRRITATION PERSISTS AFTER WASHING.

IF SWALLOWED:
IF CONSCIOUS, IMMEDIATELY INDUCE VOMITING BY GIVING 2 GLASSES OF WATER AND STICKING A FINGER DOWN THE THROAT. GET IMMEDIATE MEDICAL ATTENTION. DO NOT GIVE ANYTHING TO AN UNCONSCIOUS OR CONVULSING PERSON.

NOTE TO PHYSICIAN:
IF VICTIM IS A CHILD, GIVE NO MORE THAN 1 GLASS OF WATER AND 15CC (1 TABLESPOON) SYRUP OF IPECAC. IF SYMPTOMS SUCH AS LOSS OF GAG REFLEX, CONVULSIONS OR UNCONSCIOUSNESS OCCUR BEFORE EMISIS, GASTRIC LAVAGE SHOULD BE CONSIDERED FOLLOWING INTUBATION WITH A CUFFED ENDOTRACHEAL TUBE.

SECTION VII PRECAUTIONS FOR SAFE HANDLING AND USE

DOT Classification: NO DATA SUPPLIED

********* STEPS TO BE TAKEN IN CASE MATERIAL IS RELEASED OR SPILLED *********

ACTION TO TAKE FOR SPILLS OR LEAKS: WEAR PROTECTIVE EQUIPMENT INCLUDING RUBBER BOOTS, RUBBER GLOVES, RUBBER APRON, AND A SELF-CONTAINED BREATHING APPARATUS IN THE PRESSURE DEMAND MODE OR A SUPPLIED-AIR RESPIRATOR. IF THE SPILL OR LEAK IS SMALL, A FULL FACEPIECE AIR-PURIFYING CARTRIDGE RESPIRATOR EQUIPPED FOR ORGANIC VAPORS MAY BE SATISFACTORY. IN ANY EVENT, ALWAYS WEAR EYE PROTECTION. EXTINGUISH ALL IGNITION SOURCES AND ENSURE THAT ALL HANDLING EQUIPMENT IS ELECTRICALLY GROUNDED. FOR SMALL SPILLS OR DRIPS, MOP OR WIPE UP AND DISPOSE OF IN DOT-APPROVED WASTE CONTAINERS. FOR LARGE SPILLS, CONTAIN BY DIKING WITH SOIL OR OTHER NON-COMBUSTIBLE ABSORBENT MATERIALS AND THEN PUMP INTO DOT-APPROVED WASTE CONTAINERS; OR ABSORB WITH NON-COMBUSTIBLE SORBENT MATERIAL, PLACE RESIDUE IN DOT-APPROVED WASTE CONTAINERS. KEEP OUT OF SEWERS, STORM DRAINS, SURFACE WATERS, AND SOIL.

SECTION VII SAFE HANDLING AND USE is continued on the next page.

SECTION VII SAFE HANDLING AND USE is continued from the previous page.

COMPLY WITH ALL APPLICABLE GOVERNMENTAL REGULATIONS ON SPILL REPORTING, AND HANDLING AND DISPOSAL OF WASTE.

************************** WASTE DISPOSAL METHOD ****************************

DISPOSAL METHODS:
DISPOSE OF CONTAMINATED PRODUCT AND MATERIALS USED IN CLEANING UP SPILLS OR LEAKS IN A MANNER APPROVED FOR THIS MATERIAL. CONSULT APPROPRIATE FEDERAL, STATE AND LOCAL REGULATORY AGENCIES TO ASCERTAIN PROPER DISPOSAL PROCEDURES. NOTE: EMPTY CONTAINERS CAN HAVE RESIDUES, GASES AND MISTS AND ARE SUBJECT TO PROPER WASTE DISPOSAL, AS ABOVE.

****** PRECAUTIONS TO BE TAKEN IN HANDLING AND STORAGE/REGULATORY DATA ******

KEEP AWAY FROM HEAT, SPARKS, AND FLAMES. STORE IN A COOL, DRY PLACE. VENT CONTAINER FREQUENTLY, AND MORE OFTEN IN WARM WEATHER, TO RELIEVE PRESSURE. ELECTRICALLY GROUND ALL EQUIPMENT WHEN HANDLING THIS PRODUCT AND USE ONLY NON-SPARKING TOOLS. KEEP CONTAINER TIGHTLY CLOSED WHEN NOT IN USE. DO NOT USE PRESSURE TO EMPTY CONTAINER. WASH THOROUGHLY AFTER HANDLING. DO NOT GET IN EYES, ON SKIN, OR ON CLOTHING.

REPAIR AND MAINTENANCE PRECAUTIONS:
DO NOT CUT, GRIND, WELD, OR DRILL ON OR NEAR THIS CONTAINER.

FOR ADDITIONAL INFORMATION:
CONTACT MSDS COORDINATOR, VAN WATERS & ROGERS INC.
DURING BUSINESS HOURS, PACIFIC TIME (408) 435-8700

OTHER REGULATORY INFORMATION:
DO NOT DETACH THIS SECTION FROM THE MSDS AND BE SURE TO INCLUDE THIS SECTION WHEN COPYING THE MSDS.

THIS PRODUCT CONTAINS THE FOLLOWING TOXIC CHEMICAL(S) SUBJECT TO THE REPORTING REQUIREMENTS OF SECTION 313 OF TITLE III OF THE SUPERFUND AMENDMENTS AND REAUTHORIZATION ACT OF 1986 AND 40 CFR PART 372:

NAME	CAS NO.	%, WT
METHYL ISOBUTYL KETONE	108-10-1	4%

THEY ASSUME ALL RISKS OF THEIR USE, HANDLING, AND DISPOSAL OF THE PRODUCT, OR FROM THE PUBLICATION OR USE OF, OR RELIANCE UPON, INFORMATION CONTAINED HEREIN. THIS INFORMATION RELATES ONLY TO THE PRODUCT DESIGNATED HEREIN, AND DOES NOT RELATE TO ITS USE IN COMBINATION WITH ANY OTHER MATERIAL OR IN ANY OTHER PROCESS.

REVISION:

01/90: ADDED NOTE TO PHYSICIAN FOR SWALLOWING FIRST AID, HEALTH HAZARD IF SWALLOWED, AGGRAVATED MEDICAL CONDITIONS, UNUSUAL FIRE AND EXPLOSION INFORMATION.
REVISED EVAPORATION RATE, HEALTH HAZARDS FOR INHALATION, EYE CONTACT, SKIN CONTACT AND AGGRAVATED MEDICAL CONDITIONS.

***************************** OTHER PRECAUTIONS ******************************

CONTAINERS, EVEN THOSE THAT HAVE BEEN EMPTIED, WILL RETAIN PRODUCT RESIDUE AND VAPORS. ALWAYS OBEY HAZARD WARNINGS AND HANDLE EMPTY CONTAINERS AS IF THEY WERE FULL.

SECTION VIII CONTROL MEASURES

************************ RESPIRATORY PROTECTION ******************************

IF USE CONDITIONS GENERATE VAPORS OR MISTS, WEAR A NIOSH-APPROVED RESPIRATOR APPROPRIATE FOR THOSE EMISSION LEVELS. APPROPRIATE RESPIRATORS MAY BE A FULL FACEPIECE OR A HALF MASK AIR-PURIFYING CARTRIDGE RESPIRATOR EQUIPPED FOR ORGANIC VAPORS/MISTS, A SELF-CONTAINED BREATHING APPARATUS IN THE PRESSURE DEMAND MODE, OR A SUPPLIED-AIR RESPIRATOR.

********************************** VENTILATION **********************************

Local Exhaust: VENTILATION: LOCAL MECHANICAL EXHAUST VENTILATION CAPABLE OF MAINTAINING EMISSIONS AT THE POINT OF USE BELOW THE PEL.
Special Exhaust: NO DATA SUPPLIED
Mechanical Exhaust: SEE LOCAL EXHAUST.
Other: NO DATA SUPPLIED.

****************************** OTHER PROTECTION ******************************

Gloves: NEOPRENE GLOVES.
Eye Protection: CHEMICAL GOGGLES UNLESS A FULL FACEPIECE RESPIRATOR IS ALSO WORN. IT IS GENERALLY RECOGNIZED THAT CONTACT LENSES SHOULD NOT BE WORN WHEN WORKING WITH CHEMICALS BECAUSE CONTACT LENSES MAY CONTRIBUTE TO THE SEVERITY OF AN EYE INJURY.

SECTION VIII CONTROL MEASURES is continued on the next page.

SECTION VIII CONTROL MEASURES is continued from the previous page.

******************************** CLOTHING **************************************

PROTECTIVE CLOTHING: LONG-SLEEVED SHIRT, TROUSERS, SAFETY SHOES, NEOPRENE GLOVES, AND RUBBER APRON.

************************** WORK/HYGIENE PRACTICES ***************************

OTHER PROTECTIVE MEASURES: AN EYEWASH AND SAFETY SHOWER SHOULD BE NERABY AND READY FOR USE.

EXPOSURE/HEALTH EFFECTS

INHALATION:
MAY CAUSE IRRITATION OF THE NOSE AND THROAT. EXPOSURE TO HIGH CONCENTRATIONS HAS A NARCOCTIC EFFECT, PRODUCING SYMPTOMS OF DROWSINESS, HEADACHE, STAGGERING, UNCONSCIOUSNESS AND POSSIBLY DEATH.

INGESTION:
MAY CAUSE DROWSINESS, UNCONSCIOUSNESS, AND DEATH. GASTROINTESTINAL PAIN, CRAMPS, NAUSEA, VOMITING, AND DIARRHEA MAY ALSO RESULT. THE SINGLE LETHAL DOSE FOR A HUMAN ADULT - ABOUT 250 MIS (SAX SIXTH EDITION).

SKIN CONTACT:
HAS A DEFATING ACTION OF THE SKIN THAT CAN CAUSE IRRITATION. MAY CAUSE IRRITATION WITH A STINGING EFFECT AND BURNING SENSATION.

EYE CONTACT:
VAPORS MAY IRRITATE THE EYES. SPLASHES MAY CAUSE SEVERE IRRITATION, POSSIBLE CORNEAL BURNS AND EYE DAMAGE.

CHRONIC EXPOSURE:

SECTION VI HEALTH HAZARD DATA is continued on the next page.

SECTION VI HEALTH HAZARD DATA is continued from the previous page.

PROLONGED CONTACT WITH SKIN MAY CAUSE MILD IRRITATION, DRYING CRACKING OR CONTACT DERMATITIS MAY DEVELOP.

********************** SIGNS AND SYMPTOMS OF EXPOSURE ************************

PLEASE REFER TO ACUTE AND CHRONIC HEALTH HAZARDS.

************* MEDICAL CONDITIONS GENERALLY AGGRAVATED BY EXPOSURE *************

PERSONS WITH PRE-EXISTING SKIN DISORDERS OR EYE PROBLEMS OR IMPAIRED RESPIRATORY FUNCTION MAY BE MORE SUSCEPTIBLE TO THE EFFECTS OF THE SUBSTANCE.

******************** EMERGENCY AND FIRST AID PROCEDURES ***********************

EMERGENCY/FIRST AID:
IF SWALLOWED, GIVE WATER TO DRINK. INDUCE VOMITING IF MEDICAL HELP IS NOT IMMEDIATELY AVAILABLE. NEVER GIVE ANYTHING BY MOUTH TO AN UNCONSCIOUS PERSON. IF INHALED, REMOVE TO FRESH AIR. IF NOT BREATHING, GIVE ARTIFICIAL RESPIRATION. IF BREATHING IS DIFFICULT, GIVE OXYGEN. IN CASE OF CONTACT, IMMEDIATELY FLUSH SKIN OR EYES WITH PLENTY OF WATER FOR AT LEAST 15 MINUTES. IN ALL CASES CALL A PHYSICIAN.

PLEASE SEE INFORMATION BELOW.

INHALATION:
REMOVE TO FRESH AIR. IF NOT BREATHING, GIVE ARTIFICIAL RESPIRATION. IF BREATHING IS DIFFICULT, GIVE OXYGEN. CALL A PHYSICIAN.

INGESTION:
GIVE WATER TO DRINK. INDUCE VOMITING. IF MEDICAL HELP NOT IS(SIC) IMMEDIATELY AVAILABLE. NEVER GIVE ANYTHING BY MOUTH TO AN UNCONSCIOUS PERSON. GET MEDICAL ATTENTION IMMEDIATELY.

SKIN EXPOSURE:
REMOVE ANY CONTAMINATED CLOTHING. WASH SKIN WITH SOAP OR MILD DETERGENT AND WATER FOR AT LEAST 15 MINUTES. GET MEDICAL ATTENTION IF IRRITATION DEVELOPS OR PERSISTS.

EYE EXPOSURE:
WASH EYES WITH PLENTY OF WATER FOR AT LEAST 15 MINUTES, LIFTING LOWER AND UPPER EYELIDS OCCASIONALLY. GET MEDICAL ATTENTION IMMEDIATELY.

SECTION VII PRECAUTIONS FOR SAFE HANDLING AND USE

DOT Classification: DOT HAZARD CLASS: FLAMMABLE LIQUID

SECTION VII SAFE HANDLING AND USE is continued on the next page.

SECTION VII SAFE HANDLING AND USE is continued from the previous page.

********* STEPS TO BE TAKEN IN CASE MATERIAL IS RELEASED OR SPILLED *********

REMOVE ALL SOURCES OF IGNITION. VENTILATE AREA OF LEAK OR SPILL. CLEAN-UP PERSONNEL REQUIRE PROTECTIVE CLOTHING AND RESPIRATORY PROTECTION FROM VAPORS. SMALL SPILLS MAY BE ABSORBED ON PAPER TOWELS AND EVAPORATED IN A FUME HOOD. ALLOW ENOUGH TIME FOR FUMES TO CLEAR HOOD, THEN IGNITE PAPER IN A SUITABLE LOCATION AWAY FROM COMBUSTIBLE MATERIALS. CONTAIN AND RECOVER LIQUID FROM RECLAMATION WHEN POSSIBLE. LARGER SPILLS AND LOT SIZES CAN BE COLLECTED AS HAZARDOUS WASTE AND ATOMIZED IN A SUITABLE RCRA APPROVED COMBUSTION CHAMBER, OR ABSORBED WITH VERMICULITE, DRY SAND, EARTH OR SIMILAR MATERIAL FOR DISPOSAL AS HAZARDOUS WASTE IN A RCRA APPROVED FACILITY.

ENSURE COMPLIANCE WITH LOCAL, STATE AND FEDERAL REGULATIONS.

*************************** WASTE DISPOSAL METHOD *****************************

PLEASE REFER TO SPILL AND LEAK ABOVE.

****** PRECAUTIONS TO BE TAKEN IN HANDLING AND STORAGE/REGULATORY DATA ******

STORAGE AND SPECIAL INFORMATION:
PROTECT AGAINST PHYSICAL DAMAGE. STORE IN A COOL, DRY WELL-VENTILATED LOCATION, AWAY FROM ANY AREA WHERE THE FIRE HAZARD MAY BE ACUTE. OUTSIDE OR DETACHED STORAGE IS PREFERRED. SEPARATE FROM OXIDIZING MATERIALS. CONTAINERS SHOULD BE BONDED AND GROUNDED FOR TRANSFERS TO AVOID STATIC SPARKS. STORAGE AND USE AREAS SHOULD BE NO SMOKING AREAS. USE NON-SPARKING TYPE TOOLS AND EQUIPMENT.

PRECAUTIONARY MEASURES:
WARNING! FLAMMABLE LIQUID. HARMFUL IF SWALLOWED OR INHALED. AFFECTS CENTRAL NERVOUS SYSTEM. CAUSES IRRITATION.

KEEP AWAY FROM HEAT, SPARKS AND FLAME.
KEEP CONTAINER CLOSED.
USE WITH ADEQUATE VENTILATION.
AVOID BREATHING VAPOR.
WASH THOROUGHLY AFTER HANDLING.
AVOID CONTACT WITH EYES, SKIN AND CLOTHING.

***************************** OTHER PRECAUTIONS ******************************

NO DATA SUPPLIED

SECTION VIII CONTROL MEASURES is continued on the next page.

SECTION VIII CONTROL MEASURES is continued from the previous page.

SECTION VIII CONTROL MEASURES

RESPIRATORY PROTECTION

PERSONAL RESPIRATORS: (NIOSH APPROVED)
IF THE TLV IS EXCEEDED A FULL FACEPIECE CHEMICAL CARTRIDGE RESPIRATOR MAY BE WORN, IN GENERAL, UP TO THE MAXIMUM USE CONCENTRATION SPECIFIED BY THE RESPIRATOR SUPPLIER. ALTERNATIVELY, A SUPPLIED AIR FULL FACEPIECE RESPIRATOR OR AIRLINED HOOD MAY BE WORN.

VENTILATION

Local Exhaust: SEE BELOW
Special Exhaust: NO DATA SUPPLIED
Mechanical Exhaust: NO DATA SUPPLIED
Other: VENTILATION SYSTEM:
A SYSTEM OF LOCAL AND/OR GENERAL EXHAUST IS RECOMMENDED TO KEEP EMPLOYEE EXPOSURES BELOW THE AIRBORNE EXPOSURE LIMITS. LOCAL EXHAUST VENTILATION IS GENERALLY PREFERRED BECAUSE IT CAN CONTROL THE EMISSIONS OF THE CONTAMINANT AT ITS SOURCE, PREVENTING DISPERSION OF IT INTO THE GENERAL WORK AREA. PLEASE REFER TO THE ACGIH DOCUMENT, "INDUSTRIAL VENTILATION, A MANUAL OF RECOMMENDED PRACTICES", MOST RECENT EDITION, FOR DETAILS.

OTHER PROTECTION

Gloves: PLEASE REFER TO SKIN PROTECTION BELOW.
Eye Protection: USE CHEMICAL SAFETY GOGGLES AND/OR A FULL FACE SHIELD WHERE SPLASHING IS POSSIBLE. CONTACT LENSES SHOULD NOT BE WORN WHEN WORKING WITH THIS MATERIAL. MAINTAIN EYE WASH FOUNTAIN AND QUICK-DRENCH FACILITIES IN WORK AREA.

CLOTHING

SKIN PROTECTION: WEAR IMPERVIOUS PROTECTIVE CLOTHING INCLUDING BOOTS, GLOVES, LAB COAT, APRON OR COVERALLS TO PREVENT SKIN CONTACT.

WORK/HYGIENE PRACTICES

SEE PRECAUTIONARY MEASURES IN SECTION VII.

ROUND WATER BURF

Dear Colleague:

In response to stakeholder interest, the U.S. Department of Energy has extended until October 16, 1995 the public scoping period for the second Supplemental Environmental Impact Statement. This study will evaluate the potential impacts of the Disposal Phase of the Waste Isolation Pilot Plant in southeastern New Mexico.

The Carlsbad Area Office also will hold an additional scoping meeting for the Denver Metro Area from 7 p.m. to 9 p.m., October 11, at the Broomfield Recreation Center, 300 Community Park Drive, Broomfield, CO. Members of the public are invited to attend the meeting.

All comments should be sent to:

Harold Johnson
DOE NEPA Compliance Officer
c/o Battelle
2000 Randolph Road SE, #105
Albuquerque, NM 87106

Comments should be postmarked no later than October 16, 1995. Comments may be faxed to 505-224-8030. If you have any questions about the scoping period extension, the Supplemental Environmental Impact Statement, or the WIPP, please call the WIPP Information Center at 1-800-336-9477 (toll-free).

Sincerely,

for Robert Wise, Manager
Supplemental Environmental Impact Statement

★★★ For Your Information ★★★

October 1995

WIPP SEIS Public Scoping Period Extended

In response to stakeholder interest, the Carlsbad Area Office has extended the scoping period for the second Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant to October 16, 1995. Comments should be sent by that date to Harold Johnson, DOE NEPA Compliance Officer, c/o of Battelle, 2000 Randolph Road SE, #105, Albuquerque, NM 87106. Comments may be telefaxed to him at 505-224-8030.

Second Scoping Meeting Scheduled for Denver

The Carlsbad Area Office has scheduled one additional public scoping meeting, near Denver, for the second WIPP Supplemental Environmental Impact Statement for the Waste Isolation Pilot Plant. It will be held from 7 to 9 p.m. October 11, at the Broomfield Recreation Center, 300 Community Park Drive, Broomfield, Colorado.

Remote-Handled Transuranic Waste Study Nearing Completion

The WIPP Remote-Handled Transuranic Waste Study will be completed by the end of October 1995. The study, which is a requirement of the WIPP Land Withdrawal Act, examines the effects of remote-handled waste on the performance assessment of the WIPP and compares remote-handled with contact-handled transuranic waste. It will evaluate such factors as gas generation, flammability, explosiveness, solubility, and brine and geochemical interactions. Additional information will be published in a Federal Register Notice.

For further information on any WIPP topic, please call our Information Center, 1-800-336-WIPP (800-336-9477) 7:30 a.m. until 4:30 p.m. mountain time. At other hours, please leave a message and we'll return your call on the next work day.

Mr. George Dials, Manager
Waste Isolation Pilot Plant
Department of Energy
P.O. Box 3090
Carlsbad, NM 88221

RE: AMENDMENT APPROVAL, DISCHARGE PLAN, DP-8
PILOT PLANT

Dear Mr. Dials:

Pursuant to Water Quality Control Commission (W
application for discharge plan amendment for
K.S. Donovan for the changes to the approved tr
system of the Waste Isolation Pilot Plant
approved. The discharge plan was approved on Ja
facility is located approximately 30 miles
Section 29, T22S, R31E, Eddy County. In appr
plan amendment, the New Mexico Environment Department (NMED) has determined that the requirements of WQCC Reg. 3-109.C have been met.

The approved amendment to the treatment and disposal system at WIPP is briefly described as follows:

WIPP is currently permitted to discharge 23,000 gallons per day (GPD) of domestic wastewater and 1500 GPD of nonhazardous brine water into their existing synthetically-lined domestic wastewater lagoons. The modification consists of increasing the daily allowable discharge of nonhazardous brine water from 1500 to 2000 gallons. Depth to water below the site is approximately 608 feet and contains a total dissolved concentration of approximately 10,500 milligrams per liter.

However, approval of this amendment to your discharge plan does not relieve you of your responsibility to comply with any other conditions or requirements of the approved discharge plan, DP-831, or any other applicable federal, state, and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

The following statement shall replace the first sentence in the first paragraph on page one of the January 16, 1992 approval letter:

Pursuant to the Water Quality Control Commission (WQCC) Reg. 3-109, the discharge plan application for DP-831, submitted by the U.S. Department of Energy, Waste Isolation Pilot Plant (WIPP) Project Site Office for the discharge of 23,000 gallons per day (GPD) of sewage effluent and up to 2000 GPD of nonhazardous brine water from the WIPP is hereby approved.

OTHER REQUIREMENTS

Please be advised that the approval of this discharge plan amendment does not relieve the Department of Energy (DOE) of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

PERIOD OF APPROVAL

This amendment approval expires on January 16, 1997, the same date as the original discharge plan, and you should submit an application for new approval in ample time for that date.

If you have any questions, please contact Clint Marshall of the Ground Water Section staff at 827-0027.

Sincerely,

Marcy Leavitt, Chief
Ground Water Protection &
Remediation Bureau

Public Meeting on WIPP Regulatory Compliance Criteria

The public is invited to make oral or written comments on issues relevant to WIPP's certification of compliance and 40 CFR Part 194 at the U.S. Environmental Protection Agency National Advisory Council for Environmental Protection and Technology (NACEPT) WIPP review committee. The meeting in Albuquerque, New Mexico will be held on Wednesday, September 6 and Thursday, September 7 at the Hyatt Regency Hotel, 330 Tijeras Avenue, N.W.

WIPP SEIS-II Scoping Meetings in September

Your comments are sought during the scoping process in connection with the WIPP second **Supplemental Environmental Impact Statement (SEIS-II)**. In addition, see the reverse of this calendar for dates, times, and location of the meetings. The Carlsbad Area Office has prepared several fact sheets that describe the WIPP SEIS-II scoping process, issues, and alternatives. If you have questions or would like fact sheets or further information on the WIPP SEIS-II or any other WIPP subject, please call the WIPP Information Center toll free, 1-800-336-WIPP (1-800-336-9477).

Written, oral and faxed comments will be accepted until September 30, 1995. Direct them to Harold Johnson, NEPA Compliance Officer, Attn: Scoping Comments, MS 535, U.S. DOE, P.O. Box 3090, Carlsbad, NM 88221. Telephone comments to: 1-800-336-9477 or fax to 1-505-224-8030.

REQUEST FOR MINOR MODIFICATION TO DISCHARGE PLAN DP-831 FOR THE WASTE ISOLATION PILOT PLANT (WIPP)

Dear Ms. Leavitt:

This letter requests a minor modification to the Waste Isolation Pilot Plant (WIPP) Discharge Plan, DP-831. If approved this request would allow the discharge of an additional 500 gallons per day to the WIPP sewage system evaporation ponds. The WIPP discharge plan currently allows for the discharge of 23,000 gallons per day of sewage effluent, and 1500 gallon per day of non-hazardous brines. The U.S. Department of Energy, Carlsbad Area Office (DOE-CAO) requests that the discharge plan be modified to increase the brine discharge volume to 2000 gallons per day to accommodate peak monitoring well pumping volumes. Increasing the evaporative discharge by 500 gallons per day will significantly reduce the number of trips made by WIPP personnel to transport brine to the evaporation ponds.

This proposed increase will have a minimum effect on the total volume of brine water discharged into the WIPP sewage system. The primary source of brine waters discharged to the evaporation ponds are generated by the periodic pumping of monitoring wells at the site. This activity is seasonal, and is performed approximately 80 days per year. The total volume of sewage and brine waters currently discharged to the evaporation basins represents approximately 60 percent of total evaporative design capacity of the system. An increase of 500 gallons per day represents a less than one percent increase in the effluent directed to the evaporation basins, and will have no impact on the total capacity of the system.

If you have any questions regarding this requested modification, or require any additional information please contact Mr. D. C. Robertson of my staff at (505) 234-8240.

Sincerely,

K. S. Donovan, Manager
Environment, Safety, and Health

CORNER OF THE WELL PAD
STS OF AN APPROXIMATELY
ALICHE. CONTRACTOR SHALL
TION AND THE OWNER
E AND CONDUCT THE WORK
ITE.

LINES, GRADES, AND SLOPES
CILITIES IS SUBJECT TO OWNER

THE ENTIRE PERIMETER OF THE
IENT SHALL BE 5 FEET AS
IKMENT CREST. HEIGHT DIMENSION
CORNERS AND 6.5 FEET AT THE
THE TOP OF THE GEOMEMBRANE

SAFETY

CONTRACTOR shall be solely responsible for working in a safe manner. CONTRACTOR shall support or brace excavation sideslopes to ensure that persons working in or near excavations are protected.

CONTRACTORS shall comply with all applicable codes, ordinances, statutes, and bear sole responsibility for the penalties imposed for noncompliance.

WASTE

At all times during the course of work remove from the site all accumulations of waste material caused by the work, and maintain and leave the site in good order and condition. Waste shall be removed and disposed as specified, and in accordance with all federal, state, and local regulations at the expense of CONTRACTOR.

Dispose excess or unsuitable excavation on site in OWNER designated stockpiles. No other materials shall be disposed on site without prior approval by OWNER.

ROADS

Continuously maintain access roads and well pad surfacing during construction. Maintain drainage features to prevent disruption of surface water flow and flooding. If gravel surfacing deteriorates by traffic of construction equipment, repair and/or replace gravel and crown, as directed by OWNER, prior to CONTRACTOR's departure, at no additional cost to OWNER.

GUARANTEES

CONTRACTOR shall guarantee that materials furnished conform to the requirements set forth herein and to the specified codes, standards and regulations, and that all specified tests have been satisfactorily completed and passed.

The foregoing shall not be construed in any way to limit or negate any other standard guarantee or portion thereof, which may provide a more comprehensive guarantee than those required by these Specifications.

SEQUENCE OF WORK

CONTRACTOR shall develop and submit a work schedule for OWNER's approval. In preparing the work schedule, the CONTRACTOR shall consider the necessity and importance of preconstruction submittals and importing/ordering of construction materials.

CONTRACTOR shall submit the work schedule concurrently with his bid. The work schedule must clearly identify critical path activities necessary to complete the required work. The work schedule shall be detailed to identify all work activities, critical milestones, and float times. At a minimum, all activities addressed by the Specifications shall be incorporated into the work schedule. The work schedule shall become part of the project's contract documents.

Waste Isolation Division

Box 2078
Carlsbad NM 88221

August 28, 1995

SEP 1995
RECEIVED

Ms. Marcy Leavitt, Manager
New Mexico Environment Department
Groundwater Protection and Remediation Bureau
1190 St. Francis Drive
P.O. Box 26110
Santa Fe, NM 87502

REQUEST FOR MINOR MODIFICATION TO DISCHARGE PLAN DP-831 FOR THE WASTE ISOLATION PILOT PLANT (WIPP)

Dear Ms. Leavitt:

This letter requests a minor modification to the Waste Isolation Pilot Plant (WIPP) Discharge Plan, DP-831. If approved this request would allow the discharge of an additional 500 gallons per day to the WIPP sewage system evaporation ponds. The WIPP discharge plan currently allows for the discharge of 23,000 gallons per day of sewage effluent, and 1500 gallon per day of non-hazardous brines. The U.S. Department of Energy, Carlsbad Area Office (DOE-CAO) requests that the discharge plan be modified to increase the brine discharge volume to 2000 gallons per day to accommodate peak monitoring well pumping volumes. Increasing the evaporative discharge by 500 gallons per day will significantly reduce the number of trips made by WIPP personnel to transport brine to the evaporation ponds.

This proposed increase will have a minimum effect on the total volume of brine water discharged into the WIPP sewage system. The primary source of brine waters discharged to the evaporation ponds are generated by the periodic pumping of monitoring wells at the site. This activity is seasonal, and is performed approximately 80 days per year. The total volume of sewage and brine waters currently discharged to the evaporation basins represents approximately 60 percent of total evaporative design capacity of the system. An increase of 500 gallons per day represents a less than one percent increase in the effluent directed to the evaporation basins, and will have no impact on the total capacity of the system.

If you have any questions regarding this requested modification, or require any additional information please contact Mr. D. C. Robertson of my staff at (505) 234-8240.

Sincerely,

K. S. Donovan, Manager
Environment, Safety, and Health

COMMENTS:

Authorization to Discharge Unpermitted, Non-Hazardous Effluent Into the WIPP Sewage Treatment Facility

Name: JOE R. FRANCO

Signature: Joe R Franco

Date: 7/13/95

Department/Section: OPERATIONS / FACILITY OPERATIONS

Origin of Effluent: Condensation from INGersoll Compressors - EQUIPMENT # 41-G-021A AND 021B. Approximately 450 gallons

Type of Effluent: (In gallons) CONDENSATE 450 GALLONS

Restrictions on Discharge: INTO POND #4

A ☐ Effluent has been characterized and the generation process has not changed: (Attach analytical results to the discharge form and submit to Environmental Compliance and Support for signature.)

B ☑ Effluent Characterization is Required: (Attach sampling results to the discharge request form and return to Environmental Compliance and Support for submittal to NMED for discharge authorization signature.)

Authorization Signatures:

1. Authorization Signature: [signature] Date: 7/12/95
(Environmental Compliance and Support (EC&S))

2. Authorization Signature: Date:
(DOE Environmental, Safety and Health)

3. Authorization Signature: Clint Marshall Date: 7/13/95
(NMED Groundwater Bureau) Must be signed if box B is checked above

4. Authorization Signature: Date:
(Environmental Monitoring (EM) Section, review discharge permit prior to signing)

June 15, 1995

Dear Concerned Citizen:

On May 26, 1995, the New Mexico Environment Department (NMED) received a revised RCRA Part B Permit Application (Revision 5) from the Department of Energy (DOE) for the disposal of hazardous waste at the Waste Isolation Pilot Plant (WIPP). DOE provided this application to comply with a September 2, 1994, NMED order to submit a complete revised application that more accurately reflected future WIPP activities. The revised WIPP application is available for public review during normal business hours at the locations listed on the back of this letter.

NMED is also updating its WIPP mailing list. If any aspect of your address requires correction, or if you wish to have your name deleted from the mailing list, please contact Ms. Chika Ezeanyim at (505) 827-4308, or at the address given above. Likewise, if you are aware of any individual or group who would like to receive future mailings about the WIPP hazardous waste disposal permitting process, have them contact Ms. Ezeanyim.

If you have any questions regarding the WIPP permit application (Revision 5), please contact Mr. Steve Zappe at (505) 827-4308.

Sincerely,

Barbara Hoditschek

RE: Response to Notice of Intent to discharge
brines from hydrologic testing at WIPP

Dear Mr. Daub:

The New Mexico Environment Department (NMED)
Notice of Intent (NOI) for the discharge of one
drilling fluids and brines from hydrologic testing for the proposed Culebra Transport Test Program at the Waste Isolation Pilot Plant (WIPP) in accordance with Section 1-201. of the NM Water Quality Control Commission (WQCC) Regulations. The facility is located approximately 30 miles east of Carlsbad in Section 29, T22S, R31E, Eddy County. The application satisfies the requirements of Section 1-201 of the WQCC Regulations.

Based on the presently available information in your letter, dated May 18, 1995, a discharge plan is not being required for this discharge as long as the discharge is as described.

In accordance with WQCC regulation 3-104, a discharge plan is not being required because the information provided indicates that no effluent or leachate will move directly or indirectly into water.

The exempt discharge is briefly described as follows:

Approximately one million gallons of drilling fluids and brines produced from hydrologic testing for the Culebra Transport Test Program will be discharged to a synthetically-lined evaporation basin over a period of 4 to 6 months. The basin will be constructed to the specifications of the two drawings attached to the letter, dated May 18, 1995. A letter was issued from NMED on January 31, 1995 stating that a discharge plan was not required for the discharge of tracer chemicals to be used for the Culebra Transport Test Program. The program consists of injecting tracer solutions into the Culebra Formation at the H-19 well at the WIPP site hydropad. Movement of the tracers will be achieved by pumping approximately 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Monitoring will take place in seven additional wells at the site.

Although a discharge plan is not being required for this discharge, you are not relieved of liability should your operation result in actual pollution of surface or ground waters. Further, this decision by the NMED does not relieve you of your responsibility to comply with any other applicable federal, state, and/or local laws and regulations, such as zoning requirements, plumbing codes and nuisance ordinances.

If at some time in the future you intend to change the amount, the character, or location of your discharge so that it will not be as described, or if observation or monitoring shows that the discharge is not as described, you must file a new request for exemption with the Ground Water Section.

If you have any questions, please contact either Clint Marshall of the Ground Water Section staff at 827-0027 or the Program Manager of the Ground Water Section at 827-2900.

Sincerely,

Marcy Leavitt, Chief
Ground Water Protection &
Remediation Bureau

RE: **Response to Notice of Intent to discharge chemicals at the WIPP Site**

Dear Mr. Fitch:

The New Mexico Environment Department (NMED) Notice of Intent for the discharge of addition to be used for the Culebra Transport Test Pr Isolation Pilot Plant in accordance with Section 1-201. of the NM Water Quality Control Commission (WQCC) Regulations. The facility is located approximately 30 miles east of Carlsbad in Section 29, T22S, R31E, Eddy County. The application satisfies the requirements of Section 1-201 of the WQCC Regulations.

Based on the presently available information in your letters, dated April 12, 1995, May 16, 1995 and May 24, 1995, a discharge plan is not being required for this discharge as long as the discharge is as described.

A discharge plan is not being required because it appears that the discharge conforms to the numerical ground water standards in WQCC Reg. 3-103 and does not contain any toxic pollutants as defined in WQCC Reg.1-101.ZZ, and therefore is exempt from the discharge plan requirement under WQCC Reg.3-105.A.

The exempt discharge is briefly described as follows:

NMED issued a letter on January 31, 1995 stating that a discharge plan was not required for a group of chemical tracers to be used in the Culebra Transport Test Program. Since that time, the discharger has submitted two requests for additional chemical constituents to be added to the original group.

The Culebra Transport Test Program consists of injecting tracer solutions into the Culebra Formation at the H-19 well at the WIPP site hydropad. Movement of the tracers will be achieved by pumping approximately 10 hydrologic test wells located along the principle flow path of the Culebra aquifer. Monitoring will take place in seven additional wells at the site.

In addition to the constituents approved in the letter, dated January 31, 1995, as possible tracers for the tests, the following chemicals have been added:

SODIUM HYDROXIDE
EOSIN B, Certified
2-AMINO-6-FLOUROBENZOTHIAZOLE, 99%
EOSIN Y FREE ACID
FLUORESCENT BRIGHTENER 28
2-HYDROXYNICOTINIC ACID
PHLOXINE B, Certified
LISSAMINE GREEN B
LISSAMINE FLAVINE FF
HYDROCHLORIC ACID
AC-2 (Organic Acid)
CITRIC ACID
I-22 (Corrosion Inhibitor)
NINE 40 (Surfactant)

Although a discharge plan is not being required for this discharge, you are not relieved of liability should your operation result in actual pollution of surface or ground waters. Further, this decision by the NMED does not relieve you of your responsibility to comply with any other applicable federal, state, and/or local laws and regulations, such as zoning requirements, plumbing codes and nuisance ordinances.

If at some time in the future you intend to change the amount, the character, or location of your discharge so that it will not be as described, or if observation or monitoring shows that the discharge is not as described, you must file a new request for exemption with the Ground Water Section.

If you have any questions, please contact either Clint Marshall of the Ground Water Section staff at 827-0027 or the Program Manager of the Ground Water Section at 827-2900.

Sincerely,

Marcy Leavitt, Chief
Ground Water Protection &
Remediation Bureau

Subject: FINAL EVAPORATION BASIN DRAWINGS

Dear Mr. Marshall:

Enclosed are the final drawings to be issued for the construction of a lined evaporation basin at the H-19 Hydropad for the containment of returned drilling fluids and brines from hydrologic testing in connection with the Culebra Transport Test Program. The drawings are offered as additional documentation for the U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) request for written concurrence that a Part 3-100 Discharge Plan will not be required for the construction of the lined evaporation basin.

Please address your response to: Mr. Vernon Daub, Manager
Office of National TRU Waste Operations
U. S. Department of Energy
Carlsbad Area Office
P. O. Box 3090
Carlsbad, NM 88221-3090

If you have any questions about this proposed project or require any additional information, please contact Mr. Jim Hollen of my staff at (505) 234-8271.

Sincerely,

L. R. Fitch, Manager
Environment, Safety, Health and Regulatory Compliance

P. O. Box 287
Carlsbad, New Mexico, 88221

Dear Warren:

Here are two copies of the "final" drawings for the proposed evaporation pond. One set is for you and the other set is for Clint Marshall at the Ground Water Protection and Remediation Bureau, New Mexico Environmental Department. Because of the severe problems with returned drilling fluids accumulating at the H-19 hydropad, we appreciate the prompt attention your staff has been giving this matter. We are continuing to plan for the construction of this pond as the only, as yet, available solution to disposal of the returned drilling fluids and the brines from hydraulic and hydrologic testing of the wells on the H-19 hydropad.

Please note that CH2MHILL was consulted in the design of the evaporation pond and Re/SPEC personnel at Carlsbad and Rapid City are being consulted for the implementation and construction of the evaporation pond. Also the berm may be somewhat wider than the minimum dimension.

I join Carla Mewhinney (letter to you, 5/19) in expressing appreciation for the collaboration of your staff.

Sincerely

Allan R. Sattler
Geothermal Research Department 6111

Subject: CLARIFICATION OF PROPOSED CHEMICAL USE

Dear Mr. Marshall:

Enclosed is a hard copy of a letter from Mr. Allan R. Sattler, of Sandia National Laboratories, to Mr. Warren Bodily, of my staff, providing clarification of proposed chemical use in the Culebra Transport Test Program tracer testing. The letter was transmitted to you via facsimile on May 26, 1995, by Mr. Dan Robertson.

If you have any questions about this proposed project or require any additional information, please contact Mr. J. R. Hollen at (505) 234-8271.

Sincerely,

L. R. Fitch, Manager
Environment, Safety, Health and Regulatory Compliance

Westinghouse Waste Isolation Division
MS 170
P. O. Box 287
Carlsbad, NM 87221

Dear Warren:

The proposed use of potassium and/or sodium hydroxide and hydrochloric acid should be clarified further. These strong basic and acidic compounds are to be used at H-19 only for the mixing process detailed on a separate page which is enclosed. They are not end products of the mixing process and, therefore, will not be injected directly into the formation.

As is stated in the DOE/AL Environmental Checklist/Action Description Memorandum, Attachment A, p.7. "Because of solubility problems associated with fluorinated and chlorinated acid tracers, one gram of potassium hydroxide must be added per gram of tracer." Potassium (or sodium) hydroxide is used to raise the pH to about 11. (Potassium hydroxide, KOH, dissociates into K^+ and OH^- ions.) At this higher pH, the benzoic acid can be dissolved in the Culebra brine. The addition of the benzoic acid will lower the pH. Some benzoic acids are stronger acids than others. If the addition of the benzoic acid does not lower the pH to very close to the natural original pH of the Culebra brine (~7.5), a small amount of hydrochloric acid will be added to restore the pH to close to the original Culebra brine pH (hydrochloric acid, HCl, dissociates into H^+ and Cl^- ions). The resulting solution to be injected will be Culebra brine at its original pH with additional potassium (or sodium), chloride, and benzoate ions (tracer). Potassium, sodium and chloride occur naturally in the Culebra brine in high concentrations, so the increase in concentration of these ions will be minimal.

Potassium hydroxide, sodium hydroxide and hydrochloride acid were included in the original or amended list of proposed chemicals. The solution going into the formation will have close to the same pH as the original Culebra brine. The solution added when injecting tracers will not be a strong acid or a strong base. (Appropriate QA procedures will be in place to assure that the injected solution is at the proper pH value.) Approval of the use of hydrochloric acid for tracer mixing is needed to ensure that the injected solution will have a pH close to the original pH of Culebra water from H-19. If there are any questions, please don't hesitate to call me at 844-1019 or Lucy Meigs at 848-0507.

Sincerely,

Allan R. Sattler, drr

Subject: REQUEST FOR USE OF ADDITIONAL POTENTIAL TRACER CHEMICAL

Dear Mr. Marshall:

Approval is requested for the use of the following chemical in the Culebra Transport Test Programs under development by Sandia National Laboratories at the Waste Isolation Pilot Plant (WIPP). A Material Safety Data Sheet (MSDS) is attached.

Hydrochloric Acid (Hydrogen Chloride)
CAS Number 7647-01-0

Because of additional solubility concerns with the previously approved chlorinated and fluorinated benzoic acid tracers, the use of hydrochloric acid is requested. The total amount of material deployed will be 100 kilograms or less.

Approval is also requested for the chemicals that would be used in the acidization of the DOE-1 well. The chemical requirements for the treatment have been provided by The Western Company with specific chemicals and quantities along with MSDSs.

As with our previous requests, the U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) is requesting written concurrence that a Part 3-100 Discharge Plan will not be required for the proposed Culebra Transport Test Programs. The Culebra Transport Test Program is designed to collect additional hydrogeologic characterization data from the Culebra, and perhaps Rustler formation, to test hydrological models for the WIPP Performance Assessment.

To accomplish this, Sandia National Laboratories proposed to establish up to 10 hydrologic test wells located along the principal flow path of the Culebra aquifer. Most of the new test wells will be located on the new H-19 hydropad. Three existing wells in the vicinity of the H-19 hydropad and several new wells strategically located around H-19 will be used to monitor pressure responses associated with the hydrologic tracer tests being conducted at the H-19 hydropad.

The DOE-CAO believes that this project should be exempted from the discharge plan requirements because the existing concentration of ground water in adjacent wells exceeds 10,000 mg/l Total Dissolved Solids (TDS). Additionally, none of the proposed tracer or acidization chemicals are listed in the New Mexico Water Quality Control Regulations, Part 1-101(UU), *Toxic Pollutants*, or Part 3-103, *Standards for Ground Water of 10,000 mg/l TDS Concentration or Less*.

If you have any questions about this proposed project or require any additional information, please contact Mr. J. R. Hollen at (505) 234-8271.

Sincerely,

L. R. Fitch, Manager
Environment, Safety, Health and Regulatory Compliance

Subject: REQUEST FOR CONCURRENCE THAT A DISCHARGE PLAN IS NOT REQUIRED FOR THE CONSTRUCTION AND USE OF A LINED EVAPORATION BASIN TO COLLECT CULEBRA BRINE

Dear Mr. Marshall:

Per your telephone conversation of February 2, 1995 with Mr. Dan Robertson, the U. S. Department of Energy, Carlsbad Area Office (DOE-CAO) is requesting written concurrence that a Part 3-100 Discharge Plan will not be required for the proposed Culebra Transport Test Programs evaporation basin. The lined evaporation basin is to be constructed at the H-19 hydropad for the containment of returned drilling fluids and brines from hydrologic testing. The evaporation basin will be constructed to the specifications of the two enclosed drawings.

Please address your response to: Mr. Vernon Daub, Manager
Office of National TRU Waste Operations
U. S. Department of Energy
Carlsbad Area Office
P. O. Box 3090
Carlsbad, NM 88221-3090

If you have any questions about this proposed project or require any additional information, please contact Mr. Jim Hollen of my staff at (505) 234-8271.

Sincerely,

NFPA RATINGS (SCALE 0-4): HEALTH=3 FIRE=0 REACTIVITY=0

EMERGENCY OVERVIEW:
Colorless gas or fuming liquid with a suffocating odor.
Causes skin burns. Causes severe burns to mucous membranes. Causes respiratory tract and eye irritation, possibly severe.
Container may rupture in heat of fire. May react with water.
Do not breathe gas. Do not get in eyes, on skin, or on clothing. Keep away from heat and flame. Do not allow water to get in container. Do not puncture

container. Keep container tightly closed. Wash thoroughly after handling. Use only with adequate ventilation. Handle with caution.

POTENTIAL HEALTH EFFECTS:
INHALATION:
SHORT TERM EFFECTS: May cause irritation, possibly severe. Additional effects may include headache, lung congestion and lung effects.
LONG TERM EFFECTS: May cause effects as in short term exposure. Additional effects may include digestive disorders.
SKIN CONTACT:
SHORT TERM EFFECTS: May cause irritation, possibly severe. Additional effects may include frostbite, reaction of skin to light and shock.
LONG TERM EFFECTS: Same effects as short term exposure.
EYE CONTACT:
SHORT TERM EFFECTS: May cause irritation, possibly severe. Additional effects may include frostbite and blindness.
LONG TERM EFFECTS: Same effects as short term exposure.
INGESTION:
SHORT TERM EFFECTS: May cause burns. Additional effects may include chills, fever, nausea, vomiting, diarrhea and shock.
LONG TERM EFFECTS: Same effects as short term exposure.

CARCINOGEN STATUS:
OSHA: N
NTP: N
IARC: N

SECTION 4 FIRST AID MEASURES

INHALATION:
FIRST AID- Remove from exposure area to fresh air immediately. Perform artificial respiration if necessary. Maintain airway, blood pressure and respiration. Keep warm and at rest. Treat symptomatically and supportively. Get medical attention immediately. Qualified medical personnel should consider administering oxygen.

SKIN CONTACT:
FIRST AID- Remove contaminated clothing and shoes immediately. Wash with soap or mild detergent and large amounts of water until no evidence of chemical remains (at least 15-20 minutes). If burns occur, proceed with the following: Cover affected area securely with sterile, dry, loose-fitting dressing. Treat symptomatically and supportively. Get medical attention immediately.

EYE CONTACT:
FIRST AID- Wash eyes immediately with large amounts of water, occasionally lifting upper and lower lids, until no evidence of chemical remains (at

least 15-20 minutes). Continue irrigating with normal saline until the pH has returned to normal (30-60 minutes). Cover with sterile bandages. Get medical attention immediately.

INGESTION:
FIRST AID- Do not use gastric lavage or emesis. Give large amounts of water or milk. Repeat if vomiting occurs. Ingested corrosive should be diluted approximately 100 times to render it harmless to tissues. (Dreisbach & Robertson; Handbook of Poisoning; 12th Ed.). Do not give anything by mouth to a person who is unconscious or otherwise unable to swallow. If vomiting occurs, keep head lower than hips to help prevent aspiration. Maintain airway and respiration. Treat symptomatically and supportively. Get medical attention immediately.

NOTE TO PHYSICIAN
ANTIDOTE:
No specific antidote. Treat symptomatically and supportively.

SECTION 5 FIRE FIGHTING MEASURES

FIRE AND EXPLOSION HAZARD:
Negligible fire hazard when exposed to heat or flame.

Container may explode in heat of fire.

EXTINGUISHING MEDIA:
Dry chemical or carbon dioxide
(1993 Emergency Response Guidebook, RSPA P 5800.6).

For larger fires, use water spray, fog or regular foam
(1993 Emergency Response Guidebook, RSPA P 5800.6).

FIREFIGHTING:
Do not get water inside container. Move container from fire area if you can do it without risk. Apply cooling water to sides of containers that are exposed to flames until well after fire is out. Stay away from ends of tanks. Isolate area until gas has dispersed (1993 Emergency Response Guidebook, RSPA P 5800.6, Guide Page 15).

Use agent suitable for type of fire. Cool containers with flooding quantities of water, apply from as far a distance as possible. Avoid breathing corrosive vapors, keep upwind.

FLASH POINT: no data available
LOWER FLAMMABLE LIMIT: no data available
UPPER FLAMMABLE LIMIT: no data available
AUTOIGNITION: no data available

HAZARDOUS COMBUSTION PRODUCTS:
Thermal decomposition products may include toxic and corrosive fumes of chlorine.

SECTION 6 ACCIDENTAL RELEASE MEASURES

OCCUPATIONAL SPILL:
Stop leak if you can do it without risk. Use water spray to reduce vapors; do not put water directly on leak or spill area. Do not get water inside container. Isolate area until gas has dispersed. For small spills, flush area with flooding amounts of water. For larger spills, dike far ahead of spill for later disposal. Keep unnecessary people away; isolate hazard area and deny entry. Stay upwind, out of low areas, and ventilate closed spaces before entering. Isolate the leak or spill area immediately for at least 150 feet in all directions.

Reportable Quantity (RQ): 5000 pounds
The Superfund Amendments and Reauthorization Act (SARA) Section 304 requires that a release equal to or greater than the reportable quantity for this substance be immediately reported to the local emergency planning committee and the state emergency response commission (40 CFR 355.40). If the release of this substance is reportable under CERCLA Section 103, the National Response Center must be notified immediately at (800) 424-8802 or (202) 426-2675 in the metropolitan Washington, D.C. area (40 CFR 302.6).

SOIL SPILL:
Dig holding area such as lagoon, pond or pit for containment.

Dike flow of spilled material using soil or sandbags or foamed barriers such as polyurethane or concrete.

Use cement powder or fly ash to absorb liquid mass.

Neutralize spill with slaked lime, sodium bicarbonate or crushed limestone.

AIR SPILL:
Knock down vapors with water spray. Keep upwind.

Water used to knock down vapors may become corrosive or toxic and should be contained properly for later disposal.

WATER SPILL:
Neutralize with agricultural lime, slaked lime, crushed limestone, or sodium bicarbonate.

SECTION 7 HANDLING AND STORAGE

Observe all federal, state and local regulations when storing this substance.

Store in accordance with 29 CFR 1910.101.

Protect against physical damage. Store in cool, well-ventilated place, separated from all oxidizing materials (NFPA 49, Hazardous Chemicals Data, 1975).

Store away from incompatible substances.

Threshold Planning Quantity (TPQ):
The Superfund Amendments and Reauthorization Act (SARA) Section 302 requires that each facility where any extremely hazardous substance is present in a quantity equal to or greater than the TPQ established for that substance notify the state emergency response commission for the state in which it is located. Section 303 of SARA requires these facilities to participate in local emergency response planning (40 CFR 355.30).

Threshold quantity (TQ): 5000 pounds
The Occupational Safety and Health Administration (OSHA) Process Safety Management (PSM) standard requires that facilities utilizing a process which involves a chemical at or above its specified threshold quantity comply with the provisions of 29 CFR 1910.119, Process Safety Management of highly hazardous chemicals.

SECTION 8 EXPOSURE CONTROLS, PERSONAL PROTECTION

EXPOSURE LIMITS:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
5 ppm (7.6 mg/m3) OSHA ceiling
5 ppm (7.6 mg/m3) ACGIH ceiling
5 ppm (7.6 mg/m3) NIOSH recommended ceiling
5 ppm (7.6 mg/m3) DFG MAK TWA;
10 ppm (15.2 mg/m3) DFG MAK 5 minute peak, momentary value, 8 times/shift

Measurement method: Silica gel tube; sodium bicarbonate/sodium carbonate; ion chromatography; (NIOSH Vol. III # 7903, Inorganic Acids).

500 pounds SARA Section 302 Threshold Planning Quantity (gas)
5000 pound SARA Section 304 Reportable Quantity (gas)
5000 pounds CERCLA Section 103 Reportable Quantity (liquid)
5000 pounds OSHA Process Safety Management Threshold Quantity (gas)
Subject to SARA Section 313 Annual Toxic Chemical Release Reporting

VENTILATION:
Provide local exhaust ventilation system to meet published exposure limits.

EYE PROTECTION:

Employee must wear splash-proof or dust-resistant safety goggles and a faceshield to prevent contact with this substance.

Emergency wash facilities:
Where there is any possibility that an employee's eyes and/or skin may be exposed to this substance, the employer should provide an eye wash fountain and quick drench shower within the immediate work area for emergency use.

CLOTHING:
Employee must wear appropriate protective (impervious) clothing and equipment to prevent any possibility of skin contact with this substance.

GLOVES:
Employee must wear appropriate protective gloves to prevent contact with this substance.

RESPIRATOR:
The following respirators and maximum use concentrations are recommendations by the U.S. Department of Health and Human Services, NIOSH Pocket Guide to Chemical Hazards; NIOSH criteria documents or by the U.S. Department of Labor, 29 CFR 1910 Subpart Z.
The specific respirator selected must be based on contamination levels found in the work place, must not exceed the working limits of the respirator and be jointly approved by the National Institute for Occupational Safety and Health and the Mine Safety and Health Administration (NIOSH-MSHA).

HYDROGEN CHLORIDE (HYDROCHLORIC ACID):

50 ppm- Any supplied-air respirator.
Any self-contained breathing apparatus.
Any chemical cartridge respirator with cartridge(s) providing protection against hydrochloric acid.

100 ppm- Any supplied-air respirator operated in a continuous flow mode.
Any supplied-air respirator with a full facepiece.
Any self-contained breathing apparatus with a full facepiece.
Any air-purfiying, full-facepiece respirator (gas mask) with a chin-style, front-, or back- mounted canister providing protection against hydrochloric acid.
Any chemical cartridge respirator with a full facepiece and cartridge(s) providing protection against hydrochloric acid.
Any powered, air-purfiying respirator with cartridge(s) providing protection against hydrochloric acid.
Escape- Any air-purifying, full facepiece respirator (gas mask) with a chin-style, front- or back-mounted acid gas canister.
Any appropriate escape-type self-contained breathing apparatus.

FOR FIREFIGHTING AND OTHER IMMEDIATELY DANGEROUS TO LIFE OR HEALTH CONDITIONS:

Any self-contained breathing apparatus that has a full facepiece and is operated in a pressure-demand or other positive-pressure mode.

Any supplied-air respirator that has a full facepiece and is operated in a pressure-demand or other positive-pressure mode in combination with an auxiliary self-contained breathing apparatus operated in pressure-demand or other positive-pressure mode.

SECTION 9 PHYSICAL AND CHEMICAL PROPERTIES

DESCRIPTION: Colorless gas or fuming liquid with a suffocating odor.
MOLECULAR WEIGHT: 36.46
MOLECULAR FORMULA: H-CL
BOILING POINT: -121 F (-85 C)
FREEZING POINT: -175 F (-115 C)
VAPOR PRESSURE: 3040 mmHg @ 17.8 C
VAPOR DENSITY: 1.268
SPECIFIC GRAVITY: 1.187 @ -85 C
WATER SOLUBILITY: 82.3% @ 0 C
PH: acidic in solution
ODOR THRESHOLD: 1-5 ppm
EVAPORATION RATE: not applicable
SOLVENT SOLUBILITY: Soluble in alcohol, ether, benzene, methanol.

SECTION 10 STABILITY AND REACTIVITY

REACTIVITY:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
May react exothermically with water.

CONDITIONS TO AVOID:
Material is extremely poisonous; avoid inhalation of vapors or contact with skin. Contents may be under pressure; containers may rupture violently and travel a considerable distance.

INCOMPATIBILITIES:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
ACETIC ANHYDRIDE: Violent reaction.
ALCOHOLIC HYDROGEN CYANIDE: Explosive reaction.
ALUMINUM: Explosion.
ALUMINUM-TITANIUM ALLOYS: Ignites or incandesces when heated.
2-AMINOETHANOL: Violent reaction.
AMMONIUM HYDROXIDE: Violent reaction.
BASES: Violent reaction.
BRASS: Corrodes.
BRONZE: Corrodes.
CALCIUM CARBIDE: Reacts with incandescence.

CALCIUM HYPOCHLORITE: Ignition.
CESIUM ACETYLIDE: Ignites on contact.
CHLORINE + DINITROANILINES: Vigorous reaction with release of flammable hydrogen gas fumes.
CHLOROSULFONIC ACID: Violent reaction.
1,1-DIFLUOROETHYLENE: Extremely exothermic decomposition reaction.
DOWICIL 100: Decomposes.
ETHYLENE DIAMINE: Violent reaction.
ETHYLENE IMINE: Violent reaction.
FLUORINE: Ignites on contact.
HEXALITHIUM DISILICIDE: Incandesces.
IRON: Corrodes with evolution of flammable hydrogen gas.
MAGNESIUM BORIDE: Produces a spontaneously flammable gas.
MERCURIC SULFATE: Violent reaction at 125 C.
METAL ACETYLIDES: Violent reaction.
METALS: Severe corrosion with evolution of flammable hydrogen gas.
OLEUM: Violent reaction.
OXIDIZERS (STRONG): Violent reaction.
OXYGEN + PLATINUM: Ignites on contact.
PERCHLORIC ACID: Violent reaction.
PLASTICS, RUBBER, COATINGS: Attacks.
POTASSIUM PERMANGANATE: Explosion hazard.
BETA-PROPIOLACTONE: Violent reaction.
PROPYLENE OXIDE: Violent reaction.
RUBIDIUM ACETYLIDE: Ignites on contact.
SILICA (GEL): Incompatible.
SODIUM: Vigorous or explosive reaction.
SULFURIC ACID: Explosive reaction with release of toxic hydrogen chloride gas.
TETRASELENIUM TETRANITRIDE: Explodes on contact.
VINYL ACETATE: Violent reaction.

HAZARDOUS DECOMPOSITION:
Thermal decomposition products may include toxic and corrosive fumes of chlorine.

POLYMERIZATION:
Hazardous polymerization has not been reported to occur under normal temperatures and pressures.

SECTION 11 TOXICOLOGICAL INFORMATION

HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
IRRITATION DATA:
ANHYDROUS: 100 mg/30 seconds rinsed eye-rabbit mild.
HYDROCHLORIC ACID: 5 mg/30 seconds rinsed eye-rabbit mild.
TOXICITY DATA:
HYDROGEN CHLORIDE (ANHYDROUS GAS): 4701 ppm/30 minutes inhalation-rat LC50;

2644 ppm/30 minutes inhalation-mouse LC50.
MONOHYDRATE: No data available.
DIHYDRATE: No data available.
TRIHYDRATE: No data available.
HEXAHYDRATE: No data available.
HYDROGEN CHLORIDE (AEROSOL): 5666 ppm/30 minutes inhalation-rat LC50; 2142 ppm/30 minutes inhalation-mouse LC50.
HYDROCHLORIC ACID: 1300 ppm/30 minutes inhalation-human LCLo; 3000 ppm/5 minutes inhalation-human LCLo; 3124 ppm/1 hour inhalation-rat LC50; 1108 ppm/1 hour inhalation-mouse LC50; 4413 ppm/30 minutes inhalation-rabbit LCLo; 4413 ppm/30 minutes inhalation-guinea pig LCLo; 685 ug/m3/24 hours/84 days-continuous inhalation-rat TCLo; 900 mg/kg oral-rabbit LD50; 1449 mg/kg intraperitoneal-mouse LD50; 81 mg/kg unreported-man LDLo; mutagenic data (RTECS); reproductive effects data (RTECS).
CARCINOGEN STATUS: Human Inadequate Evidence, Animal Inadequate Evidence (IARC Group-3).
LOCAL EFFECTS: Corrosive- inhalation, skin, eye and ingestion.
ACUTE TOXICITY LEVEL: Moderately toxic by inhalation and ingestion.
TARGET EFFECTS: No data available.

HEALTH EFFECTS
INHALATION:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
CORROSIVE. 100 ppm Immediately Dangerous to Life or Health.
ACUTE EXPOSURE- Inhalation of gas or fumes at levels of 5-35 ppm may cause irritation and burning of the throat, coughing and choking; 50-100 ppm may be barely tolerable for 1 hour. High levels may cause inflammation and occasionally ulceration of the nose, throat or larynx, bronchitis, pneumonia, palpitations and headache. Higher concentrations may cause necrosis of the tracheal and bronchial epithelium, nasoseptal perforation, atelectasis, emphysema, damage to pulmonary blood vessels and lesions of the liver and other organs. Death may be due to laryngeal spasm, bronchopneumonia or pulmonary edema. 1300-2000 ppm may be dangerous, even on brief exposures. Reproductive effects have been reported in animals.
CHRONIC EXPOSURE- Repeated or prolonged exposure may cause erosion and discoloration of exposed teeth, chronic bronchitis and gastritis.

SKIN CONTACT:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
CORROSIVE.
ACUTE EXPOSURE- Contact may cause severe irritation, inflammation, ulceration, necrosis and chemical burns. Shock symptoms may develop including rapid pulse, sweating and collapse. Photosensitization reactions may occur in persons previously exposed. Contact with a compressed gas may cause frostbite.
CHRONIC EXPOSURE- Repeated or prolonged contact with vapors or dilute solutions may cause dermatitis. Photosensitization may occur.

EYE CONTACT:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
CORROSIVE.

ACUTE EXPOSURE- Contact may cause severe irritation, conjunctivitis, corneal necrosis and burns with impairment or permanent loss of vision. A drop of hydrochloric acid splashed in the eye and immediately washed out has produced a white coagulation of the corneal and conjunctival epithelium. Animals exposed to vapor concentrations of 1350 ppm for one and a half hours showed clouding of the cornea and 300 ppm for 6 hours showed slight erosion of the corneal epithelium. Contact with a compressed gas may cause frostbite.

CHRONIC EXPOSURE- Animals exposed to vapor at 100 ppm for 6 hours daily for 50 days showed only slight unrest and irritation of the eyes, but no ocular injury. Effects are dependent upon concentration and duration of exposure. Conjunctivitis or effects similar to those for acute exposure may occur.

INGESTION:
HYDROGEN CHLORIDE (HYDROCHLORIC ACID):
CORROSIVE.

ACUTE EXPOSURE- Ingestion of the acid may cause burns of the mouth, throat, esophagus and stomach with consequent pain, uneasiness, nausea, salivation, vomiting, diarrhea, chills, shock and intense thirst. Nephritis, fever and perforation of the intestinal tract, and circulatory collapse may occur. Death may be due to esophageal or gastric necrosis.

CHRONIC EXPOSURE- No data available.

SECTION 12 ECOLOGICAL INFORMATION

ENVIRONMENTAL IMPACT RATING (0-4): no data available

ACUTE AQUATIC TOXICITY: no data available

DEGRADABILITY: no data available

LOG BIOCONCENTRATION FACTOR (BCF): no data available

LOG OCTANOL/WATER PARTITION COEFFICIENT: no data available

SECTION 13 DISPOSAL CONSIDERATIONS

Observe all federal, state and local regulations when disposing of this substance.

Disposal must be in accordance with standards applicable to generators of hazardous waste, 40 CFR 262. EPA Hazardous Waste Number D002.

100 pound CERCLA Section 103 Reportable Quantity.

SECTION 14 TRANSPORT INFORMATION

U.S. DEPARTMENT OF TRANSPORTATION SHIPPING NAME-ID NUMBER, 49 CFR 172.101:

AT010025 01

THE WESTERN COMPANY

Treatment Requirements for: ACID TREATMENT

ACID BLEND: **3,000 GALLONS 20% HCL**

Containing per 1000 Gallons:

1.00 Gallons I-22, CORROSION INHIBITOR
2.00 Gallons NINE-40, SURFACTANT
5.00 Gallons AC-2, ORGANIC ACID
5.00 Gallons CITRIC ACID LIQUID, IRON CONTROL

FLUSH TO BE PROVIDED BY SANDIA NATIONAL LABS.

AT010025

PRODUCT DESCRIPTIONS

AC-2 (Organic Acid)

A concentrated acetic acid commonly mixed with hydrochloric acid to slightly retard the acid spending rate and to prevent a rise in pH of the spent acid solution and subsequent precipitation of insoluble metal compounds.

CITRIC ACID (Iron Control Agent)

A liquid sequestering agent used to prevent the precipitation of metal oxides.

HYDROCHLORIC ACID (Inorganic Acid)

An inorganic acid (HCL) used in primary acidizing of carbonate and sandstone formations. It is the most common of oil field acids. It is typically used in concentrations from 3% to 28% (by weight). Higher concentrations are avoided due to increased volumes of inhibitors required and quantities of fines generated as the acid spends on the formation rock.

I-22 (Corrosion Inhibitor)

An organic liquid acid corrosion inhibitor for use in hydrochloric acid, HCL/HF acid, Mutual Solvent/HCL acid and organic acid/HCL acid systems with total acid strengths of up to 28% (by weight) and with well conditions where exposure temperatures are less than 300 Degrees Fahrenheit. Effective acid corrosion rates are less than 0.05 LB/SQ.FT.

NINE-40 (Surfactant)

A nonionic non-emulsifier with excellent load recovery capabilities in some reservoirs.

Occupational Safety and Health Administration

MATERIAL SAFETY DATA SHEET

DATE: September, 1984

SECTION I

Supplier's Name The Western Company of North America	EMERGENCY TELEPHONE NO. (817) 731-5100
ADDRESS (Number, Street, City, State and ZIP Code) P. O. Box 186, Ft. Worth, TX 76101	
CHEMICAL NAME AND SYNONYMS Proprietary blend	TRADE NAME AND SYNONYMS We-emulsifier. Nine-40
CHEMICAL FAMILY Surfactant	FORMULA
	W.I.N. 100472

SECTION IA HAZARDOUS MATERIAL CLASSIFICATION

D.O.T. PROPER SHIPPING NAME	Flammable Liquid, n.o.s.
NAME OF HAZARDOUS COMPONENT	Methanol
HAZARD CLASS	Flammable Liquid
IDENTIFICATION NUMBER	UN1993
D.O.T. LABEL(S) REQUIRED	Flammable Liquid
PRECAUTIONARY LABEL	Attached

SECTION II - HAZARDOUS INGREDIENTS

	%	TLV (Units)
Xylene		
Methanol	2	100pp
Isopropanol		200pp
Heavy Aromatic Naphtha		400pp
		100pp

SECTION III - PHYSICAL DATA

BOILING POINT (°F.)	162	SPECIFIC GRAVITY (H_2O=1)	0.881
VAPOR PRESSURE (mm Hg.)	200	PERCENT VOLATILE BY VOLUME (%)	62
VAPOR DENSITY (AIR=1) @ 100°F	>5	EVAPORATION RATE (n-Butyl Acetate=1)	2.03
SOLUBILITY IN WATER	Dispersible		
APPEARANCE AND ODOR	light yellow liquid, hydrocarbon odor		

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

FLASH POINT (Method used) 52°F Seta CC-ASTM	FLAMMABLE LIMITS	Lel 0.5	Uel 36.0

EXTINGUISHING MEDIA
Dry chemical, foam, water spray or water fog

SPECIAL FIRE FIGHTING PROCEDURES
Use water spray to cool fire exposed surfaces and to protect personnel.

UNUSUAL FIRE AND EXPLOSION HAZARDS
Respiratory protection required for fire-fighting personnel.

(Continued on reverse side)

Form OSHA-2.

TRADE NAME: W.I.N. 100472, De-emulsifier, Nine-40

SECTION V - HEALTH HAZARD DATA

THRESHOLD LIMIT VALUE
Isopropanol, Methanol, Xylene, heavy aromatic naphtha (400, 200, 100, 100 ppm)

EFFECTS OF OVEREXPOSURE
Acute: Liquid is irritating to skin and eyes

Chronic: Prolonged or repeated skin contact may cause dermatitis

EMERGENCY AND FIRST AID PROCEDURES
Remove to fresh air. If not breathing, apply artificial respiration and call
a physician. Immediately flush eyes with plenty of water for at least
15 minutes. Call a physician. If skin contact occurs, wash with soap and water.

SECTION VI - REACTIVITY DATA

STABILITY	UNSTABLE		CONDITIONS TO AVOID None
	STABLE	X	

INCOMPATABILITY (Materials to avoid)
strong oxidizing agents

HAZARDOUS DECOMPOSITION PRODUCTS
burning will emit smoke, fumes, CO and CO_2

HAZARDOUS POLYMERIZATION	MAY OCCUR		CONDITIONS TO AVOID
	WILL NOT OCCUR	X	

SECTION VII - SPILL OR LEAK PROCEDURES

STEPS TO BE TAKEN IN CASE MATERIAL IS RELEASED OR SPILLED
Keep public away. Eliminate source of ignition. Shut off source, if possible to do so safely. Prevent liquid from entering sewers, watercourses, or low areas. Advise authorities if material has entered a watercourse, or sewer or has contaminated soil or vegetation.

WASTE DISPOSAL METHOD
Contain spilled liquid with sand or earth. Recover by pumping or with suitable absorbent. Consult an expert on disposal of recovered material.

SECTION VIII - SPECIAL PROTECTION INFORMATION

RESPIRATORY PROTECTION (Specify type) Use NIOSH/MSHA approved respiratory protection such as air-supplied mask if used in confined spaces or other poorly ventilated areas.

VENTILATION	LOCAL EXHAUST Provide 250 fpm hood or face velocity for confined spaces.	SPECIAL explosion-proof ventilation equipment.	
	MECHANICAL (General) To provide ventilation equal to outdoors.	OTHER Not Applicable	
PROTECTIVE GLOVES Chemical resistant gloves		EYE PROTECTION Chemical splash goggles	
OTHER PROTECTIVE EQUIPMENT Usually not needed.			

SECTION IX - SPECIAL PRECAUTIONS

PRECAUTIONS TO BE TAKEN IN HANDLING AND STORING
Keep container closed when not in use. Containers used for this material may be hazardous when emptied. Observe all hazard precautions outlined in this sheet. Emptied containers retain product residues (vapor, liquid, etc.).

OTHER PRECAUTIONS
Keep away from heat, sparks and open flames.

U.S. DEPARTMENT OF LABOR
Occupational Safety and Health Administration

MATERIAL SAFETY DATA SHEET

Western Pacesetters

DATE: 31JUL85

SECTION I

Supplier's Name: The Western Company of North America	EMERGENCY TELEPHONE NO.: (817) 731-5100
ADDRESS (Number, Street, City, State, and ZIP Code): P. O. Box 186, Ft. Worth, TX 76101	
CHEMICAL NAME AND SYNONYMS: 40%acetic acid 60%acetic anhydride	TRADE NAME AND SYNONYMS: ACID, AC-2
CHEMICAL FAMILY: Acid	FORMULA: W.I.N.100174

SECTION IA HAZARDOUS MATERIAL CLASSIFICATION

D.O.T. PROPER SHIPPING NAME: Corrosive liquid, N.O.S.

NAME OF HAZARDOUS COMPONENT: Acetic Anhydride

HAZARD CLASS: Corrosive material

IDENTIFICATION NUMBER: UN1760

D.O.T. LABEL(S) REQUIRED: Corrosive

PRECAUTIONARY LABEL:

SECTION II - HAZARDOUS INGREDIENTS

SECTION II - HAZARDOUS INGREDIENTS	%	TLV (Units)

SECTION III - PHYSICAL DATA

BOILING POINT (°F.)		SPECIFIC GRAVITY (H_2O=1) @20°C	1.072
VAPOR PRESSURE (mm Hg.)		PERCENT, VOLATILE BY VOLUME (%)	100
VAPOR DENSITY (AIR=1)		EVAPORATION RATE (_____ =1)	
SOLUBILITY IN WATER	miscible		

APPEARANCE AND ODOR: clear, colorless liquid - sharp acrid odor

SECTION IV - FIRE AND EXPLOSION HAZARD DATA

FLASH POINT (Method used)	FLAMMABLE LIMITS	Lel	Uel
112°F, Tag Open cup; 109°F, Tag Closed Cup		2.9%	10.3%

EXTINGUISHING MEDIA: Water spray, dry chemical, and alcohol foam are effective extinguishing agents for acetic anhydride fires.

SPECIAL FIRE FIGHTING PROCEDURES: Addition of water will reduce intensity of flames. If a leak or spill has not ignited, use water spray to disperse the vapor and to protect the personnel trying to stop the leak. Fire fighters should wear self-contained breathing apparatus and full protective clothing.

UNUSUAL FIRE AND EXPLOSION HAZARDS: Water and foam react with chemical, but the heat liberated is not enough to create a hazard. Dry chemical forced below surface can cause foaming and boiling.

(Continued on reverse side)

Form OSHA-20

SECTION V - HEALTH HAZARD DATA

THRESHOLD LIMIT VALUE
5 ppm

EFFECTS OF OVEREXPOSURE
Contact with skin or eye causes burns. Breathing of vapors causes coughing, check pain, and irritation of nose and throat. Vapor exposure may cause nausea & vomiting.

EMERGENCY AND FIRST AID PROCEDURES
Remove contaminated clothing. Immediately flush skin and eye contact for at least 15 min. with plenty of water. Get medical care for eyes at once. If inhaled, remove to fresh air. Give oxygen if breathing is difficult. Call a physician.

SECTION VI - REACTIVITY DATA

STABILITY			CONDITIONS TO AVOID
	UNSTABLE		Contact with water or alcohols if confined.
	STABLE	X	

INCOMPATABILITY (Materials to avoid)
Water, alkalies, alcohols and strong oxidizing agents.

HAZARDOUS DECOMPOSITION PRODUCTS
Thermal decomposition may produce carbon monoxide and/or carbon dioxide.

HAZARDOUS POLYMERIZATION			CONDITIONS TO AVOID
	MAY OCCUR		Avoid contamination with water & alkalies.
	WILL NOT OCCUR	X	

SECTION VII - SPILL OR LEAK PROCEDURES

STEPS TO BE TAKEN IN CASE MATERIAL IS RELEASED OR SPILLED
Eliminate ignition sources. Wear self-contained breathing apparatus & full protective clothes. Flush area with water spray, but avoid getting water into tank or other confined areas. Prevent washings from entering waterways.

WASTE DISPOSAL METHOD
Chemical incinerator; carefully mix liquid with large volumes of water or dilute alkalies.

SECTION VIII - SPECIAL PROTECTION INFORMATION

RESPIRATORY PROTECTION (Specify type)
Wear self-contained breathing apparatus.

VENTILATION		
	LOCAL EXHAUST: Preferable	SPECIAL
	MECHANICAL (General): May not be sufficient.	OTHER

PROTECTIVE GLOVES	EYE PROTECTION
Impervious gloves	Chemical safety goggles

OTHER PROTECTIVE EQUIPMENT
Full face mask, impervious boots, apron or clothing, eye bath, and safety shower.

SECTION IX - SPECIAL PRECAUTIONS

PRECAUTIONS TO BE TAKEN IN HANDLING AND STORING
Avoid contact with eyes, skin, or clothing. Avoid breathing vapro. Keep away from heat, sparks, and fires. Use only D.O.T. approved containers.

OTHER PRECAUTIONS
Do not get into eyes, on skin or on clothing. Avoid breathing vapors. Keep away from heat, sparks and fires.

Approval Expires April 30, 1971

Subject: RE: WIPP DP public notice

I checked the correspondence file. As per WQCC 3108.A(1)(a), A(2), and A(4), WIPP posted a sign at the entrance to the facility and published notices in the Carlsbad and Hobbs newspapers. A copy of the package is in your mail slot outside your door.

Subject: WIPP DP public notice

I was thinking about the issue with WIPP and the fact that the public interest groups were unaware of the DP modification. If I'm learning this stuff correctly, there are three options for public notice, only one of which requires a newspaper advertisement. So it seems that WIPP may have selected an option that meets regulatory requirements but wouldn't necessarily have been obvious to out-of-town interest groups. What do you think?

Clint:

Charles informed Mary Ann and I that Ron is interested in re-opening the permit, but Charles will get with Ron later today to see if this is still how Ron wants to proceed. Charles had two requests:
1) Distance from the site to protectable ground water.
2) Charles plans to visit WIPP during the week of September 6 and would like to have a copy of your inspection report/letter with him.

Charles will get back to us after he talks to Ron.

George

Here is the information:
1. The nearest protectable water (found so far) is approximately 0.5 miles from the WIPP sewage lagoons and about 1.2 miles from the salt piles.
2. I am working on the report now and will get a copy to Charles once I finish.

Clint:

Charles informed Mary Ann and I that Ron is interested in re-opening the permit, but Charles will get with Ron later today to see if this is still how Ron wants to proceed. Charles had two requests:
1) Distance from the site to protectable ground water.
2) Charles plans to visit WIPP during the week of September 6 and would like to have a copy of your inspection report/letter with him.

Charles will get back to us after he talks to Ron.

George

George,

Here is the latest information concerning the discharge permit, DP-831 for WIPP.

The discharge permit is currently active. It was renewed on April 23, 2003, and then later modified on December 22, 2003. The permit modification includes an extensive stormwater catchment system to contol subsurface seepage that has occurred onsite. This system includes capping the old salt stockpile and constructing a new salt storage facility.

The current activity on DP-831 includes several wastestreams. WIPP continues to discharge up to 23,000 gallons per day (gpm) of domestic effluent to a series of synthetically lined lagoons for evaporation. The actual domestic discharge is much less than this. Non-hazardous seepage and condensate water collected from the facility's exhaust shaft and exhaust fans is discharged to a synthetically lined pond (H-19) for evaporation. WIPP is also in the process of constructing stormwater control features onsite to eliminate seepage of stormwater into the subsurface. They are currently placing a cap on the existing salt pile that has been used since the facility began. They are also in the process of constructing a new salt storage facility that began receiving salt in May of this year. Synthetically lined stormwater storage ponds have been constructed for both the new and existing salt pile facilities. New and and existing stormwater basins are also being constructed and lined at several locations around the facility.

WIPP was intending to submit a permit modification (12/22/03) request to allow the facility to convert part of its domestic wastewater lagoon system to a brine storage facility. They have since decided not to pursue this change, therefore they will not be sending the letter. However, I have been informed they may change their mind in the future. The only other correspondence we have received from WIPP since the permit modification, was for a minor spill that occurred when a sewage line was accidentally severed. NMED approved the corrective action for the spill on June 9, 2004. I conducted a full-day inspection of WIPP on August 11. WIPP will be submitting additional technical information in the next few months based on findings during the inspection.

Let me know if you need addtional information.

Subject: Completed Public Notice Requirements

Dear Ms. Leavitt:

In response to your letter dated June 13, 2003, WIPP has completed your requested Public Notice requirements for the Discharge Plan 831 (DP–831) modification application as required under discharge permit public notice requirements of 20.6.2.3108.A.1 NMAC.

On June 24, 2003 the public notices (copies enclosed) were published in the Carlsbad Current Argus newspaper in Section A and Hobbs-News Sun in Local 2. A sign of a synopsis of the public notice, in English and Spanish, was placed at the entrance of the WIPP facility. A photograph of the poster and an affidavit of sign posting are enclosed with this letter. The sign was in place for a period of 30 days as of July 24, 2003.

If you have any questions regarding these actions, please contact Mr. David Emery at (505) 234-7475.

Sincerely,

Inés Triay

Dr. Inés R. Triay

AFFIDAVIT OF SIGN POSTING, DP- *831*

AUG 0 5 2003

I certify, under penalty of law, that I fulfilled the ground water Discharge Permit public notice requirements of 20.6.2.3108.A.1 NMAC. I prominently posted a synopsis of the public notice (prepared by NMED), in English and in Spanish, at a conspicuous public location, approved by NMED, at or near the proposed facility for 30 days. I am aware that there are significant penalties for false certification including the possibility of fines. I have included a payment of $15.00 for the poster (If public notice option 1 or 2 was selected).

David D. Emery

Public Notice

DP-831
U. S. Department of Energy Waste Isolation Pilot Plant

DP-831, the U.S. Department of Energy's Waste Isolation Pilot Plant, proposes to modify its discharge permit to discharge up to 3,264,360 gallons per day of domestic and industrial wastewater and storm water runoff from mined rock salt tailings at its federal facility for disposing of defense generated transuranic radioactive waste.

Potential contaminants from this type of discharge include dissolved solids, chloride and nitrogen compounds. The groundwater most likely to be affected is at a depth of nearly 608 feet and has a total dissolved solids concentration of approximately 3920 milligrams per liter. The facility is located 26 miles southeast of Carlsbad, New Mexico, Section 20, T22S, R31E, in Eddy County.

Information in this public notice was provided by the applicant and will be verified by the New Mexico Environment Department (NMED) during the permit application review process. The NMED will accept comments and statements of interest regarding the application and create a facility-specific mailing list for persons who wish to receive future notices regarding this application. Comments and statements of interest should be sent to:

RE: Discharge Permit Renewal, DP-831, Waste Isolation Pilot Plant

Dear Dr. Triay:

Pursuant to Water Quality Control Commission (WQCC) Regulation 20.6.2.3109 NMAC, the application for discharge permit renewal for DP-831, submitted by Inez Triay for the discharge of 33,000 gallons per day of sewage effluent, non-hazardous brine water and neutralized acid waste from the Waste Isolation Pilot Plant (WIPP) is hereby approved, subject to the conditions listed below. The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. In approving this discharge plan, the New Mexico Environment Department (NMED) has determined that the requirements of Section 20.6.2.3109.C NMAC have been met.

The approved WIPP treatment and disposal system is briefly described as follows:

Up to 23,000 gallons per day of sewage effluent is discharged to a series of seven synthetically lined ponds for treatment and evaporation (facultative lagoon system). Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined evaporation cell (north evaporation cell). Up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources is discharged to a synthetically lined evaporation pond (H-19 evaporation pond). Up to 100 gallons per year of neutralized acid waste will also be discharged to the facultative lagoon system. Ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3,920 milligrams per liter.

The approved discharge plan renewal consists of the materials submitted by the U.S. Department of Energy (DOE) dated June 5, 2002. In addition, the discharge plan includes information and materials submitted as part of the original discharge plan approved on January 16, 1992, the materials for discharge plan amendment, dated August 28, 1995, the materials for discharge plan renewal and modification dated July 3, 1997, and the materials for discharge plan amendments dated June 12, 1998 and January 24, 2000. The discharge shall be managed in accordance with the approved plan and is subject to the conditions listed below.

However, renewal of this discharge plan does not relieve you of your responsibility to comply with any conditions or requirements of the previously approved discharge plan, DP-831, and the New Mexico Water Quality Act, WQCC Regulations, any other applicable federal, state and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

CONDITIONS FOR APPROVAL

Pursuant to Section 20.6.2.3109 NMAC, NMED reserves the right to modify permit requirements in the event NMED determines that the requirements of the WQCC Regulations are being violated or may be violated, or the standards of Section 20.6.2.3103 NMAC are being or may be violated. This may include a determination that structural controls and/or management practices approved under the discharge permit for WIPP are not protective of ground water quality, and that more stringent requirements to protect and/or remediate ground water quality may be required by NMED. These requirements may include lining or relining lagoons, changing waste storage or land application management practices, expanding monitoring requirements and/or implementing remediation systems.

This discharge plan renewal is subject to the following conditions for the following reasons:

OPERATIONS

General:

1. The permittee is authorized to discharge up to 23,000 gallons per day of sewage effluent to a series of seven synthetically lined lagoons for treatment and evaporation.

2. The permittee is authorized to discharge up to 2,000 gallons per day of non-hazardous brine water to the synthetically lined north evaporation cell.

3. The permittee is authorized to discharge up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources to the synthetically lined H-19 evaporation pond.

4. The permittee is authorized to discharge up to 100 gallons per year of neutralized acid waste to the synthetically lined facultative lagoon system.

The reason for Conditions 1, 2, 3 and 4 is to comply with Secion 20.6.2.3104 NMAC by permitting a discharge consistent with the terms and conditions of the approved discharge plan.

Lagoon Operation and Maintenance:

5. The permittee shall properly operate and maintain all lagoons covered by this permit. The permittee shall maintain the capacity of the lagoons to store and evaporate the maximum daily discharge volume allowed by this discharge permit while maintaining two feet of freeboard at all times. In the event that a minimum of two feet of freeboard can not be maintained at all times, the permittee shall submit a corrective action plan to manage discharge volumes to the NMED for approval.

6. The permittee shall measure the thickness of the sludge blanket in each lagoon every five years. When sludge accumulation exceeds 1/3 of the total depth of any lagoon, the permittee shall remove the sludge in a manner, which is protective of the lagoon liner. Removed sludge shall be contained, transported, and disposed in accordance with all local, state, and federal (e.g., 40 CFR Part 503) regulations.

   The reason for this Conditions 5 and 6 is to comply with Section 20.6.2.3109 NMAC by preventing contaminated wastewater from moving directly or indirectly into ground water.

7. The permittee shall perform visual inspection of the lagoons and surrounding berms on a monthly basis. The water surface of the lagoons shall be kept free of floating plants and debris. Berms surrounding the lagoons shall be kept free of all "deep-rooted" plants. Berms shall be inspected for signs of wind or water erosion. In the event berms show signs of erosion, the permittee shall submit to the NMED for approval a plan for protection of the berms from erosion which may include the emplacement of rip rap or other methods for armoring the berms

   The reason for this condition is to comply with Sections 20.6.2.3107 and 20.6.2.3109 NMAC by properly maintaining and monitoring the condition of the effluent treatment and evaporation lagoons.

MONITORING AND REPORTING

8. The permittee shall measure the volume of effluent discharged to the facultative lagoon system using a totalizing flow meter or assume the discharge is equal to the total domestic water usage. Volumes of other permit-authorized discharges to the facultative lagoon system shall be calculated by a time/volume method or volumetric measurement of the transport container. Monthly meter readings, the units of measurement, monthly discharge volumes and other volumetric calculations for the previous 6-month period shall be submitted to NMED semi-annually in the monitoring reports due by January 31 and July 31 of each year.

The reason for this condition is to comply with Sections 20.6.2.3107 and 20.6.2.3109 NMAC by adequately measuring the quantity of effluent discharged.

9. The permittee shall sample and analyze semi-annually the influent to the lagoon system for nitrate-nitrogen (NO_3-N), total Kjeldahl nitrogen (TKN), total dissolved solids (TDS), plutonium 238, 239 and 240, americium 241, uranium 234, 235 and 238, and strontium 90. The permittee shall sample and analyze semi-annually the north evaporation pond (Pond B), the south evaporation pond (Pond C), and the H-19 evaporation pond for total dissolved solids (TDS), plutonium 238, 239 and 240, americium 241, uranium 234, 235 and 238, and strontium 90. Reports of the analyses shall be submitted to NMED by January 31 and July 31 of each year.

   The reason for this condition is to comply with Section 20.6.2.3107 NMAC by providing adequate monitoring of effluent quality.

10. The permittee shall notify NMED of the volume and origin of all wastewater to be discharged that is derived from miscellaneous non-hazardous sources. NMED may require more comprehensive laboratory analyses of such wastewater prior to discharge when NMED determines that additional information is needed.

    The reason for this condition is to comply with Sections 20.6.2.3106 and 20.6.2.3107 NMAC by monitoring and reporting the quality of effluent discharged.

CONTINGENCY

11. The permittee shall implement the contingency plan, dated December 16, 1996 in the event of a failure of the wastewater treatment and disposal system. The plan includes daily inspection and repair of pond liners as necessary, containment and investigation of all spills and releases, and submittal of a remediation plan to address contamination.

    The reason for this condition is to comply with Sections 20.6.2.1203 and 20.6.2.3107.A.10 NMAC by providing a contingency plan to address potential impacts to ground water quality.

CLOSURE

12. The permittee shall implement the closure plan, dated December 16, 1996 when the facility is decommissioned. The plan includes the pumping or evaporation of all wastewater ponds, removal of all solids, and recontouring and revegetation of the site. In addition, the permittee shall remove or perforate all lagoon liners upon closure of the site.

    The reason for this condition is to comply with Section 20.6.2.3107.A.11 NMAC by providing a closure plan to address potential impacts to ground water after the facility is closed.

GENERAL DISCHARGE PLAN REQUIREMENTS

In addition to any other requirements provided by law, approval of discharge plan, DP-831, is subject to the following general requirements:

Monitoring and Reporting

Monitoring and reporting shall be as specified in the discharge plan and supplements thereto. These requirements are summarized on the attached sheet(s). Any inadvertent omissions from this summary of a discharge plan monitoring or reporting requirement shall not relieve you of responsibility for compliance with that requirement.

Record Keeping

1. The discharger shall maintain at the facility, a written record of ground water and wastewater quality analyses.The following information shall be recorded and shall be made available to the NMED upon request.

   a. The dates, exact place and times of sampling or field measurements.

   b. The name and job title of the individuals who performed the sampling or measurements.

   c. The dates the analyses were performed.

   d. The name and job title of the individuals who performed the analyses.

   e. The analytical techniques or methods used.

   f. The results of such analyses, and

   g. The results of any split sampling, spikes or repeat sampling.

2. The discharger shall maintain a written record of any spills, seeps, and/or leaks of effluent, leachate and/or process fluids not authorized by this discharge permit.

3. The discharger shall maintain a written record of the operation, maintenance and repair of facilities/equipment used to treat, store and/or dispose of wastewater; to measure flow rates; and/or to monitor water quality. This will include repairs, replacement or calibration of any monitoring equipment and repairs or replacement of any equipment used in WIPP's waste or wastewater treatment and disposal system.

4. The discharger shall maintain a written record of the amount of wastewater discharged.

Inspection and Entry

In accordance with Sections 74-6-9.B & E NMSA 1978 and WQCC Regulation Section

20.6.2.3107.D NMAC, the discharger shall allow the Secretary or his authorized representative, upon the presentation of credentials, to:

1. Enter at regular business hours or at other reasonable times upon the discharger's premises or where records must be kept under the conditions of this discharge plan.

2. Inspect and copy, during regular business hours or at other reasonable times, any records required to be kept under the conditions of the discharge plan.

3. Inspect, at regular business hours or at other reasonable times, any facility, equipment (including monitoring and control equipment), practices or operations regulated or required under this discharge plan.

4. Sample or monitor, at reasonable times for the purpose of assuring discharge plan compliance or as otherwise authorized by the New Mexico Water Quality Act, any effluent at any location before or after discharge.

Duty to Provide Information

In accordance with Section 74-6-9.B NMSA 1978 and Section 20.6.2.3107.D NMAC, the discharger shall furnish to the NMED, within a reasonable time, any relevant information which it may request to determine whether cause exists for modifying, terminating and/or renewing this discharge plan or to determine compliance with this plan. The discharger shall furnish to the NMED, upon request, copies of records required to be kept by this discharge plan.

Spills, Leaks and Other Unauthorized Discharges

This approval authorizes only those discharges specified in the discharge plan. Any unauthorized discharges violate Section 20.6.2.3104 NMAC, and must be reported to the NMED and remediated as required by Section 20.6.2.1203 NMAC. This requirement applies to all seeps, spills, and/or leaks discovered from the pipelines, disposal ponds, and treatment and evaporation ponds.

Retention of Records

The discharger shall retain records of all monitoring information, including all calibration and maintenance records, copies of all reports required by this discharge plan, and records of all data used to complete the application for this discharge plan, for a period of at least five years from the date of the sample collection, measurement, report or application. This period may be extended by request of the Secretary at any time.

Enforcement

Failure to grant the Secretary or his authorized representative access to the records required to be kept by this discharge permit or to allow an inspection of the discharge facilities or to the collection of samples is a violation of this discharge permit and the WQCC Regulations. Such violations as well as other violations of the discharge permit, may subject the discharger to a compliance order, a compliance order assessing a civil penalty or an action in district court pursuant to Section 74-6-10 NMSA 1978, and/or modification or termination of this discharge permit pursuant to Section 74-6-5.L NMSA 1978. Penalties assessed as part of a compliance order shall not exceed $15,000 per day for violations of the terms of this permit or the requirements of Section 74-6-5 NMSA 1978, and shall not exceed $10,000 per day for violations of other sections of the Water Quality Act.

Modifications and/or Amendments

The discharger shall notify NMED, pursuant to Section 20.6.2.3107.C NMAC, of any modifications or additions to the WIPP's wastewater disposal system, including any increase in wastewater flow rate or wastewater storage and disposal management changes to the system as approved under this discharge plan. The discharger shall obtain NMED's approval, as a discharge permit modification, prior to any increase in the quantity or concentration of constituents in the leachate above those approved in this permit. Please note that Section 20.6.2.3109.E and F NMAC provide for possible future amendment of the permit.

Other Requirements

Please be advised that the approval of this plan does not relieve the U.S. Department of Energy of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

RIGHT TO APPEAL

If the U.S. Department of Energy is dissatisfied with this action taken by NMED, the U.S. Department of Energy may file a petition for hearing before the WQCC. This petition shall be in writing to the Water Quality Control Commission within thirty (30) days of the receipt of this letter. Unless a timely request for hearing is made, the decision of the NMED shall be final.

TRANSFER OF DISCHARGE PLAN

Pursuant to Section 20.6.2.3111 NMAC, prior to any transfer of ownership, the discharger shall provide the transferee a copy of the discharge permit, including a copy of this approval letter and shall document such to the NMED.

PERIOD OF APPROVAL

Pursuant to Section 20.6.2.3109.G.4 NMAC, this discharge permit approval is for a period of 5 years. This approval will expire **April 29, 2008**, and you must submit an application for renewal at least 180 days before that date.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

Subject: Draft Discharge Plan Renewal, DP-831, Waste Isolation Pilot Plant (WIPP)

Dear Mr. Marshall:

Thank you for the opportunity to review and comment on the *Draft Discharge Permit Renewal, DP-831*. In accordance with your letter dated February 11, 2003, we have reviewed the *Draft Discharge Permit Renewal* for accuracy and completeness. The permittee submits the following comments for your consideration:

1. The description of the facultative lagoon system (Page 1, Paragraph 2) describes the treatment and evaporation system as consisting of 5 synthetically lined ponds for treatment and evaporation.

   The system consists of seven ponds (two settling ponds, two finishing ponds and three evaporation ponds). See the enclosed diagram of the Facultative Lagoon System and the January 3, 1992 Discharge Plan Application.

2. The *Draft Discharge Permit Renewal* (Page 1, Paragraph 2) states, "Up to 100 gallons per <u>day</u> of neutralized acid waste will also be discharged to the H-19 evaporation pond." The section titled Operations, General: Item 4, reiterates the same authorization for 100 gallons per <u>day</u> of neutralized acid waste to be discharged to the <u>H-19 evaporation pond</u>.

   The permittee requests authorization to continue to discharge the neutralized acid waste stream to the facultative lagoon system, not H-19 as identified in the June 5, 2002 Discharge Permit Renewal Application. Previous discharge plans have authorized the discharge of 100 gallons per <u>year</u> of neutralized acid to the facultative lagoon system. Currently less than 100 gallons per <u>year</u> of neutralized acid are discharged and the volume is not expected to increase in the foreseeable future.

3. The section of the *Draft Discharge Permit Renewal* titled Operations, General: Item 1, (Page 2) states: "The permittee is authorized to discharge up to 33,000 gallons per day of sewage effluent to a series of five synthetically lined lagoons for treatment and evaporation." The Draft Discharge Plan Application Page 1,

CBFO:OEC:CAZ:VW:03-0375:UFC:5487

Paragraph 2, states the approved WIPP treatment and disposal system is approved for 23,000 gallons per day of sewage effluent to the facultative lagoon system. The June 5, 2002 Discharge Plan Renewal Application described the discharge as only 23,000 gallons per day of sewage effluent to the facultative lagoon system. The Discharge Plan Renewal should authorize 23,000 gallons per day of sewage effluent to seven lagoons.

4. The section entitled Monitoring and Reporting, Item 8 (page 3), states: "The permittees shall measure the monthly volume of effluent discharged to the facultative lagoon system using a totalizing flow meter. The flow meter shall be kept operational at all times.

   The June 5, 2002 Discharge Plan DP-831 Renewal Application states, "Sewage effluent discharges to the facultative lagoon system are measured through the wastewater flow meter or are assumed to equal the total domestic water usage. Volumes of other permit-authorized discharges to the facultative lagoon system/evaporation facility are calculated by a time/volume method or volumetric measurement of the transport container."

   The permittee respectfully requests to continue to have the option to use the volume of the facilities total water use as a back-up to the effluent flow meter as described in the June 5, 2002 Discharge Renewal Application. Previous discharge plans have permitted the use of the total domestic water volume to monitor the flow into the facultative lagoon system. The domestic water use volume is measured with a totalizing flow meter and there are no other sources of water discharged from the facility, except as authorized by DP-831. The total domestic water use volume is a reasonable approximation of the water discharged to the facultative lagoon system, at all times a conservative value, and complies with 20.6.2.3107 and 20.6.2.3109 NMAC.

5. The section titled Monitoring and Reporting, Item 9, states, "the permittees shall sample and analyze semi-annually the final stage domestic lagoon for NO_3-N, TKN ...[other analytes]."

   We believe Item 9 should require that the permittee sample and analyze the influent to the lagoon as described in the June 5, 2002 Discharge Plan Renewal Application and illustrated in the enclosed figure of the facultative lagoon system.

6. Monitoring and Reporting, Item 9, states "the permittee shall sample and analyze semi-annually the east evaporation pond (Pond-A), the north evaporation pond (Pond B), the south Evaporation Pond (Pond C) and the H-19 Evaporation Pond for total dissolved solids, ..."

The Discharge Plan Renewal Application dated June 5, 2002 proposed to monitor only Evaporation Pond B and Evaporation Pond C. Sampling Ponds B and C are consistent with the *Discharge Plan Amendment Approval* dated June 12, 1998. Wastewater contained in Evaporation Pond A flows into the North Evaporation Pond B and the South Evaporation Pond C. The permittee sees no added value to sampling Evaporation Pond A and requests that the final Discharge Plan Renewal only require monitoring the north Evaporation Pond (Pond B), south Evaporation Pond (Pond C), and the H-19 Evaporation Pond.

7. The Discharge Permit Summary, Facility Information, Legally Responsible Party identifies the contact as Sean White (505-234-7285). This should be changed to Mr. Bruce Lilly, (505) 234-8136 and Mr. David Reber (505) 234-8799.

Thank you for your consideration of the comments and requests discussed above. If you have any questions or need additional information, please contact Mr. David Emery at (505) 234-7475.

Sincerely,

Inés Triay

RE: Conceptual Design for Discharge Permit Modification, DP-831
Waste Isolation Pilot Plant (WIPP)

Dear Dr. Triay:

On April 1, 2003, Dave Emery and E.B. Nuckols with the Department of Energy (DOE), Dale Bignell with Washington, and I. Keith Gordon with Gordon Environmental, Inc. met with the New Mexico Environment Department (NMED) to discuss proposed plans for the modification of the discharge permit for the Waste Isolation Pilot Plant (WIPP), DP-831.

The existing discharge permit covers domestic wastewater and minor industrial discharges at the facility, and is currently in the process of being renewed. The proposed modification of DP-831 will expand permit coverage to include discharges associated with the salt pile and storm water impoundments at the site.

The preliminary plans presented at the meeting include a draft conceptual design for infiltration controls at the WIPP. The conceptual design, dated March 31, 2003, includes the following:

1. construction of two new synthetically lined cells to receive salt tailings from underground excavation,
2. construction of an evaporation basin to contain seepage and storm water runoff from the new salt storage cells,
3. capping of the existing salt piles with synthetic membranes, geotextiles, and a soil cover,
4. synthetically lining the existing salt pile evaporation pond, and
5. reconstructing and synthetically lining two stormwater retention basins on the south side of the facility (Evaporation Basins A and B).

NMED concurs with the proposed actions in the conceptual design as part of the permit modification for DP-831. NMED also understands that more detailed plans and specifications will be developed as the project moves forward.

If you have any questions, please contact me at (505) 827-0027 or Mary Ann Menetrey, Program Manager of the Mining Environmental Compliance Section at (505) 827-2944.

Sincerely,

Clint Marshall, Hydrogeologist
Mining Environmental Compliance Section
Ground Water Quality Bureau

Subject: Preliminary Plans for DP Modification of WIPP

Discussion:

WIPPpresentatives met with NMED to present conceptual designs for the modification of the discharge plan for the WIPP site. The plans included the following:

1. construction of two new synthetically lined cells to receive salt tailings from underground excavation,
2. construction of an evaporation basin to contain seepage and storm water runoff from the new salt storage cells,
3. capping of the existing salt piles with synthetic membranes, geotextiles, and a soil cover,
4. synthetically lining the existing salt pile evaporation pond, and
5. constructing and synthetically lining two stormwater retention basins on the south side of the facility (Evaporation Basins A and B).

The overall objective of these measures is to eliminate all seepage into the subsurface at the site. WIPP was informed that a monitoring plan needed to be submitted as part of the application for modification. A water balance study is presently being conducted and a report will be submitted to NMED. WIPP expects to have the modification to NMED by April 29, 2003. Comment on the existing draft DP renewal will be submitted by April 15, 2003.

NMED will submit a letter to WIPP giving preliminary approval of the plans presented at this meeting.

RE: Draft Discharge Plan Renewal DP-831, Waste Isolation Pilot Plant (WIPP)

Dear Mr. Marshall:

In Accordance with discussions and decisions made this date, WIPP will submit comments on the Draft Discharge Permit Renewal, DP-831 on April 15, 2003. We will be prepared to present and discuss several issues relating to this renewal along with our new application at 9:00am Tuesday, April 1, 2003. In attendance from WIPP will be Dr. E.B. Nuckols, Dale Bignell, and David Emery, along with Consultant, Keith Gordon.

We appreciate your consideration.

Sincerely,

David D. Emery

RE: Draft Discharge Plan Renewal, DP-831, Waste Isolation Pilot Plant (WI

Dear Ms. Triay:

Please review the enclosed draft permit for Discharge Plan Renewal, DP-831, Waste Isolation Pilot Plant (WIPP). The conditions in the draft permit should be reviewed for accuracy and completeness. Please pay special attention to Condition 7, because it differs significantly from your proposed discharge plan application. Any comments, questions, or concerns should be directed towards Clint Marshall of the New Mexico Environment Department (NMED), Ground Water Quality Bureau (GWQB) at (505) 827-0027 before **March 15, 2003**. If no comments are received by this date, the NMED GWQB will issue a signed permit with conditions as written in the enclosed draft.

Sincerely,

Clint Marshall

RE: Discharge Permit Renewal, DP-831, Waste Isolation Pilot Plant

Dear Ms. Triay:

Pursuant to Water Quality Control Commission (WQCC) Regulation 20.6.2.3109 NMAC, the application for discharge permit renewal for DP-831, submitted by Inez Triay for the discharge of 33,000 gallons per day of sewage effluent, non-hazardous brine water and neutralized acid waste from the Waste Isolation Pilot Plant (WIPP) is hereby approved, subject to the conditions listed below. The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. In approving this discharge plan, the New Mexico Environment Department (NMED) has determined that the requirements of Section 20.6.2.3109.C NMAC have been met.

The approved WIPP treatment and disposal system is briefly described as follows:

Up to 23,000 gallons per day of sewage effluent is discharged to a series of 5 synthetically lined ponds for treatment and evaporation (facultative lagoon system). Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined evaporation cell (north evaporation cell). Up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources is discharged to a synthetically lined evaporation pond (H-19 evaporation pond). Up to 100 gallons per day of neutralized acid waste will also be discharged to the H-19 lined evaporation pond. Ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3,920 milligrams per liter.

The approved discharge plan renewal consists of the materials submitted by the U.S. Department of Energy (DOE) dated June 5, 2002. In addition, the discharge plan includes information and materials submitted as part of the original discharge plan approved on January 16, 1992, the materials for discharge plan amendment, dated August 28, 1995, the materials for discharge plan renewal and modification dated July 3, 1997, and the materials for discharge plan amendments dated June 12, 1998 and January 24, 2000. The discharge shall be managed in accordance with the approved plan and is subject to the conditions listed below.

However, renewal of this discharge plan does not relieve you of your responsibility to comply with any conditions or requirements of the previously approved discharge plan, DP-831, and the New Mexico Water Quality Act, WQCC Regulations, any other applicable federal, state and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

CONDITIONS FOR APPROVAL

Pursuant to Section 20.6.2.3109 NMAC, NMED reserves the right to modify permit requirements in the event NMED determines that the requirements of the WQCC Regulations are being violated or may be violated, or the standards of Section 20.6.2.3103 NMAC are being or may be violated. This may include a determination that structural controls and/or management practices approved under the discharge permit for WIPP are not protective of ground water quality, and that more stringent requirements to protect and/or remediate ground water quality may be required by NMED. These requirements may include lining or relining lagoons, changing waste storage or land application management practices, expanding monitoring requirements and/or implementing remediation systems.

This discharge plan renewal is subject to the following conditions for the following reasons:

OPERATIONS

General:

1. The permittee is authorized to discharge up to 33,000 gallons per day of sewage effluent to a series of five synthetically lined lagoons for treatment and evaporation.

2. The permittee is authorized to discharge up to 2,000 gallons per day of non-hazardous brine water to the synthetically lined north evaporation cell.

3. The permittee is authorized to discharge up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources to the synthetically lined H-19 evaporation pond.

4. The permittee is authorized to discharge up to 100 gallons per day of neutralized acid waste to the synthetically lined H-19 evaporation pond.

The reason for Conditions 1, 2, 3 and 4 is to comply with Secion 20.6.2.3104 NMAC by permitting a discharge consistent with the terms and conditions of the approved discharge plan.

Lagoon Operation and Maintenance:

5. The permittee shall properly operate and maintain all lagoons covered by this permit. The permittee shall maintain the capacity of the lagoons to store and evaporate the maximum daily discharge volume allowed by this discharge permit while maintaining two feet of freeboard at all times. In the event that a minimum of two feet of freeboard can not be maintained at all times, the permittee shall submit a corrective action plan to manage discharge volumes to the NMED for approval.

6. The permittee shall measure the thickness of the sludge blanket in each lagoon every five years. When sludge accumulation exceeds 1/3 of the total depth of any lagoon, the permittee shall remove the sludge in a manner, which is protective of the lagoon liner. Removed sludge shall be contained, transported, and disposed in accordance with all local, state, and federal (40 CFR Part 503) regulations.

The reason for this Conditions 5 and 6 is to comply with Section 20.6.2.3109 NMAC by preventing contaminated wastewater from moving directly or indirectly into ground water.

7. The permittee shall perform visual inspection of the lagoons and surrounding berms on a monthly basis. The water surface of the lagoons shall be kept free of floating plants and debris. Berms surrounding the lagoons shall be kept free of all "deep-rooted" plants. Berms shall be inspected for signs of wind or water erosion. In the event berms show signs of erosion, the permittee shall submit to the NMED for approval a plan for protection of the berms from erosion which may include the emplacement of rip rap or other methods for armoring the berms

The reason for this condition is to comply with Sections 20.6.2.3107 and 20.6.2.3109 NMAC by properly maintaining and monitoring the condition of the effluent treatment and evaporation lagoons.

MONITORING AND REPORTING

8. The permittee shall measure the monthly volume of effluent discharged to the facultative lagoon system using a totalizing flow meter. Monthly meter readings, the units of measurement, and monthly discharge volumes for the previous 6-month period shall be submitted to NMED semi-annually in the monitoring reports due by January 31 and July 31 of each year. The flow meter shall be kept operational at all times.

The reason for this condition is to comply with Sections 20.6.2.3107 and 20.6.2.3109 NMAC by adequately measuring the quantity of effluent discharged.

9. The permittee shall sample and analyze semi-annually the final-stage domestic lagoon for nitrate-nitrogen (NO_3-N), total Kjeldahl nitrogen (TKN), total dissolved solids (TDS), plutonium 238, 239 and 240, americium 241, uranium 234, 235 and 238, and strontium 90. The permittee shall sample and analyze semi-annually the east evaporation pond (Pond A), the north evaporation pond (Pond B), the south evaporation pond (Pond C), and the H-19 evaporation pond for total dissolved solids (TDS), plutonium 238, 239 and 240, americium 241, uranium 234, 235 and 238, and strontium 90. Reports of the analyses shall be submitted to NMED by January 31 and July 31 of each year.

   The reason for this condition is to comply with Section 20.6.2.3107 NMAC by providing adequate monitoring of effluent quality.

10. The permittee shall notify NMED of the volume and origin of all wastewater to be discharged that is derived from miscellaneous non-hazardous sources. NMED may require more comprehensive laboratory analyses of such wastewater prior to discharge when NMED determines that additional information is needed.

   The reason for this condition is to comply with Sections 20.6.2.3106 and 20.6.2.3107 NMAC by monitoring and reporting the quality of effluent discharged.

CONTINGENCY

11. The permittee shall implement the contingency plan, dated December 16, 1996 in the event of a failure of the wastewater treatment and disposal system. The plan includes daily inspection and repair of pond liners as necessary, containment and investigation of all spills and releases, and submittal of a remediation plan to address contamination.

   The reason for this condition is to comply with Sections 20.6.2.1203 and 20.6.2.3107.A.10 NMAC by providing a contingency plan to address potential impacts to ground water quality.

CLOSURE

12. The permittee shall implement the closure plan, dated December 16, 1996 when the facility is decommissioned. The plan includes the pumping or evaporation of all wastewater ponds, removal of all solids, and recontouring and revegetation of the site. In addition, the permittee shall remove or perforate all lagoon liners upon closure of the site.

   The reason for this condition is to comply with Section 20.6.2.3107.A.11 NMAC by providing a closure plan to address potential impacts to ground water after the facility is closed.

GENERAL DISCHARGE PLAN REQUIREMENTS

In addition to any other requirements provided by law, approval of discharge plan, DP-831, is subject to the following general requirements:

Monitoring and Reporting

Monitoring and reporting shall be as specified in the discharge plan and supplements thereto. These requirements are summarized on the attached sheet(s). Any inadvertent omissions from this summary of a discharge plan monitoring or reporting requirement shall not relieve you of responsibility for compliance with that requirement.

Record Keeping

1. The discharger shall maintain at the facility, a written record of ground water and wastewater quality analyses.The following information shall be recorded and shall be made available to the NMED upon request.

   a. The dates, exact place and times of sampling or field measurements.

   b. The name and job title of the individuals who performed the sampling or measurements.

   c. The dates the analyses were performed.

   d. The name and job title of the individuals who performed the analyses.

   e. The analytical techniques or methods used.

   f. The results of such analyses, and

   g. The results of any split sampling, spikes or repeat sampling.

2. The discharger shall maintain a written record of any spills, seeps, and/or leaks of effluent, leachate and/or process fluids not authorized by this discharge permit.

3. The discharger shall maintain a written record of the operation, maintenance and repair of facilities/equipment used to treat, store and/or dispose of wastewater; to measure flow rates; and/or to monitor water quality. This will include repairs, replacement or calibration of any monitoring equipment and repairs or replacement of any equipment used in WIPP's waste or wastewater treatment and disposal system.

4. The discharger shall maintain a written record of the amount of wastewater discharged.

Inspection and Entry

In accordance with Sections 74-6-9.B & E NMSA 1978 and WQCC Regulation Section 20.6.2.3107.D NMAC, the discharger shall allow the Secretary or his authorized representative, upon the presentation of credentials, to:

1. Enter at regular business hours or at other reasonable times upon the discharger's premises or where records must be kept under the conditions of this discharge plan.

2. Inspect and copy, during regular business hours or at other reasonable times, any records required to be kept under the conditions of the discharge plan.

3. Inspect, at regular business hours or at other reasonable times, any facility, equipment (including monitoring and control equipment), practices or operations regulated or required under this discharge plan.

4. Sample or monitor, at reasonable times for the purpose of assuring discharge plan compliance or as otherwise authorized by the New Mexico Water Quality Act, any effluent at any location before or after discharge.

Duty to Provide Information

In accordance with Section 74-6-9.B NMSA 1978 and Section 20.6.2.3107.D NMAC, the discharger shall furnish to the NMED, within a reasonable time, any relevant information which it may request to determine whether cause exists for modifying, terminating and/or renewing this discharge plan or to determine compliance with this plan. The discharger shall furnish to the NMED, upon request, copies of records required to be kept by this discharge plan.

Spills, Leaks and Other Unauthorized Discharges

This approval authorizes only those discharges specified in the discharge plan. Any unauthorized discharges violate Section 20.6.2.3104 NMAC, and must be reported to the NMED and remediated as required by Section 20.6.2.1203 NMAC. This requirement applies to all seeps, spills, and/or leaks discovered from the pipelines, disposal ponds, and treatment and evaporation ponds.

Retention of Records

The discharger shall retain records of all monitoring information, including all calibration and maintenance records, copies of all reports required by this discharge plan, and records of all data used to complete the application for this discharge plan, for a period of at least five years from the date of the sample collection, measurement, report or application. This period may be extended by request of the Secretary at any time.

Enforcement

Failure to grant the Secretary or his authorized representative access to the records required to be kept by this discharge permit or to allow an inspection of the discharge facilities or to the collection of samples is a violation of this discharge permit and the WQCC Regulations. Such violations as well as other violations of the discharge permit, may subject the discharger to a compliance order, a compliance order assessing a civil penalty or an action in district court pursuant to Section 74-6-10 NMSA 1978, and/or modification or termination of this discharge permit pursuant to Section 74-6-5.L NMSA 1978. Penalties assessed as part of a compliance order shall not exceed $15,000 per day for violations of the terms of this permit or the requirements of Section 74-6-5 NMSA 1978, and shall not exceed $10,000 per day for violations of other sections of the Water Quality Act.

Modifications and/or Amendments

The discharger shall notify NMED, pursuant to Section 20.6.2.3107.C NMAC, of any modifications or additions to the WIPP's wastewater disposal system, including any increase in wastewater flow rate or wastewater storage and disposal management changes to the system as approved under this discharge plan. The discharger shall obtain NMED's approval, as a discharge permit modification, prior to any increase in the quantity or concentration of constituents in the leachate above those approved in this permit. Please note that Section 20.6.2.3109.E and F NMAC provide for possible future amendment of the permit.

Other Requirements

Please be advised that the approval of this plan does not relieve the U.S. Department of Energy of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

RIGHT TO APPEAL

If the U.S. Department of Energy is dissatisfied with this action taken by NMED, the U.S. Department of Energy may file a petition for hearing before the WQCC. This petition shall be in writing to the Water Quality Control Commission within thirty (30) days of the receipt of this letter. Unless a timely request for hearing is made, the decision of the NMED shall be final.

TRANSFER OF DISCHARGE PLAN

Pursuant to Section 20.6.2.3111 NMAC, prior to any transfer of ownership, the discharger shall provide the transferee a copy of the discharge permit, including a copy of this approval letter and shall document such to the NMED.

PERIOD OF APPROVAL

Pursuant to Section 20.6.2.3109.G.4 NMAC, this discharge permit approval is for a period of 5 years. This approval will expire **[Approval Date]**, and you must submit an application for renewal at least 180 days before that date.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

Discharge Permit Summary

January 31, 2003

Facility Information

Facility Name	Waste Isolation Pilot Plant (WIPP)
Discharge Plan Number	DP-831
Legally Responsible Party	U.S. Department of Energy Inez Triay, Manager P.O. Box 3090 Carlsbad, New Mexico 88221-3090 505-234-7285 (contact: Shawn White)

Treatment, Disposal And Site Information

Primary Waste Type	Domestic/Industrial	
Treatment	Lagoons	Synthetic
Discharge	Evaporation	
Discharge Location	26 miles east of Carlsbad	
Depth To Ground Water	608 feet	
Total Dissolved Solids (TDS)	3920 mg/L	

Permit Information

Application Received	June 5, 2002
Public Notice Published	September 12, 2002
Discharge Plan Approved	**Approval Date**
Discharge Plan Expires	**Expiration Date**
Permitted Discharge Volume	33,000 gallons per day

Nmed Contact Information

Mailing Address	Ground Water Pollution Prevention Section P.O. Box 26110 Santa Fe, New Mexico 87502

Discharge Permit Monitoring Summary
WASTE ISOLATION PILOT PLANT, DP-831

Monitoring Report Due Dates

Monitoring Reports are due each year by

31-JAN, 31-JUL

Monitoring Requirements

The following summarizes the monitoring requirements for this facility:

Annual Sampling Frequency	Annual Reporting Frequency	Number of Sites	Sampling Description
12	2	1	Meter discharge volumes to facultative lagoon - measured monthly & reported semi-annually
2	2	1	NO3, TKN, TDS, Pu 238, 239 & 240; Am 241, U 234, 235 & 238; and Sr 90 in effluent to facultative lagoon
2	2	4	TDS; Pu 238, 239 & 240; Am 241, U 234, 235 & 238; and Sr 90 in effluent to Ponds A, B & C and H-19 Pond.
12		7	Monthly inspections of all lagoons.
As needed	As needed	As needed	Report volume and origin of miscellaneous non-hazardous waste to be discharged.

Submit all monitoring reports to the Ground Water Quality Bureau at the address on the Discharge Plan Summary Sheet

RE: Proposed Source Control Activities and Site Investigation Work Plan, Waste Isolation Pilot Plant (WIPP), Mining Operations

Dear Dr. Triay:

This letter is in response to proposals in the October 30, 2002, Notice of Intent (NOI), which was submitted to the New Mexico Environment Department (NMED) in accordance with Section 6.2.1201 NMAC "Notice of Intent to Discharge" of the NM Water Quality Control Commission (WQCC) Regulations. In the NOI, Section 5 proposes source control activities to limit seepage from the salt pile (SP) and salt pile evaporation pond (SPEP). Section 6 of the NOI presents a site investigation work plan to gather information regarding a zone of shallow subsurface water (SSW) underlying the WIPP site.

NMED has reviewed your NOI with regard to the requirement to obtain a discharge permit and responded in a letter dated December 30, 2002. This letter is to address specific studies and activities proposed in your NOI. NMED hereby approves the proposed source control activities (Section 5) and site investigation work plan (Section 6) pending the following comments.

Section 5, Source Control Activities

1. Section 5.2 describes reshaping of the SP by placement and grading of salt. NMED agrees that this should be considered an interim step in source control and should be integrated with measures to cover the SP as described in Section 5.4.

2. Section 5.3 proposes to line the SPEP and SP run-off ditches with emulsified asphalt. Attachment 10 of the NOI provides a preliminary design for the liner including provisions for a double-lined sump with a leak detection system within the SPEP. NMED hereby approves the proposed liner system, however a schedule for inspection of cracks and other such failures must be included in the final operational plan.

3. Section 5.4 describes a proposal to cover the SP to reduce infiltration of water and solute into the subsurface. The preliminary design to be submitted to NMED should include a detailed plan that describes how the cover will be maintained while salt stockpiling operations continue.

Section 6. Site Investigation Work Plan

4. Attachment 11 of the NOI describes the proposed activities for a site investigation that focuses primarily on the nature and extent of the SSW that presently exists in the vicinity of the WIPP site. NMED agrees that the objective of the investigation is to determine the extent of the SSW and the potential for commingling with the deeper ground water located in the Dewey Lake Formation to the south of the site.

5. Section 2.5 discusses the current understanding of the subsurface hydrogeology and Figure 4 of the NOI shows a conceptual cross-section of the WIPP site. This section also states that the Santa Rosa Formation pinches out near the center of the WIPP site. Given the stratigraphic complexities in the area, NMED recommends that a subsurface geologic map be constructed at the unconformity that extends from the top of the Santa Rosa Formation along the base of the Gatuna Formation. This map should aid in understanding the relationship between the SSW and the extent of the Santa Rosa Formation. An isopach map of the Santa Rosa Formation may also be helpful.

6. Section 2.5.1 discusses the most recent water level and water quality data at the WIPP site. Please provide an updated potentiometric map reflecting the most recent water level measurements for the SSW. The most recent map NMED could find in the NOI was a map dated October 1998 in Attachment 5. Additionally, a more detailed analysis and discussion, as well as an updated TDS isoconcentration map would be helpful in explaining the high TDS concentrations in and around PZ-9 and PZ-3.

7. Section 2.5.2 discusses the natural ground water in wells south of the WIPP site. It is noted that the TDS concentrations in Barn Well are significantly lower than those in the Ranch Well. If possible, please provide an explanation for this difference.

As mentioned previously, NMED responded to the NOI in a letter dated December 30, 2002. In that letter, the WIPP facility is required to submit a discharge plan for discharges to ground water occurring from the SP and SPEP as well as other possible sources. The letter also indicates that you may choose between filing a new permit application or modifying your existing discharge permit, DP-831. The requested information and comments discussed above may be addressed in the discharge application. In addition, information provided in the NOI may be referenced in application.

If you have any questions, please contact Clint Marshall at (505) 827-0027 or Mary Ann Menetrey, Program Manager of the Mining Environmental Compliance Section at (505) 827-2944.

Sincerely,

Clint Marshall

RE: Discharge Plan Required the Waste Isolation Pilot Plant (WIPP), Mining Operations

Dear Dr. Triay:

This is in response to the October 30, 2002, Notice of Intent (NOI), which was submitted to the New Mexico Environment Department (NMED) in accordance with Section 6.2.1201 NMAC "Notice of Intent to Discharge" of the NM Water Quality Control Commission (WQCC) Regulations, copy enclosed.

The information you have provided and supplemental materials you have submitted have been reviewed by the NMED. You are hereby notified that a discharge plan, as defined in WQCC Reg. 6.2.1101.N, is required for the mining operations at the Waste Isolation Pilot Plant (WIPP) located east of Carlsbad in Eddy County.

The WIPP facility currently has a discharge permit in effect (DP-831) for the domestic sewage lagoons and miscellaneous discharges to the H-19 impoundment. The permitee may fulfill the permit requirements of this letter by submitting a separate application for a new discharge permit or a applying for a modification of the existing discharge permit, DP-831.

Enclosed are the necessary materials for the preparation of a discharge plan application. In addition, the filing of plans and specifications is required under WQCC Reg. 6.2.1202. Please mail <u>three</u> copies of your completed discharge plan and plans and specifications to the Program Manager, Ground Water Pollution Prevention Section, at the address listed above.

The application should include plans and specifications of facility operations not specifically provided for in previous submittals, including all buildings on the property, the location and size of all impoundments and tailing piles, and any other systems used for the treatment, storage and discharge of wastes and waste water. Information provided in the October 30, 2002, NOI may be included as part of the discharge plan application either by resubmitting the information or referencing the applicable portions of the NOI. Specifically, this applies to the plans and specifications for liners and the site investigation work plan.

Please submit the application to NMED within 120 days of the date of this letter. Pursuant to Section 20.6.2.3106.B of the WQCC Regulations, please include a request for temporary permission to discharge for additional 120 days. Temporary permission can only be granted for good cause shown by you and can only be for a nonrenewable period of up to 120 days.

Any appeal from this determination must be made to the New Mexico Water Quality Control Commission within 30 days, in accordance with WQCC Reg. 6.2.3112.B.

If you have any questions, please contact either Clint Marshall at (505) 827-0027 or Mary Ann Menetrey, Program Manager of the Mining Environmental Compliance Section at (505) 827-2944.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

Santa Fe, NM 87505

Subject: Notice of Intent, Waste Isolation Pilot Plant, Carlsbad, New Mexico

Dear Mr. Fetner:

Enclosed, in response to your telephone request of November 4, 2002 is a spreadsheet listing the latitudes and longitudes of the wells indicated on the maps we previously sent to you on October 10, 2002. We have divided the spreadsheet into two sections, one lists the shallow wells and piezometers currently in place that provided information about the shallow subsurface water that is the subject of our recent NOI. The other section gives the location of the deeper wells that are indicated on the maps. As noted on the spreadsheet, we do not know the exact location of the Barn and Ranch wells that are indicated on the maps we sent you.

If you have any questions regarding the enclosed information please contact me at (505) 234-7349.

Sincerely,

Harold Johnson

Subject: Notice of Intent, Waste Isolation Pilot Plant, Carlsbad, New Mexico

Dear Mr. Marshall:

In accordance with our meeting on October 4th, find enclosed two copies of a Notice of Intent (NOI) with the information we discussed. This NOI is being submitted to update the information included in the Waste Isolation Pilot Plant's (WIPP's) April 1983 NOI that covered the Salt Pile and Salt Pile Evaporation Pond.

The enclosed NOI describes a lens of shallow subsurface water existing under the WIPP surface facilities and provides a brief description of the current understanding of the shallow geology at the site. Enclosed to the NOI are copies of various reports produced from 1997 to 2002 that describe the hydrogeological conditions of the shallow subsurface at WIPP. The NOI also describes several activities that WIPP proposes to undertake to control infiltration of water, and to investigate the lens of shallow subsurface water.

As described in the enclosed NOI, WIPP proposes to do the following:

- Modify Salt Pile operations and cover the pile to improve drainage to the Salt Pile Evaporation Pond and minimize water infiltration through the pile;
- Line the Salt Pile Evaporation Pond and Salt Pile run-off ditches with a synthetic liner system;
- Pursue options for alternative management of salt;
- Perform a water budget study; and,
- Determine the rate, extent, and fate of the lens of shallow subsurface water;

If you have any questions regarding the enclosed NOI, please contact me at (505) 234-7349.

Sincerely,

Harold Johnson

Subject: Shallow Subsurface Water at WIPP

Dear Mr. Marshall:

At our meeting Friday, October 4th, you requested that we provide copies of the two large maps that were reviewed during the meeting. While we left the maps used at the meeting, with you, one map had an error in it. Enclosed are copies of the maps that contain the corrected information. We are also sending Will Fetner copies of these maps to ensure that the Hazardous Waste Bureau also has them, as he requested.

As we discussed during the meeting, WIPP will submit a Notice of Intent to the Groundwater Quality Bureau by October 31, 2002. In the meantime, if you have any questions regarding this matter or the enclosed maps, please call me at (505) 234-7349 or Mr. Dale Bignell at (505) 234-7545.

Sincerely,

Harold Johnson

Subject: Notice of Intent, Waste Isolation Pilot Plant, Carlsbad, New Mexico

Dear Mr. Marshall:

separate bound report

In accordance with our meeting on October 4th, find enclosed two copies of a Notice of Intent (NOI) with the information we discussed. This NOI is being submitted to update the information included in the Waste Isolation Pilot Plant's (WIPP's) April 1983 NOI that covered the Salt Pile and Salt Pile Evaporation Pond.

The enclosed NOI describes a lens of shallow subsurface water existing under the WIPP surface facilities and provides a brief description of the current understanding of the shallow geology at the site. Enclosed to the NOI are copies of various reports produced from 1997 to 2002 that describe the hydrogeological conditions of the shallow subsurface at WIPP. The NOI also describes several activities that WIPP proposes to undertake to control infiltration of water, and to investigate the lens of shallow subsurface water.

As described in the enclosed NOI, WIPP proposes to do the following:

- Modify Salt Pile operations and cover the pile to improve drainage to the Salt Pile Evaporation Pond and minimize water infiltration through the pile;
- Line the Salt Pile Evaporation Pond and Salt Pile run-off ditches with a synthetic liner system;
- Pursue options for alternative management of salt;
- Perform a water budget study; and,
- Determine the rate, extent, and fate of the lens of shallow subsurface water;

If you have any questions regarding the enclosed NOI, please contact me at (505) 234-7349.

Sincerely,

Harold Johnson

Sequence of NOIs and NMED Determinations Regarding Discharges to Salt Pile Evaporation Pond

Provided by WIPP

Date	Document
1) April 1983	NOI for Construction Phase of WIPP (including Salt Pile and Salt Pile Evaporation Pond)
2) May 16, 1983	Letter from EID to WIPP determining that no Discharge Plan needed
3) August 26, 1985	NOI for temporary discharge of construction water from WS to Salt Pile Evaporation Pond
4) December 29, 1987	NOI for temporary discharge of drill cuttings and brine from construction of the AIS to the Salt Pile Evaporation Pond
5) August 22, 1991	Letter from WIPP to NMED requesting an emergency permit to discharge brine to the Salt Pile Evaporation Pond
6) September 18, 1991	Letter from NMED granting temporary permission for disposal of brine into the Salt Pile Evaporation Pond
7) November 14, 1991	Discharge Plan Application for sewage lagoons and temporary discharge of brine waters from mine de-watering and monitoring wells to the Salt Pile Evaporation Pond until the sewage lagoon expansion is completed - note this DPA resulted in issuance of DP-831.
8) January 16, 1992	Discharge Plan DP-831, issued by NMED
9) September 16, 1993	Letter from NMED to WIPP granting a 60-day extension for continued temporary discharge of brine water into the salt pile evaporation pond

Subject: Discovery of Discharge from Salt Pile to Shallow Groundwater

Discussion:

A presentation was made by WIPP staff (see attached) to NMED staff describing the cause for seepage of shallow groundwater into the exhaust shaft at the facility. The operator believes the discharge is coming from runoff from the salt pile located on the north side of the facility. As a corrective action at this time, WIPP plans to line the salt pile evaporation pond and associated ditches to cut off the source of seepage into groundwater. WIPP plans to submit an update NOI to NMED by the end of October 2002.

Conclusions:

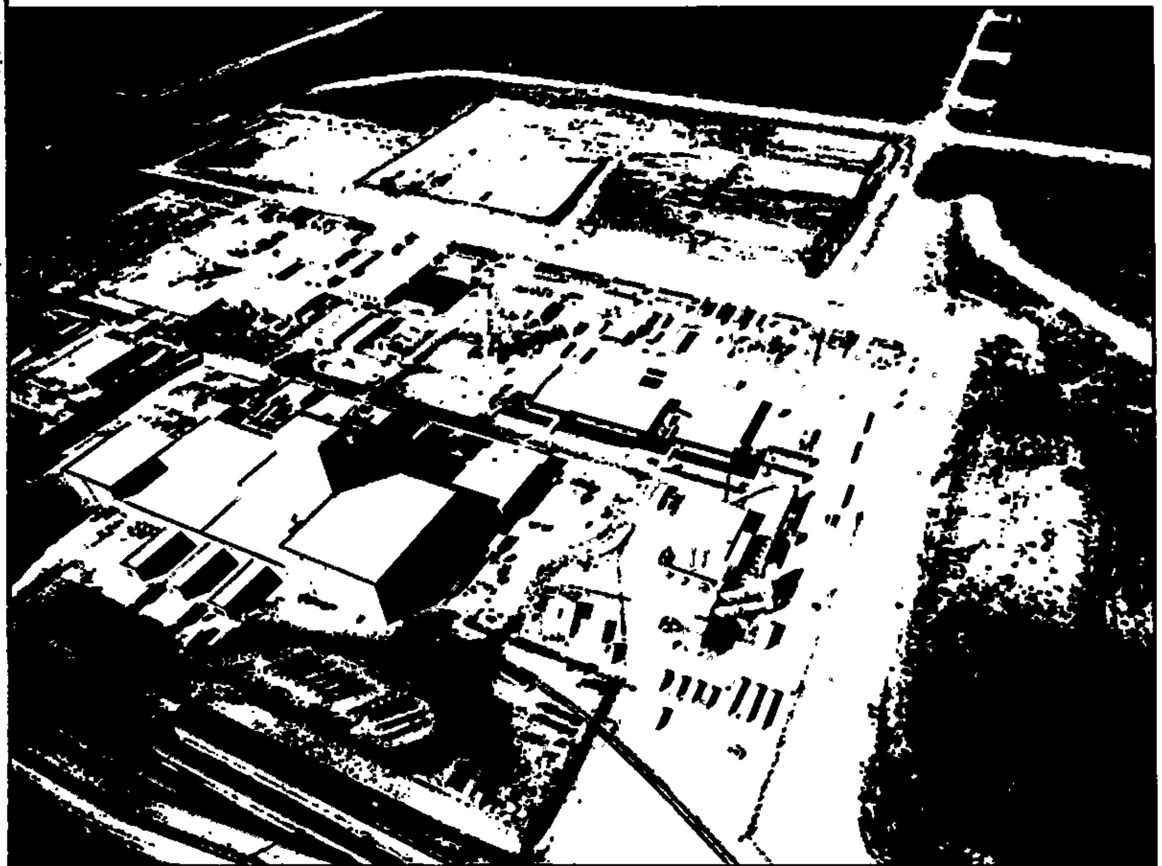
Distribution:

Initialed

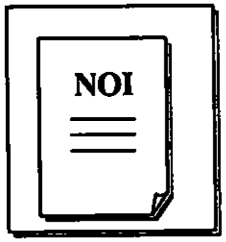
Shallow Subsurface Water at WIPP

Harold Johnson, DOE
Dale Bignell, WTS
Larry Coons, CTAC
Dennis Powers, WTS
Sean White, WTS

October 4, 2002



Purpose

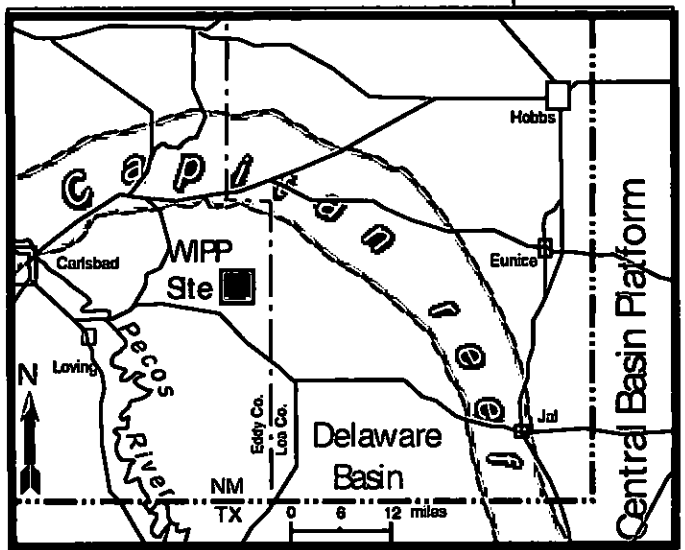


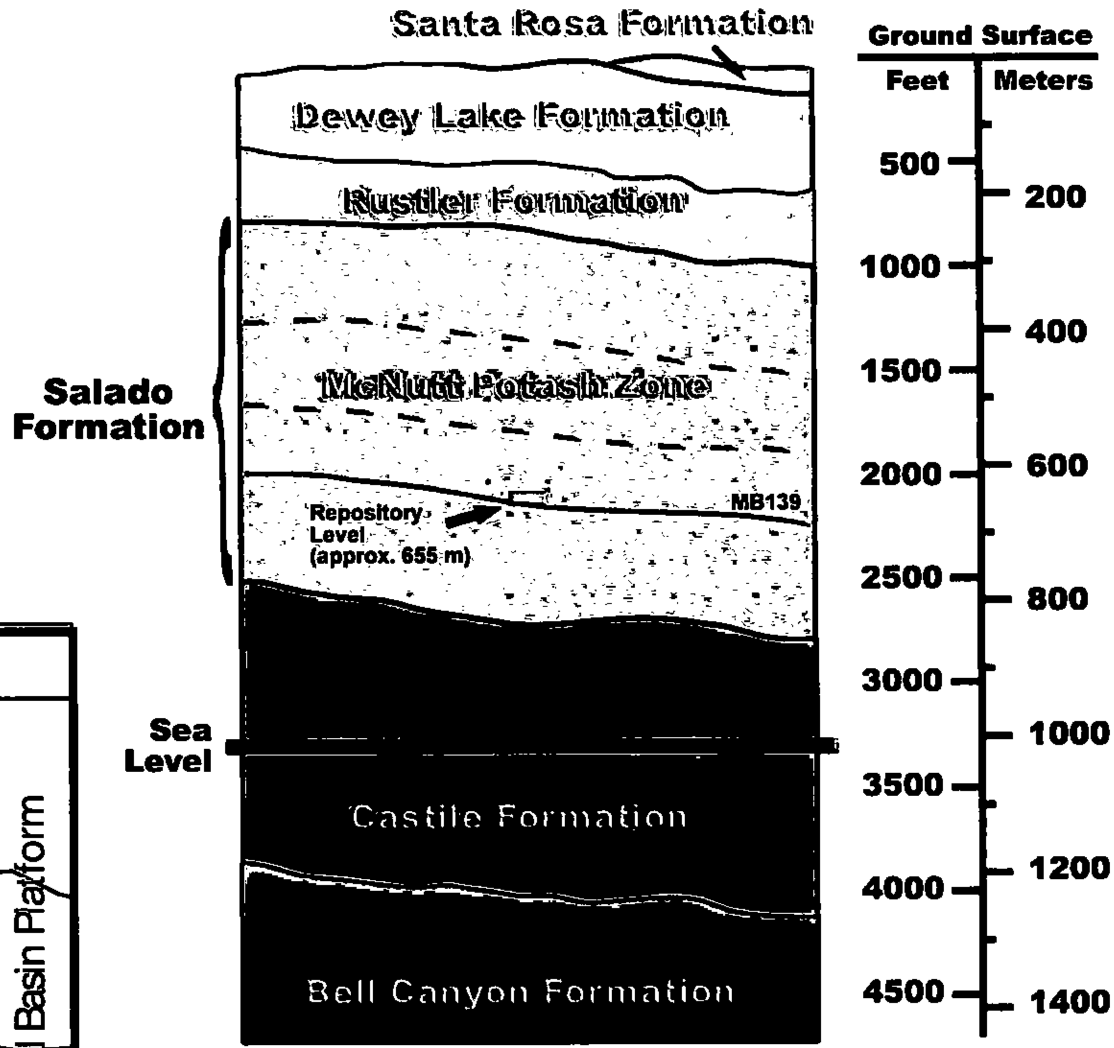
Notify you of an update to the existing NOI

Describe the nature of the update

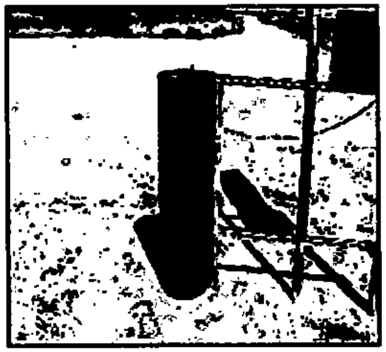
Discuss our proposed approach

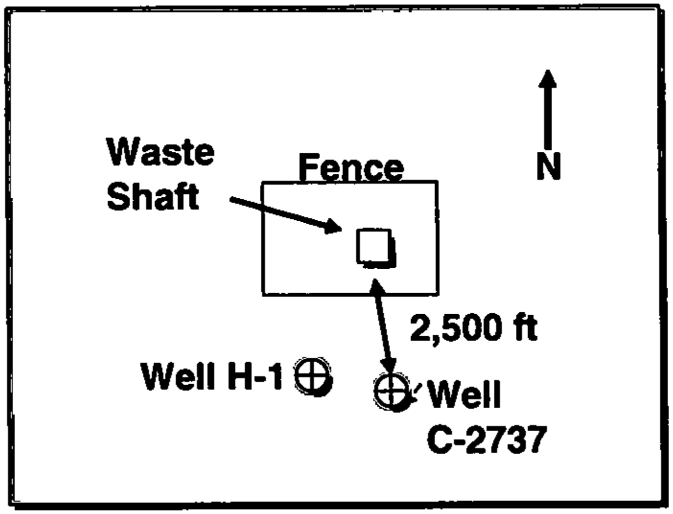
General Location and Stratigraphic Section

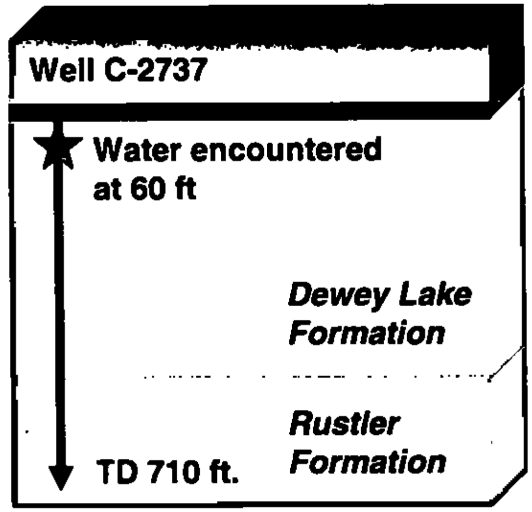




Monitoring Well C-2737 Results





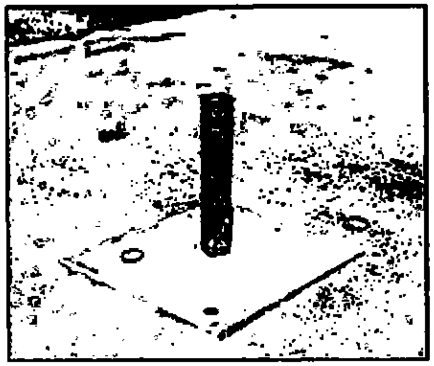


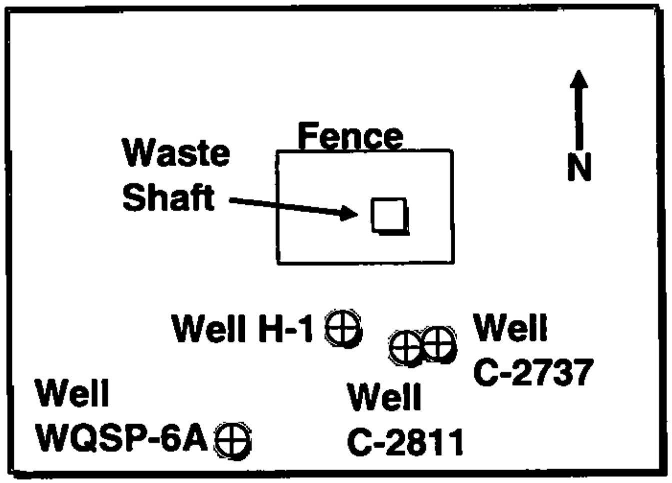
February-March 01

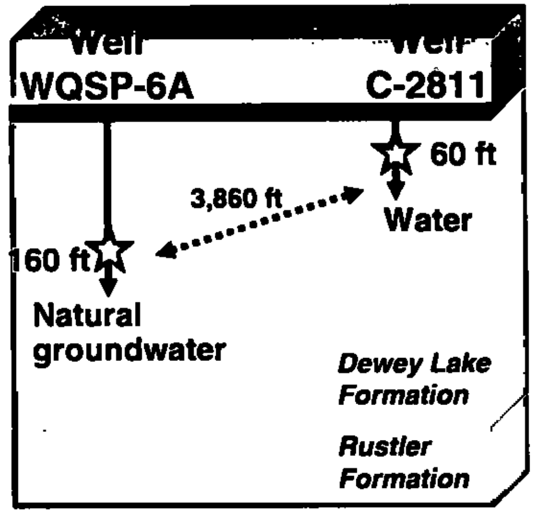
- C-2737 installed to replace H-1, which was plugged and abandoned

- Encountered water at approximately 60 feet below the ground surface in the upper portion of the Dewey Lake Formation

Monitoring Well C-2811 Results







March 01	**C-2811 installed to monitor the water found in the upper portion of Dewey Lake Formation**
January 02	**First water sample results returned from C-2811. Total Dissolved Solids (TDS): 2,630 mg/l**
July 02	**Comprehensive review of data and WIPP hydrology leads to concern that subsurface water could eventually contact natural groundwater (TDS: 3,620 mg/l) known to occur 3,860 feet to the southwest and 100 feet below C-2811**

Action Team

DOE-CBFO

CTAC

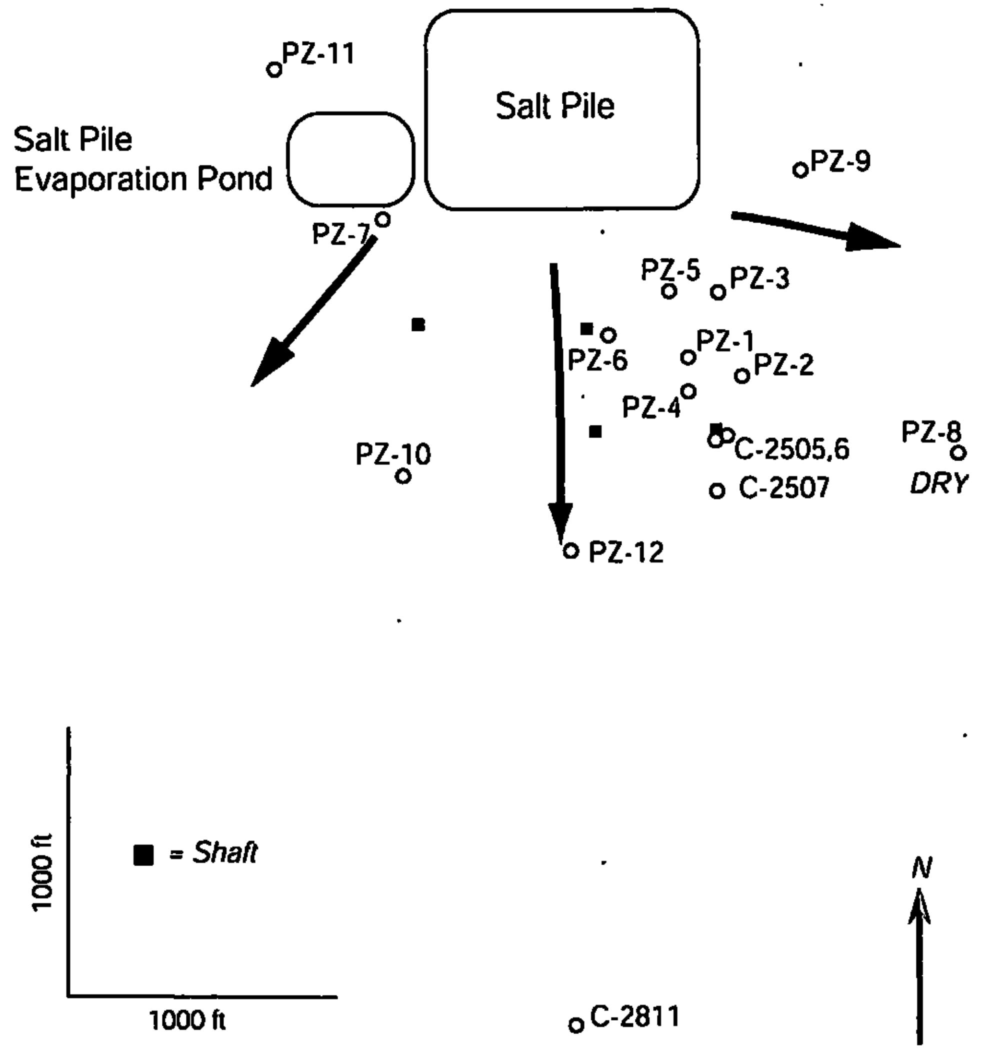
Westinghouse TRU Solutions

Other Washington Group International organizations

August-September 02

- Formed action team composed of hydrologists, geologists, and engineers
- After studying current and historic data and reviewing WIPP hydrology, the action team identified probable sources of the subsurface water and TDS

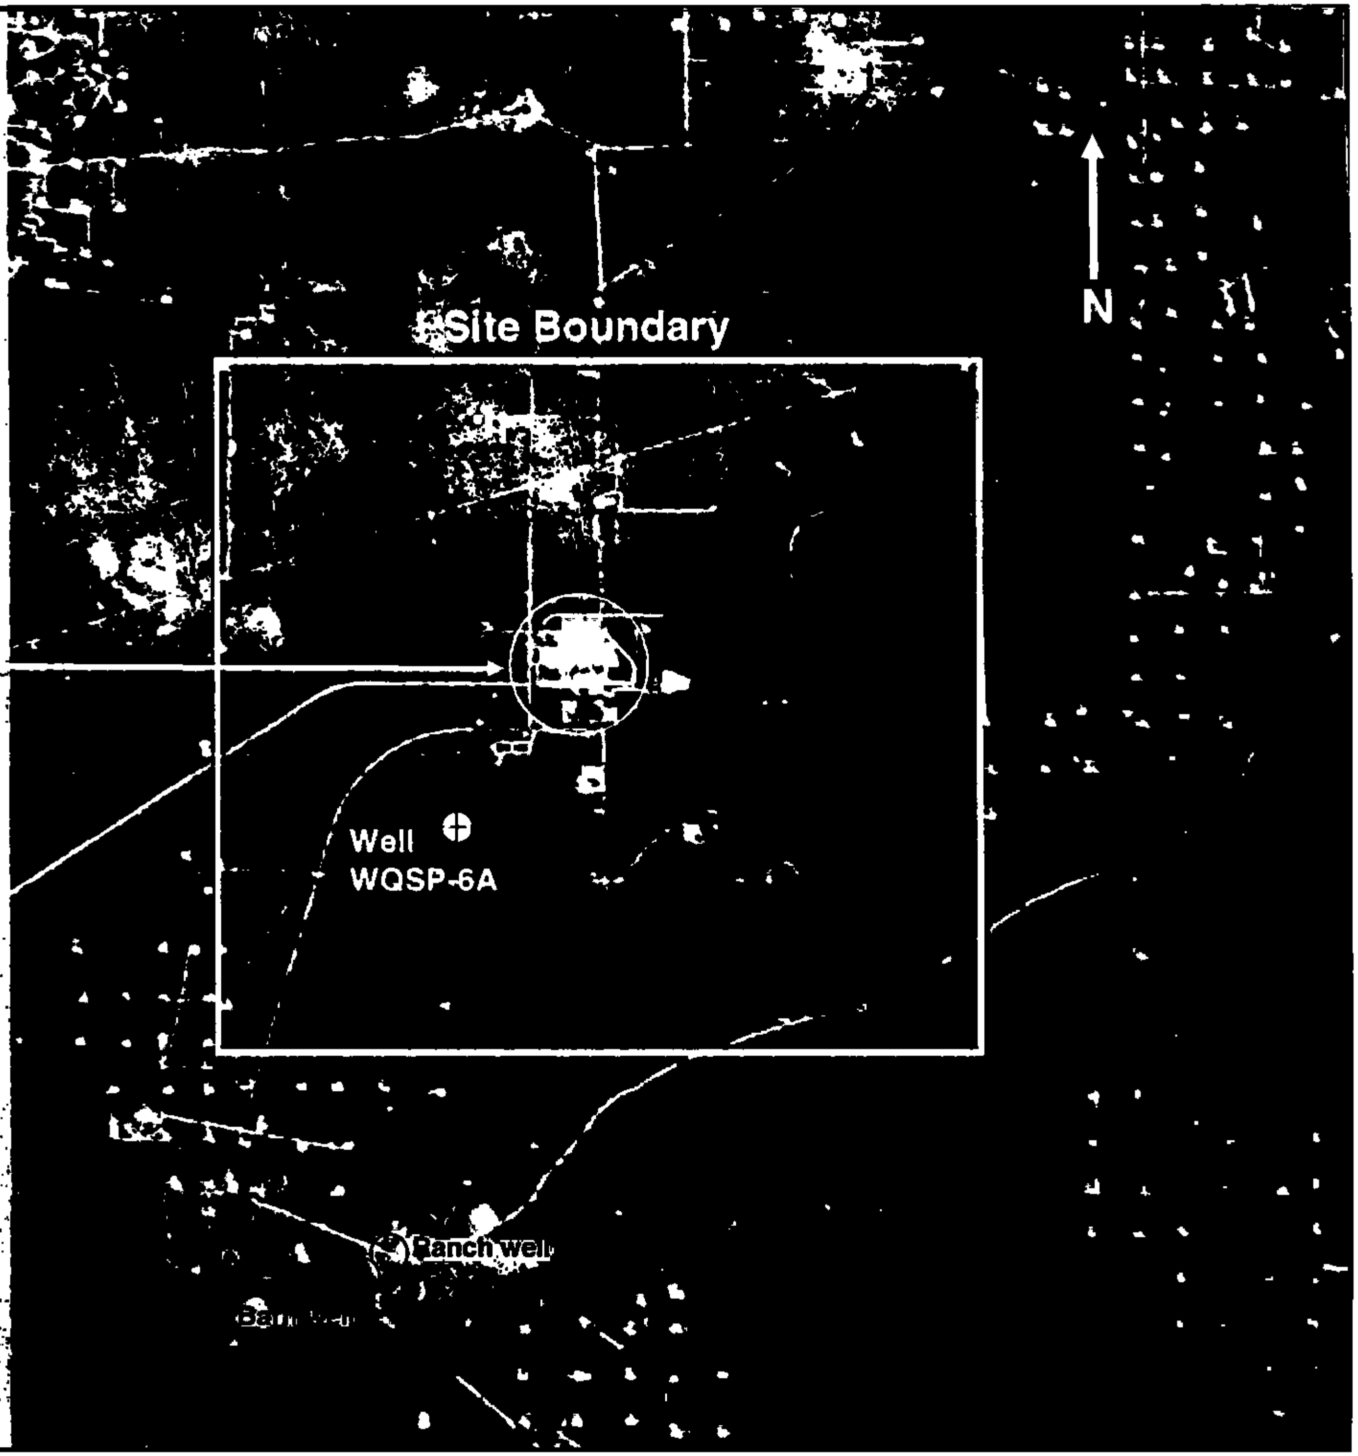
Conceptual Model



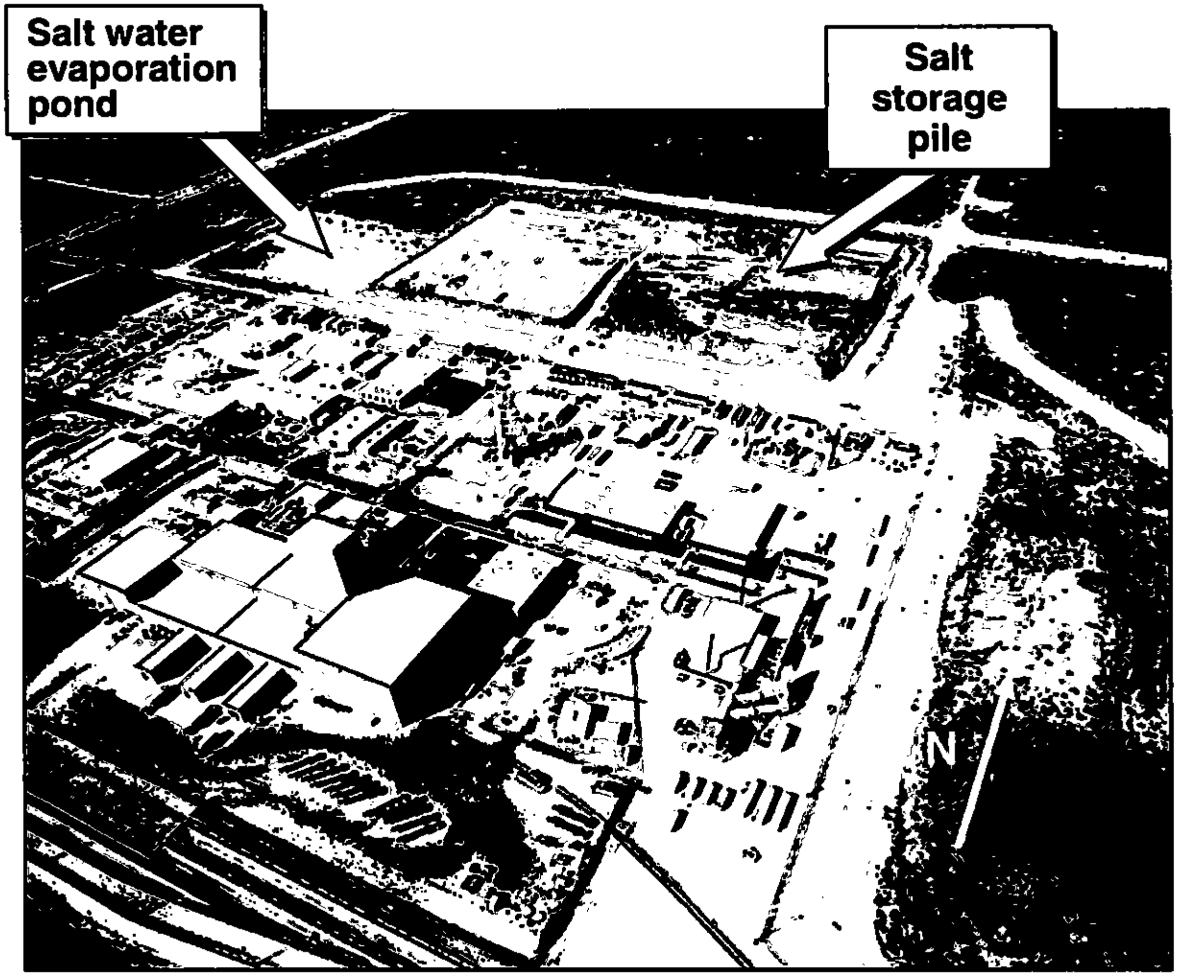
- **PZ-9 ~ 134,000 mg/l TDS (12/01)**
  (Water level 3,363.4 ft amsl; 9/12/02)
- **C-2811 ~ 2,630 mg/l TDS (12/01)**
  (Water level 3,355.8 ft amsl; 9/12/02)

Probable Sources of Shallow Subsurface Water

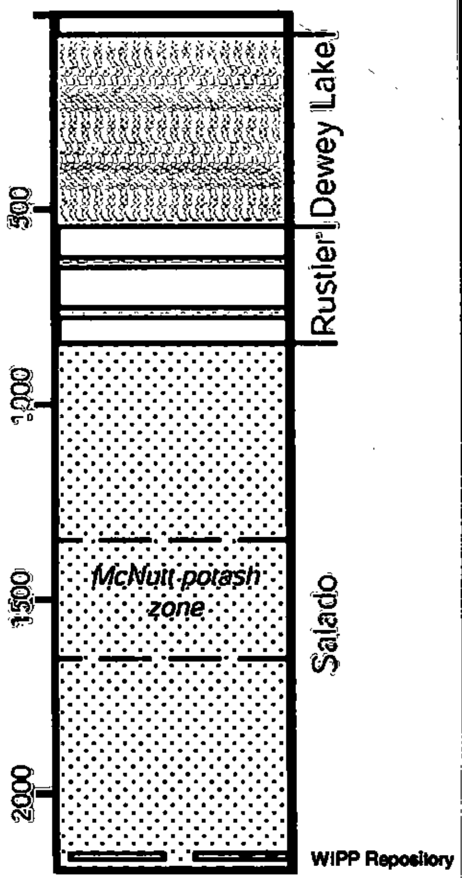
- Salt Pile Evaporation Pond
- Salt Pile
- Stormwater Basins

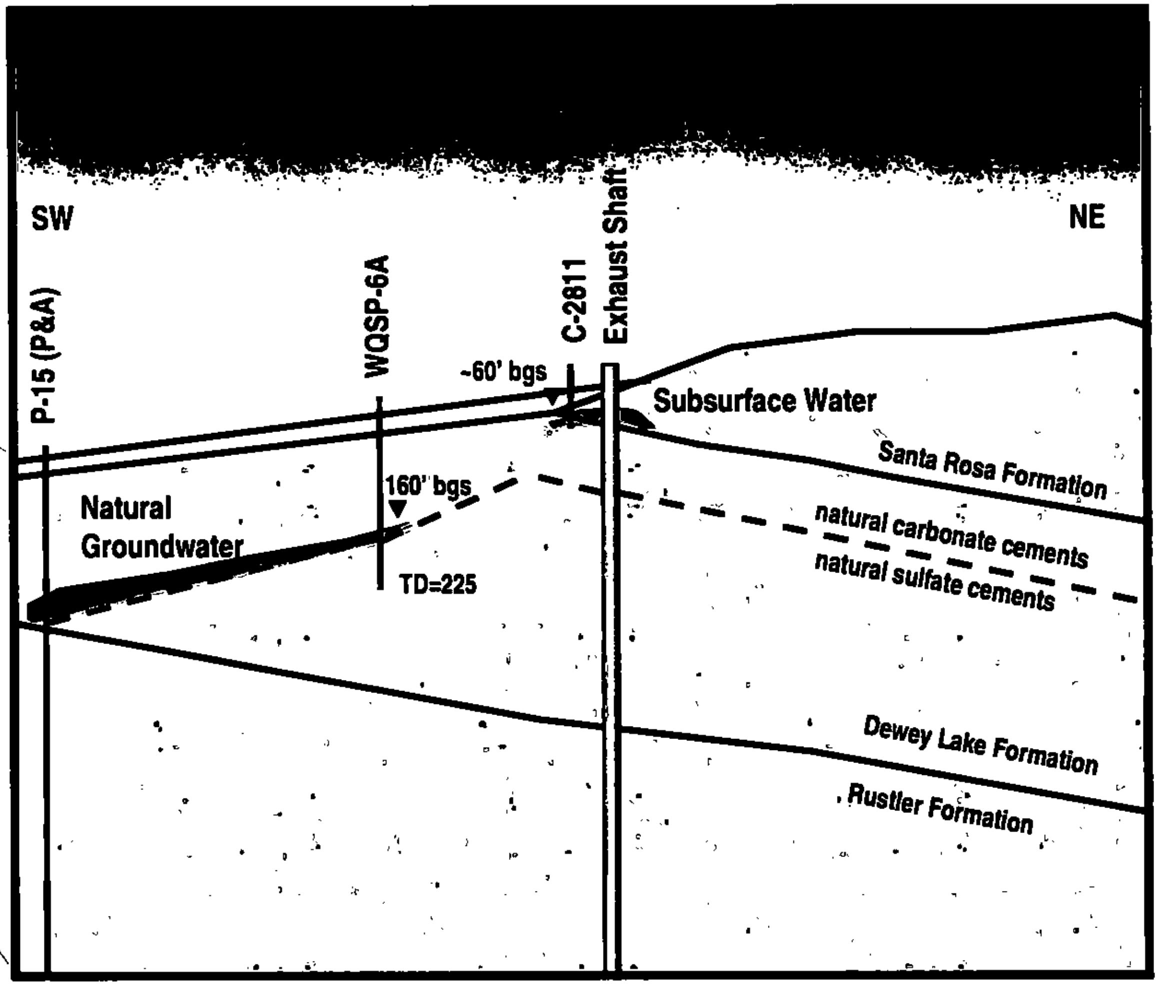


Probable Sources of TDS



Diagrammatic Cross-Section of Water Locations





Vertical scale exaggerated: not to precise scale

(Mills Ranch wells apx. 3 miles S-SW of Exhaust Shaft)

Salt Pile and Evaporation Pond Regulatory Framework

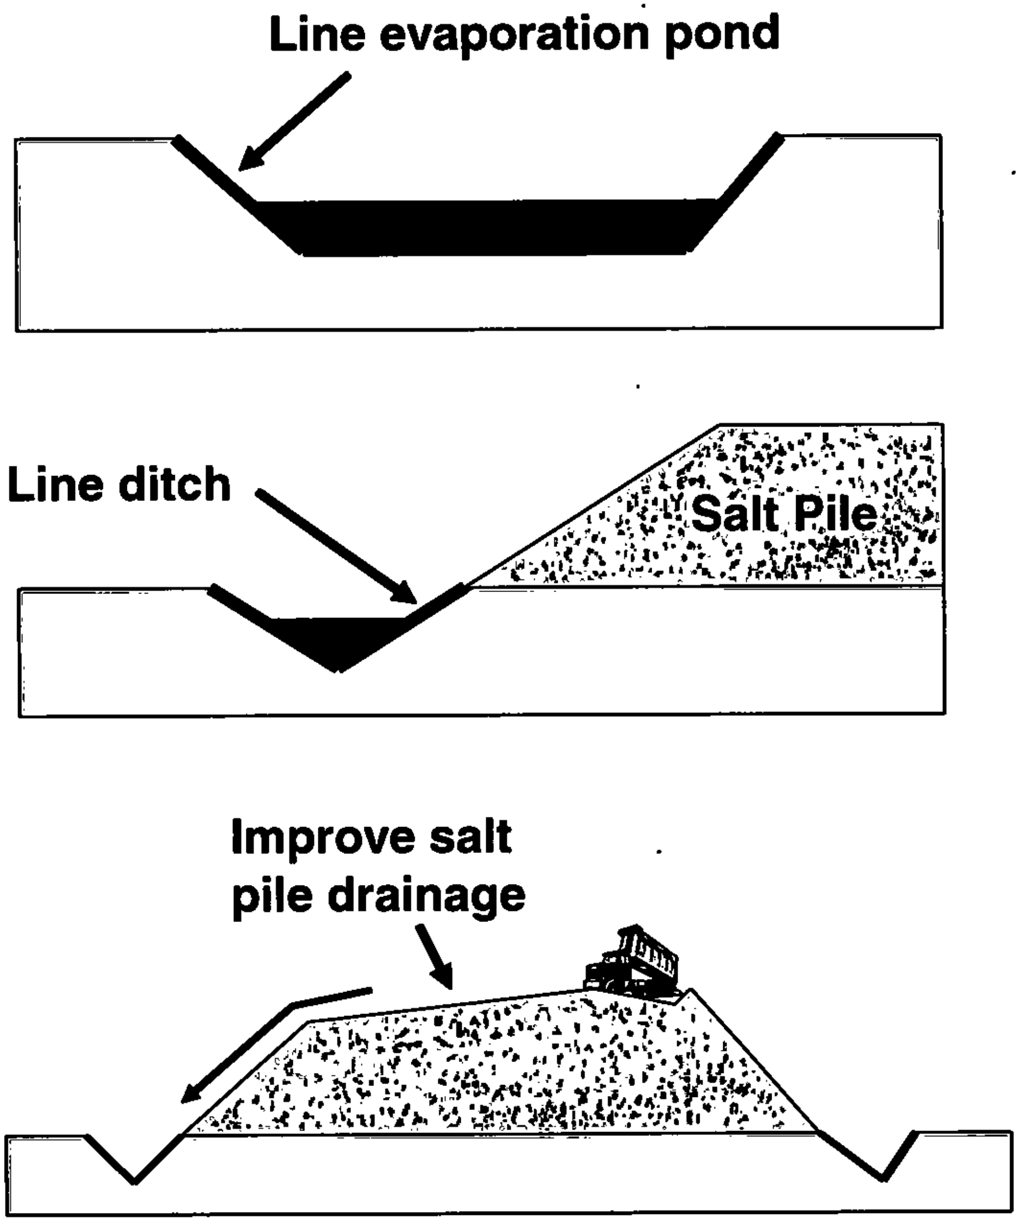
NOI: April 1983

- Addressed salt storage pile, salt pile evaporation pond
- Salt pile evaporation pond to be constructed of compacted soil that would minimize infiltration
- No impacts on groundwater expected, because of low permeability of the caliche and high net water loss
- NMED determined discharge plan not required in May 1983

Proposed Approach

- Update NOI
  - Line the salt pile evaporation pond
  - Line the salt pile runoff ditches
  - Improve drainage from the salt pile to the evaporation pond
  - Continue to monitor shallow subsurface water through piezometers and wells

Proposed Approach
--
continued



Path Forward

Discussion

Field Trip Report
Ground Water Pollution Prevention Section

Date: 8/27/02

Inspector (s)
Clint Marshall

Facility

Facility Name: WIPP
Contact: Jim Holland, Ron Reeves, Steve Kouba
Location: East of Carlsbad.
Discharge Plan Number: DP- 831
UIC Related? Yes (No)
Type of Operation: Radioactive Waste Storage facility

Inspection Summary

Purpose:
(a) Evaluation of Proposed Discharge Plan
b. Compliance Inspection (Complete Checklist o Reverse Side)
c. Other (Specify):

Activities

a. Inspection of Facilities or Construction (specify): Domestic Waste water lagoon system H-19 pond

Flow Measurement: Type: Condition:

b. Effluent Sample (s): (provide sampling location): None taken.

No. of Ponds: 6 No. in Use: 6 Condition of Ponds: Good
Condition of Pond Liner (s):

c. Ground Water Sample (s) (provide well name and location): None taken

No. of Monitor Wells: — Well Condition:

d. Other (specify):

Observations and Information Obtained

~~###~~ All facilities seem in order. Discussed DP renewal

Action Required

Move forward with renewal

Water Quality Inspection & Sampling Checklist
Reference: Regulation No. HED 86 – 14 (EID)

Entry Conference:

Was facility representative informed of EID's right of entry and authority: (To access records, inspect monitoring equipment or methods and sample effluents under Sections 74-6-9.E of the New Mexico Water Quality Act NMSA 1978)?

Was EID identification presented?

Were other potential or suspected violations which prompted inspections listed?

During the inspection, was the facility representative immediately advised or addition potential violations?

Exit Conference:

Were the preliminary inspection results summarized?

Was the facility representative advised if violations discussed during the entry conference remain under investigation?

Were other potential violations discovered during the inspection discussed?

Was a date provided as to when EID expects to complete consideration of potential violation?

Water Quality Sampling:

Was the facility representative offered a reasonable opportunity to obtain split/replicate samples, perform simultaneous tests, measurements or photographs?

Were copies of EID's results (sampling, testing, photos) requested? If yes, copies must be provided within ten working days after such results are in EID's possession.

Field Trip Report

Ground Water Pollution Prevention Section

Start Date: 08/27/2002 03:00 PM   **End Date:** 08/27/2002 04:00 PM

Facility Information
Facility Name: Waste Isolation Pilot Plant   Type of Operation: Federal Agency
Contact: Jim Holland (DOE), Ron Reeves (Westinghouse), Steven Kouba (Westinghouse) Location: Carlsbad

Inspector(s): Clinton Marshall

Inspection Summary
Purpose: Facility Inspection (GWB)

Activities
Samples Taken: No

Observations and Information Obtained
Inspected domestic waste lagoons, evaporation lagoons, and H-19 pond. Two facultative lagoons are lined with 34 mil Hypalon. Evaporation ponds lined with HDPE. Jim indicated damage in facultative lagoon made by gophers or othe rodents. Holes had been repaired. Facultative lagoons still receiving neutralized acid. WIPP facility now staffed at about 500. Lagoons are handling the effluent volume just fine. H-19 Pond lined with hypalon. Receiving purged brine water from wells and condensate water from underground. H-19 pond also acts as an overflow pond for facultative lagoons. Overflow line still in place.

TO BE PUB: IED ON OR BEFORE SEPTEMB__ 12, 2002

NEW MEXICO ENVIRONMENT DEPARTMENT

Notice is hereby given that, pursuant to New Mexico Water Quality Control Commission Regulations, the following proposed ground water discharge permit(s) have been submitted for approval to the New Mexico Environment Department. The information in this notice generally has been supplied by the applicant and may or may not have been confirmed by the NM Environment Department.

DP-109, BLUEWATER SEWAGE LAGOONS, Van Spencer, Chairman, proposes to renew the discharge permit for the discharge of up to 65,000 gallons per day of domestic waste. The facility is located in Bluewater in Section 23, T12N, R11W, Cibola County. Up to 65,000 gallons per day of domestic wastewater is treated in a package treatment plant then discharged to an unlined lagoon. Following disinfection wastewater is land applied to 4.45 acres at the Bluewater Village cemetery. Ground water most likely to be affected is at a depth of approximately 178 feet and has a total dissolved solids concentration of approximately 950 milligrams per liter.

DP-519, LOVELACE RESPIRATORY RESEARCH INSTITUTE, Stephen Rohrer, proposes to renew the discharge permit for the former sewage lagoon. The facility is located on Kirtland Air Force Base in Albuquerque in Section 3, T08N, R04E, Bernalillo County. There will be no discharge of wastewater. The permit is for post-closure monitoring of ground water following the closure of a sewage lagoon in 1996. Ground water most likely to be affected is a depth of approximately 100 feet and has a total dissolved solids concentration of approximately 1600 milligrams per liter.

DP-658, AMERICAN WASTE REMOVAL, Gregory Jarvies, President, proposes to renew the discharge permit for the discharge of 6,000 gallons per day of wastewater generated from the processing of restaurant grease trap waste. The facility is located in Albuquerque at 502 Carmony Road, NE, in projected Section 4, T10N, R3E, Bernalillo County. Restaurant grease trap waste is processed on-site in above ground tanks, and recovered grease is transported off-site for sale. Wastewater is temporarily stored in two partially buried 10,000 gallon tanks, prior to being transported to the City of Albuquerque's wastewater treatment plant. Ground water below the site is at a depth of approximately 35 feet and has a total dissolved solids concentration of approximately 200 milligrams per liter.

DP-686, CITY OF FARMINGTON SLUDGE DISPOSAL PROJECT, Dean Roquemore, Plant Manager, proposes to renew and modify the discharge permit for the discharge of 2.5 dry tons per day of municipal sludge. The facility is located approximately 2 miles northwest of Farmington in Section 29, T30N, R13W, San Juan County. Dried sludge will be land applied and disked into 80 acres at the La Plata reclamation site. The modification consists of reducing the land application area by 239 acres through discontinuing the use of the Palmer Farm land application area. Ground water most likely to be affected is at a depth of approximately 400 feet and has a total dissolved solids concentration of approximately 2,500 milligrams per liter.

DP-808, VILLAGE OF MELROSE WASTEWATER TREATMENT PLANT, Ray Hestor, Mayor, proposes to renew the discharge permit for the discharge of 90,000 gallons per day of domestic wastewater. The facility is located approximately 1 mile south of Melrose in Section 7, T2N, R32E, Curry County. Wastewater is treated by an oxidation lagoon followed by a constructed wetland, prior to disposal to infiltration ponds or to 80 acres of land application area located within the wastewater treatment plant property boundaries. Ground water most likely to be affected is at a depth of approximately 50 feet and has a total dissolved solids concentration of approximately 448 milligrams per liter.

DP-818, CONTROLLED RECO' Y INC., Ken Marsh, Owner, propose renew the discharge permit for the discharge of up to 55,550 gallons per day of industrial waste. The facility is located approximately 37 miles southwest of Hobbs in Section 27, T20S, R32E, Lea County. Up to 275 cubic yards per day of soils contaminated with hydrocarbons and agricultural solids are land applied within a 62-acre landfarm and disked to increase aeration. Limited amounts of nonhazardous hydrocarbon contaminated liquids are periodically added to the soils to enhance remediation. Ground water most likely to be affected is at a depth of approximately 14 feet and has a total dissolved solids concentration of approximately 3300 milligrams per liter.

DP-831, WASTE ISOLATION PILOT PLANT, Inez Triay, Manager, proposes to renew the discharge permit for the discharge of 33,000 gallons per day of domestic waste and non-hazardous brine water. The facility is located 26 miles east of Carlsbad in Sections 28 & 29, T22S, R31E, Eddy County. Up to 23,000 gallons per day of domestic wastewater and 100 gallons annually of neutralized acid waste is discharged to five synthetically lined lagoons for evaporation. Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined pond for total evaporation. Up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of ground water wells, and from other non-hazardous sources to a synthetically lined evaporation pond. Ground water most likely to be affected is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3920 milligrams per liter.

DP-1025, WORDEN DAIRY, Charles Worden, Owner, proposes to renew and modify the discharge permit for the discharge of 40,000 gallons per day of agricultural waste. The facility is located 3 miles south of Lovington in Section 7, T17S, R37E, Lea County. Dairy wastewater will be discharged to two clay-lined lagoons for storage. From the lagoons, the wastewater will be land applied to 120 acres of cropland by center-pivot irrigation. The modification consists of adding a new 120-acre land application area in the southeast ¼ of Section 7, T17S, R37E. Ground water most likely to be affected is at a depth of approximately 47 feet and has a total dissolved solids concentration of approximately 500 milligrams per liter.

DP-1065, GENERAL ELECTRIC AIRCRAFT ENGINES, Julie DeWane, Manager, proposes to modify the discharge permit for the discharge of 1,814,400 gallons per day of treated groundwater. The modification allows for the addition of one deep zone extraction well, and up to three additional deep zone injection wells. The facility is located in Albuquerque's South Valley on Woodward Road, in Sections 32 and 33, T10N, R03E, Bernalillo County. Ground water contaminated with volatile organic compounds is currently recovered by eight shallow zone and three deep zone extraction wells, and is treated to Water Quality Control Commission Standards using filtration, air stripping, and activated carbon polishing. Effluent is currently discharged to one shallow zone and 10 deep zone injection wells. The depth to ground water in the deep zone aquifer below the site ranges from approximately 50 feet to 150 feet, and has a total dissolved solids concentration of approximately 500 milligrams per liter. Shallow zone ground water below the site is at a depth of approximately 18 to 26 feet, and has a total dissolved solids concentration that ranges from 577 to 2210 milligrams per liter.

DP-1080, WOODLANDS SUBDIVISION WASTEWATER TREATMENT, C. J. Mead, Owner, proposes to renew the discharge permit for the discharge of 31,800 gallons per day of domestic wastewater. The facility is located in Tijeras in Section 10, T10N, R06E, Bernalillo County. Wastewater is treated using a nitrifying filter and constructed wetlands, prior to disposal in a leachfield. Ground water most likely to be affected is at a depth of approximately 150 feet and has a total dissolved solids concentration of approximately 700 milligrams per liter.

DP-1125, STULL TRAILER WASH, Dale Stull, Owner, proposes to renew the discharge permit for the discharge of 3,600 gallons per day of wastewater from a livestock trailer wash. The facility is located 0.5 miles east of Nara Visa in Section 14, T16N, R36E, Quay County. Wastewater from trailer washing is discharged to a concrete sump and then pumped to a synthetically lined lagoon for storage. Wastewater from the lagoon is land applied to either 31.11 acres adjacent to the trailer wash, to 31 acres of cropland located in Section 21, T15N, R36E, or to 200 acres of cro[illegible] l located in Section 6, T18N, R37E, [illegible] County. Ground water most likely to be affected is at a depth of approximately 40 feet and has a total dissolved solids concentration of approximately 250 milligrams per liter.

Any interested person may obtain further information from the Ground Water Pollution Prevention Section of the NM Environment Department, telephone (505) 827-2900, and may submit written comments to the Ground Water Pollution Prevention Section, NM Environment Department, P.O. Box 26110, Santa Fe, NM 87502. Prior to ruling on any proposed discharge permit or its modification, the NM Environment Department will allow thirty (30) days after the date of publication of this notice to receive written comments and during which a public hearing may be requested by any interested person. Requests for public hearing shall set forth the reasons why the hearing should be held. A hearing will be held if the NM Environment Department determines that there is significant public interest.

RE: Request for DP-831 Files VIA FAX: 505-827-2965

Dear Marcy:

This letter is to request permission to copy files pertaining to the referenced Discharge Plan for the Waste Isolation Pilot Project (WIPP) near Carlsbad, New Mexico. I have spoken with Clint Marshall of your staff regarding the specific files that I will instruct Paper Tiger in Santa Fe to pick up at your offices.

Thank you for your assistance. Please contact me with any questions.

RE: Renewal and Modification of Discharge Plan – DP-831

Dear Ms. Henning:

Enclosed please find the three (3) copies of the completed Discharge Plan Application and $100.00 filing fee for the renewal and modification of Discharge Plan DP–831 for the Waste Isolation Pilot Plant (WIPP).

The facility description, and the volumes and character of the discharges to the sewage lagoon facilities and evaporation ponds described in the current Discharge Plan DP–831 remain the same. The modifications requested to DP–831 are two fold. First, we are requesting the reduction in monitoring and reporting frequencies from quarterly to semi-annually. Secondly, we are requesting the removal of the sampling and analysis requirement for gross alpha activity. A complete description of the modification requests is found in the enclosed Discharge Plan Application for Renewal.

If you have any questions or comments, please contact Mr. Harold Johnson at (505) 234-7349.

Sincerely,

Cynthia Zvonar

RECEIVED

ADMINISTRATIVE COMPLETENESS

To be deemed administratively complete for publication of a public notice, the following information must be provided. [20.6.2.3106, 20.6.2.3108 NMAC]

1. Name of the proposed discharger and facility [20.6.2.3106, 20.6.2.3108.C.1 NMAC]:

Type of facility or operation (dairy, municipal wwtp, mining, school, etc.):

The Waste Isolation Pilot Plant (WIPP) is an underground geologic repository designed to permanently dispose of transuranic waste from the research and production of nuclear weapons. As a Hazardous Waste Treatment Storage and Disposal Facility (Permit # NM4890139088-TSDF), WIPP is authorized to dispose of transuranic waste containing hazardous constituents.

The WIPP uses a facultative lagoon system for sewage wastewater treatment and a series of evaporation ponds for storage and evaporation of the non-hazardous water generated at the site and approved for discharge under Discharge Plan DP-831. The facultative lagoon system consists of four synthetically lined ponds (two settling ponds and two polishing ponds) that discharge into an evaporation facility containing three synthetically lined evaporation ponds, the east evaporation (pond A), the north evaporation pond (pond B), and the south evaporation pond (pond C). The facultative lagoon system / evaporation ponds are located approximately ½ mile southwest of the WIPP site. In addition, a separate synthetically lined evaporation pond (H-19), located approximately one and 1/4 miles southeast of the WIPP site, is used for storage and evaporation of non-hazardous water(s) approved for discharge under DP-831.

	Name	Address	City	State	Zip	Telephone & Fax
Facility*	Waste Isolation Pilot Plant	26 miles E-SE of Carlsbad, NM	Carlsbad	NM	88221	505-234-8271 505-234-8854
Owner	U.S. Department of Energy	P.O. Box 3090	Carlsbad	NM	88221	505-234-7303 505-234-7027
Responsible Party	Same as above	Same as above	Same as above	Same as above	Same as above	Same as above
Facility Representative	Jim Hollen, Westinghouse TRU Solutions	P.O. Box 2078 MS 452-09	Carlsbad	NM	88221	505-234-8271 505-234-8854
Consultant	N/A	N/A	N/A	N/A	N/A	N/A
Other (specify)	N/A	N/A	N/A	N/A	N/A	N/A

*For the facility address, enter physical address - not mailing address.

2. Locations of the Discharges [20.6.2.3106.C.2 and 20.6.3108.C.2 NMAC]:

List the locations of the discharges covered by this permit. Add rows as necessary to include all discharge locations. Sections should be described to the nearest ¼ of a ¼ of a ¼ section (please see attachment).

Discharge Location (lagoons, leach fields, land application areas, outfalls, etc.)	County	Township	Range	Section	Latitude	Longitude
Facultative Lagoon System and evaporation facility	**Eddy**	**22S**	**31E**	**NE, NW, NE, 29**	**32.22.30N**	**103.47.30W**
H-19 Evaporation Pond	**Eddy**	**22S**	**31E**	**SE, NE, SW, 28**	**32.21.33N**	**103.46.58W**

The facultative lagoon system and evaporation facility location contains three lined evaporation ponds, the east evaporation pond (pond A), the north evaporation pond (pond B), and the south evaporation pond (pond C).

3. Brief Description of Discharge [20.6.2.3108.C.3 NMAC]:

Briefly describe the activities which produce the discharge(s) including the treatment and disposal methods. Attach additional pages as necessary.

The sewage and evaporation facilities currently permitted under DP-831 will remain the same with regard to the physical description, volumes, and character of the discharges as provided in DP-831, previous applications, renewals, and modifications. WIPP is authorized to discharge of up to:

23,000 gpd of sewage effluent to the facultative lagoon system and evaporation facility

an additional 2,000 gpd of non-hazardous brine water to the north evaporation cell (north evaporation pond [pond B] of the evaporation facility)

8,000 gpd of non-hazardous brine water to the H-19 evaporation pond

100 gallons per year of neutralized acid to the domestic wastewater lagoons (facultative lagoon system and evaporation facility)

The non-hazardous brine waters include water generated from mine dewatering activities, pumping of ground water monitoring wells, and from miscellaneous non-hazardous sources.

The neutralized acid is a buffered acidic solution generated from the conditioning of virgin resins used in laboratory separation columns.

4. Discharge Characteristics [20.6.2.3106.C.1 and 20.6.2.3108.C.4 NMAC]:

4.a. Quantity:

Peak design discharge rate in gallons per day (gpd) (design capacity of the treatment and disposal system):	**23,000 gpd to the facultative lagoon system and evaporation facility** **Additional 2,000 gpd to the north evaporation pond (pond B) of the evaporation facility** **8,000 gpd to the H-19 Evaporation Pond**
Average discharge rate on annual basis in gpd (actual flow):	**2,828 gpd to the facultative lagoon and evaporation facility** **143 gpd to the H-19 Evaporation Pond**
Methods used to meter or calculate discharge volume:	**Sewage effluent discharges to the facultative lagoon system are measured through the wastewater flow meter or assumed to equal the total domestic water usage.** **Volumes of other permit authorized discharges to the facultative lagoon system / evaporation facility or the H-19 Evaporation Pond are calculated by a time/volume method or by volumetric measurement of the transport container.**

Average discharge rate was determined by dividing annual discharge volume by 365 days.

4.b. Quality: Add rows as necessary to include all contaminants and toxic pollutants.

Contaminant(s) or Toxic Pollutant(s) generally associated with facility type (contaminants of concern are listed in 20.6.2.7.uu, and 20.6.3103 NMAC)	**Influent Concentration (mg/L)**	**Effluent Concentration (mg/L)**
Total Dissolved Solids (TDS)	**519 mg/L**	**24,800 mg/L**
Nitrate (as N)	**< 1.0 mg/L**	**N/A**
Total Kjeldahl Nitrogen	**100.50 mg/L**	**N/A**
Plutonium 238	**0.005 ± 0.007 pCi/L**	**0.005 ± 0.007 pCi/L**
Plutonium 239/240	**-0.001 ± 0.007 pCi/L**	**-0.001 ± 0.007 pCi/L**
Uranium 234	**0.773 ± 0.134 pCi/L**	**0.773 ± 0.134 pCi/L**
Uranium 235	**0.022 ± 0.034 pCi/L**	**0.022 ± 0.034 pCi/L**
Uranium 238	**0.281 ± 0.078 pCi/L**	**0.281 ± 0.078 pCi/L**
Americium 241	**-0.006 ± 0.024 pCi/L**	**-0.006 ± 0.024 pCi/L**
Strontium 90	**0.580 ± 0.540 pCi/L**	**0.580 ± 0.540 pCi/L**
Radium 226	**0.110 ± 0.170 pCi/L**	**3.910 ± 0.440 pCi/L**
Radium 228	**-0.230 ± 1.460 pCi/L**	**0.990 ± 0.540 pCi/L**
The above-listed contaminants reflect the proposed removal of the sampling and analysis requirement for gross alpha particle activity that is presented in this renewal application. Influent and effluent (evaporation pond B) concentrations are from the first quarter 2002 WIPP Discharge Monitoring Report for Discharge Plan DP-831. A copy of this report is provided as Attachment 1.		

4.c. Flow Characteristics:

Number of days per week discharge occurs:	7
Number of months per year discharge occurs (specify months):	12
Is flow continuous or intermittent: **Sewage effluent discharges to the facultative lagoon system** **Other permit authorized discharges to the facultative lagoon system / evaporation facility** **Permit authorized discharges to the H-19 Evaporation Pond**	 **Continuous** **Intermittent** **Intermittent**

5. <u>Ground Water Conditions</u> [20.6.2.3106.C.3 and 20.6.2.3108.C.5 NMAC]:

Sources for this information may be the New Mexico State Engineers Office, NMED, GWPPS web site (www.nmenv.state.nm.us), and USGS reports. If you do not have a TDS value, take a sample from the nearest well to the discharge location and submit the results from the analysis.

Depth to ground water below the discharge site:	**Approximately 608 feet**
Flow direction of ground water below the site:	**Generally North to South**
Flow gradient of ground water below the site:	**Approximately 0.00013**
Reference* or source for depth, direction and gradient:	**WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996 and approved by NMED July 3, 1997**

* If determined from well logs, please provide photocopies of well logs with application. If depth is derived from a report include copies of appropriate pages and complete reference to report including author, title, and publication date.

Total Dissolved Solids (TDS) concentration (mg/L) of ground water below the site:	**TDS concentrations ranged from 4,600 mg/L at WIPP Water Quality Sampling Program (WQSP) Well # 6a, to 234,000 mg/L at WIPP WQSP Well # 3.**
Reference or source for TDS:	**<u>WIPP Groundwater Detection Monitoring Program, Semiannual Groundwater Monitoring Report Submitted to the New Mexico Environment Department, Sampling Round 13, September through</u> November 2001, dated March 2002**

Copies of the analytical results and chains-of-custody are provided as Attachment 2. Round 13 groundwater sampling analytical results did not indicate any changes in overall groundwater chemistry and were within the expected concentration ranges as defined by the background baseline. The groundwater chemistry baseline was developed from the first 10 sample rounds collected semiannually in accordance with the WIPP hazardous waste facility permit (Permit # NM4890139088-TSDF).

TECHNICAL ADEQUACY

To be deemed technically adequate, for purposes of issuing the discharge permit, the following information must be provided. [20.6.2.3106, 20.6.2.3107, 20.6.2.3109 NMAC]. Operational, monitoring, contingency, and closure plans must be submitted and must be appropriate for the proposed treatment and disposal type and meet the site specific conditions for the proposed facility.

6. <u>Permit Plans</u> [20.6.2.3106.C.7, 20.6.2.3107.A, and 20.6.2.3109.C NMAC]:

6.a. Operational Plan [20.6.2.3106.C.7 and 20.6.2.3109.C NMAC]:

The operational plan must describe how the system(s) for conveyance, collection, treatment, distribution, and disposal of wastewaters or other discharges will be constructed, operated, inspected, and maintained. The operational plan must demonstrate that ground water standards will not be exceeded.

6.a.i. In the following table, identify all proposed conveyance, collection, treatment distribution, and disposal units included in the operational plan. Add rows as necessary to include all units.

Treatment/Storage/ or Disposal Unit **Treatment units** (lagoon, mechanical treatment plant, manure separator, clarifier, etc.) **Disposal Units** (land application area, leach field, evaporative lagoon, leach stockpile, etc.)	**Construction Material**	**Volumetric Capacity*/Area*** (gallons or cubic yards/ acres)
Facultative Lagoon System and evaporation facility	**34 mil Hypalon Geomembrane or HDPE**	**6.74 Acre Feet at Normal Depth**
H-19 Evaporation Pond	**34 mil HDPE**	**1.55 Acre Feet at Normal Depth**

*Volumetric Capacity must be provided for all tanks, chambers, and impoundments or other storage units.
*Area must be provided for all land application areas, leach fields or other area features.

6.a.ii. Describe in detail the operational plan, including all conveyance, collection, treatment, distribution and disposal systems. Attach additional pages as necessary:

The operational plan for the facultative lagoon system and evaporation facilities will remain the same as is currently permitted under DP-831 and described in previous applications, renewals, and modifications.

6.a.iii. Describe the operations and maintenance plan that will be followed to ensure the system is maintained as described. At a minimum the plan must include monthly inspections of all wastewater treatment and disposal units. Attach additional pages as necessary.

The operations and maintenance plan for the facultative lagoon system and evaporation facilities will remain the same as is currently permitted under DP-831 and described in previous applications, renewals, and modifications.

6.b. Monitoring Plan [20.6.2.3106.C.5 and 20.6.2.3107.A.1-9 NMAC]:

The monitoring plan must describe how the facility will be monitored to ensure the discharge will not adversely impact ground water quality. The plan must include all monitoring locations (effluent sampling, monitoring wells, lagoons, soil sampling, plant tissue analysis, etc.). Monitoring locations must be included on the facility map.

The monitoring plan for the facultative lagoon system and evaporation facilities will remain the same as is currently permitted under DP-831 and described in previous applications, renewals, and modifications with the exception of the following modification requests.

1. **Reduce the discharge sampling and reporting frequency requirements from quarterly (four times per year) to a semi-annual basis (two times per year).**

2. **Remove the sampling and analysis requirement for gross alpha particle activity.**

The WIPP facultative lagoon system / evaporation facility and H-19 evaporative pond are lined facilities designed to dispose of domestic sewage and non-hazardous waste water by evaporation, therefore, no discharges are released to surface or groundwater and no effluent limits were established in the current permit (DP-831). The proposed modification to reduce the sampling and reporting requirements to twice a year will comply with the Water Quality Control Commission regulations at 20.6.2 NMAC to measure the amount of effluent discharged, monitor the effluent quality, and report this information to the New Mexico Environmental Department. Since all discharges will be monitored and no discharges are released, the proposed modification will not alter the monitoring program's ability to continue to ensure discharges will not adversely impact ground water quality.

Removal of the sampling and analysis requirement for gross alpha particle activity is requested because interference from the solids present in the waste water prevent the analysis from producing meaningful results. The discharge plan amendment approved by the NMED Ground Water Quality Bureau on June 12, 1998 included analysis for gross alpha particle activity in place of Radium 226 and Radium 228 if the gross alpha activity was 15 pCi/L or less. Since the implementation of this change, the accuracy range for Gross alpha activity has consistently exceeded 15 pCi/L and additional analysis for Radium 226 and Radium 228 has been required.

6.b.i. Monitoring Locations. In the following tables, identify all monitoring locations. Add additional rows as necessary to include all monitoring locations.

Flow, Effluent and Ground Water Monitoring

Monitoring Location	State Plane Coordinates		Elevation (also specify at what point in well casing)	Sampling Frequency per year	Reporting Frequency per year	Water or Soil Contaminant Type (please refer to 20.6.2.7.uu, and 20.6.3103 NMAC)

*Identify the sampling locations as designated or named by the facility.

amsl – above mean sea level **TOC – Top of Casing**

Note #1: The sampling and reporting frequency listed represent the proposed reduction from quarterly to semiannual presented in this renewal application.

Note #2: The analytical parameters listed represent the proposed removal of the sampling and analysis requirement for gross alpha particle activity that is presented in this renewal application.

Note #3: The WQSP wells 1through 6a constitute the Resource Conservation and Recovery Act (RCRA) groundwater monitoring network specified in the WIPP Groundwater Detection Monitoring Program to comply with the requirements of 20 NMAC 4.1.500. The seven monitoring wells are sampled and reports of the analyses are submitted to the NMED on a semiannual basis pursuant to the Hazardous Waste Treatment Storage and Disposal Facility Permit # NM4890139008-TSDF.

Soil, Plant Tissue and Other Sampling

Monitoring Location*	Lat	Long	Sampling Frequency per year	Reporting Frequency per year	Water or Soil Contaminant Type
land application area soil sampling	N/A	N/A	N/A	N/A	N/A
land application area plant tissue analysis	N/A	N/A	N/A	N/A	N/A
Other	N/A	N/A	N/A	N/A	N/A

6.b.ii. Describe in detail the sampling protocols that will be used for sample collection at all monitoring locations. Attach additional pages as necessary.

The sampling protocols that will be used for sample collection at the designated sampling locations for this discharge application (facultative lagoon system / evaporation facility and the H-19 evaporative pond) are described in procedure WP 02-EM1001, Sewage Lagoon Sampling. A copy of this procedure is enclosed as Attachment 3. This procedure will be revised to incorporate specific discharge plan requirements or modifications that are approved by the WQCC.

The sampling protocols that are used for sample collection at the monitoring wells forming the RCRA groundwater monitoring network are described in procedure WP 02-1, WIPP Groundwater Monitoring Program Plan and comply with the standard permit conditions in 6.b.iii. A copy of this procedure is enclosed as Attachment 4.

6.b.iii. Standard Monitoring Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

- [x] All monitoring wells will be installed according to NMED Monitoring Well Construction and Abandonment Guidelines (copy enclosed).

- [x] All monitoring wells (if 3 or more monitoring wells are on site) will be surveyed to a common permanent benchmark and that the survey will be submitted to the NMED, GWQB within 60 days of installation of all monitoring wells. Survey data will include northing, easting, and elevation to the nearest hundredth of a foot. One of the wells may be used as the benchmark.

- [x] This facility will measure the depth to ground water in each monitoring well to the nearest hundredth of a foot prior to purging and sampling, and that three well volumes will be purged from each monitoring well prior to sample collection.

- [ ] This facility will complete land application data sheets (LADS, copy enclosed) documenting the amount of nitrogen applied to each land application area if applicable. The LADS will incorporate the wastewater volume and analytical results of the wastewater testing to determine total nitrogen applied to each field.

6.c. Contingency Plan [20.6.2.3107.A.10 NMAC]:

The contingency plan must describe the actions to be taken if Regulation 20.6.2.3103 NMAC ground water standards are exceeded or if toxic pollutants are present (20.6.2.7.uu) as a result of discharges regulated under the proposed permit, and to cope with failure of the discharge permit or system.

6.c.i. Standard Contingency Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

- [x] This Facility will comply with the following contingency language:

In the event that monitoring indicates ground water standards are violated or may be violated during the term of the discharge permit or upon post closure monitoring, this facility will collect a confirmation sample from the monitoring wells within 15 days to confirm the initial sampling results. Upon confirmation of contamination, all ground water monitoring will be conducted monthly and a corrective action plan will be submitted to the NMED. The corrective action plan will include a site investigation to define the source, nature and extent of ground water contamination and a proposed abatement option; and a schedule for implementation. The site investigation and abatement option must be consistent with the requirements and provisions of Regulations 20.6.2.4101, 20.6.2.4103, 20.6.2.4106.E, 20.6.2.4107, and 20.6.2.4112 NMAC. The corrective action plan will be submitted to NMED for approval within 30 days of confirmation of ground water contamination, and will be initiated within 30 days of NMED approval.

[V] This facility will comply with the following contingency language:

In the event of a spill or release that is not as prescribed in the approved discharge permit, this facility will take immediate corrective action to contain or mitigate the damage caused by the discharge and will initiate the notifications and corrective actions as required by Regulation 20.6.2.1203 NMAC. Within 24 hours discovery of the incident, this facility will verbally notify NMED and provide the information outlined in Regulation 20.6.2.1203.A.1. NMAC. Within 7 days of discovering the incident, this facility will submit a written notification verifying the oral notification and providing any additional pertinent information or changes. Within 15 days of the incident, this facility will submit a corrective action plan describing actions taken and/or to be taken to remedy the impact of the unauthorized discharge.

6.c.ii. Specific Contingency Plan:

Describe any additional specific corrective actions or contingencies that will be taken to cope with failure of the discharge system: Attach additional pages as necessary.

The standard permit conditions in 6.c.i will be incorporated into the contingency plan for the facultative lagoon system and evaporation facilities currently permitted under DP-831 and described in section 17 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, previous applications, renewals, and modifications.

The plan includes weekly inspection and repair of the pond liners as necessary, containment and investigation of all spills and releases, and submittal of a corrective action plan to address contamination. In the event of a tear in a liner that results in a release to the environment, an effluent spill or unauthorized discharge, the Ground Water Section of the NMED will be notified pursuant with the standard permit conditions in 6.c.i. The WIPP Environmental Compliance and the Operations Department will assess damages and attempt to isolate any discharge. Samples will be taken to determine the extent and severity of contamination. A corrective action plan will be developed based on communications with the NMED Ground Water Section.

6.d. Closure Plan [20.6.2.3107.A.11 NMAC]:

The closure plan must describe the closure actions to be taken to prevent Regulation 20.6.2.3103 NMAC ground water standards from being exceeded, or the introduction of a toxic pollutant in ground water after cessation of operations. At a minimum, the closure plan must include a description of closure measures, post closure monitoring plans, and financial assurance (if required by NMED).

6.d.i. Specific Closure Plan: Describe the specific closure activities to ensure that ground water quality will be protected after cessation of operations. The plan shall include plugging, removal, and/or filling of all conveyance, collection, treatment, distribution and disposal features in order to prevent future discharges at the facility. The plan must also describe how all liquid and solid wastes will be removed and disposed of according to local, state, and federal laws. The plan must also describe how disturbed areas will be backfilled to blend with the original surface topography to prevent future ponding and to prevent a discharge at the facility from occurring after the cessation of operations. Attach additional pages as necessary.

The standard permit conditions in 6.d.ii will be incorporated into the closure plan for the facultative lagoon system and evaporation facilities currently permitted under DP-831 and described in section 19 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996.

At the time the WIPP facility is decommissioned, the closure plan will specify the closure activities required to ensure that ground water quality will be protected. These activities include the pumping or evaporation of all wastewater ponds, removal and disposal of all solids in accordance with applicable regulations, and contouring and revegetation of the site.

6.d.ii. Standard Closure Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

This facility will comply with the following closure requirements:

[V] The discharger will notify NMED at least 30 days prior to cessation of operations and will provide a schedule for implementation of the closure plan.

[V] This facility will conduct post closure monitoring at the frequency and locations prescribed under the active permit for a period approved by NMED. If Regulation 20.6.2.3103 NMAC ground water standards are violated or toxic pollutants are present during post closure monitoring, this facility will implement the contingency plan required in the active permit.

[V] All monitoring wells will be plugged and abandoned in accordance with NMED Monitoring Well Construction and Abandonment Guidelines once NMED has agreed in writing that post closure ground water monitoring may cease.

[V] Once NMED has approved all closure activities, this facility will submit a letter requesting termination of the discharge permit.

TECHNICAL SUPPORT

The following information must be submitted as required by Regulation 20.6.2.3106, and 20.6.2.3109 NMAC.

7. <u>Other Discharge Locations</u> [20.6.2.3106.C.2 NMAC]:

7.a. List the locations of any other discharges at this facility not covered by this permit but permitted under the New Mexico Liquid Waste Disposal Regulations, Hazardous Waste Management Regulations, Federal Clean Water Act (NPDES), and any un-permitted discharges. Add rows as necessary to include all other discharge locations.

Discharge Type (septic tank/leach fields, surface water discharges, etc.)	**Permit Identification**	**Discharge Location Description**
None	**N/A**	**N/A**

7.b. **Area Map:** On the appropriate United States Geological Survey (USGS) 7.5 minute topographic quadrangle map, identify the location of all water supply wells, injections wells, seeps, springs, bodies of water, and watercourses within one mile of the outside perimeter of the discharge site.

As described in section 8 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, previous applications, renewals, and modifications, there are no water supply wells, injection wells, seeps, springs, bodies of water, or watercourses within one mile of the outside perimeter of the discharge site.

8. <u>Flooding Potential</u> [20.6.2.3106.C.4 NMAC]:

8.a. Describe the flooding potential of the discharge site based on the latest Federal Emergency Management Agency flood plain map or site specific analysis:

As described in section 12 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, the flooding potential of the WIPP facility is considered minimal since the general ground elevation in the vicinity of the surface facilities is approximately 400 feet above the 100-year floodplain. The potential for flash flooding is minimal because the facility is constructed on the sand dunes of the Los Medanos plateau.

8.b. Describe the methods used to control flooding, run-on and run-off at the discharge site (berms, diversion channels, etc.):

As described in section 13 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, flooding, run-on, and run-off is controlled by

diversion berms that surround the facultative lagoon system / evaporation facility and by the construction of the H-19 evaporative pond on an elevated caliche pad.

9. **Geologic and Soil Information** [20.6.2.3106.5 NMAC]:

9.a. **Lithology:** Describe the lithology and thickness of each geologic unit below the discharge site and indicate which units bear water. This information may be obtained from a driller's log or geologic report. Include photocopies of all well logs with the application. Add rows as necessary to include all units.

As described in section 15 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, previous applications, renewals, and modifications.

9.b. **Soil Map:** Attach a copy of the United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) soil survey map and descriptive information for soil(s) associated with the discharge site.

As provided in attachment 9 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996.

10. **Signatures:**

Owner: I certify that I am the legal owner of the property in which all discharges will occur. I certify that I am knowledgeable about the information contained in this application, and believe the information is true, complete and accurate.

Print Name: ______________________________

Signature: ______________________________ Date ____________________

Responsible Party* (if property is leased or operated by someone other than the owner):

I certify that I am knowledgeable about the information contained in this application, and believe the information is true, complete and accurate.

Print Name: **N/A**

Signature: **N/A** Date **N/A**

* Enclose a signed copy of the lease agreement between the responsible party and the owner of the property on which the proposed discharge will occur. Lease agreement should be valid for the duration of the discharge permit or until the discharge permit is modified to reflect a new lessee.

ATTACHMENT 1

WASTE ISOLATION PILOT PLANT (WIPP) DISCHARGE MONITORING REPORT FOR DISCHARGE PLAN DP-831

REPORT NUMBER 33: FIRST QUARTER, 2002

SPECIFIC REQUIREMENTS OF DP-831

1. DISCHARGE VOLUMES:

Facultative Lagoon System *	(Total Domestic Water Flow)	965,558 gallons
Miscellaneous Water Discharged to the Lagoon System		None
"B" Evaporation Pond		None
H-19 Evaporation Pond		1,600 gallons
Neutralized Spent Acid Waste		14.8 gallons

* The flow meter for waste water discharged to the Facultative Lagoon System is out of order as of 11/26/01. A work order is in place for repair and calibration of the meter. The volume discharged to the Facultative Lagoon System above, is the total amount of domestic water used by the facility which demonstrates that flow to the Lagoon System could not exceed 23,500 gallons per day as prescribed by DP-831.

The water discharged to the H-19 Evaporation Pond was generated as a result of ground water monitoring well pumping and sampling activities and fan condensate.

Laboratory analyses used in characterization of these waste waters is on file.

2. WATER QUALITY ANALYSIS

Analysis of Inflow to Facultative Lagoon System:

Nitrate (as N)	<1.0 mg/L
Total Kjeldahl Nitrogen (as N)	100.50 mg/L
Total Dissolved Solids (TDS)	519 mg/L
	Activity ± TPU*
Plutonium 238	0.014 ± 0.015 pCi/L
Plutonium 239/240	0.004 ± 0.011 pCi/L
Americium 241	-0.005 ± 0.024 pCi/L
Uranium 234	1.250 ± 0.158 pCi/L
Uranium 235	0.040 ± 0.028 pCi/L
Uranium 238	0.494 ± 0.019 pCi/L
Strontium 90	0.290 ± 0.470 pCi/L

Analysis of Inflow to Facultative Lagoon System (Cont.)

Gross Alpha	1.570 ± 2.580 pCi/L
Radium 226	0.110 ± 0.170 pCi/L
Radium 228	-0.230 ± 1.460 pCi/L

Analysis of Evaporation Ponds:

Evaporation Pond "B"

Total Dissolved Solids (TDS)	24,800 mg/L
	Activity ± TPU*
Plutonium 238	0.005 ± 0.007 pCi/L
Plutonium 239/240	-0.001 ± 0.007 pCi/L
Americium 241	-0.006 ± 0.024 pCi/L
Uranium 234	0.773 ± 0.134 pCi/L
Uranium 235	0.022 ± 0.034 pCi/L
Uranium 238	0.281 ± 0.078 pCi/L
Strontium 90	0.580 ± 0.540 pCi/L
Gross Alpha	143.000 ± 88.200 pCi/L
Radium 226	3.910 ± 0.440 pCi/L
Radium 228	0.990 ± 0.540 pCi/L

Evaporation Pond "C"

Total Dissolved Solids (TDS)	28,300 mg/L
	Activity ± TPU*
Plutonium 238	0.008 ± 0.011 pCi/L
Plutonium 239/240	0.014 ± 0.015 pCi/L
Americium 241	-0.021 ± 0.020 pCi/L
Uranium 234	0.681 ± 0.111 pCi/L
Uranium 235	-0.003 ± 0.019 pCi/L

Evaporation Pond "C" (Cont.)

Uranium 238	0.296 ± 0.007 pCi/L
Strontium 90	0.540 ± 0.550 pCi/L
Gross Alpha	60.7 ± 82.0 pCi/L
Radium 226	4.33 ± 0.46 pCi/L
Radium 228	0.88 ± 1.53 pCi/L

H-19 Evaporation Pond

Total Dissolved Solids (TDS)	100,000 mg/L
	Activity ± TPU*
Plutonium 238	0.004 ± 0.010 pCi/L
Plutonium 239/240	0.003 ± 0.008 pCi/L
Americium 241	-0.004 ± 0.023 pCi/L
Uranium 234	2.960 ± 0.315 pCi/L
Uranium 235	0.055 ± 0.033 pCi/L
Uranium 238	1.060 ± 0.160 pCi/L
Strontium 90	0.280 ± 0.610 pCi/L
Gross Alpha	20.700 ± 234.000 pCi/L
Radium 226	9.630 ± 0.790 pCi/L
Radium 228	1.650 ± 1.620 pCi/L

3. BERMS PROTECTING THE LAGOON WILL BE MAINTAINED TO PROTECT AGAINST PRECIPITATION RUN-OFF AND RUN-ON

   Berms are maintained and inspected on a regular basis. All berms are stable and functioning properly.

4. SPILLS
   No spills, seeps, and/or leaks of effluent, leachate and/or process fluids have occurred that are not authorized by DP-831.

* - Total Propagated Uncertainty

Attachment 3 - Quarterly Sewage Samples Data/Worksheet 15

INTRODUCTION

This procedure provides instructions necessary for Environmental Monitoring (EM) personnel to sample the sewage lagoon as required by DP-831, Sewage System Discharge Plan, and DOE/WIPP 99-2194, Environmental Monitoring Plan.

One or more of the following records are generated by the use of this procedure:

- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis
- WP Form 15-PM3525-1, Shipping Authorization
- WP 02-EM3001, Attachment 1, Sample Tracking Log Book

REFERENCES

BASELINE DOCUMENTS

- 40 CFR 503, Standards for the Use or Disposal of Sewage Sludge
- 49 CFR Subpart B, Transportation
- SW 846, EPA Test Methods for Evaluating Solid Waste
- WP 12-IH.02, WIPP Industrial Hygiene Program

REFERENCED DOCUMENTS

- DOE/WIPP 99-2194, Environmental Monitoring Plan
- DP-831, Sewage System Discharge Plan, New Mexico Environment Department, July 3, 1997
- WP 02-EM3001, Administrative Processes for Environmental Monitoring Programs
- WP 12-IS1832, Emergency Eyewash and Shower Equipment
- WP 15-PM3525, Preparation and Processing of Shipping Authorization

EQUIPMENT

SAMPLING EQUIPMENT

- Buckets (2)
- Clock or watch
- Communications equipment (radio or cellular phone)
- Portable eye wash station
- Eye protection
  - Splash goggles
  - Face shield
- Key to sewage lagoon
- Sample containers (in accordance with Attachment 1, Sampling Parameters and Environmental Monitoring Sample Plan)
- Sample shipping cases
- Sampling boom
- Tyvek suits/Tyvek Lab coats

CONSUMABLES

- Biohazard bags (large size preferable, available from site nurse)
- Disinfecting solution
- Deionized (DI) water (5 gallons minimum)
- Disposable paper towels
- Frozen ice packs
- Gloves, for handling nitric acid
- Gloves, nitrile
- Tape, clear for sampling labels

- Tape, plastic (for sealing container caps)
- Tape, tamper evidence seal
- pH strips
- Concentrated nitric and sulfuric acids
- Disposable pipettes

PRECAUTIONS AND LIMITATIONS

- Only personnel qualified in accordance with EM-12, or a qualification card, or under the direct supervision of a qualified individual, may perform this procedure.
- Sampling must be performed by a team of at least two people.
- Material Safety Data Sheets (MSDS) must be reviewed, kept up to date, and readily available.
- Requirements for personal protective equipment (PPE) must be followed.
- All personnel performing this procedure must have Hepatitis B vaccination series, current tetanus immunization, and hepatitis A vaccination.
- Sampling team will reglove when changing sampling locations.
- Use caution when moving about sewage lagoons; the liner surfaces may be slippery, which could result in slips or falls.

PREREQUISITE ACTIONS

1.0 Order sample containers two to three weeks prior to planned sampling date, including containers for selected control samples per Attachment 3.

NOTE

Contract laboratory may substitute sample containers different from those listed on Attachment 1.

Trip blanks received from laboratories with preserved containers must be kept with the sample containers and returned to the contract laboratory with each set of samples.

2.0 Upon receipt of sample containers, verify the following:

- Appropriate container types and size match container criteria listed on Attachment 1.
- Preservatives indicated on container labels match preservative criteria shown on Attachment 1.
- Containers are visually clean.

3.0 At least two working days prior to sampling, contact Shipping Coordination for shipping guidance.

4.0 If substitute sample containers are required, add required preservatives shown on Attachment 1.

5.0 Verify all necessary equipment for the type sampling to be performed is available and ready for use.

6.0 Collect sampling equipment and materials for transport to lagoon.

7.0 Notify Central Monitoring Room Operator (CMRO) prior to entering sewage facility area (at extension 8125 or 8457).

PERFORMANCE

1.0 EFFLUENT SAMPLING

1.1 Set up a portable eye wash station at the sampling location.

1.2 Don PPE.

1.3 Set up decontamination equipment as follows:

1.3.1 Fill two buckets ½ full with DI water.

1.3.2 Add disinfectant to one of the buckets, following manufacturer's recommended concentration.

WARNING

Liner surface may be slippery. Slips or falls while walking on the liner may result in personnel injury or contamination.

CAUTION

Overflowing prepreserved sample containers can invalidate the sample.

NOTE

Touching the inside of sample containers and caps can cross-contaminate the sample. Sample containers and caps need to remain free of contamination from soil, debris and blowing sand.

NOTE

Sample chain of custody is established and maintained in accordance with WP 02-EM3001.

1.4 Obtain sample using sampling boom, taking care **NOT** to overfill sample container.

1.5 Install sample container cap.

1.6 Rinse outside of sample container with DI water.

1.7 Dry sample container with disposable towel(s).

1.8 Seal sample container with plastic tape.

1.9 Place tamper evidence seal tape on cap so that seal tape will have to be broken to open sample container.

1.10 Date and initial evidence tape.

1.11 Affix sample code label to the sample container.

1.12 Cover label with clear tape.

1.13 Verify chilled samples meet chilling requirements per Attachment 1.

1.14 Place container in shipping case.

1.15 **IF** additional samples are to be taken at this sample location, **THEN** repeat Steps 1.4 through 1.14.

1.16 Clean and disinfect reusable sampling equipment as follows:

1.16.1 Wash in disinfectant solution.

1.16.2 Rinse with DI water.

1.16.3 Rinse again in free flowing stream of DI water.

1.17 Repeat Steps 1.4 through 1.16.3 for remaining sample locations.

1.18 Notify CMRO (at extension 8125 or 8457) when leaving sewage facility.

1.19 Dispose of nonreusuable equipment, materials and trash in a biohazard bag and deliver to the site nurse for disposal.

NOTE

Sample must be handled, packaged, and shipped in accordance with contract laboratory requirements and Shipping Coordination requirements.

1.20 Complete the following documents prior to final packaging of sample containers for shipment:

- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis
- WP 02-EM3001, Attachment 1, Sample Tracking Log Book

1.21 Prepare the following for hand-delivered samples:

- Shipping cases
- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis

1.22 If samples are to be shipped via carrier, perform the following:

1.22.1 <u>At least two working days prior to sampling, contact Shipping Coordination for shipping guidance.</u>

1.22.2 Prepare a transmittal letter and WP Form 15-PM3525-1, Shipping Authorization.

1.22.3 Deliver the following to the warehouse for shipment to the contract laboratory:

- Shipping cases
- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis
- WP Form 15-PM3525-1, Shipping Authorization
- Transmittal letter

2.0 SLUDGE SAMPLING

NOTE
Sludge sampling will be requested by Environmental Compliance (EC).

2.1 Obtain the following information from EC:

- Sampling locations
- Preservatives to be used
- Container types, sizes, and analytical parameters

2.2 Notify CMRO (at extension 8125 or 8457) prior to entering sewage facility area.

2.3 Set up a portable eye wash station at the sampling location.

2.4 Don PPE.

2.5 Set up decontamination equipment as follows:

2.5.1 Fill two buckets ½ full with DI water.

2.5.2 Add disinfectant to one of the buckets, following the manufacturer's recommended concentration.

WARNING

Liner surface may be slippery. Slips or falls while walking on the liner may result in personnel injury or contamination.

CAUTION

Overflowing prepreserved sample containers can invalidate the sample.

NOTE

Touching the inside of sample containers and caps can cross-contaminate the samples. Sample containers and caps need to remain free of contamination from soil, debris, and blowing sand.

NOTE

Sample chain of custody is established and maintained in accordance with WP 02-EM3001.

2.6 Obtain sample.

2.7 Install sample container cap.

2.8 Rinse outside of sample container with DI water.

2.9 Dry sample container with disposable towel(s).

2.10 Seal sample container with plastic tape.

2.11 Place tamper evidence seal tape on cap so that seal tape will have to be broken to open sample container.

2.12 Date and initial evidence tape.

2.13 Affix sample code labels to sample container.

2.14 Cover label with clear tape.

2.15 Place container in shipping case.

2.16 **IF** additional samples are to be taken at this sample location, **THEN** repeat Steps 2.6 through 2.15.

2.17 Clean and disinfect reusable sampling equipment as follows:

2.17.1 Wash in disinfectant solution.

2.17.2 Rinse in DI water.

2.17.3 Rinse again in free-flowing stream of DI water.

2.18 Repeat Steps 2.6 through 2.17.3 for remaining sample locations.

2.19 Notify CMRO (at extension 8125 or 8457) when leaving sewage facility.

2.20 Dispose of nonreusuable equipment, materials, and trash in a biohazard bag and deliver to the site nurse for disposal.

NOTE

Sample must be handled, packaged, and shipped in accordance with contract laboratory requirements and Shipping Coordination requirements.

2.21 Complete the following documents prior to final packaging of sample containers for shipment:

- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis
- WP 02-EM3001, Attachment 1, Sample Tracking Log Book

2.22 Prepare the following for hand delivered samples:

- Shipping cases
- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis

2.23 If samples are to be shipped via carrier, perform the following:

2.23.1 <u>At least two working days prior to sampling, contact Shipping Coordination for shipping guidance</u>.

2.23.2 Prepare a transmittal letter and WP Form 15-PM3525-1, Shipping Authorization.

2.23.3 Deliver the following to the warehouse for shipment to the contract laboratory:

- Shipping cases
- WP Form 02-EM3001-1, Chain of Custody
- WP Form 02-EM3001-2, Request for Analysis
- WP Form 15-PM3525-1, Shipping Authorization
- Transmittal letter

1.0 INTRODUCTION

This is the implementing document for the Waste Isolation Pilot Plant (WIPP) Groundwater Monitoring Program (GMP). The GMP ensures compliance with the Final WIPP Hazardous Waste Permit mandated by 20 NMAC 4 of the New Mexico Administrative Code incorporating applicable sections of 40 CFR 264 and 40 CFR 265. The GMP also ensures compliance with the WIPP Compliance Certification Application mandated by 40 CFR 191 and 40 CFR 194 of the Code of Federal Regulations. DOE orders 5400.1 and 5400.5, which were the driving documents for the previous groundwater surveillance program, now become secondary to the above mentioned regulatory drivers. The intent of the orders and subsequent documents required by these DOE orders continue to be implemented and carried out by the current GMP. A hierarchy of GMP governing documents are outlined in Figure 1.

The Waste Isolation Pilot Plant (WIPP) is a geologic repository for the disposal of transuranic (TRU) waste. The disposal horizon is located 2,150 feet (ft) (655 meters [m]) below the land surface in the bedded salt of the Salado Formation (hereinafter referred to as the Salado). At WIPP, water-bearing units occur both above and below the disposal horizon. Groundwater monitoring of the uppermost aquifer below the facility is not proposed at WIPP because that water-bearing unit (the Bell Canyon Formation) is not considered a credible pathway for a release from the repository. This is because the repository horizon and water-bearing sandstones of the Bell Canyon Formation are separated by over 2000 ft (610 m) of very low-permeability evaporite sediments. No natural credible pathway has been established for contaminant transport to aquifers below the repository horizon, as there is no hydrologic communication between the repository and underlying aquifers. The U.S. Environmental Protection Agency (EPA) concluded in 1990 that natural vertical communication does not exist based on their review of numerous studies (EPA, 1990). Furthermore, drilling boreholes for groundwater monitoring through the Salado and the Castile Formation (hereinafter referred to as the Castile) into the Bell Canyon aquifer would compromise the isolation properties of the repository medium.

Two types of waste are to be disposed of at the WIPP; TRU waste and TRU mixed waste. Disposal of TRU waste is subject to regulation under 40 CFR 191 and 40 CFR 194.

Disposal of TRU mixed waste in the WIPP facility is subject to regulation under Title 20 of the New Mexico Administrative Code, Chapter 4, Part 1, Subpart V (20 NMAC 4.1.500). As required by 20 NMAC 4.1.500 (incorporating 40 CFR § 264.601), the WIPP intends to demonstrate that the environmental performance standards for all regulatory requirements will be met.

Groundwater monitoring at WIPP in the past has focused on the Culebra member of the Rustler Formation (hereinafter referred to as the Culebra) because it represents the most significant hydrologic contaminant migration pathway to the accessible environment. The Culebra is the most significant water-bearing unit lying above the repository. Modeling of groundwater movement in the Culebra, based on the concept of a groundwater basin, is discussed in detail in Appendix D6, Section D6-2a(1), of the WIPP RCRA Part B Permit Application (DOE, 1997b). Groundwater modeling is also discussed in chapter six of the Compliance Certification Application (DOE, 1996b).

The WIPP site is located in Eddy County in southeastern New Mexico (Figure 2) within the Pecos Valley section of the southern Great Plains physiographic province (Powers et al., 1978). The site is 26 miles (mi) (42 kilometers [km]) east of Carlsbad, New Mexico in an area known as Los Medaños (the dunes). Los Medaños is a relatively flat, sparsely inhabited plateau with little water and limited land uses.

The WIPP site (Figure 2) consists of 16 sections of Federal land in Township 22 South, Range 31 East. The 16 sections of Federal land were withdrawn from the application of public land laws by the WIPP Land Withdrawal Act (LWA), Public Law 102-579. The WIPP LWA transferred the responsibility for the administration of the 16 sections from the Department of Interior, Bureau of Land Management, to the U.S. Department of Energy (DOE). This law specified that mining and drilling for purposes other than support of the WIPP project are prohibited within this 16 section area with the exception of Section 31. Oil and gas drilling activities are restricted in Section 31 from the surface down to 6,000 feet.

This monitoring plan addresses requirements for sample collection, groundwater surface elevation monitoring, groundwater flow direction, data management, and reporting of groundwater monitoring data. It also identifies analytical parameters selected to assess groundwater quality, and establishes personnel responsibilities for the WIPP groundwater detection monitoring program (DMP). Because quality assurance is an integral component of the groundwater sampling, analysis, and reporting process, quality assurance/quality control (QA/QC) elements and associated data acceptance criteria are included in this plan.

Instructions for performing field activities that will be conducted in conjunction with this sampling and analysis plan are provided in field operating procedures. Procedures are required for each aspect of the groundwater sampling process, including groundwater surface elevation measurement, groundwater flow direction, sampling equipment installation and operation, field water-quality measurements, and sample collection. These procedures prescribe proper field sampling techniques. Samples will be collected by trained personnel under the supervision and direction of qualified engineers, scientists, or other technical personnel.

3.0 GEOLOGIC AND HYDROLOGIC CHARACTERISTICS

3.1 Geology

The WIPP site is situated within the Delaware Basin, which is part of the larger Permian Basin, located in the south-central region of North America. During the Permian period, which came to a close about 245 million years ago, ancient seas covered the basin. Their later evaporation resulted in the deposition of a thick sequence of evaporites. Appendix D6 of the WIPP RCRA Part B Permit Application (DOE, 1997b) presents a detailed discussion of the regional geologic history. Three major evaporite-bearing formations were deposited in the Delaware Basin (see Figure 3):

- The Castile, which formed through evaporation of the Permian Sea, consists of interbedded anhydrites and halite. Its upper boundary is at a depth of about 2,825 ft (861 m) below ground surface (bgs), and its thickness at the WIPP facility is 1,250 ft (381 m).

- The repository is located in the Salado, which overlies the Castile and resulted from prolonged desiccation that produced predominantly halite, with some carbonates, anhydrites, and clay seams. Its upper boundary is at a depth of about 850 ft (259 m) bgs, and it is about 2,000 ft (610 m) thick in the repository area.

- The Rustler Formation (hereinafter referred to as the Rustler) was deposited in a lagoonal environment during a major freshening of the basin and consists of carbonates, anhydrites, and halites. Its beds consist of clay and anhydrite and contain small amounts of brine. The Rustler's upper boundary is about 500 ft (152 m) bgs, and it ranges up to 350 ft (107 m) in thickness in the area.

These evaporite-bearing formations lie between two other formations significant to the geology and hydrology of the WIPP site. The Dewey Lake overlying the Rustler is dominated by non-marine sediments and consists almost entirely of mudstone, claystone, siltstone, and interbedded sandstone. This formation forms a 500-ft- (152-m) thick barrier of fine-grained sediments that retard the downward percolation of water into the evaporite units below. The Bell Canyon Formation (hereinafter referred to as the Bell Canyon), the first water-bearing unit below the repository, is confined by the thick evaporite sequences of the Castile above. It consists of 1,200 ft (366 m) of interbedded sandstone, shale, and siltstone.

The Salado was selected to host the WIPP repository for several reasons. First, it is regionally extensive, underlying an area of more than 36,000 square mi (mi^2) (93,240 square kilometers [km^2]). Second, its permeability is extremely low. Third, salt behaves mechanically in a plastic manner under pressure (the pressure at the disposal horizon is more than 2,000 pounds per square inch [lb/in.^{2}] or 13.8 megapascals [MPa]) and eventually moves to fill any opening (referred to as creep). Fourth, any fluid remaining in small fractures or openings is saturated with salt, is incapable of further salt dissolution, and has probably remained in place for millions of years. Finally, the Salado lies between the Rustler and the Castile, which contain very low permeability layers that help confine and isolate waste within and keep water outside of the WIPP.

Further discussions of site geology can be found in Appendix D6 of the RCRA Part B Permit Application and Appendix GCR of the CCA.

3.2 Groundwater Hydrology

The general hydrogeology of the area surrounding the WIPP facility is described in this section starting with the first geologic unit below the Salado. Relevant hydrological parameters for the various rock units above the Salado at WIPP are summarized in Table 1.

3.2.1 The Castile

The Castile is a basin-filling evaporite sequence of sediments surrounded by the Capitan Reef. The Castile represents a major regional groundwater aquitard that effectively prevents upward migration of water from the underlying Bell Canyon. Fluid present in the Castile is very restricted because evaporites do not readily maintain pore space, solution channels, or open fractures at depth. Drill-stem tests conducted in the Castile during construction of the WIPP facility found its permeability to be lower than detection limits; however, the hydraulic conductivity has been conservatively estimated to be less than 10^{-8} ft (3×10^{-9} m) per day.

3.2.2 The Salado

The Salado is an evaporite sequence that filled the remainder of the Delaware Basin and lapped extensively over the Capitan Reef and the back-reef sediments beyond. The Salado consists of approximately 2,000 ft (610 m) of bedded halite, with interbeds or seams of anhydrite, clay, and polyhalite. It acts hydrologically as a regional confining bed. The porosity of the Salado is very low and interconnected pores are probably nonexistent in halite at the depth of the disposal horizon. Fluids associated with the Salado occur mainly as very small fluid inclusions in the halite crystals and also occur between crystal boundaries (interstitial fluid) of the massive crystalline salt formation; fluids also occur in clay seams and anhydrite beds. Permeabilities measured from the surface in the area of the WIPP facility range from 0.01 to 25 microdarcies. The most reliable value, 0.3 microdarcy, was obtained from well DOE-2. The results of permeability testing at the disposal horizon are within the range of 0.001 to 0.01 microdarcy. As a comparison, the permeability of the Salado is roughly a thousand times less than that of a lower clay liner required of surface impoundments and landfills, assuming similar thicknesses.

3.2.3 The Rustler

The Rustler has been the subject of extensive characterization activities because it contains the most transmissive hydrologic units overlying the Salado specifically, the Culebra. Within the Rustler, five members have been identified. Of these, the Culebra is the most transmissive and has been the focus of most of the Rustler hydrologic studies.

The Culebra is the first continuous water-bearing zone above the Salado and is up to approximately 30 ft (9 m) thick. Water in the Culebra is usually present in fractures and is confined by overlying gypsum or anhydrite and underlying clay and anhydrite beds. The hydraulic gradient within the Culebra in the area of the WIPP facility is approximately 20 ft per mi (3.8 m per km) and becomes much flatter south and southwest of the site. Culebra transmissivities in the Nash Draw range up to 1,250 square ft (ft^2) (116 square m [m^2]) per day; closer to the WIPP facility, they are as low as 0.007 to 74 ft^2 (0.00065 to 7.0 m^2) per day. The Culebra is hydrologically confined.

The two primary types of field tests that are being used to characterize the flow and transport characteristics of the Culebra are hydraulic tests and tracer tests.

The hydraulic tests consist of pump, injection, and slug testing of wells across the study area (e.g., Beauheim, 1987a). The most detailed hydraulic test data exist for the WIPP hydropads (e.g., H-19). The hydropads generally comprise a network of three or more wells located within a few tens of meters of each other. Long-term pumping tests have been conducted at hydropads H-3, H-11, and H-19 and at well WIPP-13 (Beauheim, 1987b, 1987c). These pumping tests provided transient pressure data both at the hydropad and over a much larger area. Tests often included use of automated data-acquisition systems, providing high-resolution (in both space and time) data sets.
In addition to long-term pumping tests, slug tests and short-term pumping tests have been conducted at individual wells to provide pressure data that can be used to interpret the transmissivity at that well (Beauheim, 1987a). (Additional short-term pumping tests have been conducted in the Water Quality Sampling Program (WQSP) wells [Stensrud, 1995]). Detailed cross-hole hydraulic testing has recently been conducted at the H-19 hydropad (Kloska et al., 1995).

The hydraulic tests are designed to yield pressure data for estimation of hydrologic characteristics such as transmissivity, permeability, and storativity. The pressure data from long-term pumping tests and the interpreted transmissivity values for individual wells are used for input to flow modeling. Some of the hydraulic test data and interpretations are also important for the interpretation of transport characteristics. For instance, the permeability values interpreted from the hydraulic tests at a given hydropad are needed for interpretations of tracer test data at that hydropad.

There is strong evidence that the permeability of the Culebra varies spatially and varies sufficiently that it cannot be characterized with a uniform value or range over the region of interest to WIPP. The transmissivity of the Culebra varies spatially over six orders of magnitude from east to west in the vicinity of WIPP. Over the site, Culebra transmissivity varies over three to four orders of magnitude. Transmissivities have been calculated at 1×10^{-3} square feet per day (1×10^{-9} square meters per second) at well P-18 east of the WIPP site to 1×10^{3} square feet per day (1×10^{-3} square meters per second) at well H-7 in Nash Draw.

Transmissivity variations in the Culebra are believed to be controlled by the relative abundance of open fractures rather than by primary (that is, depositional) features of the unit. Lateral variations in depositional environments were small within the mapped region, and primary features of the Culebra show little map-scale spatial variability, according to Holt and Powers, 1988. Direct measurements of the density of open fractures are not available from core samples because of incomplete recovery and fracturing during drilling, but observation of the relatively unfractured exposures in the WIPP shafts suggests that the density of open fractures in the Culebra decreases to the east. Qualitative correlations have been noted between transmissivity and several geologic features possibly related to open-fracture density, including (1) the distribution of overburden above the Culebra, (2) the distribution of halite in other members of the Rustler, (3) the dissolution of halite in the upper portion of the Salado, and (4) the distribution of gypsum fillings in fractures in the Culebra.

Measured matrix porosities of the Culebra vary from 0.03 to 0.30. Fracture porosity values have not been measured directly, but interpreted values from tracer tests at the H-3, H-6, and H-11 hydropads vary from 5×10^{-4} to 3×10^{-3}. Data are insufficient to determine whether the average porosity of the matrix and fractures varies significantly on a regional scale.

Geochemical and radioisotope characteristics of the Culebra have been studied. There is considerable variation in groundwater geochemistry in the Culebra. The variation has been described in terms of different hydrogeochemical facies that can be mapped in the Culebra. A halite-rich hydrogeochemical facies exists in the region of the WIPP site and to the east, approximately corresponding to the regions in which halite exists in units above and below the Culebra, and in which a large portion of the Culebra fractures are gypsum filled. An anhydrite-rich hydrogeochemical facies exists west and south of the WIPP site, where there is relatively less halite in adjacent strata and where there are fewer gypsum-filled fractures. Radiogenic isotopic signatures suggest that the age of the ground water in the Culebra is on the order of 10,000 years or more (see, for example, Lambert, 1987; Lambert and Carter, 1987; and Lambert and Harvey, 1987).

The radiogenic ages of the Culebra ground water and the geochemical differences provide information potentially relevant to the groundwater flow directions and groundwater interaction with other units and are important constraints on conceptual models of groundwater flow. Previous conceptual models of the Culebra (see for example, Chapman, 1986; Chapman, 1988; LaVenue et al., 1990) have not been able to consistently relate the hydrogeochemical facies, radiogenic ages, and flow constraints (that is, transmissivity, boundary conditions, etc.) in the Culebra.

However, new conceptual models have been developed for groundwater flow that could explain observed geochemical facies and groundwater flow patterns. The new conceptualization, referred to as the groundwater basin model, offers a three dimensional approach to treatment of Supra-Salado rock units, and assumes vertical leakage (albeit very slow) between rock units of the Rustler exists (where hydraulic head is present).

Flow in the Culebra is considered transient. This differs from previous interpretations, wherein no-flow was assumed between Rustler units. The model assumes that the groundwater system is dynamic and is responding to the drying of climate that has occurred since the late Pleistocene period. The Model assumes that recharge rates during the late Pleistocene period were sufficient to maintain the water table near land surface, but has since dropped significantly. Therefore, the impact of local topography on groundwater flow was greater during wetter periods, with discharge from the Rustler to the west; flow is dominated by more regional topographic effects during drier times, with flow to a more southerly direction.

Four hydrogeochemical facies within the Culebra in the WIPP area (DOE, 1997a) have been identified:

- Zone A - saline (2-3 molal) NaCl brines, Mg/Ca ratio of 1.2 to 2;
- Zone B - dilute (<0.1 molal) $CaSO_4$ - rich ground water;
- Zone C - variable composition (0.3-1.6 molal); Mg/Ca ratio 0.3 to 1.2; and
- Zone D - high salinities (3-7 molal); K/Na weight ratios (0.2).

Facies A groundwater flow is slow, has not changed over the last 14,000 years, and probably recharged more than 600,000 years ago. Vertical leakage occurs to Facies A, and both lateral and vertical groundwater flow rates are extremely low. Facies B occurs in an area with greater vertical fracturing in the Culebra, and therefore exhibits more vertical infiltration and more rapid lateral flow in the Culebra. Flow in Facies B is currently to the south (it may mix with Facies C water to the southeast) but was more toward the west during wetter climates; vertical infiltration from the Dewey Lake to the Culebra Facies B is assumed to have occurred during wetter climates in an area south of the WIPP site. Facies C water was not diluted to create Facies B water. Facies C occurs "in between" Facies A and B, and groundwater flow entered the Culebra prior to the climate change (to drier conditions) 14,000 years ago. Facies C groundwater flow is to the south at WIPP, where it is theorized that it joins with a small amount of Facies A solute being transported from the east. Groundwater flow rate in Facies C is faster than in A but slower than in B, and the proposed recharge area from the Dewey Lake to the Culebra was to the northeast of the WIPP site. Facies C ground water infiltrated into the Dewey Lake and then interacted with anhydrite and halite along its path to the Culebra, wherein it mixed with smaller amounts of Facies A water. The Conclusion can be drawn that the presence of anhydrite within Rustler units does not preclude slow downward infiltration (DOE, 1997a).

Previously, some believed the geochemistry of Culebra ground water was inconsistent with flow directions. This was based on the premise that Facies C water must transform to facies B water (e.g. become "fresher"), which is inconsistent with the observed flow direction. It is now believed that the observed geochemistry and flow directions can be explained with different recharge areas and Culebra travel paths (DOE, 1997a).

Head distribution in the Culebra is consistent with groundwater basin modeling results indicating that the generalized groundwater flow direction in the Culebra is currently north to south. However, the fractured nature of the Culebra, coupled with variable fluid densities, can cause localized flow patterns to differ from general flow patterns.

Groundwater levels in the Culebra in the WIPP region have been measured for several decades. Water-level rises have been observed in the WIPP region and are possibly related to recovery from impacts caused by shaft installation, response to potash effluent discharge, or are unexplained, as discussed below. The extent of water-level rise observed at a particular well depends on several factors, but the proximity of the observation point to the potential cause of the water-level rise appears to be a primary factor.

In the vicinity of the WIPP site, water-level rises are believed to be caused by recovery from drainage into the shafts. Drainage into shafts has been reduced by a number of grouting programs over the years, most recently in 1993 around the Air Intake Shaft. Northwest of the site, in and near Nash Draw, water levels appear to fluctuate in response to effluent discharge from potash mines. Correlation of water-level fluctuation with potash mine discharge, however, cannot be proven definitively because sufficient data on the timing and volumes of discharge are not available. Water-level rises in the vicinity of the H-9 hydropad, about 6.5 miles south of the site, are thought to be caused by neither WIPP activities nor potash mining discharge. They remain unexplained. WIPP continues to monitor groundwater levels throughout the region.

Inferences about vertical flow directions in the Culebra have been made from well data collected. Beauheim (1987a) reported flow directions towards the Culebra from both the underlying unnamed lower member of the Rustler and the overlying Magenta member of the Rustler over the WIPP site, indicating that the Culebra acts as a drain for the units around it. This is consistent with results of groundwater basin modeling. Recent simulations to enhance the conceptual understanding of the geohydrology of the Rustler can be found in Corbet and Knupp, 1996.

Use of water from the Culebra in the WIPP area is quite limited because of its varying yields and high salinity. The Culebra is not used for water supply in the immediate WIPP site vicinity. Its nearest use is approximately 7 mi (11 km) southwest of the WIPP facility, where salinity is low enough to allow its use for livestock watering. However, the Culebra has been identified as a potential aquifer in the Compliance

Certification Application (DOE, 1996b). Because of this, the Culebra will be the focus of future groundwater monitoring at WIPP as it is also the most transmissive continuous water-bearing zone at WIPP and is the most likely pathway for contaminant migration.

Appendix D6 of the WIPP RCRA Part B Permit Application (DOE, 1997b) and appendix Hydro of the Compliance Certification Application (DOE, 1996b) provide more detailed discussions of the local and regional hydrogeology.

4.0 GENERAL REGULATORY REQUIREMENTS

DOE Order 5400.1 contains the following policy statement:

> *POLICY. a. It is DOE policy to conduct its operations in an environmentally safe and sound manner. Protection of the environment and the public are responsibilities of paramount importance and concern to DOE. All DOE activities should recognize and reflect this concern and public trust. To that end, DOE is firmly committed to ensuring incorporation of national environmental protection goals in the formulation and implementation of DOE programs. It has an equal commitment to advance the goals of restoring and enhancing environmental quality, and ensuring public health. Accordingly, it is DOE policy to conduct the Department's operations in compliance with the letter and spirit of applicable environmental statutes, regulations, and standards. In addition, DOE is committed to good environmental management of all its programs and at all its facilities to correct existing environmental problems, to minimize risks to the environment or public health, and to anticipate and address potential environmental problems before they pose a threat to the quality of the environment or the public welfare. Finally, it is DOE's policy that efforts to meet environmental obligations be carried out consistently across all operations and among all field organizations and programs.*

DOE Order 5400.5 states the following:

> *Regulatory Requirements. DOE facilities and operations, in some instances, are subject to the regulatory requirements of the NRC and the EPA, e.g., 10 CFR Parts 60 and 72 and 40 CFR Parts 61, 191, and 192. It is Departmental policy that DOE facilities and operations will comply fully with the requirements of those and other applicable regulatory requirements. In addition, these same DOE facilities and operations shall comply with all applicable requirements in this Order unless they are duplicative or conflict with any of the other Federal regulatory requirements.*

Earlier groundwater programs such as the WQSP and the WIPP Groundwater Surveillance Program (GWSP) were structured to meet the requirements of DOE orders. The current GMP is structured to be inclusive of the DOE Orders mentioned above and meet the requirements of more stringent regulatory drivers.

Because geologic repositories such as the WIPP facility are defined under the Resource Conservation and Recovery Act (RCRA) as land disposal facilities and as miscellaneous units, the groundwater monitoring requirements of 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.600 through 264.603) shall be addressed. 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.90 through 264.101) applies to miscellaneous unit treatment, storage, and disposal facilities (TSDF) only if groundwater monitoring is needed to satisfy 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.601 through 264.603) environmental performance standards.

The New Mexico Environment Department (NMED) has concluded that groundwater monitoring in accordance with 20 NMAC 4.1.500 (incorporating 40 CFR § 264 Subpart F) at WIPP is necessary to meet the requirements of 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.601 through 264.603).

The DOE has demonstrated that the WIPP facility can be operated and closed in a manner that complies with federal standards found in Title 40 of the Code of Federal Regulations, Part 191 (40 CFR Part 191), titled Environmental Radiation Protection Standards for the Management and Disposal of Spent Nuclear Fuel, High-Level and Transuranic Radioactive Waste.

In 1992, the U.S. Congress passed the WIPP Land Withdrawal Act (LWA) which, among other things, mandated that the U.S. Environmental Protection Agency (EPA) certify the DOE's compliance with 40 CFR Part 191, Subparts B and C. The EPA issued the criteria that it intends to use for certification as 40 CFR Part 194, Criteria for the Certification and Re-Certification of the Waste Isolation Pilot Plant's Compliance with the 40 CFR Part 191 Disposal Regulations (61 FR 5224). This application, titled Title 40 CFR Part 191 Compliance Certification Application for the Waste Isolation Pilot Plant, was the DOE submittal to the EPA, requesting certification which was granted in 1997.

5.0 WIPP GROUNDWATER DETECTION MONITORING PROGRAM (DMP) OVERVIEW

5.1 Scope

A RCRA "Groundwater Detection Monitoring Program (DMP) Plan" has been established to define and protect groundwater resources at WIPP. One of the objectives of the WIPP DMP is to establish, by means of groundwater sampling and analysis, an accurate and representative groundwater database that is scientifically defensible and demonstrates regulatory compliance. In addition, the DMP will be used to determine background or existing conditions of groundwater quality and quantity, including groundwater surface elevation and direction of flow, around the WIPP facility area.

The WIPP Compliance Certification Application specifically states:

> *The DOE has addressed the need for monitoring the disposal system during both the preclosure period and the postclosure period in its application for a hazardous waste facility operating permit (see Appendix MON). In its Pre-Closure and Post-Closure (Long-Term) Monitoring Plan (Appendix MON), the DOE incorporates three monitoring programs that will be used to ensure compliance with the hazardous waste regulations of RCRA as implemented by the NMED. These programs include (1) a confirmatory volatile organic compound (VOC) monitoring program to demonstrate that the numerical predictions of VOC releases are reasonable, (2) a groundwater monitoring program to verify knowledge regarding the characteristics of groundwater flow, including periodic testing for releases from the repository, and (3) a geomechanical monitoring program to support decisions regarding operations and maintenance of underground openings. Only the groundwater program is expected to extend into the 30-year RCRA postclosure period. The EPA has established, as a certification criterion, that the monitoring programs in this application must be complementary with the RCRA programs that the DOE will be required to implement.*

This plan governs all groundwater sampling events conducted to meet the requirements of 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.90 through 264.101), as well as 40 CFR 191 and 40 CFR 194 requirements of the CCA. It also ensures that all such data are gathered in accordance with these and other applicable requirements. The groundwater quality data generated by monitoring activities will provide a comprehensive background database against which future analytical results can be compared during the DMP.

Groundwater monitoring at WIPP has been historically conducted by several programs including the WIPP Site Characterization Program, the WIPP WQSP, and recently the GWSP. Groundwater quality and groundwater surface elevation data have been collected by these programs for over 12 years at WIPP. Data from the WQSP wells will be used to continually define changes in the area's potentiometric surface and groundwater flow directions to meet the requirements of the CCA. New monitoring wells included in the WIPP GWSP (WQSP wells 1-6a) were constructed to the specifications provided in the RCRA Groundwater Monitoring Technical Enforcement Guidance Document (EPA, 1986) and constitute the RCRA groundwater monitoring network specified in this DMP as required by 20 NMAC 4.1.500 (incorporating 40 CFR

§§ 264.90 through 264.101). These wells are being used to establish background groundwater quality, groundwater surface elevations and flow directions in accordance with 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.97(f) and (g) and 264.98(e)). Justification for the locations of these wells (3 upgradient and 4 downgradient) is presented below.

5.2 Current WIPP DMP

The WQSP wells 1 through 6a constitute the RCRA DMP for WIPP (Figure 4) during detection monitoring as required by 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.90 through 264.101). This monitoring plan is a continuation of the current WIPP GWSP, and these wells will serve as the monitoring locations during background water-quality characterization and the RCRA DMP (Figure 4).

Wells WQSP-1, WQSP-2, and WQSP-3 were located directly upgradient of the WIPP shaft area. The locations of the three upgradient wells were selected to be representative of the flow vectors of ground water moving downgradient onto the WIPP site. Figure 34 of Davies, 1989, shows the simulation of direction and magnitude of groundwater flow. The upgradient wells were located based on the flow vectors resulting from this model simulation. The original WQSP observation wells, as well as those in the RCRA DMP, have been and will continue to be used as piezometer wells to support collection of groundwater surface elevation and groundwater flow modeling data to demonstrate regulatory compliance(40 CFR 191). Well location surveys for each of the seven wells were performed by survey personnel using the State Plane Coordinates-North American Datum Model 27 method. Results of the surveys are on file with the New Mexico State Engineers Department along with the associated extraction permits for each well.

WQSP-4, WQSP-5, and WQSP-6 were located downgradient of the WIPP shaft area in concert with the flow vectors shown by this model simulation. WQSP-6a was installed in the Dewey Lake Formation at the WQSP-6 location to assess groundwater conditions at this location. All three Culebra downgradient wells (WQSP-4, 5, and 6) were sited based on the greatest velocity magnitude of groundwater flow leaving the shaft area as shown on Figure 34 of Davies, 1989, and upgradient of the WIPP LWA boundary. WQSP-4 was also specifically located to monitor the zone of higher transmissivity around wells DOE-1 and H-11, which may represent faster flow path away from the WIPP shaft area to the LWA boundary (DOE, 1996b).

The Culebra has been selected for the focus of the DMP due to it being regionally extensive and exhibiting the most significant transmissivity of the water-bearing units at WIPP. The Culebra has been extensively studied during all past hydrologic characterization programs and found to be the most likely hydrologic pathway to the accessible environment or compliance point for any potential contamination.

The compliance point is defined in 20 NMAC 4.1.500 (incorporating 40 CFR § 264.95) as the vertical plane immediately downgradient of the hazardous waste management unit area (i.e., at the downgradient footprint of the WIPP repository). RCRA Permit Module V specifies the point of compliance as "the vertical surface located at the hydraulically downgradient limit of the Underground HWDUs that extends to the Culebra Member of the Rustler Formation." The RCRA groundwater monitoring network was not installed immediately downgradient of this plane. However, because the Underground HWDUs at WIPP are Subpart X units, and due to the relatively unique containment and transport aspects of the site, monitoring at the proposed locations will allow for detection of releases prior to release of these contaminants to the general public at the LWA boundary.

The DMP wells were located to intercept flow vectors downgradient away from the WIPP shafts area based on density corrected potentiometric surfaces. The selected well placement locations are downgradient of the general flow direction from the shaft area. Transport modeling of contaminant migration throughout the Culebra to the Land Withdrawal Act boundary suggests that travel times could be on the order of thousands of years if, under worst case conditions, hazardous constituents could migrate from the sealed repository. If contaminants were to migrate from the disposal facility, they would be detected by the DMP wells located midway between the shafts and LWA such that samples from wells could detect these contaminants long before they could reach the LWA boundary.

Potentiometric surfaces and groundwater flow directions defined prior to large-scale pumping in the WIPP area and the excavation of WIPP shafts suggests that flow was generally to the south-southeast from the waste disposal and shaft areas (Mercer, 1983; Davies, 1989). Potentiometric surface maps (December 1998) of the Culebra adjusted for density differences show very similar characteristics (Figure 4). WQSP-4, WQSP-5, and WQSP-6 have been located downgradient of the waste emplacement areas according to adjusted potentiometric surfaces.

Potentiometric surfaces that have not been corrected for density differences and that contain transient relics of previous pumping-drawdown events, do not reflect accurate natural groundwater flow directions and should not be used to assess the adequacy of groundwater monitoring locations.

5.2.1 DMP Well Construction Specification

a. WQSP-1

Well WQSP-1 was drilled between September 13 and 16, 1994, to a total depth of 737 ft (225 m) bgs. The borehole was drilled through the Culebra and extends 15 ft (5 m) into the unnamed lower member of the Rustler. The well was drilled to a depth of 693 ft (211 m) bgs using compressed air as the drilling fluid. The interval from 693 to

737 ft (211 to 225 m) bgs (the total depth) was drilled using air mist with a foaming agent as the drilling fluid. WQSP-10 was drilled to 695.6 ft (212 m) bgs using a 9⅞-in. drill bit and was cored from 695.6 to 737 ft (212 to 225 m) bgs using a 5¼-in. core bit to cut 4-in. diameter core. After coring, WQSP-1 was reamed to 9⅞-in. in diameter to total depth. WQSP-1 was cased from the surface to 737 ft (224.6 m) bgs with 5-in. blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen across the Culebra interval from 702 to 727 ft (214 to 222 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 640 to 651 ft (195 to 198 m) bgs and with 8/16 Brady gravel from 651 to 737 ft (198 to 225 m) bgs. Based on core log results, the Culebra is located from 699 to 722 ft (213 to 220 m) bgs (see Figure 6).

b. WQSP-2

Well WQSP-2 was drilled between September 6 and 12, 1994, to a total depth of 846 ft (257.9 m) bgs. The borehole was drilled through the Culebra and extends 12.3 ft (3.7 m) into the unnamed lower member of the Rustler. The well was drilled to a depth of 800 ft (244 m) bgs with a 9⅞-in. drill bit using compressed air as the drilling fluid. The interval from 800 to 846 ft (244 to 258 m) bgs (the total depth) was drilled with a 5¼-in. core bit to cut 4-in. diameter core using air mist with a foaming agent as the drilling fluid. After coring, WQSP-2 was reamed to 9⅞-in. in diameter to total depth. WQSP-2 was cased from the surface to 846 ft (258 m) bgs with 5-in. blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen across the Culebra interval from 811 to 836 ft (247 to 255 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 790 to 793 ft (241 to 242 m) bgs and with 8/16 Brady gravel from 793 to 846 ft (242 to 258 m) bgs. Based on core log results, the Culebra is located from 810.1 to 833.7 ft (247 to 254 m) bgs (see Figure 7).

c. WQSP-3

Well WQSP-3 was drilled between October 21 and 26, 1994, to a total depth of 880 ft (268 m) bgs. The borehole was drilled through the Culebra and extends 10 ft (3.1 m) into the unnamed lower member of the Rustler. The well was drilled to a depth of 880 ft (268 m) bgs using compressed air as the drilling fluid. The borehole was cleaned using air mist with a foaming agent. WQSP-3 was drilled to 833 ft (254 m) bgs using a 9⅞-in. drill bit and was cored from 833 to 879 ft (254 to 268 m) bgs using a 5¼-in. core bit to cut 4 inch diameter core. After coring, WQSP-3 was reamed to 9⅞-in. in diameter to total depth of 880 ft (268 m) bgs. WQSP-3 was cased from the surface to 880 ft (268 m) bgs with 5-in. blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen across the Culebra interval from 844 to 869 ft (257 to 265 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 827 to 830 ft (252 to 253 m) bgs and with 8/16 Brady gravel from 830 to 880 ft (253 to 268 m) bgs. Based on core log results, the Culebra is located from 844 to 870 ft (257 to 265 m) bgs (see Figure 8).

d. WQSP-4

Well WQSP-4 was drilled between October 5 and 10, 1994, to a total depth of 800 ft (244 m) bgs. The borehole was drilled through the Culebra and extends 9.2 ft (2.8 m) into the unnamed lower member of the Rustler. The well was drilled to a depth of 740 ft (226 m) bgs with a 9⅞-in. drill bit using compressed air as the drilling fluid. The interval from 740.5 to 798 ft (225.7 to 243 m) bgs was cored with a 5¼-in. core bit to cut 4-in. diameter core using air mist with a foaming agent as the drilling fluid. After coring, WQSP-4 was reamed to 9⅞-in. in diameter to total depth of 800 ft (244 m) bgs. WQSP-4 was cased from the surface to 800 ft (244 m) bgs with 5-in. blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen across the Culebra interval from 764 to 789 ft (233 to 241 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 752 to 755 ft (229 to 230 m) bgs and with 8/16 Brady gravel from 755 to 800 ft (230 to 244 m) bgs. Based on core log results, the Culebra is located from 766 to 790.8 ft (233 to 241 m) bgs (see Figure 9).

e. WQSP-5

Well WQSP-5 was drilled between October 12 and 19, 1994, to a total depth of 681 ft (208 m) bgs. The borehole was drilled through the Culebra and extends into the unnamed lower member of the Rustler. The well was drilled to a depth of 676 ft (206 m) bgs using compressed air as the drilling fluid. The borehole was cleaned using air mist with a foaming agent. WQSP-5 was drilled to 648 ft (198 m) bgs using a 9⅞-in. drill bit and was cored from 648 to 676 ft (198 to 206 m) bgs using a 5¼-in. core bit to cut 4-in. diameter core. After coring, WQSP-5 was reamed to 9⅞-in. in diameter to total depth of 681 ft (208 m) bgs. WQSP-5 was cased from the surface to 681 ft (208 m) bgs with 5-in. blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen across the Culebra interval from 646 to 671 ft (197 to 205 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 623 to 626 ft (190 to 191 m) bgs and with 8/16 Brady gravel from 626 to 681 ft (191 to 208 m) bgs. Based on core log results, the Culebra is located from 648 to 674.4 ft (198 to 205.6 m) bgs (see Figure 10).

f. WQSP-6

Well WQSP-6 was drilled between September 26 and October 3, 1994, to a total depth of 616.6 ft (187.9 m) bgs. The borehole was drilled through the Culebra and extends 9.7 ft (3 m) into the unnamed lower member of the Rustler. The well was drilled to a depth of 367 ft (112 m) bgs using compressed air as the drilling fluid. The interval from 367 to 616 ft (112 to 188 m) bgs (the total depth) was drilled using brine as the drilling fluid. WQSP-6 was drilled to 568 ft (173 m) ft bgs using a 9⅞-in. drill bit and was cored from 568 to 616 ft (173 to 188 m) bgs using a 5¼-in. core bit to cut 4-in. diameter core. After coring, WQSP-6 was reamed to 9⅞-in. in diameter to total depth of 616.6 ft (188 m) bgs. WQSP-6 was cased from the surface to 616.6 ft (188 m) bgs with 5-in.

blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen across the Culebra interval from 581 to 606 ft (177 to 185 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 567 to 570 ft (173 to 173.7 m) bgs and with 8/16 Brady gravel from 570 to 616.6 ft (174 to 188 m) bgs. Based on core log results, the Culebra is located from 582 to 606.9 ft (177 to 185 m) bgs (see Figure 11).

g. WQSP-6A

Well WQSP-6A was drilled between October 31 and November 1, 1994, to a total depth of 225 ft (69 m) bgs. It is located approximately 100 feet immediately west of WQSP-6. The borehole was drilled through a water-producing zone in the Dewey Lake Redbeds that had been previously encountered while drilling well WQSP-6. The well was drilled to a depth of 225 ft (69 m) bgs using compressed air as the drilling fluid. The borehole was cleaned using air mist with a foaming agent. WQSP-6A was drilled to 160 ft (49 m) bgs using a 9⅞-in. drill bit and was cored from 160 to 220 ft (49 to 67 m) bgs using a 5¼-in. core bit to cut 4-in. diameter core. After coring, WQSP-6A was reamed to 9⅞-in. in diameter to total depth of 225 ft (69 m) bgs. WQSP-6A was cased from the surface to 225 ft (69 m) bgs with 5-in. blank fiberglass casing with in-line 5-in. diameter fiberglass 0.02-in. slotted screen from 190 to 215 ft (58 to 66 m) bgs. The annulus between the borehole wall and the casing/screen is packed with sand from 172 to 175 ft (52 to 53 m) bgs and with 8/16 Brady gravel from 175 to 225 ft (53 to 69 m) bgs (see Figure 12).

5.3 Well Plugging and Abandonment (P&A)

The main purposes of the P&A program is to reduce CAO liability and potential environmental damage by preventing disturbances to the existing hydrologic conditions in the subsurface domain in the vicinity of the WIPP. The objectives of the P&A program include:

- Eliminate physical hazards
- Prevent groundwater contamination
- Conserve aquifer yield and hydrostatic head
- Prevent intermixing of formation waters
- Comply with state and federal regulations

At the present time, the WIPP area wide groundwater-monitoring network contains more than 70 accessible wells, the majority of which are completed in the Culebra. Most of these wells are in reasonably good operating condition. Wells are selected for P&A based on health and safety factors, condition of the well (i.e. casing, annular seal, and production interval), geographic location, and the ability of the well to yield useful data.

The New Mexico State Engineers Office has regulatory authority over the plugging and abandoning of groundwater production and monitoring wells in the state. The State of New Mexico has several groundwater basins, with each basin having it's own district office providing oversight of groundwater issues. The WIPP area is under the jurisdiction of the Roswell, New Mexico branch of the State Engineers Office. The Roswell office will be the regulatory body to approve the WIPP plans for well P&A.

A proposal may be made to P&A a DMW by submitting a permit modification request to the Secretary in compliance with 20 NMAC 4.1.900 (incorporating 40 CFR 270.42). The DMW must be plugged and abandoned in a manner which eliminates physical hazards, prevents groundwater contamination, conserves hydrostatic head, and prevents intermixing of subsurface water. A report will be submitted to the NMED which summarizes and certifies DMW plugging and abandoning methods within ninety (90) calendar days from the date a DMW is removed from the DMP.

6.0 MONITORING PROGRAM DESCRIPTION

The WIPP DMP has been designed to meet the groundwater monitoring requirements of 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.90 through 264.101) and the CCA. The following sections of the monitoring plan specify the components of the DMP.

6.1 Monitoring Frequency

The seven RCRA monitoring wells have been sampled on a semiannual basis since their installation in 1995 to establish background groundwater quality in accordance with 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.97 and 264.98). This has included at least two full rounds of 20 NMAC 4.1.500 (incorporating 40 CFR § 264) Appendix IX analysis for samples from each of the proposed RCRA detection monitoring wells. In addition, groundwater samples were collected from the DMP wells (from March 1997 until waste emplacement) at a frequency of four sample replicates collected semiannually from each well for the indicator parameters of pH, specific conductance (SC), total organic carbon (TOC), and total organic halogen (TOX) to further establish background groundwater quality until detection monitoring in accordance with 20 NMAC 4.1.500 (incorporating 40 CFR § 264.98) becomes applicable. A total of four rounds of Appendix IX analysis will be conducted for samples from each well for use in background groundwater quality determinations.

Detection monitoring will start with the emplacement of waste and continue through the post-closure phase as required by 20 NMAC 4.1.500 (incorporating 40 CFR § 264.90[c]). During detection monitoring, one sample and one sample duplicate will be collected semiannually from each well in the RCRA detection monitoring network. As shown in Table 2, the DMP will continue to collect groundwater quality samples for all seven wells on a semiannual basis during the life of the DMP. 20 NMAC 4.1.500 (incorporating 40 CFR §264.97[g][2]) provides that an alternate sampling frequency to that provided in 20 NMAC 4.1.500 (incorporating 40 CFR § 264.98) may be proposed. Given the nature and rate of groundwater flow in the area surrounding WIPP, collecting and analyzing one sample semiannually will be protective of human health and the environment because any hazardous constituent leaving the underground disposal facility will not have the potential to migrate beyond the groundwater monitoring network in a one-year time frame. Groundwater flow characteristics are presented in detail in Appendices D6 and E1 of the RCRA Part B Permit Application (DOE, 1997b) and appendix Hydro of the CCA (DOE, 1996b).

Groundwater surface elevations will be monitored in each of the seven DMP wells on a monthly basis. The groundwater surface elevation in each DMP well will also be measured prior to each sampling event. Groundwater surface elevation measurements in the other existing WQSP well sites will also be monitored on a monthly basis to supplement the area water-level database and to help define regional changes in groundwater flow directions and gradients. The characteristics of the RCRA DMP (frequency, location) will be evaluated if significant changes are observed in the groundwater flow direction or gradient. If any change occurs which could affect the ability of the DMP to fulfill the requirements of 20 NMAC 4.1.500 (incorporating 40 CFR § 264 Subpart F), the proper notifications and actions will be taken to comply with applicable permit requirements (Table 5).

6.2 Analytical Parameters

The analytes of interest measured to establish background groundwater quality prior to emplacement of waste include all indicator parameters and all other parameters listed in 20 NMAC 4.1.500 (incorporating 40 CFR § 264) Appendix IX. Field measurements of pH, SC, temperature, chloride, Eh, total iron, and alkalinity are also measured during background sampling.

The DMP will be initiated upon waste emplacement, at which time the semiannual samples will be analyzed for the parameters listed in Table 3. Parameters to be analyzed by the contract laboratory such as specific conductance, total dissolved solids, total suspended solids, density, pH, total organic carbon, and total organic halogens were included as indicator parameters because of their universal commonality to ground water. Parameters such as chloride, alkalinity, calcium, magnesium, and potassium were included as matrix-specific general indicator parameters. Calcium, magnesium, potassium, chloride, and iron may be deleted during detection monitoring, with prior approval of NMED. Organic and inorganic compounds on the right hand side of Table 3 were chosen because they will occur in the waste to be disposed at the WIPP facility. Additional parameters may be identified through the tentatively identified compound (TIC) process resulting from a library search performed by the contracted Laboratory. If compounds are identified, these will be added to the DMP list, unless omission of these compounds is justified, and this omission is approved by NMED.

6.3 Groundwater Surface Elevation Measurement, Sample Collection and Laboratory Analysis

Groundwater surface elevations will be measured in each well prior to groundwater sample collection. Ground water will be extracted using serial and final sampling methods. Serial samples will be collected until groundwater field indicator parameters stabilize, after which the final sample for complete analysis will be collected. Final samples will then be analyzed for the DMP analytical suite.

6.3.1 Groundwater Surface Elevation Monitoring Methodology

The WIPP Water Level Monitoring Program (WLMP) is a subprogram of the DMP. The quality assurance activities of the WLMP are in strict accordance with the WID Quality Assurance Program Description (QAPD), WP 13-1, and the quality assurance implementing procedures specific to groundwater surface elevation monitoring. Groundwater surface elevation monitoring is in progress now and will continue through the post-closure care period. This section of the plan addresses the activities of the WLMP during the preoperational and operational phases of WIPP.

Collection of groundwater surface elevation data is required by 20 NMAC 4.1.500 (incorporating 40 CFR § 264.97(f)) and 40 CFR 191 Performance Assessment. These data also provide:

- Data collection as required by the Environmental Monitoring Plan.
- A means to fulfill commitments made in the Final Environmental Impact Statement (FEIS).
- A means to comply with future groundwater inventory and monitoring regulations.
- Input for making land use decisions, (i.e., designing long-term active and passive institutional controls for the site).
- Assistance in understanding any changes to readings from the water-pressure transducers installed in each of the shafts to monitor water conditions behind the liners.
- An understanding of whether or not the horizontal and vertical gradients of flow are changing over time.

The objective of the WLMP is to extend the documented record of groundwater surface elevation fluctuations in the Culebra and Magenta members of the Rustler in the vicinity of the WIPP facility and to meet the requirements of 20 NMAC 4.1.500 (incorporating 40 CFR § 264.97(f)) and 40 CFR 191, Performance Assessment, and 40 CFR 194.42, Monitoring. Groundwater surface elevation data will be collected from each well of the RCRA DMP. Groundwater surface elevation data will also be collected from other Culebra wells, as well as monitoring wells completed in other water-bearing zones overlying and underlying the WIPP repository horizon when access to those zones is possible (Figure 5). This includes, but is not limited to, the Bell Canyon, the Forty-niner, the contact zone between the Rustler and Salado, and the Dewey Lake.

Groundwater surface elevation measurements will be taken monthly in at least one accessible completed interval at each available well pad. At well pads with two or more wells completed in the same interval, quarterly measurements will be taken in the redundant wells. Groundwater surface elevation measurements will be taken monthly at each of the seven DMP wells, as well as prior to each sampling event. If a cumulative groundwater surface elevation change of more than 2 feet is detected in any DMP well over the course of one year which is not attributable to site tests or natural stabilization of the site hydrologic system, notification will be made to NMED in writing and discuss the origin of the changes in the report specified in Permit Module V. Abnormal, unexplained changes in groundwater surface elevation may indicate changes in site recharge/discharge which could affect the assumptions regarding DMP well placement and constitute new information as specified in 20 NMAC 4.1.900 (incorporating
40 CFR § 70.41(a)(2)).

Groundwater surface elevation monitoring will continue through the post-closure care period. The frequency of monitoring may be temporarily increased to effectively document naturally occurring or artificial perturbations that may be imposed on the hydrologic systems at any point in time. This will be conducted in selected key wells by increasing the frequency of the manual groundwater surface elevation measurements or by monitoring water pressures with the aid of electronic pressure transducers and remote data-logging systems. Such additional data will be included in the reports specified in Section V.J.2 of the RCRA permit.

Interpretation of groundwater surface elevation measurements and corresponding fluctuations over time is complicated at WIPP by spatial variation in fluid density both vertically in well bores and areally from well to well. To monitor the hydraulic gradients of the hydrologic flow systems at WIPP accurately, actual groundwater surface elevation measurements will be monitored at the frequencies specified in Table 2, and the densities of the fluids in the well bores will be measured annually. When both of these parameters are known, equivalent freshwater heads can be calculated. The concept of freshwater head is discussed in Lusczynski (1961).

A discussion explaining the calculation of freshwater heads from mid-formation depth at WIPP can be found in Haug, et al (1987). Freshwater heads are useful in identifying hydraulic gradients in aquifers of variable density such as those existing at the WIPP site. Freshwater head at a given point is defined as the height of a column of freshwater that will balance the existing pressure at that point (Lusczynski, 1961).

Measured groundwater surface elevation data can be converted to equivalent freshwater head from knowledge of the density of the borehole fluid, using the following formula.

$$p = \rho g h$$

where

p = freshwater head (pressure)
ρ = average specific gravity of the borehole fluid (unitless)
g = freshwater density (mass/volume)
h = fluid column height above the datum (length)

If the freshwater density is assumed to be 1.000 gram per cubic centimeter (g/cm^3), then the equivalent freshwater head is equal to the fluid column height times the average borehole fluid density (expressed as specific gravity).

Groundwater surface elevation data will be used to determine the direction and rate of flow in the Culebra at least annually. The results of the determination of direction and flow rate will be presented annually in the Site Environmental Report.

6.3.2 Field Methods and Data Collection Requirements

To obtain an accurate groundwater surface elevation measurement, a calibrated water-level measuring device will be lowered into a test well and the depth to water recorded from a known reference point. When using an electrical conductance probe, the depth to water will be determined by reading the appropriate measurement markings on the embossed measuring tape when the alarm is activated at the surface. WIPP procedures specify the methods to be used in obtaining groundwater-level measurements.

6.3.3 Groundwater Surface Elevation Records and Document Control

All incoming data will be processed in a timely manner to assure data integrity. The data management process for groundwater surface elevation measurements will begin with completion of the field data sheets. Date, time, tape measurement, equipment identification number, calibration due date, initial of the field personnel, and equipment/comments will be recorded on the field data sheets. If, for some unexpected reason, a measurement is not possible (i.e., a test is under way that blocks entry to the well bore), then a notation as to why the measurement was not taken will be recorded in the comment column. Personnel will also use the comment column to report any security observations (i.e., well lock missing).

Data recorded on the field data sheets and submitted by field personnel will be subject to guidelines outlined in WIPP environmental procedures. These procedures specify the processes for administering and managing such data. The data will be entered onto a computerized work sheet. The work sheet will calculate groundwater surface elevation in both feet and meters relative to the top of the casing and also relative to mean sea level. The work sheet will also adjust groundwater surface elevations to equivalent freshwater heads.

A check print will be made of the work sheet printout. The check print will be used to verify that data taken in the field was properly reported on the database printout. A minimum of 10 percent of the spreadsheet calculations will be randomly verified on the check print to ensure that calculations are being performed correctly. If errors are found, the work sheet will be corrected. The data contained on the computerized work sheet will be translated into a database file. A printout will be made of the database file. The data each month will then be compiled into report format and transmitted to the appropriate agencies as requested by the CAO. Groundwater surface elevation data and equivalent freshwater heads for all Culebra wells will be transmitted to NMED one month after data are collected.

A computerized database file will be maintained for all groundwater surface elevation data. Monthly and quarterly data will be appended into a yearly file. Upon verification that the yearly database is free of errors, it will be appended into the project database file. A printed copy of the current project database (through December of the preceding year) will be kept in the Environment, Safety and Health Department (ES&H) EM fire-resistant storage area (Operating Record).

6.4 Groundwater Sampling

6.4.1 Groundwater Pumping and Sampling Systems

The water-bearing units at WIPP are highly variable in their ability to yield water to monitoring wells. The Culebra, the most transmissive hydrologic unit in the WIPP area, exhibits transmissivities that range many orders of magnitude across the site area and is the primary focus of the DMP.

The groundwater pumping and sampling systems used to collect a groundwater sample from the seven DMP wells will provide continuous and adequate production of water so that a representative groundwater sample can be obtained. The wells used for groundwater quality sampling vary in yield, depth, and pumping lift. These factors affect the duration of pumping as well as the equipment required at each well.

The type of pumping and sampling system to be used in a well depends primarily on the aquifer characteristics of the Culebra and well construction. The DMP wells will be individually equipped with dedicated submersible pumping assemblies. Each well has a specific type of submersible pump, matched to the ability of the well to yield water during pumping. The down hole submersible pumps will be controlled by a variable electronic flow controller to match the production capacity of the formation at each well. The electronic flow controller allows personnel collecting samples to control the rate of discharge during well purging to minimize the potential for loss of volatiles from the sample. As recommended in the "RCRA Groundwater Monitoring Technical Enforcement Guidance Document" (EPA, 1986) the wells will be purged a minimum of three well bore volumes at a rate that will minimize the agitation of recharge water. This will be accomplished by monitoring formation pressure and matching the rate of discharge from the well as nearly as possible to the rate of recharge to the well. WIPP procedures specify the methods used for controlling flow rates and monitoring formation pressure. Well purging requirements will be used in conjunction with serial sampling to determine when the groundwater chemistry stabilizes and is therefore representative of undisturbed ground water.

The DMP wells will be cased and screened through the production interval with materials that do not yield contamination to the aquifer or allow the production interval to collapse under stress (high epoxy fiberglass). An electric, submersible pump installation without the use of a packer will be used in this instance. The largest amount of discharge from the submersible pump will take place from a discharge pipe. In addition to this main discharge pipe a dedicated sample line, running parallel to the discharge pipe, will also be used. Flow through the pipe will be regulated on the surface by a flow control valve and/or variable speed drive controller. Cumulative flow will be measured using a totalizing flow meter. Flow from the discharge pipe will be routed to a discharge tank for disposal.

The dedicated sampling line will be used to collect the water sample that will undergo analysis. By using a dedicated sample line, the water will not be contaminated by the metal discharge pipe. The sample line will branch from the main discharge pipe a few inches above the pump. Flow from the sample line will be routed into the sample collection area. Flow through the sample collection line will be regulated by a flow-control valve. The sample line will be insulated at the surface to minimize temperature fluctuations.

6.4.2 Pressure Monitoring Systems

The DMP wells do not require the installation of a packer because sample biases due to well construction deficiencies are not present. However, pressures will be monitored using down hole automatic air line bubblers in the formation to maintain the water level above the pump intake. Pressure transducers may be used in line with bubblers to provide continual electronic monitoring through data acquisition systems. WIPP procedures provide instructions for monitoring formation pressure using automatic airline bubblers in conjunction with pressure transducers and data acquisition systems. The mobile field laboratory provides a work place for conducting field sampling and analyses. The laboratory will be positioned near the wellhead, will be climate controlled, and will contain the necessary equipment, reagents, glassware, and deionized water for conducting the various field analyses.

6.4.3 Sampling Overview

Two types of water samples will be collected: serial samples and final samples. Serial samples will be taken at regular intervals and analyzed in the mobile field laboratory for various physical and chemical parameters (called field indicator parameters). The serial sample data will be used to determine whether the sample is representative of undisturbed ground water as a direct function of the stabilization of field indicator parameters and the volume of the water being pumped from the well. Interpretation of the serial sampling data will enable the Team Leader to determine when conditions representative of undisturbed ground water are attained in the pumped ground water.

Final samples will be collected when the serially sampled field indicator parameters have stabilized and are therefore representative of undisturbed ground water.

a. Serial Samples

Serial sampling is the collection of sequential samples for the purpose of determining when the groundwater chemistry stabilizes and is therefore representative of undisturbed ground water. A serial sample is considered representative of undisturbed ground water when the majority of field indicator parameter measurements have stabilized within ±5 percent of the average of analytical results for the field indicator parameter from the background groundwater quality for each DMP well. Nonstabilization of one or two field indicator parameters attributable to matrix interferences, instrument drift, or other unforeseen reasons will not preclude the collection of final samples, provided the volume of purged water exceeds three well bore volumes. Final samples collected, when field indicator parameters were not stabilized, will be reported in the operating record, and an explanation of why the sample was collected when field indicator parameters were not stabilized will be provided.

Serial samples will be collected and analyzed to detect and monitor the chemical variation of the ground water as a function of the volume of water pumped. Once serial sampling begins, the frequency at which serial samples are collected and analyzed will be left to the discretion of the Team Leader, but will be performed a minimum of three times during a sampling round.

The appropriate field methods to identify stabilization of the following field indicator parameters: chloride, divalent cations (hardness), alkalinity, total iron, pH, Eh, temperature, specific conductance, and specific gravity will be used. Protocols for collection of serial samples are specified in WIPP procedures.

The three field indicator parameters of temperature, Eh, and pH will be determined by either an "in-line" technique, using a self-contained flow cell, or an "off-line" technique, in which the samples will be collected from a sample line at atmospheric pressure. The iron, divalent cation, chloride, alkalinity, specific conductance, and specific gravity samples will be collected from the nylon sample line at atmospheric pressure. Because of the lack of sophisticated weights and measures equipment available for field density assessments, field density evaluations will be expressed in terms of specific gravity, which is a unitless measure. Density is expressed as unit weight per unit volume.

New polyethylene containers will be used to collect the serial samples from the sample line. Serial sampling water collected for solute and specific conductance determinations will be filtered through a 0.45 micrometers (μm) membrane filter using a stainless-steel, in-line filter holder. Filtered water will be used to rinse the sample bottle prior to serial sample collection. Unfiltered ground water will be used when determining temperature, pH, Eh, and specific gravity. Sample bottles will be properly identified and labeled.

The filtered sample collected for solute analyses will be immediately analyzed for iron and alkalinity because these two solution parameters are extremely sensitive to changes in the ambient water-sample pressure and temperature. A sample and duplicate of filtered water will be collected and analyzed for solute parameters (alkalinity, chloride, divalent cations, and iron). Temperature, pH, and Eh, when not measured in a flow cell, will be measured at the approximate time of serial sample collection. These samples will be collected from the unfiltered sample line.

Samples to be analyzed for chloride and divalent cations (after preservation with nitric acid and stored at 4°C) may be stored for one week prior to analysis with confidence that the analytical results will not be altered.

Upon completion of the collection of the last serial sample suite, the serial sample bottles accrued throughout the duration of the pumping of the well will be discarded. No serial sample bottles will be reused for sampling purposes of any sort. However, serial samples may be stored for a period of time depending upon the need.

During the first two years of DMP well serial sampling, the first sample will be analyzed as soon as possible after the pump is turned on and daily thereafter for a period of four days or until the field indicator parameters (chloride, divalent cations, alkalinity, and iron) stabilize. Eh, pH, and SC will be continually monitored by using a flow cell with ion-specific electrodes and a real-time readout. When detection monitoring begins, the serial sampling process may be modified and the decision to collect final samples would then be based on the number of well bore volumes purged and results of the analysis of chloride, temperature, specific gravity, pH, Eh, and SC. Removal of serial sampling from the DMP will be accomplished through a permit modification and a modification to this plan.

b. Final Samples

The final sample will be collected once the measured field indicator parameters have stabilized. A serial sample will also be collected and analyzed for each day of final sampling to ensure that samples collected for laboratory analysis are still representative of stable conditions. Sample preservation, handling, and transportation methods will maintain the integrity and representativeness of the final samples.

Prior to collecting the final samples, the collection team shall consider the analyses to be performed so that proper shipping or storage containers can be assembled. Table 4 presents the sample containers, volumes, and holding times for laboratory samples collected as part of the DMP.

The monitoring system will use dedicated pumping systems and sample collection lines from the sampled formation to the well head. Non-dedicated sample collection lines from the well head to the sample collection area will be discarded after each use.

Sample integrity will be ensured through appropriate decontamination procedures. Laboratory glassware will be washed after each use with a solution of nonphosphorus detergent and deionized (DI) water and rinsed in DI water. Sample containers will be new, certified clean containers that will be discarded after one use. Groundwater surface elevation measurement devices will be rinsed with fresh water after each use. Non-dedicated sample collection manifold assemblies will be rinsed with two gallons of fresh water, then rinsed with five gallons of 5 percent nitric acid solution and rinsed with five gallons of DI water after each use. The exposed ends will be capped off during storage. Prior to the next use of the sampling manifold, it will be rinsed a second time with DI water and a blank rinsate sample will be collected to verify decontamination.

Water samples will be collected at atmospheric pressure using either the filtered or unfiltered sampling lines branching from the main sample line. Detailed protocols, in the form of procedures, assure that final samples will be collected in a consistent and repeatable fashion.

Final samples will be collected in the appropriate type of container for the specific analysis to be performed. The samples will be collected in new and unused glass and plastic containers (refer to Table 4). For each parameter analyzed, a sufficient volume of sample will be collected to satisfy the volume requirements of the analytical laboratory (as specified by laboratory Standard Operating Procedures [SOPs]). This includes an additional volume of sample water necessary for maintaining quality control standards. All final samples will be treated, handled, and preserved as required for the specific type of analysis to be performed. Details about sample containers, preservation, and volumes required for individual types of analyses are found in the applicable procedures generated, approved, and maintained by the contract analytical laboratory.

Before the final sample is taken, all plastic and glass containers will be rinsed with the pumped ground water, either filtered or unfiltered, dependent upon analysis protocol. When the rinsing procedure is completed the final sample will be collected.

Final samples will be sent to contract laboratories and analyzed for general chemistry, radionuclides, metals, and selected VOCs that are specific to the waste anticipated to arrive at WIPP. Table 3 presents the specific analytes for the DMP.

WIPP has not accepted TRU mixed waste for disposal prior to issuance of a hazardous waste disposal permit, and previous WQSP sample analyses have shown that requested hazardous constituents have not been introduced to the ground water in the vicinity of WIPP by other activities. Appendix D18, Attachment A, of the RCRA Part B Permit Application (DOE, 1997b) presented analytical data obtained from WQSP wells 1-6 which indicated that, for the Appendix IX parameters analyzed for, none of the anticipated waste constituents presented on Table 3 were present in sampled ground water at WIPP.

Duplicates of the final sample will be provided to WIPP oversight agencies as requested by the CAO or NMED.

Resulting wastes are disposed of in accordance with the WID "Site Generated, Non-Radioactive Hazardous Waste Management Plan," WP 02 -RC.01.

6.4.4 Sample Preservation, Tracking, Packaging, and Transportation

Many of the chemical constituents measured by the DMP are not chemically stable and require preservation and special handling techniques. Samples requiring acidification will be treated with either high purity hydrochloric acid, nitric acid, or sulfuric acid (ULTREX or equivalent), depending upon the standard method of treatment required for the particular parameter suite or as requested by contract laboratory SOPs (see Table 4).

The contract laboratory receiving the samples will use procedures that prescribe the type and amount of preservative, the container material type, and the required sample volumes that shall be collected. This information will be recorded on the Final Sample Checklist for use by field personnel when final samples are being collected. EPA "RCRA Groundwater Monitoring Technical Enforcement Guidance Document," Table 4-1 (EPA, 1986), will be followed if laboratory SOPs do not specify sample container, volume, or preservation requirements.

The sample tracking system at WIPP will use uniquely numbered chain of custody (CofC) Forms and request for analysis (RFA) Forms. The primary consideration for storage or transportation is that samples shall be analyzed within the prescribed holding times for the parameters of interest. WIPP procedures provide instructions to ensure proper sample tracking protocol.

Insulated shipping containers packaged with crushed ice or reusable ice packs will be used to keep the samples cool during transport to the contract laboratory. Holding times for specific analytical parameters require samples to be shipped by express air freight. The coolers will be packaged to meet Department of Transportation and International Air Transportation Association commercial carrier regulations.

6.4.5 Sample Documentation and Custody

To ensure the integrity of samples from the time of collection through reporting date, sample collection, handling, and custody shall be documented. Sample custody and documentation for EM sampling and analysis activities are detailed in WIPP procedures. These procedures will be strictly followed throughout the course of each sample collection and analysis event.

Standardized forms used to document samples will include sample identification numbers, sample labels, custody tape, the sample tracking log books, and the request for analysis/chain of custody (RFA and CofC) form. The forms are briefly defined in the following subsections.

All sample documentation will be completed for each sample and reviewed by the Team Leader or his/her designee for completeness and accuracy.

a. Sample Numbers and Labels

A unique sample identification number will be assigned to each sample sent to the laboratory for analysis. The Team Leader will assign the numbers prior to sample collection. The sample identification numbers will be used to track the sample from the time of collection through data reporting. Every sample container sent to the laboratory for analysis will be identified with a label affixed to it. Sample label information will be completed in permanent, indelible ink and will contain the following information: sample identification number with sample matrix type; sample location; analysis requested; time and date of collection; preservative(s), if any; and the sampler's name or initials.

b. Custody Seals

Custody seals will be used to detect unauthorized sample tampering from collection through analysis. The custody seals will be adhesive-backed strips that are destroyed when removed or when the container is opened. The seal will be dated, initialed, and affixed to the sample container in such a manner that it is necessary to break the seal to open the container. Seals will be affixed to sample containers in the field immediately after collection. Upon receipt at the laboratory, the laboratory custodian will inspect the seal for integrity; a broken seal will invalidate the sample.

c. Sample Tracking Logbook

A sample tracking logbook (STLB) form will be completed for each sample collected. The STLB will include the following information: C of C number; RFA No.; date sample(s) were sent to the lab; laboratory name; acknowledgment of receipt or comments; well name and round number. Sample codes will indicate the well location; the geologic formation where the water was collected from, the sampling round number; and the sample number. The code is broken down as follows:

WQ6[1]C[2]R2[3]N1[4]

[1] Well identification (e.g., WQSP-6 in this case)
[2] Geologic formation (e.g., the Culebra in this case)
[3] Sample round no. (Round 2)
[4] Sample no. (N1)

To distinguish duplicate samples from other samples, a "D" is added as the last digit to signify a duplicate. STLB information will be completed in the field by the sampling team and checked by the Team Leader. When samples are shipped, the STLB will remain in the custody of the EM Section for sample tracking purposes.

d. Request for Analysis and Chain of Custody

An RFA and CofC form will be completed during or immediately following sample collection and will accompany the sample through analysis and disposal. The RFA and CofC form will be signed and dated each time the sample custody is transferred.
A sample will be considered to be in a person's custody if: the sample is in his/her physical possession; the sample is in his/her unobstructed view; and/or the sample is placed, by the last person in possession of it, in a secured area with restricted access. During shipment, the carrier's air bill number serves as custody verification. Upon receipt of the samples at the laboratory, the laboratory sample custodian acknowledges possession of the samples by signing and dating the RFA and CofC. The completed

original (top page) of the RFA and CofC will be returned to the Team Leader with the laboratory analytical report and becomes part of the permanent record of the sampling event. The RFA and CofC form also contains specific instructions to the laboratory for sample analysis, potential hazards, and disposal instructions.

6.5 Laboratory Analysis

Analysis of samples will be performed by a commercial laboratory. Methods will be specified in procurement documents and will be selected to be consistent with EPA recommended procedures in SW 846 (EPA, 1996). Additional detail on analytical techniques and methods will be given in laboratory SOPs. Table 3 presents the analytical parameters for the WIPP DMP.

The WID has established criteria for laboratory selection, including the stipulation that the laboratory follow the procedures specified in SW 846 and that the laboratory follow EPA protocols. The selected laboratory shall demonstrate, through laboratory SOPs, that it will follow appropriate EPA SW 846 requirements and the requirements specified by the EPA protocols. The laboratory shall also provide documentation to the WIPP describing the sensitivity of laboratory instrumentation. This documentation will be retained in the facility operating record and will be available for review upon request by an authorized agency. Instrumentation sensitivity needs to be considered because of regulatory requirements governing constituent concentrations in ground water and the complexity of brines associated with the WIPP repository.

Once the initial qualification criteria, as specified above, have been met, a laboratory will be selected based upon competitive bid. The selected laboratory will perform analytical work for the DMP for a predetermined period of time, as specified in the contract between the WID and the selected laboratory. As this period of performance comes to an end, a new laboratory selection/competitive bid process will be initiated by the DMP. The same or a different laboratory may be selected for the new contract period. The SOPs for the laboratory currently under contract will be maintained in a file in the operating record. An initial set of SOPs will be provided to the NMED for information purposes along with any SOP updates on an annual basis.

Data validation will be performed by WID Environmental Monitoring. Data validation results are documented on an Approval/Variation Request (AR/VR) form. If no discrepancies are found in the data, the AR/VR form will be signed and the approved box will be checked. If however, discrepancies are found, the AR/VR form will be signed and the disapproved or approved-on-condition box will be checked and the form will be returned to the team leader accompanied by an attached report discussing the data validation results, any anomalies, and resolutions. Copies of the data validation report will be distributed to the EM Manager, QA Manager, the Team Leader, and the Contract Administrator. Copies of the data validation report will be kept on file in the EM records section for review upon request by NMED.

7.0 CALIBRATION

7.1 Sampling Equipment Calibration Requirements

The equipment used to collect data for the WQSP and this DMP will be calibrated in accordance with maintenance administrative procedures. The EM Section will be responsible for calibrating needed equipment on schedule, in accordance with written procedures. The EM Section will also be responsible for maintaining current calibration records for each piece of equipment.

7.2 Groundwater Surface Elevation Monitoring Equipment Calibration Requirements

The equipment used in taking groundwater surface elevation measurements will be maintained in accordance with WIPP procedures. The EM Section will be responsible for calibrating the needed equipment on schedule in accordance with written procedures. The EM Section will also be responsible for maintaining current calibration records for each piece of equipment.

8.0 STATISTICAL ANALYSIS OF LABORATORY DATA

As required by 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264.97 and 264.98), data collected to establish background groundwater quality and as part of the DMP will be evaluated using appropriate statistical techniques. The following specifies the statistical analysis to be performed by the DMP. Statistical analysis of DMP data will conform to EPA guidance "Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities (EPA, 1989), "Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities, Addendum to Interim Final Guidance" (EPA, 1992), and DOE/EH-0173T, "Environmental Regulatory Guide for Radiological Effluent Monitoring and Environmental Surveillance".

8.1 Temporal and Spatial Analysis

Environmental parameters vary with space and time. The effect of one or both of these two factors on the expected value of a point measurement will be statistically evaluated through spatial analysis and time series analysis. These methods often require extensive sampling efforts that may exceed the practical limits of the DMP sampling procedures.

Spatial analysis may have limited use during the operational period, although the effect of spatial auto-correlation on the interpretation of the data will be considered for each parameter. Spatial variability will be accounted for by the use of predetermined key sampling locations. Data analysis will be performed on a location-specific basis, or data from different locations will be combined only when the data are statistically homogeneous. Statistical homogeneity will be determined by evaluating mean values and variances from the residuals from the individual well data.

Time series analysis plays a more important role in data analysis for the DMP. Parameters will be reported as time series, either in tabular form or as time plots. For key time series parameters, these plots will be in the form of control charts on which control levels will be identified based on preoperational database, fixed standards, control location databases, or other standards for comparison. Where significant seasonal changes in the expected value of the parameter are identified in the preoperational database or in the control locations, corrections in the control levels which reflect the seasonal change will be made and documented.

8.2 Distributions and Descriptive Statistics

For data sets which include more than ten data points that are homogeneous in space and time (including seasonal homogeneity) and have less than ten percent missing data, a test for conformance to the normal distribution will be performed. The test for normality of the data will be performed in accordance with the methodologies presented in "Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities, Addendum to Interim Final Guidance" (EPA, 1992). Examples of test performed on the data are Shapiro-Wilk Test or Olmogorov-Smirnov Test at the 95% confidence level, there is only a one-in-twenty chance of falsely identifying the distribution as normal when it really is not.

If normality is not met, the data will be log-transformed (or transformed using a suitable mathematical transformation, e.g., square root) and retested for normality. If the transformed data fit a normal distribution, the original data will be accepted as having lognormal or an otherwise mathematically-transformed normal distribution. If normality is still not found, two courses may be taken. One will be to continue to test the fit to standard families of distributions, such as the gamma, beta, and Weibull, with proper modifications to subsequent analyses based on these results. The other course will be to use nonparametric methods of data analysis. Non-radiological data sets with greater than 15 percent nondetect are automatically treated as nonparameteric distributions.

For data sets smaller than ten, but homogeneous and complete, the lognormal distribution will be assumed. Data sets with more than ten percent missing data will be analyzed using nonparametric methods. Nonhomogeneous data sets will be subdivided into homogeneous sets and each of these analyzed individually.

Descriptive statistics will be calculated for each homogeneous data set. At a minimum, these include a central value and a range of variation. The central value is the arithmetic mean of the untransformed data if the data are not censored at either end. If the data are censored, either a trimmed mean or the median will be used as the central value (which may be within the censored range). If the data set is greater than ten and is uncensored, the standard deviation will be calculated and used as a basis for the reported range in variation. If these criteria are not met, the range between the 0.25 and 0.75 cartelist will be used. Radiological normally distributed data with a small number of extreme or less than detectable values, the arithmetic mean is the estimator of central tendency. When data set contains large extreme values, the median, which is less sensitive to extreme values than the mean, will be used to summarize the data. All of the actual values, including those that are negative will be included in the statistical analysis for radiological data. Radiological data will also be transformed to approximate a normal distribution before the central values are calculated. Most often a log transformation will normalize environmental data.

8.3 Data Anomalies

Data anomalies include data points reported as being below the limit of detection (LD) or otherwise censored over a specific range of values, missing data points occurring randomly in the data set, and outliers that cannot be ascribed to a known source of variation.

Whenever possible, sample values which are reported below detection limits will be incorporated into the database as sample values measured at one-half the detection limit for statistical analysis. When values are not available, alternative methods of analysis, as specified in previous sections, will be used. In particular, the use of nonparametric statistics will be required.

Missing data points comprising less than 10 percent of the data set do not significantly affect data analyses. Results based on data in which more than 10 percent is missing will be identified as such at the time of reporting. Consideration of the potential effect of missing data shall be made when the majority of the data are missing from a discrete time span.

Formal testing for outliers will only be done in accordance with EPA guidance.
The methodologies specified in Section 8.2 of the "Statistical Analysis of Groundwater Monitoring Data at RCRA Facilities" (EPA, 1989) will be used to check for outliers.

If an outside source of variation is not identified to account for outliers in a data set, it will be included in the data set and all subsequent analyses. If the inclusion of such outliers is found to affect the final results of the analyses significantly, both results (with and without outliers) will be reported. Radiological outliers will be tested with respect to the mean or median of the entire data set for outliers. Trend analyses on radiochemical data will be performed by comparing the results for the current year with the results of last several years to identify changes or inconsistencies in the results. Radiological data will also be plotted in time series for historical comparison. Data points falling outside ± 3 standard deviations could be considered outliers. Time plot and other yearly or seasonal trends in the data should be considered to reject/accept outliers.

9.0 COMPARISONS AND REPORTING

Prior to waste receipt, measurements will have been made of each background groundwater quality parameter and constituent specified in Table 3 at every DMP groundwater monitoring well during each of the four background sampling events. If any background groundwater quality parameter or constituent has not been measured prior to waste receipt, measurements will be made for those parameters or constituents in hydraulically upgradient DMP groundwater monitoring wells for a sequence of four sampling events. Following completion of the four sampling events, the arithmetic mean and variance shall then be calculated by the field supervisor or designee for each well. These measurements will then serve as a background value against which statistical values for subsequent sampling events during detection monitoring will be compared. Statistical analysis and comparison will be accomplished within sixty (60) days after the final sample is taken, using one of the five statistical tests specified in 20 NMAC 4.1.500 (incorporating 40 CFR § 264.98(h)), which may include Cochran's Approximation to the Behrens-Fisher students' t-test at the 0.01 level of significance (described in Appendix IV to 20 NMAC 4.1.500 (incorporating 40 CFR §264). If the comparisons show a significant increase at any monitoring site (as defined in 20 NMAC 4.1.500 (incorporating 40 CFR § 264.98(f)), the well shall be resampled and an analysis performed as soon as possible, in accordance with 20 NMAC 4.1.500 (incorporating 40 CFR § 264.98(g)(2))(Final WIPP Hazardous Waste Permit Requirement V.J.3.b). The results of the statistical comparison will be reported annually in the Annual Site Environmental Report (ASER), and will be reported to NMED as stated in module V, section V.J.3 of the Final WIPP Hazardous Waste Permit and as required under 20 NMAC 4.1.500 (incorporating 40 CFR § 264.98(g)).

9.1 Reporting

9.1.1 Laboratory Data Reports

Laboratory data will be provided in electronic and hard copy reports. Laboratory data reports will be forwarded to the Team Leader and NMED and will contain the following information for each analytical report:

- A brief narrative summarizing laboratory analyses performed, date of issue, deviations from the analytical method, technical problems affecting data quality, laboratory quality checks, corrective actions (if any), and the project manager's signature approving issuance of the data report.

- Header information for each analytical data summary sheet including: sample number and corresponding laboratory identification number; sample matrix; date of collection, receipt, preparation and analysis; and analyst's name.
- Analytical parameter, analytical result, reporting units, reporting limit, analytical method used.
- Results of QC sample analyses for all concurrently analyzed QC samples.

9.1.2 Statistical Analysis and Reporting of Results

Analytical results from semi-annual groundwater sampling activities will be compared and interpreted by the Team Leader through generation of statistical analyses as specified in Section L-4e of the Final WIPP Hazardous Waste Permit. The Team Leader will perform statistical analyses; the results will be included in the ASER in summary form, and will also be provided to NMED as specified in Permit Module V (Final WIPP Hazardous Waste Permit section V.J.2).

9.1.3 Annual Site Environmental Report

Data collected from this DMP will be reported to NMED as specified in Permit Module V, and to the EM Manager and NMED in the ASER. The ASER will include all applicable information that may affect the comparison of background groundwater quality and groundwater surface elevation data through time. This information will include but is not limited to:

- Well configuration changes that may have occurred from the time of the last measurement (i.e., plug installation and removal, packer removal and reinstallation, or both; and the type and quantity of fluids that may have been introduced into the test wells).
- Any pumping activities that may have taken place since publication of the last annual report (i.e., groundwater quality sampling, hydraulic testing, and shaft installation or grouting activities).

The DMP data used in generating the ASER will be maintained as part of the WIPP operating record and will be provided to NMED for review as specified in the permit.

10.0 RECORDS MANAGEMENT

Records generated during groundwater sampling and groundwater surface elevation monitoring events will be maintained in the form project files (operating record) in the EM section. Project records will include, but are not limited to:

- Sampling and Analysis Plans (SAP)
- SOPs
- STLBs
- RFA and CofC forms
- Contract Analytical Laboratory Data Reports
- Variance Logs and Nonconformance Reports
- Corrective Action Reports

These and all raw analytical records generated in conjunction with groundwater sampling and groundwater surface elevation monitoring will be stored in fire resistant cabinets in the EM section according to the Records Management Program (WP 15-PR) and the Records Inventory and Disposition Schedule (RIDS) and will be made available for inspection upon request. The following records will be transmitted to the Project Records Services (PRS) for long-term storage in accordance with the RIDS:

- Instrument maintenance and calibration records
- QC sample data
- Control charts and calculation
- Sample tracking and control documentation
- Raw analytical results

11.0 PROJECT ORGANIZATION AND RESPONSIBILITIES

11.1 Environmental Monitoring Manager

The EM Manager will be responsible for the overall design and implementation of the DMP. The EM Manager will develop and approve specific procedures all DMP activities, and will review and approve programmatic reports. The EM Manager will provide oversight of appropriate levels of cooperation and consultation between the EM Section and the State of New Mexico regarding environmental monitoring and will revise the QA section of the DMP, if necessary, and submit revisions as permit modifications as specified in 20 NMAC 4.1.900 (incorporating 40 CFR § 270.42).

The EM Manager and staff will be responsible for achieving and maintaining quality in the DMP. All DMP data will be reviewed and approved by the EM Manager, or designee, prior to release.

The EM Manager will establish minimum qualification criteria and training requirements for all DMP personnel. The EM Manager will assure that position descriptions for assigned DMP personnel are adequately prepared. The EM Manager and/or Team Leader will assure that training is performed on an individual basis to maintain an acceptable level of proficiency by all new or temporary DMP staff and by all permanent GWSP staff. The EM Manager will assure that documents detailing all staff training are current and properly filed. Copies of training records will be on file in the WID Technical Training Section.

The EM Manager will appoint a DMP Team Leader and Field Team, and assign the following responsibilities specified below.

11.2 Team Leader

The Team Leader will coordinate and oversee field sampling activities, ensuring that sampling and associated procedures will be followed and that QA/QC and safety guidelines will be met. The Team Leader will direct the DMP per written approved procedures, and initiate the review of programmatic plans and procedures. The Team Leader will review and evaluate sample data, prepare and review programmatic reports, and assure that appropriate samples will be collected and analyzed. The Team Leader will assure that adequate technical support is provided to the QA Department, when required during audits of vendor facilities. Any nonconformances or project changes will be immediately communicated to the Team Leader.

11.3 Field Team

The field team members will consist of one or more scientists, engineers, or technicians, who will be responsible for sample collection, handling, shipping, and preparation and maintenance of appropriate data sheets, and completion of sample tracking documentation under the direction of the Team Leader, in accordance with this DMP and associated field procedures. The field team will inspect, maintain, and ensure proper calibration of equipment prior to use at each site, while ensuring that site health and safety requirements will be met at all times. The field team will communicate any nonconformances, malfunctions, or project changes to the Team Leader immediately.

11.4 Safety Manager

The Safety Manager will be responsible for ensuring that the necessary requirements for the health and safety of personnel associated with sampling and analysis activities are met. The cognizant manager will be responsible for ensuring that field team members operate in a safe manner and personnel have appropriate training.
The Safety Manager will ensure that periodic health and safety assessments are conducted and that the cognizant manager will initiate corrective actions where deficiencies are identified.

11.5 Analytical Laboratory Manager

Sample collection containers supplied by the laboratory will be certified as clean by either the laboratory or their supplier. The WIPP will supply containers for radiological samples. The analytical laboratory will be responsible for performing analyses in accordance with this DMP Plan and regulatory requirements. The laboratory will maintain documentation of sample handling and custody, analytical results, and internal QC data. Additionally, the laboratory will analyze QC samples in accordance with this plan and its own internal QC program for indicators of analytical accuracy and precision. Data generated outside laboratory acceptance limits will trigger an investigation and, if appropriate, corrective action, as directed by the EM Manager. The laboratory will report the results of the environmental sample and QC sample analyses and any necessary corrective actions that were performed. In the event that more than one analytical laboratory is used (e.g., for different analyses), each one will have the responsibilities specified above.

11.6 Quality Assurance (QA) Manager

The QA Manager will provide independent oversight of the DMP, via the assigned cognizant QA engineer, to verify that quality objectives are defined and achieved. The QA Manager will ensure objective, independent assessments of the DMP quality performance and the quality performance of the contract analytical laboratory. The QA Manager has been delegated authority on behalf of the WID General Manager and will have access to work areas, identify quality problems, initiate or recommend corrective actions, verify implementation of corrective actions, and ensure that work will be controlled or stopped until adequate disposition of an unsatisfactory condition has been implemented.

12.0 QUALITY ASSURANCE REQUIREMENTS

Specific Quality Assurance (QA) requirements for WIPP are defined in the WID Quality Assurance Program Description (QAPD), WP 13-1. Requirements specific to the DMP are presented in this section.

12.1 QA Program Review

The QA program was developed to assure that integrity and quality will be maintained for all samples collected and that equipment and records will be maintained in accordance with EPA guidance. The QA Program identifies data quality objectives (DQO), processes for assuring sample quality, and processes for generating and maintaining quality records.

12.1.1 Data Quality Objectives (DQOs)

DQOs are qualitative and quantitative statements that specify the quality of data required to support project decisions. DQOs will be established to ensure that the data collected will be of a sufficient and known quality for their intended uses. The overall DQO for this project will be to collect accurate and defensible data of known quality that will be sufficient to assess the concentrations of constituents in the ground water underlying the WIPP area. The data generated thus far by the DMP has been used to establish background groundwater quality. For the purpose of this DMP, DQOs for measurement data will be specified in terms of accuracy, precision, completeness, representativeness, and comparability. Measurements of data quality in terms of accuracy and precision will be derived from the analysis of QC samples generated in the field and laboratory. Appropriate QC procedures will be used so that known and acceptable levels of accuracy and precision will be maintained for each data set. This section defines the acceptance criteria for each QC analysis performed. The following subsections define each DQO.

a. Accuracy

Accuracy is the closeness of agreement between a measurement and an accepted reference value. When applied to a set of observed values, accuracy is a combination of a random component and a common systematic error (bias) component. Measurements for accuracy will include analysis of calibration standards, laboratory control samples, matrix spike samples, and surrogate spike samples. The bias component of accuracy is expressed as percent recovery (%R). Percent recovery is expressed as follows:

$$\%R = \frac{(measured\ sample\ concentration)}{true\ concentration} x\ 100$$

1. Accuracy Objectives for Field Measurements

Field measurements will include pH, SC, temperature, Eh, and static groundwater surface elevation. Field measurement accuracy will be determined using calibration check standards. Thermometers used for field measurements will be calibrated to the National Institute for Standards and Technology (NIST) traceable standard on an annual basis to assure accuracy. Accuracy of groundwater surface elevation measurements will be checked before each measurement period by verifying calibration of the device within the specified schedule. The QAPD, Section 2.4.4, Monitoring, Measuring, Test and Data Collection Equipment, outlines the basic requirements for field equipment use and calibration. WP10-AD.01 "Metrology Program" contains instructions that outline protocols for maintaining current calibration of groundwater surface elevation measurement instrumentation.

2. Accuracy Objectives for Laboratory Measurements

Analytical system accuracy will be quantified using the following laboratory accuracy QC checks: calibration standards, laboratory control samples (LCS), laboratory blanks, matrix and surrogate spike samples. Single LCSs and matrix spike and surrogate spike sample analyses will be expressed as %R. Laboratory analytical accuracy is parameter dependent and will be prescribed in the laboratory SOP.

b. Precision

Precision is the agreement among a set of replicate measurements without assumption or knowledge of the true value. Precision data will be derived from duplicate field and laboratory measurements. Precision will be expressed as relative percent difference (RPD), which is calculated as follows:

$$RPD = \frac{|(measured\ value\ sample\ 1 - measured\ value\ sample\ 2)|}{average\ of\ measured\ samples\ 1 + 2} x\ 100$$

1. Precision Objectives for Field Measurements

Precision of field measurements of water-quality parameters will meet or exceed required reporting levels. SC, pH, temperature, and optionally Eh will be measured during well purging and after sampling. SC measurements will be precise to ±10% pH to 0.10 standard unit, and temperature to 0.10 degrees Celsius (°C), Eh to 10 millivolts (mV).

c. Precision Objectives for Laboratory Measurements

Precision of laboratory analyses will be assessed by performing the same analyses twice on LCSs with each analytical batch assessed at a minimum frequency of 1 in 20 groundwater samples for nonradiological parameters and 1 in 10 for radiological parameters. The laboratory will determine analytical precision control limits by performing replicate analyses of control samples. Precision measurements will be expressed as RPD. Laboratory analytical precision is also parameter dependent and will be prescribed in laboratory SOPs.

d. Contamination

In addition to measurements of precision and bias, QC checks for contamination will be performed. QC samples including trip blanks, field blanks, and method blanks will be analyzed to assess and document contamination attributable to sample collection equipment, sample handling and shipping, and laboratory reagents and glassware. Trip blanks will be used to assess volatile organic compound (VOC) sample contamination during shipment and handling and will be collected and analyzed at a frequency of one sample per sample shipment. Field blanks will be used to assess field sample collection methods and will be collected and analyzed at a minimum frequency of one sample per 20 samples (five percent of the samples collected). Method blanks will be used to assess contamination resulting from the analytical process and will be analyzed at a minimum frequency of one sample per 20 samples, or five percent of the samples collected. Evaluation of sample blanks will be performed following U.S. EPA "National Functional Guidelines for Organic Data Review" (EPA, 1991) and "Functional Guidelines for Evaluating Inorganics Analyses" (EPA, 1988). Only method blanks will be analyzed via wet chemistry methods. The criteria for evaluating method blanks will be established as follows: If method blank results exceed reporting limits, then that value will become the detection limit for the sample batch. Detection of analytes of interest in blank samples may be used to disqualify some samples, requiring resampling and additional analyses on a case-by-case basis.

e. Completeness

Completeness is a measure of the amount of usable valid data resulting from a data collection activity, given the sample design and analysis. Completeness may be affected by unexpected conditions that may occur during the data collection process. Occurrences that reduce the amount of data collected include sample container breakage in the laboratory and data generated while the laboratory was operating outside prescribed QC limits. All attempts will be made to minimize data loss and to recover lost data whenever possible. The completeness objective for noncritical measurements (i.e., field measurements) will be 90 percent and 100 percent for critical measurements (i.e., compliance data). If the completeness objective is not met, the WIPP EM Manager will determine the need for resampling on a case-by-case basis. Numerical expression of the completeness (%C) of data is as follows:

$$\%C = \frac{number\ of\ accepted\ samples}{total\ number\ of\ samples\ collected} x\ 100$$

f. Representativeness

Representativeness is the degree to which sample analyses accurately and precisely represent the media they are intended to represent. Data representativeness for this DMP will be accomplished through implementing approved sampling procedures and the use of validated analytical methods. Sampling procedures will be designed to minimize factors affecting the integrity of the samples. Groundwater samples will only be collected after well purging criteria have been met. The analytical methods selected will be those that will most accurately and precisely represent the true concentration of analytes of interest.

g. Comparability

Comparability is the extent to which one data set can be compared to another. Comparability will be achieved through reporting data in consistent units and collection and analysis of samples using consistent methodology. Aqueous samples will consistently be reported in units of measures dictated by the analytical method. Units of measure include:

- Milligrams per liter (mg/L) for alkalinity, inorganic compounds and metals
- Micrograms per liter (mg/L) for VOCs.

Groundwater surface elevation measurements will be expressed as equivalent freshwater elevation in feet above mean sea level.

12.2 Design Control

The groundwater monitoring system was designed and will be maintained to meet specifications established in 20 NMAC 4.1.500 (incorporating 40 CFR §§ 264 Subpart F and 264.601 through 264.603).

12.3 Instructions, Procedures, and Drawings

Provisions and responsibilities for the preparation and use of instructions and procedures at WIPP are outlined in Section 1.4, Documents, Section 2.1.2, Implementing Procedures, and Section 4, Sample Control, and Quality Assurance Requirements, of the QAPD. Any activities performed for groundwater monitoring that may affect ground water will be performed in accordance with documented and approved procedures which comply with the Permit and the requirements of 20 NMAC 4.1.500 (incorporating 40 CFR § 264 Subpart F).

Technical procedures, as specified elsewhere in this DMP, have been developed for each quality-affecting function performed for groundwater monitoring. The technical procedures unique to the DMP will be controlled by the ES&H at WIPP. The procedures are sufficiently detailed and include, when applicable, quantitative or qualitative acceptance criteria.

Procedures were prepared in accordance with requirements in Section 1.4, Documents, Section 2.1.2, Implementing Procedures, and Section 4, Sample Control, and Quality Assurance Requirements, of the QAPD.

12.4 Document Control

Document controls will ensure that the latest approved versions of procedures will be used in performing groundwater monitoring functions and that obsolete materials will be removed from work areas.

12.5 Control of Work Processes

Process control requirements, defined in the QAPD Section 2.1, Work Processes and Section 4, Sample Control and Quality Assurance Requirements, are met, and will continue to be met, for this DMP.

12.6 Inspection and Surveillance

Inspection and surveillance activities will be conducted as outlined in Section 2.4, Inspection and Testing, and Section 3.2, Independent Assessment of the QAPD. The QA Department will be responsible for performing the applicable inspections and surveillance on the scope of work. EM section personnel will be responsible for performance checks as defined in applicable procedures and determined by WID metrology laboratory personnel. Performance checks for the DMP will determine the acceptability of purchased items and assess degradation that occurs during use.

12.7 Control of Monitoring and Data Collection Equipment

QAPD Section 2.4.4, Monitoring, Measuring, Testing, and Data Collection Equipment, outline the basic requirements for control and calibrating monitoring and data collection (M&DC). M&DC equipment shall be properly controlled, calibrated, and maintained according to WIPP Procedures to ensure continued accuracy of groundwater monitoring data. Results of calibrations, maintenance, and repair will be documented. Calibration records will identify the reference standard and the relationship to national standards or nationally accepted measurement systems. Records will be maintained to track uses of M&DC equipment. If M&DC equipment is found to be out of tolerance, the equipment will be tagged and it will not be used until corrections are made.

12.8 Control of Nonconforming Conditions

Section 1.3, Quality Improvement, Section 4.4, Disposition of Nonconforming Samples, of the QAPD specifies the system used at WIPP for ensuring that appropriate measures are established to control nonconforming conditions. Nonconforming conditions connected to the DMP will be identified in and controlled by documented procedures. Equipment that does not conform to specified requirements will be controlled to prevent use. The disposition of defective items will be documented on records traceable to the affected items. Prior to final disposition, faulty items will be tagged and segregated. Repaired equipment will be subject to the original acceptance inspections and tests prior to use.

12.9 Corrective Action

Requirements for the development and implementation of a system to determine, document, and initiate appropriate corrective actions after encountering conditions adverse to quality at WIPP are outlined in Section 1.3, Quality Improvement, of the QAPD. Conditions adverse to acceptable quality will be documented and reported in accordance with corrective action procedures and corrected as soon as practical. Immediate action will be taken to control work performed under conditions adverse to acceptable quality and its results to prevent quality degradation.

12.10 Quality Assurance Records

Section 1.5, Records, of the QAPD outlines the policy that will be used at WIPP regarding identification, preparation, collection, storage, maintenance, disposition, and permanent storage of QA records.

Records to be generated in the DMP will be specified by procedure. QA and RCRA operating records will be identified. This will be the basis for the labeling of records as "QA" or "RCRA operating" on the EM RIDS.

QA records will document the results of the DMP implementing procedures and will be sufficient to demonstrate that all quality-related aspects are valid. The records will be identifiable, legible, and retrievable.

TABLE 1 HYDROLOGICAL PARAMETERS FOR ROCK UNITS ABOVE THE SALADO AT WIPP

Unit		Hydraulic Conductivity	Storage Coefficient	Transmissivity	Permeability	Thickness	Hydraulic Gradient
Santa Rosa		2×10^{-8} to 2×10^{-6} m/s (1) (2)	Specific capacity 0.029 to 0.041 ℓ/s/m	6×10^{-7} to 6×10^{-5} m^2/s (3)	10^{-10} m^2	0 to 91 m	0.001 (5)
Dewey Lake		10^{-8} m/s	Specific storage 1×10^{-5} (1/m) (2)	2.8×10^{-8} to 2.8×10^{-4} m^2/s (4)	5.01×10^{-17} m^2	152 m	0.001 (5)
Rustler	Forty-niner	1×10^{-13} to 1×10^{-11} m/s (anhydrite) 1×10^{-9} m/s (mudstone) (2)	Specific storage 1×10^{-5} (1/m) (2)	8×10^{-8} to 8×10^{-9} m^2/s	0 m^2	13 to 23 m	NA (6)
	Magenta	$1 \times 10^{-8.5}$ to $1 \times 10^{-6.5}$ m/s (2)	Specific storage 1×10^{-5} (1/m) (2)	4×10^{-4} to 1×10^{-9} m^2/s	6.31×10^{-14} m^2	7 to 8.5 m	3 to 6
	Tamarisk	1×10^{-13} to 1×10^{-11} m/s (anhydrite) 1×10^{-9} m/s (mudstone) (2)	Specific storage 1×10^{-5} (1/m) (2)	$<2.7 \times 10^{-11}$ m^2/s	0 m^2	26 to 56 m	NA (6)
	Culebra	$1 \times 10^{-7.5}$ to $1 \times 10^{-5.5}$ m/s (2)	Specific storage 1×10^{-5} (1/m) (2)	1×10^{-3} to 1×10^{-9} m^2/s	2.1×10^{-14} m^2	4 to 11.6 m	0.003 to 0.007 (5)
	Unnamed lower member	6×10^{-15} to 1×10^{-13} m/s 1.5×10^{-11} to 1.2×10^{-11} m/s (basal interval)	Specific storage 1×10^{-5} (1/m) (2)	2.9×10^{-10} to 2.2×10^{-13} m^2/s 2.9×10^{-10} to 2.4×10^{-10} m^2/s (basal interval)	0 m^2	29 to 38 m	NA (6)

Matrix characteristics relevant to fluid flow include values used in this table such as permeability, hydraulic conductivity, gradient, etc.)

Table Notes:

(1) The Santa Rosa Formation is not present in the western portion of the WIPP site. It was combined with the Dewey Lake Red Beds in three-dimensional regional groundwater flow modeling (Corbet and Knupp, 1996), and the range of values entered here are those used in that study for the Dewey Lake/Triassic hydrostratigraphic unit.

(2) Values or ranges of values given for these entries are the values used in three-dimensional regional groundwater flow modeling (Corbet and Knupp, 1996). Values are estimated based on literature values for similar rock types, adjusted to be consistent with site-specific data where available. Ranges of values include spatial variation over the WIPP site and differences in values used in different simulations to test model sensitivity to the parameter.

(3) The range of values given here for transmissivity of the Santa Rosa is estimated for the center of the site. Transmissivity is the product of the thickness of the productive interval times its hydraulic conductivity. Thickness of the Santa Rosa is estimated to be 30 meters at the center of the WIPP site, and the range of derived transmissivities are based on the range of hydraulic conductivity values used by Corbet and Knupp (1996) for the combined Dewey Lake/Triassic unit.

(4) The range of values given here by transmissivity of the Dewey Lake is estimated for the center of the site. Transmissivity is the product of the thickness of the productive interval times its hydraulic conductivity. Thickness of the Dewey Lake is estimated to be 140 meters at the center of the WIPP site, and the range of derived transmissivities are based on the range of hydraulic conductivity values used by Corbet and Knupp (1996) for the combined Dewey Lake/Triassic unit.

(5) Hydraulic gradient is a dimensionless term describing change in the elevation of hydraulic head divided by change in horizontal distance. Values given in these entries are determined from potentiometric surfaces. The range of values given for the Culebra reflects the highest and lowest gradients observed within the WIPP site boundary. Values for the Dewey Lake and Santa Rosa are assumed to be the same as the gradient determined from the water table. Note that the Santa Rosa Formation is absent or above the water table in most of the controlled area, and that the concept of a horizontal hydraulic gradient is not meaningful for these regions.

(6) Flow in units of very low hydraulic conductivity is slow, and primarily vertical. The concept of a horizontal hydraulic gradient is not applicable.

TABLE 5 RCRA PERMIT STIPULATIONS REQUIRING ACTIONS, REPORTING, OR NOTIFICATIONS

Permit Stipulation	Action, Report or Notification due date	Permit §
Determination of statistically significant contamination of parameters or constituents in table V.D.	7 calendar days from determination	V.J.3.a., V.J.4.a., L-4e(4)
If the Permittees determine, pursuant to permit condition V.I that there is a statistically significant difference for parameters or constituents specified in Table V.D at any DMW at the Compliance point, they may demonstrate that a source other than a regulated unit caused the increase or that the detection is an artifact caused by an error in sampling, analysis, statistical evaluation, or natural variation in the groundwater.	Submittal of modification request-the permittees shall, within 90 calendar days, submit to the Secretary an application for a permit modification to make any appropriate changes to the DMP, as required by 20 NMAC 4.1.500	V.J.4.c.
Changes that occur that could affect the DMP's ability to fulfill the requirements of 20 NMAC 4.1.500	Permit modification request - no time specified	L-4a
Groundwater Flow results Report-Direction and Rate of flow in the Culebra	Annually in the Site Environmental Report	V.J.2.c.,V.H
Background Water quality data report	Prior to waste receipt	V.F.3, L-4e(4)
For those parameters and constituents listed in Table V.D which the Permittees have not met the requirements of Permit Condition V.F1. For establishing background water quality at the time the Permit is approved, the Permittees shall collect additional background water quality data.	The permittees shall submit the background water quality data to the secretary within three months of complying with the permit condition V.F.1.	V.F.4.c
Groundwater Surface Elevation Results Report	30 days after data are collected	V.J.2b., L-4c(1)ii
DMP Statistical Comparison Report	Annually in the Site Environmental Report	L-4e(4)
The Permittees shall determine the groundwater flow rate and direction in the Culebra Member of the Rustler Formation at least annually.	Determine groundwater flow rate and direction annually	V.H.
For those parameters and constituents listed in Table V.D which the permittees have not met the requirements of Permit condition V.F.1 for establishing background Groundwater quality at the time the Permit is approved, the permittees shall collect additional background Groundwater quality data to comply with the following conditions:	The permittees shall collect background Groundwater quality data only from hydraulically upgradient DMWs.	V.F.4.a-b
Evidence that a source other than a regulated unit caused groundwater contamination, or that contamination resulted from error in sampling, analysis, or evaluation	90 calendar days from determination	V.J.4.b
DMW plugging and abandoning Reports	90 days after date DMW is removed from the DMP	V.C.3

Permit Stipulation	Action, Report or Notification	Permit §
The Permittees shall collect one (1) DMP sample and (1)DMP sample duplicate semiannually from each DMW using the procedure specified in Permit Attachment L section L-4c, as required by 20 NMAC 4.1.500 (incorporating 40 CFR 264.97(g)(2), 264.98(d), and 264.601(a)).	Collect one sample and one duplicate sample semiannually.	V.E.1.
DMP Data Evaluation Results Report	Biannually	V.J.2.a.
Cumulative groundwater surface elevation changes more than 2 feet in any DMW during one year which is not attributable to site tests or natural stabilization.	Notification in writing (time not specified) Report in the Site Environmental Report	L-4c(1), V.J.2.c
The permittees shall immediately, but no later than one(1) month, sample the groundwater in all DMWs specified in table V.C.1 for which there was statistically significant evidence of contamination. The remaining DMWs shall be sampled within two (2) months after statistically significant evidence of contamination is found in any DMW. All DMWs shall be sampled to determine the concentration of all substances identified in 20 NMAC 4.1.500 (incorporating 40 CFR 264 appendix IX), as required by 20 NMAC 4.1.500 (incorporating 40 CFR 264.98(g)(2)).	Contaminated well within 1 month All other DMWs within 2 months	V.J.3.b
Permittees may resample within one(1) month and repeat the analysis for those compounds detected. If the results of the second analysis confirm the initial analysis, these substances shall form the basis for compliance monitoring specified in permit condition V.J.3.d. If the permittees do not resample, the substances found during the initial analysis specified in condition V.J.3.b shall form the basis for compliance monitoring specified in permit condition V.J.3.d.	Resample within (1) month	V.J.3.c.
If the permittees determine, pursuant to Permit Condition V.I ...that there is statistically significant evidence of contamination for any parameter or constituent specified in Table V.D, the permittees shall comply with the following: ... The permittees shall within ninety(90) calendar days, submit to the secretary an application for a permit modification to establish a compliance monitoring program...	Submit an application for permit modification accompanied by a compliance monitoring program plan with in 90 days	V.J.3.d.
If the Permittees determine, pursuant to Permit Condition V.I ... that there is statistically significant evidence of contamination for any parameter or constituent specified in table V.D, the Permittees shall comply with the following: (i)All data necessary to justify an alternate concentration limit proposed in compliance with permit condition V.J.3.d.iv. (ii)An engineering feasibility plan for corrective action required by 20 NMAC 4.1.500 (incorporating 40 CFR 264.100) if necessary	Submit plan for corrective action within 180 calendar days accompanied by an engineering feasibility study if necessary	V.J.3.e.
The Permittees shall submit a report to the Secretary which summarizes and certifies DMW plugging and abandoning methods...	Ninety (90) calendar days from the date the DMW is removed from the DMP.	V.C.3

Permit Stipulation	Action, Report or Notification	Permit §
If the Permittees determine, pursuant to Permit condition V.I, that there is significant evidence of contamination for any parameter or constituents specified in Table V.d...	Submittal of compliance monitoring program within 90 calendar days with an application for a permit modification to establish a compliance monitoring program.	V.J.3.d
Releases have caused, or are expected to cause, concentrations of radionuclides or estimated doses due to radionuclides in underground sources of drinking water in the accessible environment to exceed the limits established pursuant to Part 191, Subpart C, of this Chapter.	Report to EPA, within 24 hours, in writing.	40 CFR 194.4(b)iic 40 CFR 194.4(b)iii

Note: Notifications to the NMED as specified in this table will be transmitted by the RCRA Compliance Section of the ES&H Department.

RE: Discharge Plan Renewal Reminder, Waste Isolation Pilot Plant, DP-831

~~Dear Mr. Dials~~: Dear Candice Jierree:

On July 3, 1997, the NM Environment Department (NMED) approved DP-831. According to our records, the discharge plan approval will expire on July 3, 2002.

An application for discharge plan renewal must be submitted to the NMED Ground Water Quality Bureau pursuant to the New Mexico Water Quality Control Commission (WQCC) Regulations 3106.F and 3109.H. The application for discharge plan renewal must include complete and updated operational, monitoring, contingency and closure plans, and any information necessary to ensure that the discharge will not result in an exceedance of WQCC ground and/or surface water quality standards. Your renewal application may be made by submitting a completed New Mexico Environment Department Ground Water Discharge Permit Application (copy enclosed). . Previously submitted materials may be included by reference provided they are current and readily available to the Ground Water Quality Bureau. Include in the application a detailed description of any changes you are planning to your operation which will affect the amount, quality or location of your discharge.

All requests for renewal must be accompanied by a filing fee of $100. An additional fee will be assessed prior to approval to cover the estimated cost to the NMED for investigation and issuance of the approval. The fee amounts for investigation and issuance are listed in Section 3114 of the WQCC Regulations.

If you are no longer discharging, please notify this office so that we may correct our records.

We look forward to your response. Processing of discharge plan renewals requires a minimum of 120 days. Timely action on your part can avoid a lapse in your permit coverage, which would be a violation of the WQCC Regulations. The person whom you may contact is Clint Marshall at 827-2900, if you have any questions.

Sincerely,

Maura Hanning
Program Manager
Ground Water Pollution Prevention Section

RECEIVED
JAN 22 2001
GROUND WATER BUREAU

Dear Mr. Maggiore:

This is a letter of introduction to tell you about myself and Westinghouse TRU Solutions LLC. As you are aware, the U.S. Department of Energy (DOE), Carlsbad Field Office, has awarded a five-year management and operating (M&O) contract for the Waste Isolation Pilot Plant (WIPP) to Westinghouse TRU Solutions LLC. Westinghouse Government Environmental Services, LLC (WGES) and Roy F. Weston, Inc. formed Westinghouse TRU Solutions LLC specifically for the WIPP, of which WGES serves as managing member.

As a result of this award, several key management positions have been filled by personnel selected by Westinghouse TRU Solutions LLC to carry out the mission and initiatives requested by the DOE in its request for proposal. These personnel appear on the enclosed brochure along with a synopsis of the experience they bring to WIPP. My new management team and I are excited to be coming on board and look forward to mutual success at the WIPP.

Westinghouse TRU Solutions LLC is presently performing transition at the WIPP site. This activity involves a few organizational changes, a revised budget, and familiarization with ongoing activities. Westinghouse TRU Solutions LLC will take over the WIPP contract starting February 1, 2001. Despite these changes, there will be no change with regard to the people with whom your staff routinely interfaces.

A Class 1 permit modification is being prepared to change the name on the Hazardous Waste Facility Permit from Westinghouse Government Environmental Services LLC, Waste Isolation Division, to Westinghouse TRU Solutions LLC, as co-permitee with DOE. This informational change will be submitted within seven (7) days from February 1, 2001, pursuant to the requirements of 40 CFR 270.42(a)(1) and Appendix I to section 270.42(A)(1).

When it is convenient with you, DOE will introduce me to you in person and brief you on the mission activities they have requested Westinghouse TRU Solutions LLC to begin performing in the coming year. Until then, please feel free to contact me at 505-628-1277 until January 31, 2001, or at 505-234-7400 after February 1, 2001. I look forward to meeting you and to discussing our mutual goals of responsible mixed waste management and disposal, which protects personnel and the environment.

Sincerely,

Henry F. Herrera

Comments:

Clint,

Here is some data on a waste stream we would like to discharge to the H-19 Evaporation pond. The waste water is generated in our radiochemistry lab during routine radiochemical analysis of bioassay and environmental samples.. The waste is acidic, and is neutralized and contains very low levels of radioactive constituents. The chemical and radiological components and concentrations are listed on pages 3 & 4 of 4 of the waste stream profile. The process will generate approximately 110 gallons per year. We currently have less than 150 gallons on hand. This waste stream is very similar to the one we got approval for in January of this year.

If you approve of the waste stream please sign the "NMED Authorization" block and fax it back to me. If you have any questions or need more information, please give me a call.

Thanks for your help.

SUBJECT: Discharge of Non-hazardous Brines under Discharge Plan DP-831

Dear Mr. Marshall:

The purpose of this letter is to confirm our discussion of August 25, 2000. During this discussion DOE informed the NMED of its intent to discharge non-hazardous brine collected from the surface ventilation ductwork of the exhaust shaft into the H-19 evaporation basin under WIPP's Discharge Plan DP-831.

This water consists of brine that seeps into the exhaust shaft and then follows one of two pathways. The brine either falls to the base of the exhaust shaft where it is collected in a catch basin or it becomes entrained in the exhaust shaft's air stream and collects in the exhaust fan ductwork.

The brine has been sampled and analyzed for total metals, and the analytical data demonstrate that the brines collected in the exhaust fan ductwork are consistently non-hazardous (Please see the attached data). Because these waters are non-hazardous brine, their discharge into the H-19 Evaporation Pond is allowed by WIPP's existing Discharge Plan. No change is required to the permitted volume of the H-19 Evaporation Pond.

In addition to the brine that collects in the exhaust shaft ductwork, WIPP intends to dispose of other non-hazardous brines that meet the Discharge Plan requirements. This includes the non-hazardous brine that falls into the catch basin at the bottom of the exhaust shaft. Since this brine has exceeded hazardous constituent limits in the past, it will be sampled each time it is removed from the catch basin to assure that it is non-hazardous. The volumes discharged to H-19 will be reported in the quarterly discharge monitoring report. The analytical data and the brine volumes generated will be maintained at the WIPP site.

Printed on recycled paper

FIELD TRIP REPORT
GROUND WATER POLLUTION PREVENTION SECTION

Date: 2/3/2000 Inspector(s): Clint Marshall

FACILITY

Facility Name: Waste Isolation Pilot Plant (WIPP) Contact: Jim Holland
Location:
Discharge Plan Number: DP-831 UIC Related? (Yes/No): No
Type of Operation: Nuclear Waste Depository

INSPECTION SUMMARY

Purpose:

___ a. Evaluation of Proposed Discharge Plan
✓ b. Compliance Inspection (Complete Checklist on Reverse Side)
___ c. Other (specify):

ACTIVITIES

a. Inspection of Facilities or Construction (specify): Sewage disposal ponds, H-19 evaporation pond, laboratory

Flow Measurement: Type: Flow meters Condition: New - just installed

b. Effluent Sample(s) (provide sampling location): None taken

No. of Ponds: 8 No. in Use: 8 Condition of Ponds: good
Condition of Pond Liner (s): Synthetic - good

c. Ground Water Sample(s) (provide well name and location): No monitoring required.

No. of Monitoring Wells: -0- Well Condition:

d. Other (specify):

OBSERVATIONS AND INFORMATION OBTAINED

Sewage ponds (1A, 1B, 2A, 2B) and evaporation ponds 1, 2, 3 and H-19 evaporation pond all in excellent condition. New flow meter just installed. H-19 pond has been recieving most of brine from the site as well as compressor + air conditioner condensate.

ACTION REQUIRED

WATER QUALITY INSPECTION & SAMPLING CHECKLIST
Reference: Regulation No. HED 86-14 (EID)

ENTRY CONFERENCE:

_____ Was facility representative informed of EID's right of entry and authority: (To access records, inspect monitoring equipment or methods and sample effluents under Section 74-6-9.E of the New Mexico Water Quality Act (NMSA 1978)?

_____ Was EID identification presented?

_____ Were potential or suspected violations which prompted inspection listed?

_____ During the inspection, was the facility representative immediately advised or addition potential violations?

EXIT CONFERENCE

_____ Were the preliminary inspection results summarized?

_____ Was the facility representative advised if violations discussed during the entry conference remain under investigation?

_____ Were other potential violations discovered during the inspection discussed?

_____ Was a date provided as to when EID expects to complete consideration of potential violations.

WATER QUALITY SAMPLING

_____ Was the facility representative offered a reasonable opportunity to obtain split/replicate samples, perform simultaneous tests, measurements or photographs?

_____ Were copies of EID's results (sampling, testing, photos) requested? If yes, copies must be provided within ten working days after such results are in EID's possession.

RE: Discharge Plan Amendment, DP-831, Waste Isolation Pilot Plant

Dear Mr. Donovan:

Pursuant to Water Quality Control Commission (WQCC) Reg. 3109, the application for amendment for DP-831, submitted by K. S. Donovan for the discharge of 100 gallons per year of buffered acidic solution to the approved treatment and disposal system of Waste Isolation Pilot Plant (WIPP) is hereby approved, subject to the condition listed below. The discharge plan was renewed and modified on July 3, 1997. The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. In approving this discharge plan amendment, the New Mexico Environment Department (NMED) has determined that the requirements of WQCC Reg. 3109.C have been met.

The approved amendment to the treatment and disposal system of the WIPP is briefly described as follows:

The WIPP will generate a waste stream of 20.8 gallons of acid per year as a result of conditioning virgin resins used in laboratory separation columns. The acid waste stream consists of 75% hydrochloric acid and 25% nitric acid. The acid will be neutralized to a pH between 6 and 8 prior to discharge resulting in a final annual volume of 100 gallons. The neutralized acid will be discharged to the synthetically lined domestic wastewater lagoons resulting in an addition of 5.4 lbs. of nitrogen annually.

However, approval of this amendment to your discharge plan does not relieve you of your responsibility to comply with any other conditions or requirements of the approved discharge plan, DP-831, or any other applicable federal, state, and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

SPECIFIC REQUIREMENTS

This discharge plan amendment contains specific requirements which are summarized in the discharge plan renewal and modification dated July 3, 1997 and the specific requirement listed below.

1. WIPP will verify and record the volume and pH of each batch of neutralized acid prior to release in the wastewater lagoons. The volume and pH of each release will be submitted to NMED in the quarterly monitoring reports.

OTHER REQUIREMENTS

Please be advised that approval of this discharge plan amendment does not relieve the U.S. Department of Energy of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

PERIOD OF APPROVAL

This amendment approval expires on July 3, 2002, the same date as the original plan, and you should submit an application for renewal at least 120 days before that date.

If you have any questions, please contact Clint Marshall of the Ground Water Pollution Prevention Section staff at 827-0027.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

SUBJECT: PERMIT AMENDMENT/MODIFICATION REQUEST FOR DP-831

Dear Mr. Marshall:

With this letter the Waste Isolation Pilot Plant (WIPP) requests an amendment/modification to the applicable sections of Discharge Plan DP-831 for a minor waste stream to be discharged to the site sewage facility.

The waste stream is generated as a result of the use of nitric and hydrochloric acids to condition virgin resins used in laboratory separation columns. The quantities of acids are 50 mL of 8N nitric acid and 150 mL of 9N hydrochloric acid per column. The resin columns are conditioned in batches of twelve. Using 200 mL of acids per column, times twelve columns, and an estimated 36 batches per year, the process will generate approximately 86.4 liters, or 20.8 gallons of waste acid per year.

After in-container neutralization to a pH between 6 and 8 the estimated waste stream volume will be 100 gallons per year. Prior to discharge the laboratory personnel verify and record the volume and pH. These values will be reported in the quarterly discharge monitoring report.

Approximately 2,420 grams, or 5.4 pounds, of total nitrogen from the nitric acid will be discharged to the sewage system annually. With the annual permitted flow to the sewage system being over 8 million gallons the additional nitrogen will have no adverse effect.

If you have any questions about this request or require any additional information, please contact Mr. Dan Robertson at (505) 234-8459, or Mr. Jim Hollen at (505) 234-8271.

Sincerely,

for

RE: Discharge Plan Amendment Approval, DP-831, Waste Isolation Pilot Plant (WIPP)

Dear Mr. Dials:

Pursuant to Water Quality Control Commission (WQCC) Reg. 3109, the May 1, 1998 application for amendment for DP-831, submitted by K.S. Donovan for changes in the monitoring plan for the approved treatment and disposal system of the WIPP is hereby approved, subject to the condition listed below. The discharge plan was renewed on July 3, 1997. The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. In approving this discharge plan amendment, the New Mexico Environment Department (NMED) has determined that the requirements of WQCC Reg. 3109.C have been met.

The approved amendment to the treatment and disposal system of WIPP is briefly described as follows:

Monitoring for Radium 226 and 228 will be replaced with monitoring for Plutonium 238, 239/240, Americium 241, Uranium 234, 235, and 238, and Strontium 90 for the east evaporation pond (Pond A), the north evaporation pond (Pond B), the south evaporation pond (Pond C), and the H-19 evaporation pond.

However, approval of this amendment to your discharge plan does not relieve you of your responsibility to comply with any other conditions or requirements of the approved discharge plan, DP-831, or any other applicable federal, state, and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

CONDITIONS FOR APPROVAL

Condition No. 2 of the July 3, 1997 discharge plan renewal shall be replaced with Specific Requirement No. 7 as follows:

2. WIPP shall sample and analyze the inflow the to the facultative lagoon system for nitrate as nitrogen (NO_3-N), total Kjeldahl nitogen (TKN), total dissolved solids (TDS), Plutonium 238, 239/240, Americium 241, Uranium 234, 235, 238, Strontium 90 and gross alpha particle activity (including Radium 226 but excluding Radon and Uranium). WIPP shall sample and analyze the north evaporation pond (Pond B), the south evaporation pond (Pond C), and the H-19 evaporation pond for total dissolved solids (TDS), Plutonium 238, 239/240, Americium 241, Uranium 234, 235, 238, Strontium 90 and gross alpha particle activity. If gross alpha particle activity is greater than 15pCi/l then additional samples for radioactivity, as combined Radium 226 and Radium 228, will be collected and analyzed within 30 days of the initial analysis. Reports of the analyses shall be submitted to NMED by January 31, April 30, July 31 and October 31 of each year.

OTHER REQUIREMENTS

Please be advised that approval of this discharge plan amendment does not relieve U.S Department of Energy of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

PERIOD OF APPROVAL

This amendment approval expires on July 3, 2002, the same date as the original plan, and you should submit an application for renewal at least 120 days before that date.

If you have any questions, please contact Clint Marshall of the Ground Water Pollution Prevention Section staff at 827-0027.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

MEMORANDUM

To: DP-831 File

From: Clint Marshall, GWPPS *Cm*

Subject: June 12, 1998 Discharge Plan Amendment for DP-831

Date: June 12, 1998

A discharge plan amendment to change the monitoring requirements for DP-831 was approved on June 12, 1998. WIPP requested to amend their monitoring plan to sample and analyze for Pu 238, 239/240, Am 241, U 234, 235, 238, Sr 90 and gross alpha particle activity instead of Ra 226 and 228. This change is being requested because sampling and analysis for Ra is complex and expensive while analysis of Pu, U, Am and Sr can be conducted onsite at less expense. As an alternative, the parameters listed above will be good indicators of impacts to the wastestream by radionuclides. WIPP has proposed that if gross alpha particle activity exceeds 15 mg/l, then analysis for Ra 226 and 228 will be conducted.

From: Hollen, Jim <HollenJr@wipp.carlsbad.nm.us>
To: 'CLINT_MARSHALL@NMENV.STATE.NM.US' <CLINT_MARSHALL@edser.nmenv.state.nm.us>
Date: Wednesday, June 03, 1998 1:32 PM
Subject: Amendment to DP-831

Clint,

After much discussion with our radiochemists, this is the language we came up with to trigger radium-226 and 228 sampling. It is a combination of drinking water standards found at New Mexico Title 20, Chapter 7, Part 1, Subpart 2, Section 206 and the ground water regulations at Title 20, Chapter 6, Part 2, Subpart 3, Section 3103(A).

* If gross alpha particle activity (including radium-226 but excluding radon and uranium) is greater than 15 pCi/l then additional samples for radioactivity, as combined radium 226 and radium 228, will be collected and analyzed in accordance with section 3103(A) of the current New Mexico Water Quality Control Commission Regulations.

If these words are OK use them, if not let me know and we can do something else.

Please contact me if I can be of assistance.

Thanks for your help.

Subject: AMENDMENT TO DISCHARGE PLAN DP-831

Dear Mr. Marshall:

With this letter the Waste Isolation Pilot Plant requests an amendment to the sampling and analyses required in Part 2 of the Conditions for Approval of the current discharge plan, DP-831.

Specifically, we are asking that the sample and analysis requirements for radium 226 and 228 in the three evaporation cells and the H-19 evaporation pond be removed and replaced with the same radionuclide suite specified for the inflow to the facultative lagoon system. The radiochemical analysis for the inflow to the facultative lagoon system, the three evaporation cells and the H-19 evaporation pond would then consist of the following radionuclides:

- Plutonium 238, 239/240
- Americium 241
- Uranium 234, 235, 238
- Strontium 90

Since these radionuclides make up the major percentage of the radioactive waste stream at the WIPP, we feel that this analysis will provide better target parameters for the evaporation cells and the H-19 evaporation pond than radium analysis. Historically, during the more than five years of analysis, radium 226 and 228 have been at, or below detection limits.

We are also requesting that we be allowed to composite the radionuclide samples for the three evaporation cells. The H-19 evaporation pond would be sampled and analyzed separately.

If you have any questions about this request or require any additional information, please contact Mr. S. C. Kouba at (505) 234-8332, or Mr. J. R. Hollen at (505) 234-8271.

RE: Revised Discharge Plan Summary

Dear Mr. Dials:

Please find enclosed a revised Discharge Plan Summary Sheet to replace the one that accompanied your discharge plan renewal and modification, dated July 3, 1997. During a telephone conversation with Jim Hollen on October 23, 1997, it was brought to our attention that the monitoring requirements outlined in the summary were not consistent with the requirements stated in Condition No. 2 of the permit. Therefore we are issuing a revised summary to correct the error.

Thank you for your attention to this matter. If you have any questions, please contact me at 505-827-0027.

Sincerely,

Clint Marshall

Enclosure: Discharge Plan Summary Sheet

MEMORANDUM OF MEETING OR PHONE CONVERSATION

☑ Telephone ☐ Meeting | Time 1:50 PM | Date 10/23/97

Individuals Involved

Jim Hollen | Clint Marshall

Subject Discharge Volumes at WIPP and other misc. issues.

Discussion Jim called to discuss 3 issues as follows

1) They have still not located the source of excessive water entering the sewage lagoons. However in investigating the problem they have discovered that the metering system which measure flows is inaccurate. They are checking + calibrating the meters and will let us know what they find.

2) They want to discharge purge water from monitoring wells to the stormwater retention structures instead of the H-19 pond

~~Conclusions~~ Told them to send me an NOI.

3) Condition #2 of the Renewal + Mod ~~does no~~ is not consistent with the ~~a~~ DP summary. I told them I would check and send them a new summary sheet.

Subject: TRANSFER OF BRINE FROM WIPP SEWAGE SYSTEM B EVAPORATION POND TO THE H-19 EVAPORATION POND

Dear Mr. Marshall:

As follow up to your September 26, 1997, telephone conversation with Mr. J. R. Hollen, the following actions occurred to alleviate the high level condition experienced at the WIPP sewage system facility:

- An emergency contract was initiated with a local provider for the installation of a pump, and installation of approximately 6,700 feet of 3-inch plastic temporary pipeline (Fas-Line) from the WIPP sewage system B evaporation pond to the WIPP H-19 evaporation pond. Both facilities are currently permitted under New Mexico Environment Department Discharge Permit DP-831.

- From Friday September 26, through Friday October 3, 1997, approximately 300,000 gallons were transferred from the B evaporation pond to the H-19 evaporation pond.

- An investigation is underway to determine where and how the additional water is entering the sewage system.

It is not anticipated that additional fluid will be transferred from the sewage facility evaporation pond to the H-19 evaporation pond; however, should this become necessary you will be notified prior to any action.

If you have any questions about this report or require any additional information, please contact Mr. J. R. Hollen at (505) 234-8271.

Sincerely,

Ken Donovan

Subject Discharge increase to sewage lagoons

Discussion Jim called to inform us that the sewage lagoons have been filling up due to an increase in discharge from the WIPP facility. They are currently investigating where the increase is coming from and put it in a ~~[illegible]~~ letter to NMED. There is still two feet of freeboard in pond B however they want to pump out some water ~~[illegible]~~ and take it to the H-19 pond as a precautionary measure. I approved this action.

Conclusions Written notification coming next week.

RE: Discharge Plan Renewal and Modification, DP-831, Waste Isolation Pilot Plant

Dear Mr. Dials:

Pursuant to Water Quality Control Commission (WQCC) Regulation 3109, the application for discharge plan renewal and modification for DP-831, submitted by George Dials for the discharge of 33,000 gallons per day of sewage effluent and non-hazardous brine water from the Waste Isolation Pilot Plant (WIPP) is hereby approved, subject to the conditions listed below. The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. In approving this discharge plan, the New Mexico Environment Department (NMED) has determined that the requirements of WQCC Regulation 3109.C have been met.

The approved WIPP treatment and disposal system is briefly described as follows:

Up to 23,000 gallons per day of sewage effluent is discharged to a series of 5 synthetically lined ponds for settling and evaporation (facultative lagoon system). Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined evaporation cell (north evaporation cell). The modification consists of discharging an additional 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources to a synthetically lined evaporation pond (H-19 evaporation pond). Ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3,920 to 218,000 milligrams per liter.

The approved discharge plan renewal and modification consists of the materials submitted by George Dials dated December 16, 1996. In addition, the discharge plan includes information and materials submitted as part of the original discharge plan approved on January 16, 1992, and materials for discharge plan amendment, dated August 28, 1995. The discharge shall be managed in accordance with the approved plan and is subject to the conditions listed below.

However, renewal and modification of this discharge plan does not relieve you of your responsibility to comply with any conditions or requirements of the previously approved discharge plan, DP-831, and the New Mexico Water Quality Act, WQCC Regulations, any other applicable federal, state and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

CONDITIONS FOR APPROVAL

This discharge plan renewal and modification is subject to the following conditions for the following reasons:

1. WIPP shall measure the volume of sewage effluent discharged to the facultative lagoon system and the volumes of non-hazardous brine water individually discharged to the north evaporation cell and the H-19 evaporation pond. The origins of all waters discharged to the north evaporation cell and the H-19 evaporation pond shall be specifically described and reported. Reports of the volumes and water sources will be submitted to NMED by January 31, April 30, July 31 and October 31 of each year.

   The reason for this condition is to comply with WQCC Regulation 3106 by measuring the amount of effluent discharged.

2. WIPP shall sample and analyze the inflow to the facultative lagoon system for nitrate as nitrogen (NO_3-N), total Kjeldahl nitrogen (TKN), total dissolved solids (TDS), plutonium 238, 239 and 240, americium 241, uranium 234, 235 and 238, and strontium 90. WIPP shall sample and analyze the east evaporation pond (Pond A), the north evaporation pond (Pond B), the south evaporation pond (Pond C), and the H-19 evaporation pond for total dissolved solids (TDS), and Radium 226 and 228. Reports of the analyses shall be submitted to NMED by January 31, April 30, July 31, and October 31 of each year.

3. WIPP shall notify NMED of the volume and origin all wastewater to be discharged that is derived from miscellaneous non-hazardous sources. NMED may require more comprehensive laboratory analyses of such wastewater prior to discharge when

NMED determines that additional information is needed.

The reasons for Conditions 2 and 3 are to comply with Regulations 3106 and 3107 by monitoring the quality of effluent discharged.

SPECIFIC REQUIREMENTS

The terms and conditions of this renewal and modification contain specific requirements which are summarized below.

1. WIPP is authorized to discharge up to 23,000 gallons per day of sewage effluent 5 synthetically lined lagoons for solids settling and evaporation.

2. WIPP is authorized to discharge up to 2,000 gallons per day of non-hazardous brine water to the synthetically lined north evaporation cell.

3. WIPP is authorized to discharge up to 8,000 gallons per day of non-hazardous brine water to the synthetically lined H-19 evaporation pond.

4. WIPP will maintain all berms surrounding the facultative lagoon system to protect against stormwater runon and runoff.

5. WIPP will implement the contingency plan, dated December 16, 1996 in the event of a failure of the wastewater treatment and disposal system. The plan includes daily inspection and repair of pond liners as necessary, containment and investigation of all spills and releases, and submittal of a remediation plan to address contamination.

6. WIPP will implement the closure plan, dated December 16, 1996 when the facility is decommissioned. The plan includes the pumping or evaporation of all wastewater ponds, removal of all solids, and recontouring and revegetation of the site.

GENERAL DISCHARGE PLAN REQUIREMENTS

In addition to any other requirements provided by law, approval of discharge plan, DP-831, is subject to the following general requirements:

Monitoring and Reporting

Monitoring and reporting shall be as specified in the discharge plan and supplements thereto. These requirements are summarized on the attached sheet(s). Any inadvertent omissions from this summary of a discharge plan monitoring or reporting requirement shall not relieve you of responsibility for compliance with that requirement.

Record Keeping

1. The discharger shall maintain at the facility, a written record of ground water and wastewater quality analyses.

The following information shall be recorded and shall be made available to the NMED upon request.

a. The dates, exact place and times of sampling or field measurements.

b. The name and job title of the individuals who performed the sampling or measurements.

c. The dates the analyses were performed.

d. The name and job title of the individuals who performed the analyses.

e. The analytical techniques or methods used.

f. The results of such analyses, and

g. The results of any split sampling, spikes or repeat sampling.

2. The discharger shall maintain a written record of any spills, seeps, and/or leaks of effluent, leachate and/or process fluids not authorized by this discharge plan.

3. The discharger shall maintain a written record of the operation, maintenance and repair of facilities/equipment used to treat, store and/or dispose of wastewater; to measure flow rates; and/or to monitor water quality. This will include repairs, replacement or calibration of any monitoring equipment and repairs or replacement of any equipment used in WIPP's waste or wastewater treatment and disposal system.

4. The discharger shall maintain a written record of the amount of wastewater discharged.

Inspection and Entry

In accordance with § 74-6-9.B & E NMSA 1978 and WQCC Regulation 3107.D., the discharger shall allow the Secretary or his authorized representative, upon the presentation of credentials, to:

1. Enter at regular business hours or at other reasonable times upon the discharger's premises or where records must be kept under the conditions of this discharge plan.

2. Inspect and copy, during regular business hours or at other reasonable times, any records required to be kept under the conditions of the discharge plan.

3. Inspect, at regular business hours or at other reasonable times, any facility, equipment (including monitoring and control equipment), practices or operations regulated or required under this discharge plan.

4. Sample or monitor, at reasonable times for the purpose of assuring discharge plan compliance or as otherwise authorized by the New Mexico Water Quality Act, any effluent at any location before or after discharge.

Duty to Provide Information

In accordance with § 74-6-9.B NMSA 1978 and WQCC Regulation 3107.D., the discharger shall furnish to the NMED, within a reasonable time, any relevant information which it may request to determine whether cause exists for modifying, terminating and/or renewing this discharge plan or to determine compliance with this plan. The discharger shall furnish to the NMED, upon request, copies of records required to be kept by this discharge plan.

Spills, Leaks and Other Unauthorized Discharges

This approval authorizes only those discharges specified in the discharge plan. Any unauthorized discharges violate WQCC Regulation 3104, and must be reported to the NMED and remediated as required by WQCC Regulation 1203. This requirement applies to all seeps, spills, and/or leaks discovered from the pipelines, disposal ponds and evaporation ponds.

Retention of Records

The discharger shall retain records of all monitoring information, including all calibration and maintenance records, copies of all reports required by this discharge plan, and records of all data used to complete the application for this discharge plan, for a period of at least five years from the date of the sample collection, measurement, report or application. This period may be extended by request of the Secretary at any time.

Enforcement

Failure to grant the Secretary or his authorized representative access to the records required to be kept by this discharge plan or to allow an inspection of the discharge facilities or to the collection of samples is a violation of this discharge plan and the WQCC Regulations. Such violations as well as other violations of the discharge plan, may subject the discharger to a compliance order, a compliance order assessing a civil penalty or an action in district court pursuant to § 74-6-10 NMSA 1978, and/or modification or termination of this discharge plan pursuant to § 74-6-5.L NMSA 1978. Penalties assessed as part of a compliance order shall not exceed $15,000 per day for violations of the terms of this permit or the requirements of § 74-6-5 NMSA 1978, and shall not exceed $10,000 per day for violations of other sections of the Water Quality Act.

Modifications and/or Amendments

The discharger shall notify NMED, pursuant to WQCC Regs. 3107.C, of any modifications or additions to the WIPP's wastewater disposal system, including any increase in wastewater flow rate or wastewater storage and disposal management changes to the system as approved under this discharge plan. The discharger shall obtain NMED's approval, as a discharge plan modification, prior to any increase in the quantity or concentration of constituents in the leachate above those approved in this plan. Please note that WQCC Regs. 3109.E and F provide for possible future amendment of the plan.

Other Requirements

Please be advised that the approval of this plan does not relieve Department of Energy of liability should your operation result in actual pollution of surface or ground water which may be actionable under other laws and/or regulations.

RIGHT TO APPEAL

If the Department of Energy is dissatisfied with this action taken by NMED, the Department of Energy may file a petition for hearing before the WQCC. This petition shall be in writing to the Water Quality Control Commission within thirty (30) days of the receipt of this letter. Unless a timely request for hearing is made, the decision of the NMED shall be final.

TRANSFER OF DISCHARGE PLAN

Pursuant to WQCC Regulation 3111, prior to any transfer of ownership, the discharger shall provide the transferee a copy of the discharge plan, including a copy of this approval letter and shall document such to the NMED.

PERIOD OF APPROVAL

Pursuant to WQCC Reg. 3109.G.4., this discharge plan approval is for a period of 5 years. This approval will expire July 3, 2002, and you must submit an application for renewal at least 120 days before that date.

Sincerely,

Marcy Leavitt, Chief
Ground Water Quality Bureau

Subject: Comments to the WIPP Biennial Environmental Compliance Report (BECR)

Date: February 21, 1997

The following comments are in response to the BECR as required under the WIPP Land Withdrawal Act of 1992, as amended. The reporting period for this BECR is from April 1, 1994 to March 31, 1996; however additional comments are included on the current compliance status of WIPP as it applies to the New Mexico Water Quality Act.

<u>April 1, 1994 to March 31, 1996</u>: To the best of my knowledge WIPP has not been in violation of any of the requirements of their discharge permit during this time period.

<u>April 1, 1996 to present</u>: Regarding 20 NMAC 6.2 Section 3104, WIPP is currently in violation of their discharge plan, DP-831, because they are discharging without an approved discharge plan. WIPP failed to renew their discharge permit within the required time period, therefore the permit expired on January 16, 1997. WIPP is required to submit a request for renewal 120 days prior to expiration. NMED received a request for discharge plan renewal and modification on December 16, 1996 and is currently reviewing the request.

In addition to reporting on the compliance status, I would like to make the following comments on the Chapter 30 of the BECR report regarding requirements under the NM Water Quality Act.

Section 30.2.5 on page 30-5 states, "The discharge of 2,000 gpd of nonhazardous brine water at WIPP is authorized by NMED Discharge Plan approval, DP-831."

It should be noted that the discharge plan approval also authorizes the discharge of 32,000 gpd of domestic wastewater in addition to the 2,000 gpd of brine water.

Section 30.2.9 on page 30-6 states, "Since the approval of discharge may not exceed seven years from the date of issuance of the Discharge Plan approval, it will be necessary to find an alternative means of disposal for the nonhazardous brine solution currently being discharged."

Even though the approval period for a discharge permit is for a limited period of time, the permit can be renewed. Pursuant to 20 NMAC 6.2 Section 3106.F, the applicant may apply for renewal of the discharge permit which, upon approval, may extend the approval period for up to five additional years.

From: Benito J. Garcia, Chief
Hazardous and Radioactive Materials Bureau

Subject: WIPP Biennial Environmental Compliance Report

The Carlsbad Area Office of the U.S. Department of Energy (DOE/CAO) recently delivered to the State two copies of the 1996 *Waste Isolation Pilot Plant Biennial Environmental Compliance Report (BECR)*. This report is mandated under Section 9(a) of the federal WIPP Land Withdrawal Act of 1992, as amended [Public Law 102-579].

DOE/CAO must submit to the State of New Mexico and the U.S. EPA, on a biennial basis, documentation of WIPP's compliance with certain laws, regulations, and permit requirements listed in the WIPP Act. The *WIPP BECR* is DOE/CAO's documentation of WIPP's compliance.

It is important to note that the WIPP Act makes the following directive: "The [EPA] Administrator or the State, as appropriate, shall determine not later than 6 months after receiving [the Biennial Environmental Compliance Report] whether the [DOE] Secretary is in compliance with the laws, regulations, and permit requirements..." listed in the WIPP Act. The deadline for EPA and the State to make their determinations is April 30, 1997.

Enclosed are key sections of the report which fall under the purview of your bureau, along with a copy of the Introduction and a partial Table of Contents. Please identify an individual within your bureau who will review and comment on the enclosed sections, and provide their name to Steve Zappe of my staff (827-1561), who will be coordinating the review for NMED. Please review these materials, and provide comments and/or recommendations on the *WIPP BECR* to Mr. Zappe no later than March 1, 1997.

The full report is available in our office at 2044A Galisteo if you wish to review it or check it out for an extended period. Please contact me at 827-1557 if you have any further questions. Thank you for your assistance in this effort.

28.0 NEW MEXICO GROUND WATER PROTECTION ACT

28.1 Summary of the Law

The Ground Water Protection Act (GWPA; § 74-6B NMSA 1978) was enacted in 1990 in response to the threat facing public health and safety and the environment from pollution of ground-water resources from leaking USTs. The purpose of this act includes the provision of substantive direction that allows the State of New Mexico to take corrective action at sites contaminated by leakage from USTs.

The GWPA is implemented by the regulations of the NMED, NMED-92-1, *Ground Water Protection Act Corrective Action Fund Regulations*. These regulations provide guidelines for the payment or reimbursal of the costs of a minimum site assessment and corrective action and specify the requirements for owners or operators of leaking USTs.

The GWPA is also implemented by the GWPA regulations, which are provided in the New Mexico USTR as Part XV. These regulations are discussed in Chapter 25. WIPP has installed two new UST systems that meet the new standards and requirements for USTs. Procedures are in place for routine operations regarding the tanks and for dealing with any spills or releases from the UST systems. Two sections in Chapter 25 (25.2.6.84 and 25.2.6.85) deal specifically with the applicable New Mexico GWPA regulations.

28.2 Compliance Status of the Regulatory Requirement

Table 28-1 summarizes the general regulatory requirement and its compliance status under the implementing regulation of the New Mexico Ground Water Protection Act. See also Sections 25.2.6.84 and 25.2.6.85 for the applicable portions of the Ground Water Protection Act Regulations.

TABLE 28-1. New Mexico Ground Water Protection Act - Summary of Regulatory Compliance Status

CITATION	REQUIREMENT	COMPLIANCE STATUS
New Mexico Environment Department 92-1, *Ground Water Protection Act Corrective Action Fund Regulations*		
NMED 92-1	Reimbursement of costs from corrective actions for spills/releases from USTs	**NOT APPLICABLE** No spills or leaks from new UST systems [Section 28.2.1]

28.2.1 Corrective Action for Spills/Releases From USTs, NMED-92-1

The owners or operators of USTs that release a regulated substance must take appropriate corrective action. The NMED will reimburse certain costs associated with performing a minimum site assessment and other corrective actions taken for spills or releases from USTs.

The WIPP will take appropriate corrective actions if a regulated substance is released from a UST.

30.0 NEW MEXICO WATER QUALITY ACT

30.1 Summary of the Law

With the enactment of the New Mexico Water Quality Act (WQA; 74-6-1 through 74-6-17 NMSA 1978), a mechanism was provided at the state level to establish water-quality standards that are consistent with the CWA. The state act created the Water Quality Control Commission (WQCC) and directed the WQCC, as the state's water-pollution-control agency for all purposes of the CWA, to adopt a comprehensive water quality management program and water quality standards. The *New Mexico Water Quality Control Commission Regulations* include water-quality standards for ground and surface water and regulations regarding discharges to surface-water courses and ground water.

Pursuant to the regulations of § 3-109, *Director Approval, Disapproval, Modification, or Termination of Proposed Discharge Plans*, the Discharge Plan submitted by the DOE for the discharge of 23,000 gallons per day (gpd) of sewage effluent and up to 1,500 gpd of nonhazardous brine water from the WIPP was approved in 1992. On August 28, 1995, the WID submitted a request to the NMED requesting a minor amendment to DP-831 increasing the amount of nonhazardous brine for disposal to 2,000 gpd. On October 4, 1995, the NMED approved the amendment to the Discharge Plan. The increase was required, not because additional brine was being generated but because on days the observation wells were pumped, greater than 1,500 gallons were produced, necessitating that the brine be disposed of over two days' time.

The WQA was formerly implemented by WQCC 82-1. It is now implemented by Chapter 6 of Title 20 of the NMAC.

Title 20 NMAC 7.4 defines public water supply systems and public wastewater facilities. Under these definitions, and because of the size of the population served, the WIPP is classified as a Class 1 public wastewater facility and a Class 2 public water supply system. Since these systems require certified operators, the WIPP facility employs operators and supervisors certified to the requirements of Subpart II of this Part.

30.2 Compliance Status of the Regulatory Requirements

Table 30-1 summarizes the regulatory requirements and their compliance status under the New Mexico Water Quality Act. Following the table, the text gives more detail on the compliance status for each requirement.

TABLE 30-1. New Mexico Water Quality Act - Summary of Regulatory Compliance Status

CITATION	REQUIREMENT	COMPLIANCE STATUS
20 NMAC 6.2, *New Mexico Water Quality Control Commission Regulations*		
20 NMAC 6.2, § 1-201	NOI to discharge	**ACHIEVED** NOI filed as required [Section 30.2.1]
20 NMAC 6.2, § 1-202	Filing of plans and specifications--sewerage systems	**ACHIEVED** Submitted to NMED [Section 30.2.2]
20 NMAC 6.2, § 1-203	Notification of discharge--removal: requirements for notification, corrective action, and reporting in the event of an unauthorized discharge of oil or other water contaminant that could have adverse effects	**UP TO DATE** *RCRA Contingency Plan* [Section 30.2.3]
20 NMAC 6.2, § 2-101	General discharge limitations and sampling/analytical requirements	**UP TO DATE** Specified in NMED Discharge Plan approval [Section 30.2.4]
20 NMAC 6.2, § 3-104	Authorization only of effluent(s)/leachate(s) as specified in Discharge Plan	**UP TO DATE** Authorization granted [Section 30.2.5]

CITATION	REQUIREMENT	COMPLIANCE STATUS
20 NMAC 6.2, § 3-106	Application for Discharge Plan approval	**ACHIEVED** Application sent to NMED [Section 30.2.6]
20 NMAC 6.2, § 3-107	Monitoring, reporting, and other requirements	**UP TO DATE** Monitoring reports filed [Section 30.2.7]
20 NMAC 6.2, § 3-108	Public notice and participation	**ACHIEVED** Public notice published [Section 30.2.8]
20 NMAC 6.2, § 3-109	Director approval, disapproval, modification, or termination of proposed Discharge Plans	**UP TO DATE** Discharge plan to be revised if necessary [Section 30.2.9]
20 NMAC 6.1	Water quality standards for interstate and intrastate streams in New Mexico	**NOT APPLICABLE** No streams affected by WIPP [Section 30.2.10]
20 NMAC 7.4	Utility Operator Certification	**UP TO DATE** Operators and supervisors undergo recertification and training every three years [Section 30.2.11]

Not for long - Permit expires 1/16/97

3109. G.4

30.2.1 Notice of Intent to Discharge, 20 NMAC 6.2, § 1-201

Any party intending to make a new water contaminant discharge or to alter the character or location of an existing water contaminant discharge, unless the discharge is being made or will be made into a community sewer system or subject to the Liquid Waste Disposal Regulations adopted by the New Mexico Environmental Improvement Board, shall file a notice with the Water Pollution Control Bureau of the New Mexico Environment Department (NMED).

NOIs to discharge have been filed as required. The latest filing occurred on August 28, 1995.

30.2.2 Filing of Plans and Specifications - Sewerage Systems, 20 NMAC 6.2, § 1-202

Any party proposing to construct a sewerage system or proposing to modify any sewerage system in a manner that will change the quantity or quality of the discharge from the system substantially must file plans and specifications for the construction or modification with the Water Pollution Control Bureau of the NMED.

Sewerage system plans and specifications were included in the transmittal of the Discharge Plan application to the NMED.

30.2.3 Notification of Discharge - Removal, 20 NMAC 6.2, § 1-203

Requirements for reporting, notifications, and corrective action with respect to any discharge from any facility of oil or other water contaminant, in such quantity as may with reasonable probability injure or be detrimental to human health, animal or plant life, or property, or unreasonably interfere with the public welfare or the use of property are specified.

In the event of an unauthorized discharge of oil or other potentially harmful water contaminants, notification and reporting will be performed and corrective action taken according to WID procedures and the *RCRA Contingency Plan*. The discharge will be reported to the Chief of the Groundwater Bureau of the NMED within 24 hours. A written report will be submitted within seven days, as required under this regulation.

30.2.4 General Requirements, 20 NMAC 6.2, § 2-101

General discharge limitations and sampling/analytical requirements for the discharge of effluents to a watercourse must be met.

These limitations and requirements are specified in the NMED's Discharge Plan Approval DP-831. The discharge limitations and the sampling/analytical requirements are met. Reports are submitted quarterly to the NMED.

30.2.5 Discharge Plan Required, 20 NMAC 6.2, § 3-104

No party shall cause or allow effluent or leachate to discharge so that it may move directly or indirectly into ground water unless the discharge meets the requirements of a discharge plan approved by the Director. When a plan has been approved, discharges must be consistent with the terms and conditions of the plan.

The discharge of 2,000 gpd of nonhazardous brine water at WIPP is authorized by NMED Discharge Plan approval, DP-831.

30.2.6 Application for Discharge Plan Approval, 20 NMAC 6.2, § 3-106

Any party who intends to begin discharging any listed water contaminants or any toxic pollutant so that they may move directly or indirectly into ground water must submit a Discharge Plan as required.

A Discharge Plan application was submitted to the NMED on November 14, 1991. The NMED approved the plan on January 16, 1992; it will expire on January 16, 1997.

30.2.7 Monitoring, Reporting, and other Requirements, 20 NMAC 6.2, § 3-107

Requirements include notification of the NMED of any facility expansion, production increase, or process modifications that would result in the discharge of water contaminants.

Monitoring reports are filed quarterly according to the following schedule: January 16, April 16, July 16, and October 16.

30.2.8 Public Notice and Participation, 20 NMAC 6.2, § 3-108

Within 30 days of filing of a proposed discharge plan, or modification or renewal of an approved discharge plan, the

NMED must ensure that the public and affected governmental agencies are notified.

The NMED made public notice of the Discharge Plan on December 15, 1991. No comments were received from the public.

30.2.9 Director Approval, Disapproval, Modification, or Termination of Proposed Discharge Plans, 20 NMAC 6.2, § 3-109

If the monitoring data submitted indicate that these regulations are being or may be violated or that the standards in 20 NMAC 6.2, § 3-102, "Standards for Ground Water of 10,000 mg/L TDS [total dissolved solid] Concentration or Less," are being or will be exceeded in ground water at any place of withdrawal for the present or reasonably foreseeable future due to the discharge, it may be necessary to modify the Discharge Plan.

If the monitoring data submitted indicate that the Discharge Plan conditions or the standards are being or will be exceeded, the plan may be revised.

7 Since the approval of discharge may not exceed seven years from the date of issuance of the Discharge Plan approval, it will be necessary to find an alternative means of disposal for the nonhazardous brine solution currently being discharged.

30.2.10 Water Quality Standards for Interstate and Intrastate Streams in New Mexico, 20 NMAC 6.1

The State has set a number of water-quality standards for interstate and intrastate streams in New Mexico.

The water-quality standards for interstate and intrastate streams in New Mexico do not apply to WIPP because there are no streams, either intermittent or permanent, that will be affected by WIPP.

30.2.11 Utility Operator Certification, 20 NMAC 7.4

The State requires that operators of public water supply systems and public wastewater facilities be certified to the educational and experience requirements of Subpart II of Part 4.

Under these regulations, the WIPP is considered a public water supply system, which is defined as a system for the provision to the public of piped water for human consumption or domestic purposes, and the system regularly serves an average of at least 25 individuals at least 60 days of the year; it includes any water supply source and any treatment, storage, and distribution facilities. The WIPP is classified as a Class 2 public water supply system because of the population served, 501 to 5,000, and the treatment process being chlorination.

The WIPP is also considered a Class 1 public wastewater facility because of the population served and the treatment process being raw wastewater lagoons.

Since these systems at WIPP require certified operators, the WID's Facility Operations Section employs operators and supervisors certified to the section's requirements. All operators undergo recertification and training every three years; training and certification records are maintained by Facility Operations.

30.3 Compliance Status of the Permit Requirements

Table 30-2 summarizes the specific and general requirements from the Discharge Plan for WIPP and their compliance status. Additional information is provided in the text.

TABLE 30-2. New Mexico Water Quality Act - Summary of Compliance Status of Permit Requirements

CITATION	REQUIREMENT	COMPLIANCE STATUS
Approval DP-831, *New Mexico Discharge Plan for the WIPP*		
DP-831 Specific Requirement (SR) #1	Monitoring and quarterly reports	**UP TO DATE** Monitoring conducted and reports submitted quarterly [Section 30.3.1]
DP-831 SR #2	Submittal of water quality analysis with quarterly report	**UP TO DATE** Analysis submitted quarterly [Section 30.3.2]
DP-831 SR #3	Quarterly sampling of each evaporation lagoon	**UP TO DATE** Sampling and results reported quarterly [Section 30.3.3]

CITATION	REQUIREMENT	COMPLIANCE STATUS
DP-831 SR #4	Maintenance of berms protecting the lagoon system from precipitation runoff and run-on	**UP TO DATE** Performed quarterly [Section 30.3.4]
DP-831 SR #5	Completion of proposed evaporation ponds	**ACHIEVED** Completed July 16, 1993 [Section 30.3.5]
DP-831 General Requirement (GR)--Record-keeping	Records to be kept and made available to the NMED upon request	**UP TO DATE** Information recorded and available [Section 30.3.6]
DP-831 GR - Inspection and Entry	Allowing inspections, entry, sampling, and monitoring by NMED personnel	**UP TO DATE** Activities allowed on site [Section 30.3.7]
DP-831 GR - Duty to Provide Information	Providing information relevant to Discharge Plan/records required by Discharge Plan that has been requested by NMED	**UP TO DATE** No information requested to date [Section 30.3.8]
DP-831 GR - Spills, Leaks, and Other Unauthorized Discharges	Reporting and remediation of any spills, leaks, and any other unauthorized discharges	**UP TO DATE** Reports to be made if unauthorized discharges occur; no reporting required to date [Section 30.3.9]
DP-831 GR - Retention of Records	Retention of all monitoring information, Discharge Plan reports, and data used to complete the Discharge Plan application for at least five years	**UP TO DATE** Documentation being retained [Section 30.3.10]

CITATION	REQUIREMENT	COMPLIANCE STATUS
DP-831 GR - Modifications and/or Amendments	Notification of NMED of any modifications or additions to the wastewater disposal system; approval by NMED required prior to increasing the quantity or concentration of constituents in waste water above those approved in the plan	**UP TO DATE** Approval to be obtained as required [Section 30.3.11]

30.3.1 Requirements for Monitoring and Quarterly Reports, DP-831 Specific Requirement (SR) #1

The applicant shall monitor the quantity of brine water pumped into the evaporation ponds monthly and submit a quarterly report to the Ground Water Section's Office.

The monitoring required by the NMED Discharge Plan Approval DP-381 has been conducted as required. The results have been submitted in the quarterly Discharge Monitoring Reports required by the Discharge Plan, which are prepared in accordance with a WID procedure.

30.3.2 Requirement for Water Quality Analysis Submitted with Quarterly Report, DP-831 SR #2

A water quality analysis shall be submitted with the quarterly report mentioned above in SR #1.

Water quality analyses have been submitted with the quarterly reports.

30.3.3 Requirement that the Evaporation Lagoon be Sampled and the Results Reported, DP-831 SR #3

Each evaporation lagoon shall be sampled quarterly for total dissolved solids (TDS) and the results submitted in the quarterly report.

Each evaporation lagoon has been sampled quarterly, and the results provided in the quarterly reports.

30.3.4 Requirement for Berm Maintenance, DP-831 SR #4

Berms protecting the lagoon system shall be maintained to protect it from precipitation runoff and runon.

Maintenance of the berms is performed quarterly.

30.3.5 Requirement for Completion of Proposed Evaporation Ponds, DP-831 SR #5

The applicant has 18 months from the date of approval to complete construction of the proposed evaporation ponds. The applicant can discharge brine waters into the existing salt pile evaporation pond until the new evaporation ponds are completed.

The evaporation ponds were completed by July 16, 1993, as required.

30.3.6 General Requirement, *Record-keeping*, DP-831

The discharger must maintain a written record of ground-water and wastewater quality analyses at the facility. The information must be recorded and made available to the NMED upon request.

Monitoring, reporting, and record-keeping requirements are met as specified in the Discharge Plan.

30.3.7 General Requirement, *Inspection and Entry*, DP-831

The discharger shall allow the NMED Secretary or her authorized representative, upon the presentation of credentials, to enter the discharger's facility during regular business hours or at other reasonable times under the conditions of this discharge plan.

NMED personnel are allowed on site to conduct inspections, sampling, and monitoring during normal business hours.

30.3.8 General Requirement, *Duty to Provide Information*, DP-831

The discharger shall furnish to the NMED, within a reasonable time frame specified by the NMED, any relevant information which it may request to determine whether cause exists for modifying, terminating, and/or renewing this *discharge plan or to determine compliance with this plan. The discharger shall furnish to the NMED, upon request, copies of records required to be kept by this Discharge Plan.*

No requests have been received from the NMED to provide information relevant to the Discharge Plan. Similarly, the NMED has not requested copies of the records to be maintained under the terms of the Discharge Plan.

30.3.9 General Requirement, *Spills, Leaks, and other Unauthorized Discharges*, DP-831

Any unauthorized discharges must be reported to the NMED and remediated as required. This requirement applies to all seeps, spills, and/or leaks discovered from the sewerage lagoons or that may directly or indirectly leave the boundaries of the WIPP site.

Any spills, leaks, and other unauthorized discharges will be reported to NMED and remediated in accordance with WIPP procedures.

30.3.10 General Requirement, *Retention of Records*, DP-831

The discharger shall retain records of all monitoring information, including all calibration and maintenance records, copies of all reports required by this discharge plan, and records of all data used to complete the application for this discharge plan, for a period of at least 5 years from the date of the sample collection, measurement, report, or application.

All monitoring information, analytical results, Discharge Plan reports, and data used to complete the Discharge Plan application will be retained for at least five years.

30.3.11 General Requirement, *Modifications and/or Amendments*, DP-831

The discharger must notify the NMED of any modifications or additions to the applicant's wastewater disposal system, including any increase in wastewater flow rate and wastewater storage and disposal management changes to the system as approved under this discharge plan. The discharger shall obtain the NMED's approval, as a discharge plan modification, prior to any increase in the quantity or concentration of constituents in the wastewater above those approved in this plan.

If any modifications or additions to the wastewater disposal system are planned for WIPP that would increase the quantity and/or the concentration of constituents in the waste water above those approved in the discharge plan, the NMED will be notified. No work will be initiated until the NMED approves the modification or addition.

1.0 INTRODUCTION

This *Biennial Environmental Compliance Report* (BECR) addresses regulatory compliance at the Waste Isolation Pilot Plant (WIPP), a research and development facility designed to demonstrate the safe disposal of transuranic (TRU) radioactive waste. As required by the WIPP Land Withdrawal Act (LWA) (Public Law [PL] 102-579), the BECR documents WIPP's compliance with applicable federal laws implemented by the U.S. Environmental Protection Agency (EPA) and applicable New Mexico laws, regulations, and permit conditions.

The BECR also addresses compliance with some federal laws implemented by other United States agencies including the Council on Environmental Quality, Department of Energy (DOE), Nuclear Regulatory Commission, Department of Transportation, Department of Interior Bureau of Land Management and Fish and Wildlife Service, and the Advisory Council on Historic Preservation.

1.1 Background of the Waste Isolation Pilot Plant (WIPP)

The WIPP Project was authorized by the DOE National Security and Military Applications of Nuclear Energy Authorization Act of 1980 (PL 96-164). This legislation mandated that DOE provide a research and development facility to demonstrate the safe disposal of radioactive waste resulting from U.S. defense activities and programs. Initially, the WIPP mission was to include experimentation with high-level wastes, but subsequent legislation has restricted the radioactive waste to TRU waste. TRU waste is radioactive waste that contains alpha-emitting radionuclides of atomic number greater than 92 with half-lives longer than 20 years which are present in concentrations greater than 100 nanocuries per gram of waste. Most of this waste is generated from plutonium reprocessing and fabrication.

In January 1981, the DOE announced its decision to proceed with a phased development of the WIPP, to be located in Eddy County in southeastern New Mexico, 26 miles east of the city of Carlsbad. The decision called for the WIPP to be designed to accommodate approximately 6.2 million cubic feet of contact-handled (CH) TRU waste and 0.25 million cubic feet of remote-handled (RH) TRU waste. The WIPP LWA has limited the total WIPP capacity to 6.2 million cubic feet of transuranic waste.

After completing a site and preliminary design validation (SPDV) phase, the construction phase at the WIPP began in 1983. At present, surface and underground facilities to support waste handling and emplacement operations have been constructed. Of the nine surface buildings, the largest structure is the Waste Handling Building, which includes areas for the receipt, inventory, inspection, and transfer of waste to the underground. The WIPP underground facility, which is 2,150 feet below the land surface in a 2,000-foot-thick bedded salt formation, consists of four shafts, the waste disposal area, the experimental area (for repository safety and mine performance studies), an equipment and maintenance facility, and connecting tunnels. Only a few waste disposal rooms have been mined at present because of the natural phenomenon of salt creep, which causes eventual room closure. Additional waste disposal rooms will be mined prior to permanent waste emplacement.

Originally, the construction phase was to have been followed by the pilot plant phase. Following the preparation of the Supplement Environmental Impact Statement (SEIS) in 1990, the DOE decided that the construction phase was to be followed by the test phase, during which tests with TRU waste would have been conducted underground at the WIPP. However, on October 21, 1993, the DOE announced its decision not to conduct TRU waste tests underground at the WIPP facility, but to conduct enhanced laboratory tests at existing DOE facilities elsewhere. Thus no TRU or TRU-mixed waste (radioactive waste with hazardous constituents) will be sent to WIPP until after the initiation of the disposal phase. The disposal phase will be followed by the decontamination and decommissioning phase.

More detailed information on the background of the WIPP project can be found in the DOE's *Final Environmental Impact Statement, Waste Isolation Pilot Plant* (FEIS; DOE, 1980); the DOE's 1981 Record of Decision (ROD) to the FEIS (DOE, 1981); the 1990 *Final Supplement Environmental Impact Statement, Waste Isolation Pilot Plant* (SEIS; DOE, 1990a); and the 1990 ROD to the SEIS (DOE, 1990b).

A second supplemental environmental impact statement (SEIS-II) is presently being prepared to address information that has become available since 1990. Further information is also available in documents referenced by the SEIS-II.

1.2 Biennial Environmental Compliance Report under the WIPP Land Withdrawal Act

This BECR provides the documentation required by the 1992 LWA. The LWA specifies that :

> *The Secretary shall, not later than 2 years after the date of the enactment of this Act, and biennially thereafter, submit documentation of continued compliance with the laws, regulations and permit requirements described in paragraph (1) to the Administrator, and, with the law described in paragraph (1)(C), to the State [§ 9(a)(2)].*

Paragraph (1) requires that the WIPP comply with Subpart A of 40 *Code of Federal Regulations* (CFR) Part 191; the Clean Air Act; the Solid Waste Disposal Act (SWDA); the Safe Drinking Water Act; the Toxic Substances Control Act; the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA); "all other applicable Federal laws pertaining to public health and safety or the environment;" and "all regulations promulgated, and all permit requirements" under these laws.

1.3 Regulatory Requirements Hierarchy

The first step in documenting regulatory compliance is the identification of all applicable regulatory requirements. This section describes the interrelationships among laws, regulations, and permit conditions and identifies the origins of the detailed regulatory requirements discussed in this report.

1.3.1 Federal/State Laws

Laws result from legislative processes at either the federal, state, or local level. This report will summarize the purpose of each relevant law and discuss its applicability and importance to the WIPP.

1.3.2 Implementing Regulations

Once a law has been enacted, it must be implemented. Authority for implementation of each new act is usually assigned to a particular agency. That agency is responsible for developing regulations to implement the act. At the federal level, these regulations are first published in the *Federal Register* (FR) as "proposed" for comment from interested groups and individuals. The implementing agency must then respond appropriately to the comments and prepare the final regulations. These final regulations are again published in the *Federal Register*, along with a discussion of the comments, and are inserted into the appropriate part(s) of the Code of Federal Regulations (CFR).

New Mexico agencies use a similar process in the promulgation of regulations, with the proposed and final regulations published in the *New Mexico Register*. Many state environmental laws evolve from federal statutes, many of which allow that the state become authorized to administer and enforce its own regulatory program in lieu of the federal program as long as the state regulations are no less stringent than the federal requirements. In these cases, the state must send its "final" regulations to the governing agency, such as the EPA, for approval. The governing agency may approve all, part, or none of the final regulations. After agency approval, notification of the agency's authorization of the state program is published in the *Federal Register*.

Local laws or ordinances that apply to the WIPP are limited to those under the authority of the county commission. The only local laws or ordinances applicable to the facility are zoning ordinances. These do not affect the facility's ability to protect human health and the environment. Therefore, these laws and ordinances are not included in this report.

This report identifies specific requirements from federal/state implementing regulations that apply to the WIPP facility. In some cases where implementing regulations have not been promulgated or where a particular statute requirement is not covered by the implementing regulations, this report identifies specific requirements directly from the statute.

1.3.3 Permit Conditions

A number of federal/state implementing regulations include permit programs. Because many implementing regulations are couched in general terms, permits and permit programs allow the regulatory agency to regulate individual facilities and stipulate site-specific conditions that must be met by a specific facility to meet the statutory goals of protection of the public and the environment. Thus, permits are used to regulate discharges and activities (construction, modifications, and/or operations) of a facility. This report identifies site-specific permit conditions that apply to the WIPP.

1.4 Regulatory Compliance at the WIPP

The DOE and the Westinghouse Electric Corporation's Waste Isolation Division (WID), the Prime Contractor for the WIPP, are fully committed to conducting operations at the WIPP in a way that achieves and demonstrates compliance with applicable regulations and permit conditions. Both organizations have implemented plans and procedures to achieve and maintain compliance with the regulations and have established aggressive assessment programs to validate continued successful implementation of these activities.

In a number of areas throughout this document, it is noted that procedures and manuals are in place to guide and direct WIPP personnel in the performance of specific job tasks which have or could have a direct impact on the compliance status in a given situation. These procedures and manuals are in place to supplement personnel training, education, and qualifications and to promote the operation of the WIPP facility in a safe and environmentally sound manner. Because this is the intended purpose of these documents, they are continually evaluated and revised to ensure that they are effective and current with respect to both regulatory and operational changes. For this reason, specific procedures and manuals are not referenced in the body of this document.

In addition, a number of reports (especially those reports which are a result of regulatory requirements) are referenced throughout the document. Due to the continual update and revision requirements for reports of this nature, they are referenced only by the report title or by the citation that requires their submittal rather than by document numbers.

1.4.1 Organizational Structure

The organizational structure of the DOE Carlsbad Area Office (CAO) and WID reflect the importance of regulatory compliance at the WIPP and the commitment of both organizations to achieving and maintaining full compliance.

The CAO's organizational structure consists of the Area Manager, who oversees three major branches: the Office of Program Support and Assurance, the Office of

Regulatory Compliance, and the Office of National TRU Waste Operations. These branches function together to ensure that the WIPP's day-to-day and long-term environmental compliance programs remain exemplary. The Office of Program Support and Assurance interprets environment, safety, health, and quality assurance requirements applicable to WIPP. The Office of Regulatory Compliance develops the overall strategy and criteria to demonstrate and validate long-term compliance for the disposal of TRU waste. The Office of National TRU Waste Operations manages the day-to-day operation of the WIPP facility.

WID's commitment to compliance is also represented in their organizational structure, consisting of the General Manager, the Deputy General Manager, and eight department managers. The department manager of Environment, Safety, and Health reports directly to the General Manager and manages the WID's environmental compliance activities including document preparation, monitoring, analysis, and oversight. The department manager for Quality and Regulatory Assurance provides support to ensure that compliance activities are managed and performed in a manner consistent with WID's commitment to compliance.

1.4.2 Compliance Assurance

Compliance includes a wide range of activities, ranging from the preparation of plans, procedures, reports, or permit applications to hands-on actions such as record keeping, monitoring, sampling and analysis, performing assessments or audits, and housekeeping.

There are three programs to assess WIPP programs and activities that have an impact on the WIPP's environmental compliance status. These include the WID Environmental Compliance Assessment Program (ECAP), the WID Quality Assurance Programs, and the CAO Assurance Plan.

The ECAP provides a comprehensive system to appraise compliance with applicable environmental laws and regulations, and identifies environmentally sound corrective action measures for any findings or observations identified. The ECAP assessments are used to identify and eliminate deficiencies that could lead to the following unacceptable events:

- Permit violations
- Regulatory noncompliance
- Safety and health risks to WIPP site workers and/or the general public
- Spills, releases, or discharges of environmental pollutants

Complimenting the ECAP are the CAO and WID Quality Assurance Programs. Quality Assurance Program surveillances, audits, and assessments of WIPP activities are designed to verify compliance with quality assurance requirements and determine the adequacy and effectiveness of the activities. Elements of these oversight activities include:

- Monitoring work in progress
- Documenting compliance or non-compliance with established requirements and procedures
- Identifying actual and potential conditions adverse to quality
- Obtaining timely corrective action commitments from cognizant managers.
- Providing notification to responsible managers of the status and performance of work under assessment
- Verifying timely implementation of corrective actions.

1.5 Organization of and Reporting Period for the Report

The organization of and reporting period for the BECR are discussed in the following subsections.

1.5.1 Organization of the Report

This report organizes the pertinent regulatory requirements into 14 parts, each of which corresponds to a federal or state agency that is authorized to administer regulatory programs. Under each agency, separate chapters identify and discuss each law administered by the agency that is relevant to the WIPP facility. For example, the first part contains pertinent regulatory programs administered by the EPA. Within this part, ten chapters correspond to the ten environmental laws and sets of regulations that apply to the WIPP for which the EPA is responsible (Chapters 2 through 11).

Each of the following 37 chapters summarizes a law and its implementing regulations and briefly describes its applicability to the WIPP. For ease in identifying compliance status, summary tables in each chapter provide a synopsis of WIPP's compliance with each specific requirement and a cross-reference to the more detailed discussion in the text. Each section of the text summarizes a requirement and addresses its compliance status.

The WIPP is subject to oversight by a number of regulatory agencies. The scope of the BECR chapters includes the documentation of occasions in which the WIPP may have received a notice of violation by a regulatory agency. Audits, appraisals, and assessments conducted by regulatory agencies did not result in notices of violation during this reporting period.

Within the BECR summary tables the compliance status is identified as "achieved," "up to date," or "not applicable."

ACHIEVED Items with the status of "achieved" are requirements that have been met and do not require any further action. They are essentially "one-time" occurrences.

Example: As a generator of hazardous waste, WIPP must obtain an EPA ID number; this requirement has been achieved.

UP TO DATE Items with the status of "up to date" are requirements that require some type of ongoing activity to maintain compliance.

Example: The DOE must file a biennial hazardous waste report; these reports are up to date.

NOT APPLICABLE Items with the status of "not applicable" were evaluated and determined not to be applicable to the WIPP either during this reporting. period or throughout the duration of the project.

Example: Since the WIPP disposes of its construction and demolition debris at a landfill located on DOE property and in accordance with the applicable regulations, the requirement for obtaining a permit is not applicable.

Following the list of references, Appendix A presents an index of the specific requirements discussed in the report by regulating agency. Appendix B indexes the specific requirements in terms of their technical subject areas (for example, waste management requirements, water quality requirements, historic preservation requirements).

1.5.2 Reporting Period

The first BECR, issued October 24, 1994, addressed the status of WIPP compliance programs and activities for the period from the congressional approval of the WIPP LWA on October 30, 1992 to March 31, 1994. This BECR addresses the compliance status of WIPP programs and activities for the reporting period beginning April 1, 1994, and ending on March 31, 1996.

23.1 Summary of the Law 23-1

23.2 Compliance Status of the Regulatory Requirements 23-2

23.2.1 Permit Application Procedures, 50 CFR 13.11 23-3

23.2.2 Application for Endangered or Threatened Species Permit, 50 CFR 17.22(a)(1), 17.32, 17.52, and 17.62 23-4

23.2.3 Biological Assessment of Impacts on Recognized Species, 50 CFR 402.12 23-4

23.2.4 Formal Consultation with the FWS Regarding Impacts on Recognized Species, 50 CFR 402.14 23-4

ADVISORY COUNCIL ON HISTORIC PRESERVATION

24.0 National Historic Preservation Act 24-1

24.1 Summary of the Law 24-1

24.2 Compliance Status of the Regulatory Requirements 24-2

24.2.1 Assessment of Effects on Historic Properties, 36 CFR 800.5 24-3

24.2.2 Development of a Plan for the Treatment of Historical Property Discovered during a Federal Agency Undertaking, 36 CFR 800.11 24-3

24.2.3 Application for Permits and Information Collection, 43 CFR 7.5 24-4

NEW MEXICO ENVIRONMENT DEPARTMENT

25.0 New Mexico Hazardous Waste Act 25-1

25.1 Summary of the Law 25-1

25.2 Compliance Status of Regulatory Requirements 25-6

25.2.1 Compliance Status of the Hazardous Waste Regulatory Requirements 25-6

25.2.1.1 Compliance with Other Regulations, 20 NMAC 4.1, § 1001 25-6

25.2.2 Compliance with Regulations for Hazardous Waste Generators, 20 NMAC 4.1, Subpart III, § 300 25-6

25.2.2.1 Hazardous Waste Determination, 40 CFR 262.11 25-11
25.2.2.2 EPA Identification Number, 40 CFR 262.12 25-11
25.2.2.3 Manifest Requirements, 40 CFR 262.20 25-12
25.2.2.4 Acquisition of Manifests, 40 CFR 262.21 25-12
25.2.2.5 Number of Copies, 40 CFR 262.22 25-12
25.2.2.6 Use of the Manifest, 40 CFR 262.23 25-12
25.2.2.7 Packaging Requirements, 40 CFR 262.30 25-13
25.2.2.8 Labeling Requirements, 40 CFR 262.31 25-13
25.2.2.9 Marking Requirements, 40 CFR 262.32 25-13
25.2.2.10 Placarding Requirements, 40 CFR 262.33 25-13
25.2.2.11 Accumulation Time, 40 CFR 262.34(a) 25-13
25.2.2.12 Compliance with Subpart I of 40 CFR Part 265, 40 CFR 262.34(a)(1)(i) 25-14
25.2.2.13 Accumulation of Hazardous Wastes, 40 CFR 262.34(a)(1)(ii) 25-14
25.2.2.14 Compliance with Subpart W of 40 CFR Part 265, 40 CFR 262.34(a)(1)(iii) 25-14
25.2.2.15 Marking with Date of Initial Accumulation, 40 CFR 262.34(a)(2) 25-14
25.2.2.16 Marking as Hazardous Waste, 40 CFR 262.34(a)(3) 25-15
25.2.2.17 Compliance with Emergency Response, Training, and Waste Analysis Plan Requirements, 40 CFR 262.34(a)(4) 25-15
25.2.2.18 Extension of Storage Period, 40 CFR 262.34(b) 25-17
25.2.2.19 Restrictions and Requirements, 40 CFR 262.34(c)(1) 25-18
25.2.2.20 Compliance with 40 CFR 265.171, 265.172, and 265.173(a), 40 CFR 262.34(c)(1)(i) 25-18
25.2.2.21 Labeling of Container as "Hazardous Waste," 40 CFR 262.34(c)(1)(ii) 25-19
25.2.2.22 Management of Waste, 40 CFR 262.34(c)(2) 25-19
25.2.2.23 Recordkeeping Requirements, 40 CFR 262.40 25-19
25.2.2.24 Generator–Biennial Report, 40 CFR 262.41 25-19
25.2.2.25 Exception Reporting, 40 CFR 262.42 25-20
25.2.2.26 Additional Reporting, 40 CFR 262.43 25-20
25.2.2.27 Special Requirements for Generators of Between 100 and 1,000 kg/mo, 40 CFR 262.44 25-20

25.2.3 Compliance with Standards Applicable to Transporters of Hazardous Waste, 40 CFR Part 263 25-20

25.2.3.1 Compliance with Department of Transportation (DOT) Regulations, 40 CFR 263.10(a) 25-22

25.2.3.2 EPA Identification Number, 40 CFR 263.11 25-22
25.2.3.3 Compliance with the Manifest System and with Recordkeeping Requirements, 40 CFR 263.20-263.22 25-22
25.2.3.4 Immediate Action after Hazardous Waste Discharges, 40 CFR 263.30 25-22
25.2.3.5 Discharge Cleanup, 40 CFR 263.31 25-23

25.2.4 Compliance Status of the Regulatory Requirements for Interim-Status Treatment/Storage/Disposal Facilitie, 40 CFR Part 265 25-23

25.2.4.1 Applicability, 40 CFR 265.10 25-32
25.2.4.2 EPA Identification Number, 40 CFR 265.11 25-32
25.2.4.3 Required Notices, 40 CFR 265.12 25-33
25.2.4.4 General Waste Analysis, 40 CFR 265.13 25-33
25.2.4.5 Security, 40 CFR 265.14 25-33
25.2.4.6 General Inspection Requirements, 40 CFR 265.15 25-34
25.2.4.7 Personnel Training, 40 CFR 265.16 25-34
25.2.4.8 General Requirements for Ignitable, Reactive, or Incompatible Wastes, 40 CFR 265.17 25-35
25.2.4.9 Location Standards, 40 CFR 265.18 25-36
25.2.4.10 Maintenance and Operation of Facility, 40 CFR 265.31 25-36
25.2.4.11 Required Equipment, 40 CFR 265.32 25-36
25.2.4.12 Testing and Maintenance of Equipment, 40 CFR 265.33 25-37
25.2.4.13 Access to Communications or Alarm Systems, 40 CFR 265.34 25-37
25.2.4.14 Required Aisle Space, 40 CFR 265.35 25-37
25.2.4.15 Arrangements with Local Authorities, 40 CFR 265.37 25-38
25.2.4.16 Purpose and Implementation of the Contingency Plan, 40 CFR 265.51 25-38
25.2.4.17 Content of the Contingency Plan, 40 CFR 265.52 25-38
25.2.4.18 Copies of Contingency Plan, 40 CFR 265.53 25-39
25.2.4.19 Amendment of Contingency Plan, 40 CFR 265.54 25-39
25.2.4.20 Emergency Coordinator, 40 CFR 265.55 25-40
25.2.4.21 Emergency Procedures, 40 CFR 265.56 25-40
25.2.4.22 Use of Manifest System, 40 CFR 265.71 25-41
25.2.4.23 Manifest Discrepancies, 40 CFR 265.72 25-42
25.2.4.24 Operating Record, 40 CFR 265.73 25-42
25.2.4.25 Availability, Retention, and Disposition of Records, 40 CFR 265.74 25-42
25.2.4.26 TSDF Biennial Report, 40 CFR 265.75 25-43
25.2.4.27 Unmanifested Waste Report, 40 CFR 265.76 25-43
25.2.4.28 Additional Reports, 40 CFR 265.77 25-43
25.2.4.29 Applicability of the Ground-Water Monitoring System, 40 CFR 265.90 25-44
25.2.4.30 Ground-Water Monitoring System, 40 CFR 265.91 25-44
25.2.4.31 Sampling and Analysis, 40 CFR 265.92 25-44
25.2.4.32 Preparation, Evaluation, and Response 40 CFR 265.93 25-45
25.2.4.33 Recordkeeping and Reporting, 40 CFR 265.94 25-45

25.2.4.34 Applicability of the Closure/Postclosure Requirements, 40 CFR 265.110 25-45
25.2.4.35 Closure Performance Standard, 40 CFR 265.111 25-46
25.2.4.36 Closure Plan; Amendment of Plan, 40 CFR 265.112 25-46
25.2.4.37 Time Allowed for Closure, 40 CFR 265.113 25-46
25.2.4.38 Disposal or Decontamination of Equipment, Structures, and Soils, 40 CFR 265.114 25-47
25.2.4.39 Certification of Closure, 40 CFR 265.115 25-47
25.2.4.40 Survey Plat, 40 CFR 265.116 25-48
25.2.4.41 Postclosure Care and Use of Property, 40 CFR 265.117 25-48
25.2.4.42 Postclosure Plan; Amendment of Plan, 40 CFR 265.118 25-48
25.2.4.43 Postclosure Notices, 40 CFR 265.119 25-48
25.2.4.44 Certification of Completion of Postclosure Care, 40 CFR 265.120 25-49
25.2.4.45 Cost Estimate for Closure, 40 CFR 265.142 25-49
25.2.4.46 Financial Assurance for Closure, 40 CFR 265.143 25-49
25.2.4.47 Cost Estimate for Postclosure Care, 40 CFR 265.144 25-50
25.2.4.48 Financial Assurance for Postclosure Care, 40 CFR 265.145 25-50
25.2.4.49 Use of a Mechanism for Financial Assurance of Both Closure and Postclosure Care, 40 CFR 265.146 25-50
25.2.4.50 Liability Requirements, 40 CFR 265.147 25-50
25.2.4.51 Incapacity of Owners or Operators, Guarantors,or Financial Institutions, 40 CFR 265.148 25-50
25.2.4.52 Use of State-required Mechanisms, 40 CFR 265.149 25-51
25.2.4.53 State Assumption of Responsibility, 40 CFR 265.150 25-51
25.2.4.54 Condition of Containers, 40 CFR 265.171 25-51
25.2.4.55 Compatibility of Waste with Containers, 40 CFR 265.172 25-52
25.2.4.56 Management of Containers, 40 CFR 265.173 25-52
25.2.4.57 Inspections, 40 CFR 265.174 25-53
25.2.4.58 Special Requirements for Ignitable or Reactive Waste, 40 CFR 265.176 25-53
25.2.4.59 Special Requirements for Incompatible Wastes, 40 CFR 265.177 25-53
25.2.4.60 Tank Systems; Surface Impoundments; Waste Piles; Land Treatment; Landfills; Incinerators; Thermal Treatment; Chemical, Physical, and Biological Treatment; Underground Injection; and Drip Pads, 40 CFR 265.190-.445 25-54
25.2.4.61 Air Emission Standards for Process Vents, 40 CFR 265.1032 25-54
25.2.4.62 Air Emission Standards for Equipment Leaks, 40 CFR 265.1052-1062 25-54
25.2.4.63 Air Emission Standards for Tanks, Surface Impoundment, and Containers, 40 CFR 265.1080 25-55

25.2.5 Compliance with the Hazardous/Mixed Waste Permit Program, 40 CFR Part 270 25-55

25.2.5.1 Purpose and Scope of the RCRA Permit Program Regulations, 40 CFR 270.1 25-57

25.2.5.2 General Application Requirements, 40 CFR 270.10 25-58
25.2.5.3 Signatories to Permit Applications and Reports, 40 CFR 270.11 25-58
25.2.5.4 Contents of Part A of the Permit Application, 40 CFR 270.13 25-59
25.2.5.5 Contents of Part B: General Requirements, 40 CFR 270.14 25-59
25.2.5.6 Specific Part B Information Requirements for Containers, 40 CFR 270.15 25-60
25.2.5.7 Specific Part B Information for Miscellaneous Units, 40 CFR 270.23 25-60
25.2.5.8 Conditions Applicable to All Permits, 40 CFR 270.30 25-60
25.2.5.9 Requirements for Recording and Reporting of Monitoring Results, 40 CFR 270.31 25-61
25.2.5.10 Permit Modification at the Request of the Permittee, 40 CFR 270.42 25-61
25.2.5.11 Operation during Interim Status, 40 CFR 270.71 25-62
25.2.5.12 Changes during Interim Status, 40 CFR 270.72 25-62

25.2.6 Compliance Status of the Underground Storage Tank Regulatory Requirements under 20 NMAC, Chapter 5 25-62

25.2.6.1 Applicability, 20 NMAC 5.1, § 103; 40 CFR 280.10 25-76
25.2.6.2 Existing Tanks, 20 NMAC 5.2, § 200 25-77
25.2.6.3 Transfer of Ownership, 20 NMAC 5.2, § 201 25-77
25.2.6.4 New UST System, 20 NMAC 5.2, § 202 25-77
25.2.6.5 Substantially Modified UST Systems, 20 NMAC 5.2, § 203 25-78
25.2.6.6 Notification of Spill or Release, 20 NMAC 5.2, § 204 25-78
25.2.6.7 Emergency Repairs and Tank Replacement, 20 NMAC 5.2, § 205 25-78
25.2.6.8 Application Forms, 20 NMAC 5.2, § 206 25-79
25.2.6.9 Registration Certificate, 20 NMAC 5.2, § 207 25-79
25.2.6.10 Payment of Fee, 20 NMAC 5.3, § 300 25-79
25.2.6.11 Amount of Fee, 20 NMAC 5.3, § 301 25-80
25.2.6.12 Late Payment Penalties, 20 NMAC 5.3, § 302 25-80
25.2.6.13 Performance Standards for Tanks in New UST Systems, 20 NMAC 5.4, § 400(a); 40 CFR 280.20(a) 25-80
25.2.6.14 Design and Construction of Piping, 20 NMAC 5.4, § 400(b); 40 CFR 280.20(b) 25-80
25.2.6.15 Spill Prevention Equipment, 20 NMAC 5.4, § 400(c)(1)(i); 40 CFR 280.20(c)(1)(i) 25-81
25.2.6.16 Overfill Prevention Equipment, 20 NMAC 5.4, § 400(c)(1)(ii); 40 CFR 280.20(c)(1)(ii) 25-81
25.2.6.17 Installation of Tanks and Piping, 20 NMAC 5.4 § 400(d); 40 CFR 280.20(d) 25-82
25.2.6.18 Certificate of Installation, 20 NMAC 5.4, § 400(e); 40 CFR 280.20(e) 25-82
25.2.6.19 Upgrading Existing UST Systems, 20 NMAC 5.4, § 401(a); 40 CFR 280.21(a) 25-83
25.2.6.20 Tank Upgrading Requirements, 20 NMAC 5.4, § 401(b); 40 CFR 280.21(b) 25-83

25.2.6.21 Piping Upgrading Requirements, 20 NMAC 5.4, § 401(c); 40 CFR 280.21(c) 25-83
25.2.6.22 Spill and Overfill Prevention Equipment, 20 NMAC 5.4, § 401(d); 40 CFR 280.21(d) 25-83
25.2.6.23 Certificate of Compliance and Notification Requirements, 20 NMAC 5.4, § 402; 40 CFR 280.22 25-84
25.2.6.24 Spill and Overflow Control, 20 NMAC 5.5, § 500; 40 CFR 280.30 25-84
25.2.6.25 Operation and Maintenance of Corrosion Protection, 20 NMAC 5.5, § 501(a); 40 CFR 280.31(a) 25-84
25.2.6.26 Inspections of Cathodic Protection System, 20 NMAC 5.5, § 501(b); 40 CFR 280.31(b) 25-85
25.2.6.27 Inspections of Impressed-Current Cathodic Protection Systems, 20 NMAC 5.5, § 501(c); 40 CFR 280.31(c) 25-85
25.2.6.28 Records of Operation of the Cathodic Protection System, 20 NMAC 5.5, § 501(d); 40 CFR 280.31(d) 25-85
25.2.6.29 Compatibility, 20 NMAC 5.5, § 502; 40 CFR 280.32 25-86
25.2.6.30 Repairs Allowed, 20 NMAC 5.5, § 503(a); 40 CFR 280.33(a) 25-86
25.2.6.31 Repairs to Fiberglass Reinforced Plastic Tanks, 20 NMAC 5.5, § 503(b); 40 CFR 280.33(b) 25-86
25.2.6.32 Repairs of Pipe Sections and Fittings, 20 NMAC 5.5, § 503(c); 40 CFR 280.33(c) 25-86
25.2.6.33 Tightness Testing after Repairs, 20 NMAC 5.5, § 503(d); 40 CFR 280.33(d) 25-86
25.2.6.34 Testing of Repaired Cathodically Protected UST System, 20 NMAC 5.5, § 503(e); 40 CFR 280.33(e) 25-87
25.2.6.35 Records of All Repairs, 20 NMAC 5.5, § 503(f); 40 CFR 280.33(f) 25-87
25.2.6.36 Reporting, 20 NMAC 5.5, § 504(a); 40 CFR 280.34(a) 25-87
25.2.6.37 Recordkeeping Requirements, 20 NMAC 5.5, §504(b); 40 CFR 280.34(b) 25-87
25.2.6.38 Availability and Maintenance of Records, 20 NMAC 5.5, § 504(c); 40 CFR 280.34(c) 25-88
25.2.6.39 Inspections, Monitoring, and Testing of USTs, 20 NMAC 5.5, § 505(a) 25-88
25.2.6.40 Inspections of UST Installations, Repairs or Modifications, or Removals or System Closures, 20 NMAC 5.5, § 505(c) 25-89
25.2.6.41 General Requirements for All UST Systems, 20 NMAC 5.6, § 600(a); 40 CFR 280.40(a) 25-89
25.2.6.42 Notification of Releases, 20 NMAC 5.6, § 600(b); 40 CFR 280.40(b) 25-90
25.2.6.43 Schedule for Required Release Detection, 20 NMAC 5.6, § 600(c); 40 CFR 280.40(c) 25-90
25.2.6.44 Failure to Comply with Release-Detection Requirements, 20 NMAC 5.6, § 600(d); 40 CFR 280.40(d) 25-90
25.2.6.45 Requirements for Tanks of Petroleum UST Systems, 20 NMAC 5.6, § 601(a); 40 CFR 280.41(a) 25-90

25.2.6.46 Requirements for Piping of Petroleum UST Systems, 20 NMAC 5.6, § 601(b); 40 CFR 280.41(b) 25-91
25.2.6.47 Requirements for Pressurized Piping, 20 NMAC 5.6, § 601(b)(1); 40 CFR 280.41(b)(1) 25-91
25.2.6.48 Requirements for Suction Piping, 20 NMAC 5.6, § 601(b)(2); 40 CFR 280.41(b)(2) 25-91
25.2.6.49 Requirements for Hazardous Substance UST Systems, 20 NMAC 5.6, § 602; 40 CFR 280.42 25-92
25.2.6.50 Methods of Release Detection for Tanks, 20 NMAC 5.6, § 603; 40 CFR 280.43 25-92
25.2.6.51 Inventory Control, 20 NMAC 5.6, § 603(a); 40 CFR 280.43(a) 25-92
25.2.6.52 Manual Tank Gauging, 20 NMAC 5.6, § 603(b); 40 CFR 280.43(b) 25-93
25.2.6.53 Tank Tightness Testing, 20 NMAC 5.6, § 603(c); 40 CFR 280.43(c) 25-93
25.2.6.54 Automatic Tank Gauging, 20 NMAC 5.6, § 603(d); 40 CFR 280.43(d) 25-94
25.2.6.55 Vapor Monitoring, 20 NMAC 5.6, § 603(e); 40 CFR 280.43(e) 25-94
25.2.6.56 Ground-Water Monitoring, 20 NMAC 5.6, § 603(f); 40 CFR 280.43(f) 25-95
25.2.6.57 Interstitial Monitoring, 20 NMAC 5.6, § 603(g); 40 CFR 280.43(g) 25-95
25.2.6.58 Other Methods of Detecting Releases, 20 NMAC 5.6, § 603(h); 40 CFR 280.43(h) 25-96
25.2.6.59 Methods of Release Detection of Piping, 20 NMAC 5.6, § 604; 40 CFR 280.44 25-97
25.2.6.60 Release Detection Recordkeeping, 20 NMAC 5.6, § 605; 40 CFR 280.45 25-97
25.2.6.61 Reporting of Suspected Releases, 20 NMAC 5.7, § 700; 40 CFR 280.50 25-98
25.2.6.62 Investigation of Off-Site Impacts, 20 NMAC 5.7, § 701; 40 CFR 280.51 25-98
25.2.6.63 Release Investigation and Confirmation Steps, 20 NMAC 5.7, § 702; 40 CFR 280.52 25-98
25.2.6.64 Reporting and Cleanup of Large Spills and Overfills, 20 NMAC 5.7, § 703(a); 40 CFR 280.53(a) 25-99
25.2.6.65 Reporting and Cleanup of Small Spills and Overfills, 20 NMAC 5.7, § 703(b); 40 CFR 280.53(b) 25-99
25.2.6.66 Temporary Closure, 20 NMAC 5.8, § 800; 40 CFR 280.70 25-100
25.2.6.67 Permanent Closure and Changes in Service, 20 NMAC 5.8, § 801(a); 40 CFR 280.71(a) 25-100
25.2.6.68 Permanent Closure of a Tank, 20 NMAC 5.8, § 801(b); 40 CFR 280.71(b) 25-100
25.2.6.69 Change in Service, 20 NMAC 5.8, § 801(c); 40 CFR 280.71(c) 25-100

33.0 New Mexico Emergency Management Act 33-1

33.1 Summary of the Law 33-1

Based on the presently available information in your letter, dated February 2, 2005, a discharge permit is not being required for the discharges described above. A discharge permit is not being required because the discharges conform to the numerical ground water standards in 20.6.2.3103 NMAC and do not contain any toxic pollutants as defined in 20.6.2.1101.TT NMAC, and therefore are exempt from the discharge permit requirement under 20.6.2.3105.A NMAC.

If at some time in the future WIPP intends to change the amount, the character, or location of the discharges so that they will not be as described, or if observation or monitoring shows that the discharges are threatening ground water quality, you must file a new request for exemption with the NMED.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

Bill Olson

RE: Corrective Action Approval, DP-831, Condition 5, Operational Freeboard of the Sewage Lagoons and H-19 Evaporation Pond, Waste Isolation Pilot Plant

Dear Mr. Piper:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received Written Notification and Corrective Action Reports, submitted by the U.S. Department of Energy Waste dated October 28, November 23, and December 10, 2004. The reports address the reduction in operating freeboard of the Sewage Lagoon System and H-19 Evaporation Pond at the Waste Isolation Pilot Plant (WIPP) in accordance with Condition 5 of Discharge Permit 831 (DP-831) renewed on April 29, 2003. Freeboard levels rose above permitted levels due to heavy rainfall from September through early December.

Heavy rainfall in September and October 2004 caused water levels in the Sewage Lagoon System to rise above the permitted freeboard allowances. Subsequent water management activities restored the permitted freeboard in the lagoon system by November 7, 2004.

Additional rainfall in mid November 2004 caused the evaporation ponds of the Sewage Lagoon System to rise above the permitted freeboard levels. As a corrective action, WIPP proposed to monitor water levels daily until the two feet of freeboard is restored. If freeboard becomes less than 12 inches, water will be pumped from the evaporation ponds upstream to the settling and polishing ponds of the lagoon system or transferred to the H-19 Evaporation Pond.

Heavy rainfall in early December caused the water levels in the H-19 pond to rise above the permitted two feet of freeboard. As a corrective action, WIPP proposed to temporarily operate the H-19 Pond with one foot of freeboard under weekly inspections until two feet of freeboard is restored.

The corrective action reports are hereby approved with the following conditions.

1. WIPP is authorized to operate each pond in the Sewage Lagoon System and the H-19 Evaporation Pond with one foot of freeboard until June 30, 2005.

2. Until June 30, 2005, WIPP shall notify NMED by the last day of each month of the freeboard level in each pond of the Sewage Lagoon System and the H-19 Evaporation Pond.

3. Until June 30, 2005, WIPP shall notify NMED within 24 hours and submit a corrective action plan if freeboard in any pond becomes less than 12 inches.

If additional information becomes available indicating these corrective actions are inadequate, then additional actions may be required. Approval of this corrective action report does not relieve you of your responsibility to comply with any other applicable federal, state and/or local laws and regulations.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

William C. Olson, Chief
Ground Water Quality Bureau

Subject: H-19 Evaporation Pond and Permit Condition 5 of the Discharge Permit, DP-831, Renewed on April 29, 2003, Maintain Two Feet of Freeboard in All Lagoons at all Times

Dear Mr. Marshall:

The purpose of this letter is to follow-up on the November 24, 2004, phone conversation in which you were notified that recent precipitation has resulted in the H-19 Evaporation Pond rising to a level that is slightly above the two feet of freeboard. Uncommonly high precipitation rates resulted in the loss of freeboard in the H-19 Evaporation Pond. You're office has already been notified of the effect of the high precipitation rates on freeboard capacity in the sewage lagoons in letters dated October 28, 2004, and November 23, 2004.

During the phone conversation notifying you of the status of the H-19 Evaporation Pond on November 24, 2004, you:

(1) verbally authorized us to temporarily operate the H-19 Evaporation Pond with one foot of freeboard;

(2) requested that we send you a letter regarding the H-19 Evaporation Pond; and,

(3) stated that you would provide a combined response addressing the November 23, 2004, letter proposing corrective actions for the sewage lagoon system and this notice regarding the H-19 Evaporation Pond.

As part of our corrective actions for the lack of freeboard at the H-19 Evaporation Pond, we will continue weekly inspections and inspect the pond following significant precipitation events (greater than one inch). We will notify your office when all ponds are returned to a level that maintains two feet of freeboard, if continued precipitation results in the need for additional corrective actions, or of any event in which wastewater is released from the H-19 Evaporation Pond.

Thanks for your assistance in this matter. If you have any questions or require additional information, please contact Mr. H. L. Plum of my staff at (505) 234-7495.

Sincerely,

Lloyd L. Piper
Acting Manager

New Mexico Environment Department
P.O. Box 26110
Santa Fe, NM 87502

Subject: Permit Condition 5 of the Discharge Permit, DP-831, Renewed On April 29, 2003, Maintain Two Feet of Freeboard in All Lagoons At All Times

Dear Mr. Marshall:

We notified you in a phone conversation on September 30, 2004, that two feet of freeboard was not maintained in the Sewage Lagoons following 6.48 inches of rain during the last week of September 2004. All ponds in the sewage lagoon system were returned to an operating level with a minimum of two feet of freeboard by November 7, 2004. We notified you of our corrective actions in a letter dated October 28, 2004.

The purpose of this letter is to confirm our notification to you by phone last week that an additional 3.04 inches of rain between Saturday, November 13 and Tuesday, November 16, 2004, resulted in Evaporation Ponds A, B and C of the sewage lagoon system rising to a level that is approximately two to three inches above the two feet of freeboard level. The ponds still have at least 21 inches of freeboard.

In accordance with Condition 5 of DP-831, we propose corrective actions of monitoring the water level in each pond daily until the ponds return to a level that maintains two feet of freeboard. If the freeboard becomes less than 12 inches, we will either:

(1) pump water from the evaporation ponds to upstream settling or polishing ponds which are currently at two feet of freeboard (maintaining at least one foot of freeboard); or

(2) request temporary authorization to transfer water from the sewage lagoons to the H-19 Evaporation Pond. Due to the 3:1 side slopes, we believe that 12 inches of freeboard is more than adequate to prevent the release of wastewater due to wave action. As you know, prior to the April 2003 DP-831 renewal, the sewage lagoons were operated at one-foot of freeboard for more than 15 years without overflowing.

We will notify your office when all ponds are returned to a level that maintains two feet of freeboard, if continued precipitation results in the need for additional corrective actions, or of any event in which wastewater is released from the sewage lagoon system.

If you have any questions or require additional information, please contact Mr. H. L. Plum of my staff at (505) 234-7495.

Sincerely,

Lloyd L. Piper
Acting Manager

RE: Approval of Extension Request for Salt Pile Infiltration Controls Construction Schedule, DP-831, U.S Department of Energy Waste Isolation Pilot Plant

Dear Mr. Piper:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received a November 12, 2004 letter from the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) requesting an extension of completion of the scheduled activities for construction of infiltration controls referenced in the discharge permit application, DP-831. WIPP cites inclement weather and low evaporation rates as reasons why the activities have been delayed. The revised schedule presented in the November 12, 2004 request is hereby approved.

If you have any questions regarding this matter please contact me at 505-827-2919 or Clint Marshall at 505-827-0027.

Sincerely,

William C. Olson, Chief
Ground Water Quality Bureau

Subject: Request for an Extension for the Salt Pile Infiltration Controls Construction Schedule, Discharge Plan - 831

Dear Mr. Marshall:

The purpose of this letter is to request an extension for completion of the scheduled activities for construction of the infiltration controls referenced in Discharge Plan – 831 (DP-831). The schedule contains six items which were to be completed by November 2004. Five of those six items have been completed on or before the scheduled date as reflected in the table below.

The construction and lining of the Salt Storage Extension, Salt Pile Evaporation Pond and Salt Storage Evaporation Basin with High Density Polyethylene (HDPE) and the placement of a HDPE cap to cover the Salt Pile have been completed. The remaining work includes the lining of the salt pile run-off ditches with HDPE, the placement of native soils and vegetative cover on the old Salt Pile, and the lining of Evaporation Basin A and Ponds 1 and 2 with HDPE. This work was anticipated to be complete in late September or early October, 2004. However, an unexpected 5.22 inches rain on the weekend of September 24-26, 2004 prevented the completion of these tasks. Due to the rainfall events that have occurred at the site, considerable rework will have to be done before the installation of HDPE material in these locations or placement of soil can resume.

Continued wet weather and low evaporation rates have prevented resuming construction activities. The completion of the salt pile run-off ditches will not be able to be completed as scheduled in November 2004. Stormwater Evaporation Basin A may not be able to be completed by the scheduled date of January 2005. The lining of Evaporation Ponds 1 and 2 remain on schedule for completion in April 2005.

For the reasons stated above we are requesting that the infiltration controls schedule be amended. The table below illustrates the scheduled dates referenced in DP-831 and a proposed schedule that we believe can be met.

Construction Activity	Existing Schedule Referenced in DP-831	Proposed Schedule
Place Contract	September 2003	NA (Task Accomplished)
Begin On-Site Construction	October 2003	NA (Task Accomplished)

CBFO:AMO:HLP:GS:04-1752:UFC 5487.00

Stormwater Diversion Berm Completion	December, 2003	NA (Task Accomplished)
Begin Storage of Mined Salt in Cell A	May 2004	NA (Task Accomplished)
Salt Pile 1) Completion of pond 2) Completion of ditches 3) Completion of liner cap	 1) November 2004 2) November 2004 3) November 2004	 1) NA (Task Accomplished) 2) April 2005 3) NA (Task Accomplished)
Stormwater Evaporation Basin A	January 2005	April 2005
Stormwater Evaporation Basin B (Ponds 1 and 2)	April 2005	April 2005
Salt Storage Extension Cell B	Begin Construction: May 2006 Completion: October 2006	Begin Construction: May 2006 Completion: October 2006

We have made a good faith effort to complete the installation of the infiltration controls in accordance with the schedule referenced in DP-831, as amended. The revised schedule presented herein is based on the following factors:

1) The difficulty associated with predicting when the area will be dry enough to resume construction activities considering we are entering the winter season when evaporation rates are low;

2) Acknowledgement that the liner subcontractor has several jobs that have been postponed due to the wet weather which will complicate scheduling once conditions are suitable for construction; and,

3) Completing the soil cover and reclamation activities associated with establishing vegetation on the covered salt pile will require a considerable volume of dry, screened soil material.

Currently, salt is stored in Cell A of the Salt Storage Extension Area and run-off from this area is contained in the Salt Storage Evaporation Basin, both of which are lined with HDPE. The old salt pile is capped with a HDPE material. We believe that these structures virtually eliminate the contribution of salt contact water to the subsurface.

Your consideration of our revised schedule is appreciated. If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7495.

Sincerely,

Lloyd Piper
Acting Manager

Subject: New Mexico Environment Department Discharge Plan-831, Condition 5

Dear Mr. Marshall:

The purpose of this letter is to confirm our verbal notification to you on September 30, 2004, that two feet of freeboard was not maintained in sewage lagoons operated at the Department of Energy's (DOE) Waste Isolation Pilot Plant (WIPP) as required by Discharge Plan – 831, Condition 5. The cause of this condition is believed to be significant rainfall events that occurred between September 24 and 30, 2004. Total rainfall during this period was 6.48 inches. We believe these rainfall events caused the effluent level in the settling ponds (Ponds 1A and 2A) and polishing ponds (Ponds 1B and 2B) of the sewage lagoon system to rise above the level required to maintain two feet of freeboard as required by DP-831, Condition 5. The measurements for freeboard remaining on September 30, 2004 were:

Pond	Freeboard
Settling Pond 1A (off line)	1.16 feet
Settling Pond 2A (on-line)	0.90 feet
Polishing Pond 1B	1.34 feet
Polishing Pond 2B	0.92 feet.

The high lagoon levels were noted during an inspection of the lagoons on Sunday, September 26, 2004. On Monday, September 27, 2004 the valve between Evaporation Pond A and Evaporation Pond C was opened to lower the water levels in Settling Ponds 1A and 2A and Polishing Ponds 1B and 2B, which are upstream of Evaporation Pond A. Evaporation Pond C was out of service at the time of the rain and its additional capacity of about 425,000 gallons allows us to lower the levels in the ponds that are filled beyond their freeboard requirements. On Thursday, September 30, we began mechanical pumping of effluent from Evaporation Pond A to Evaporation Pond C to accelerate the corrective action. For your convenience a diagram of the sewage lagoon system is enclosed.

As we discussed, an evaluation of the sewer and storm water drainage systems is being conducted to determine whether storm water from within the plant or adjacent roads and parking areas is significantly contributing to the volume of effluent directed to the sewage lagoons.

Additional engineering surveys will be conducted to determine if operational practices or plant adjustments can be made to maintain lower effluent levels in the lagoons and prevent the loss of required freeboard during future precipitation events. We are also evaluating the means used to measure depth of effluent in the lagoons and calculate remaining freeboard to confirm the adequacy of this procedure.

Additional rain and overcast days with high humidity have occurred subsequent to September 30, 2004 and these conditions have exacerbated our efforts to lower levels of effluent in the lagoons to the required levels. As of October 18, 2004, all settling and polishing ponds in the sewage lagoon system have been restored to greater than two feet of freeboard. As of Octobedr 26, 2004 evaporation Pond A has less than the required two feet of freeboard. If evaporation Pond A is not within the freeboard limit by October 29, 2004 mechanical pumping from evaporation Pond A to evaporation Pond B or C will occur until a minimum of two feet of freeboard is achieved.

No release or threat to human health or the environment occurred as the result of the elevated effluent levels in the sewage lagoons. There was no release of effluent from the sewage lagoon system. If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

R. Paul Detwiler for

RE: Discharge Permit Modification Required, DP-831, Waste Isolation Pilot Plant

Dear Mr. Detwiler:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) renewed the Discharge Permit, DP-831, for the U.S. Department of Energy's Waste Isolation Pilot Plant (WIPP) on April 29, 2003. At the time of the renewal, the permit primarily covered discharges to a domestic waste lagoon system, and miscellaneous industrial and brine discharges to evaporation ponds. On April 25, 2003, WIPP submitted an application to modify DP-831 to construct and incorporate storm water control systems to reduce subsurface seepage from runoff at the plant facility, and particularly from salt tailings stored north of the facility. The storm water control systems include the lining of storm water runoff collection basins, installing a cover on the existing salt tailings and construction of a new salt storage facility. The discharge permit modification was issued on December 22, 2003.

NMED conducted an inspection of the WIPP facility on August 11, 2004, to inspect facility components covered under the discharge permit, and to observe the construction activities on the storm water control systems addressed under the permit modification. NMED raised questions about the ultimate disposition of the salt tailings during the inspection, however WIPP personnel indicated uncertainty about final closure. NMED has conducted a file review and determined that the closure plan included in the discharge permit only addresses the domestic waste lagoons and does not include final closure measures for other evaporation ponds, storm water control systems and the salt tailings.

UNIQUE #	DOE UFC	DATE RCVD	ADDRESSEES
040859	5487.00	SEP 14 2004	P. Detwiler K. Watson L. Piper J. Plum R. Nelson R. Chavez WIPP Ops Records

Upon conducting the file review, NMED has also determined that potential sources of ground water contamination exist on the facility property that were not included the permit modification of DP-831. Specifically, a salt storage facility located on the east side of the WIPP facility, identified as the SPDV Salt Storage Area, was not addressed for its potential to contaminate ground water. According to a May 1994 document titled *Assessment of Solid Waste Management Units at the Waste Isolation Pilot Plant* (NMED/WIPP 93-001), this storage area contains approximately 155,000 cubic yards of salt covering approximately 7 acres. NMED is concerned that the presence of salt in this storage area has the same potential to contaminate ground water as the salt tailings WIPP is mitigating on the north side of the plant.

NMED requires that all discharge permits for mining facilities include a comprehensive closure plan to ensure the prevention and/or abatement of ground water contamination after the facility is closed. Water Quality Control Commission (WQCC) Regulation 20.6.2.3107.A(11) NMAC authorizes the NMED Secretary to require a closure plan to prevent the exceedence of standards of Section 20.6.2.3103 NMAC or the presence of a toxic pollutant in ground water after cessation of operation, which includes: a description of closure measures, maintenance and monitoring plans, post-closure maintenance and monitoring plans, financial assurance, and other measures necessary to prevent and/or abate such contamination.

NMED also requires that discharge permits address all components at the facility that have the potential to contaminate ground water. WQCC Regulation 20.6.2.3104 NMAC states that no person shall cause or allow effluent or leachate to discharge so that it may move directly or indirectly into ground water unless he is discharging pursuant to a discharge permit issued by the secretary. Discharges from the SPDV Salt Storage Area must be addressed because it is not covered by DP-831.

NMED has determined that further permitting actions are necessary to address additional potential contamination sources at the WIPP facility and to incorporate all potential sources into a comprehensive closure plan. Pursuant to WQCC Regulation 20.6.2.3104, 20.6.2.3109.E(1) and 20.6.2.3107.A(11) NMAC, and NMSA 1978 § 74-6-5.L(5) of the Water Quality Act, NMED hereby requires WIPP to modify its discharge permit, DP-831 to include all potential contamination sources at the facility and a comprehensive closure plan that addresses all facility components covered under DP-831.

Potential contamination sources to be addressed under this permit modification must include all active and inactive salt storage areas and waste disposal areas located within the WIPP property boundary defined by the Land Withdrawal Act. To the extent practicable, full disclosure of the contents of these facilities must be included. The closure plan must address closure of all evaporation ponds used to dispose of industrial and brine discharges as well as domestic waste discharges. The plan must also address final closure of all active and inactive salt tailings storage areas and waste disposal facilities not presently included in DP-831. An alternatives analysis must be conducted that examines different closure scenarios for all salt tailing storage facilities. Such scenarios must include removal of the salt tailings from the site as well as onsite closure options.

Within 120 days of this letter, WIPP must submit an application for the modification of DP-831. The application may reference current activities and existing documents, plans and specifications that apply towards final closure of facility components covered under DP-831.

Any appeal from this determination must be made to the New Mexico Water Quality Control Commission within 30 days, in accordance with Section 20.6.2.3112.B NMAC.

If you have any questions, please call Clint Marshall, 505-827-0027, or Mary Ann Menetrey, 505-827-2944, of the Mining Environmental Compliance Section.

Sincerely,

George Schuman

To: Roush, Parrish - WRES

Subject: RE: Salt Haul Road Construction

Parrish,

This response to your e-mail is to confirm the September 9, 2004 conversation regarding stormwater runoff from the haul road. NMED understands that WIPP will be using salt as a base for the haul road, and that stormwater runoff from the haul road will enter the Salt Pile Evaporation Pond (SPEP). The SPEP is lined with a 60 mil HDPE liner. The relatively minor salt contribution to the total stormwater discharge to this pond does not warrant a permit modification or amendment by NMED at this time.

>
> Clint,
>
> The purpose of this e-mail is to document our conversation at 1:00 pm on September 9, 2004. As discussed during your August 11, 2004 inspection of the WIPP Site, you informed me that a permit modification would not be necessary for using salt as a road base on the salt haul road. You acknowledged that our permit application dated April 24, 2003 stated that the Salt Storage Extension Basin will be the only drainage element receiving salt water contact run-off. Further you stated that your supervisor Mary Ann Menetrey (Supervisor of the Mining Environmental Compliance Section) concurred that a permit modification would not be necessary for this action. You stated that if we wanted documentation of this determination, we could send you an e-mail or write you a letter referencing this discussion.
>
> We would appreciate it if you could take the time to respond to this e-mail acknowledging your receipt of this e-mail and concurrence that I have accurately restated your position on this matter. Thanks for your assistance.

Subject: Change in the Design for the Infiltration Controls Project and Map of the Paved and Unpaved Areas at the WIPP Site

Dear Mr. Marshall:

The purpose of this letter is to provide notification of changes relating to the substitution of the geotextile cushion under the high density polyethylene (HDPE) liner with a soil cushion for the salt pile infiltration controls and a map illustrating the paved and unpaved areas within the fenced area at the WIPP Site. You requested that this information be provided within 30 days of your August 11, 2004 visit to the WIPP site.

The April 24, 2003 Discharge Plan Modification Application for the infiltration controls project stated that:

- Mined salt would be used to shape the crown to a minimum two percent slope. In some cases native soil may be used for reshaping the salt pile crown and side slopes; and,

- A 16-ounce geotextile cushion would be emplaced at the salt contact with a 60-millimeter textured HDPE liner on the salt-pile. The drawings contained in the permit application specified a double-sided textured liner.

The double-sided textured liner provides better friction angles and improves slope stability on the 3:1 side slopes. Prior to installation it was determined that the double textured liner tends to snag the geotextile while positioning the liner during installation causing folds and displacement of the geotextile cushion. It was concluded that the use of salt or soil would provide an adequate base and equivalent cushion for the liner and improve the installation process for the textured liner. For this reason, the design was modified to require a liner base of soil or salt sized such that no material is larger than 0.5 inches in size and all material is free of trash and debris. One to two inches of screened soil was added to the salt surface, except where the salt could be prepared to meet the liner base specification.

This design change improves constructability of the overall liner system, provides adequate and equivalent protection of the liner, and is consistent with the base material used in the construction of the other infiltration controls (i.e., evaporation ponds and the Salt Storage Area).

CBFO:OEC:HLP:JGW:04-1720:UFC:5486

Finally, a map illustrating the paved and unpaved areas of the site that you requested during the August 11, 2004 visit to the WIPP site is enclosed, drawing number 24-028-W1, Revision W. If you have any questions or require additional information, please contact Mr. Daryl Mercer at (505) 234-7495.

Sincerely,

R. Paul Detwiler fr

RE: Discharge Permit Modification Required, DP-831, Waste Isolation Pilot Plant

Dear Mr. Detwiler:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) renewed the Discharge Permit, DP-831, for the U.S. Department of Energy's Waste Isolation Pilot Plant (WIPP) on April 29, 2003. At the time of the renewal, the permit primarily covered discharges to a domestic waste lagoon system, and miscellaneous industrial and brine discharges to evaporation ponds. On April 25, 2003, WIPP submitted an application to modify DP-831 to construct and incorporate storm water control systems to reduce subsurface seepage from runoff at the plant facility, and particularly from salt tailings stored north of the facility. The storm water control systems include the lining of storm water runoff collection basins, installing a cover on the existing salt tailings and construction of a new salt storage facility. The discharge permit modification was issued on December 22, 2003.

NMED conducted an inspection of the WIPP facility on August 11, 2004, to inspect facility components covered under the discharge permit, and to observe the construction activities on the storm water control systems addressed under the permit modification. NMED raised questions about the ultimate disposition of the salt tailings during the inspection, however WIPP personnel indicated uncertainty about final closure. NMED has conducted a file review and determined that the closure plan included in the discharge permit only addresses the domestic waste lagoons and does not include final closure measures for other evaporation ponds, storm water control systems and the salt tailings.

Upon conducting the file review, NMED has also determined that potential sources of ground water contamination exist on the facility property that were not included the permit modification of DP-831. Specifically, a salt storage facility located on the east side of the WIPP facility, identified as the SPDV Salt Storage Area, was not addressed for its potential to contaminate ground water. According to a May 1994 document titled *Assessment of Solid Waste Management Units at the Waste Isolation Pilot Plant* (NMED/WIPP 93-001), this storage area contains approximately 155,000 cubic yards of salt covering approximately 7 acres. NMED is concerned that the presence of salt in this storage area has the same potential to contaminate ground water as the salt tailings WIPP is mitigating on the north side of the plant.

NMED requires that all discharge permits for mining facilities include a comprehensive closure plan to ensure the prevention and/or abatement of ground water contamination after the facility is closed. Water Quality Control Commission (WQCC) Regulation 20.6.2.3107.A(11) NMAC authorizes the NMED Secretary to require a closure plan to prevent the exceedence of standards of Section 20.6.2.3103 NMAC or the presence of a toxic pollutant in ground water after cessation of operation, which includes: a description of closure measures, maintenance and monitoring plans, post-closure maintenance and monitoring plans, financial assurance, and other measures necessary to prevent and/or abate such contamination.

NMED also requires that discharge permits address all components at the facility that have the potential to contaminate ground water. WQCC Regulation 20.6.2.3104 NMAC states that no person shall cause or allow effluent or leachate to discharge so that it may move directly or indirectly into ground water unless he is discharging pursuant to a discharge permit issued by the secretary. Discharges from the SPDV Salt Storage Area must be addressed because it is not covered by DP-831.

NMED has determined that further permitting actions are necessary to address additional potential contamination sources at the WIPP facility and to incorporate all potential sources into a comprehensive closure plan. Pursuant to WQCC Regulation 20.6.2.3104, 20.6.2.3109.E(1) and 20.6.2.3107.A(11) NMAC, and NMSA 1978 § 74-6-5.L(5) of the Water Quality Act, NMED hereby requires WIPP to modify its discharge permit, DP-831 to include all potential contamination sources at the facility and a comprehensive closure plan that addresses all facility components covered under DP-831.

Potential contamination sources to be addressed under this permit modification must include all active and inactive salt storage areas and waste disposal areas located within the WIPP property boundary defined by the Land Withdrawal Act. To the extent practicable, full disclosure of the contents of these facilities must be included. The closure plan must address closure of all evaporation ponds used to dispose of industrial and brine discharges as well as domestic waste discharges. The plan must also address final closure of all active and inactive salt tailings storage areas and waste disposal facilities not presently included in DP-831. An alternatives analysis must be conducted that examines different closure scenarios for all salt tailing storage facilities. Such scenarios must include removal of the salt tailings from the site as well as onsite closure options.

Within 120 days of this letter, WIPP must submit an application for the modification of DP-831. The application may reference current activities and existing documents, plans and specifications that apply towards final closure of facility components covered under DP-831.

Any appeal from this determination must be made to the New Mexico Water Quality Control Commission within 30 days, in accordance with Section 20.6.2.3112.B NMAC.

If you have any questions, please call Clint Marshall, 505-827-0027, or Mary Ann Menetrey, 505-827-2944, of the Mining Environmental Compliance Section.

Sincerely,

George Schuman

Facility

Facility Name: Waste Isolation Pilot Plant (WIPP) Contact: Parrish Rouch, Jody Plum, Jon Gailbraith, Daryl Mercer

Location: Approx. 40 miles east of Carlsbad, Eddy County

Discharge Plan Number: DP- 831 UIC Related? Yes No

Type of Operation: Low level nuclear waste storage and disposal facility

Inspection Summary

Purpose:

a. Evaluation of Discharge Plan: Yes

b. Compliance Inspection: Yes

c. Other (Specify):

Activities

a. Inspection of Facilities or Construction (specify): Piezometers, stormwater controls, exhaust fans, exhaust shaft (underground), existing salt pile, new salt storage facility, H-19 pond, domestic waste lagoon system.

b. Effluent Sample (s): (provide sampling location): None
No. of Ponds: 12 No. in Use: 9 Condition of Ponds: good to excellent
Condition of Pond Liner (s): Good to excellent; 3 ponds currently under construction and not yet lined.

c. Ground Water Sample (s) (provide well name and location): None
No. of Monitor Wells: 17 Well Condition: Good

Observations and Information Obtained:

The facility grounds were walked to observe locations of piezometers, and paved and unpaved areas. The #700 exhaust fan system which draw air through the underground facility were also observed. The area around the exhaust fans was observed not to be paved. WIPP personnel indicated the stormwater diversion pathways for different areas of the facility. WIPP and NMED personnel discussed how the collection and disposal of condensate water from the #700 fan system to the H-19 evaporation pond. Mr. Rouch stated that the water has been sampled up to 3 times annually, however there is no regular sampling schedule. The H-19 pond is sampled semi-annually under DP-831. Rick Salness, hydrologist for WIPP, explained his interpretation of why TDS concentrations in the shallow subsurface water (SSW) are lower in the south part of the facility. Stormwater collection ponds #1, #2 and Evaporation Basin A were observed to be excavated, but not yet lined.

WIPP and NMED entered the underground waste storage area to observe the collection of seepage water that occurs at the base of the exhaust shaft. Two HDPE receptacles were located beneath shaft and contained solids and water. WIPP personnel stated that the receptacles are emptied of water periodically. A new receptacle system is being designed and will be installed in the near future. It was observed that the edges of the existing receptacle were not flush with the edges of the shaft and a gap of approximately 9-12 inches was present on both sides. Due to low lighting, the back of the receptacle was not visible.

After lunch, WIPP and NMED staff viewed a video recording of the subsurface water seeping into the exhaust shaft. WIPP personnel emphasized that the video we watched was not representative of typical seepage rates into the shaft, but did show seepage events that were easy to view. The seepage was seen coming through cracks in a concrete liner that covers the shaft walls. Most of the seepage was occurring in a zone ranging from 60 to 80 feet below ground surface.

The Salt Storage Area (SSA) was inspected with the assisitance of Kent Aveson (WTS) beginning with the Salt Pile Evaporation Pond (SPEP). The dimensions of the SPEP were reported to have been altered slightly to accommodate a haul road located east of the pond. The pond contained a newly installed 60 mil HDPE liner with four anchor trenches to keep the liner intact. The Salt Storage Extension (SSE) Evaporation Pond has been installed directly north of the SPEP. The pond contains a double 60 mil HDPE synthetic liner with a leak detection system. Slopes are constructed at 3:1. Immediately east of the SSE Evaporation Pond is Cell A of the Salt Storage Extension. This storage area is lined with a 60 mil HDPE liner and the liner has been covered with two feet of soil for protection. A French drain has been installed through the center of the cell running east to west. Seepage collected in the drain empties into the SSE Evaporation Pond to the west. Cell B of the SSE is being constructed adjacent to Cell A on the east side. Salt is presently being deposited in Cell A of the newly constructed SSE (see attached photo). The old salt pile is located immediately south of the SSE and a cover is presently being installed on the salt pile. The cover consists of a 60 mil HDPE membrane covered by two feet of soil, which will be vegetated. Lined ditches around the perimeter of the salt pile divert runoff to the SPEP located west of the pile. WIPP personnel stated that a geotextile, originally specified to be installed under the HDPE membrane, was instead replaced with several inches of soil or sand. It was reported that the soil provided better protection for the liner. I informed WIPP personnel that NMED should have been contacted in advance of the change in specifications. I requested that WIPP submit a letter detailing the change.

The H-19 evaporation pond located south of the facility was visited next. The pond is lined with 36 mil Hypalon. The pond was approximately half full of water at the time of the inspection. This pond receives non- hazardous condensate water from the #700 exhaust fan system and non-hazardous seepage water from the exhaust shaft catchment. WIPP personnel reported that seepage water from the catchment system that fails TCLP testing is shipped offsite to an approved hazardous waste disposal facility.

The domestic sewage lagoon system was the last facility to be inspected. The system contains seven synthetically lined (36 mil hypalon) ponds, six of which contained effluent. The south evaporation pond was dry and WIPP personnel stated that three of the ponds are being decommissioned because the system is oversized. I requested that WIPP submit a plan within 6 months to fully inspect the liners in all of the lagoons.

Actions Required:

At the closing meeting I requested three submittals from WIPP:

1. A letter detailing the specification change to the cover on the salt pile. Due September 11, 2004.
2. A map showing all unpaved areas at the facility. Due September 11, 2004.
3. A plan to fully inspect the synthetic liners at the domestic sewage lagoon system. Due February 11, 2005.

Comments and Suggestions Relating to the New Mexico Environment Department Oversight and Monitoring of the Waste Isolation Pilot Plant Operations
George Anastas, June 23, 2004

The Waste Isolation Pilot Plant is well into operations. Key activities are either underway or on the horizon. There are a number of concerns relating to the operation of the WIPP. These include, but are not limited to:

Department of Energy proposed changes to New Mexico State regulations relating to the waste that can be disposed at the WIPP,

Transportation, handling and emplacement of remote handled transuranic (RH TRU) waste,

Occupational radiation safety,

Underground mine safety,

Industrial safety,

Compliance Recertification by the US Environmental Protection Agency,

Radioactive releases to the environment (note that in June 2003 a small release of Pu was detected from the exhaust shaft) and related doses to the public, and

Increasing number of waste shipments over New Mexico highways.

Important Items for Oversight and Monitoring of WIPP Operations

I. Based upon the extant and planned activities at the WIPP, the NMED reviews and evaluations shall focus on the technical, scientific and procedures in the areas such as, but not necessarily limited to, the following:

1. New information on site characterization (for example, the effect of the water flow into the exhaust shaft on site characterization).
2. Compliance with the regulatory requirements of the US Environmental Protection Agency.
3. All WIPP facilities, programs and issues either directly or indirectly relating to:
    a. Ventilation,
    b. Hoists,
    c. Engineered barriers,
    d. Plugging and sealing,
    e. Quality assurance and quality control,
    f. Effluent monitoring systems,
    g. Effluent filtration and other safety systems,
    h. Waste handling,
    i. Occupational radiation control,
    j. Hazardous materials control,
    k. Unusual and routine occurrences relating to potential or real impact on public health and safety or the environment, and
    l. Transportation of waste to the WIPP.

4. Operational on-site and off-site environmental monitoring (including the right to either take samples independently or to take split samples).
5. Decontamination activities.
6. Decommissioning plans.
7. Closure and post-closure plans.
8. The WIPP Waste Acceptance Criteria.
9. Waste inventories
10. Evaluation of any waste transportation, storage or disposal containers.
11. Compliance with the health and safety or environmental protection requirements of the Department of Energy, Department of Transportation, Nuclear Regulatory Commission, Environmental Protection Agency, and such other federal agencies, including the Congress, that have promulgated regulatory requirements that have a bearing on the health and safety or environmental protection.
12. Such other WIPP activities, programs or plans as may arise from time to time that have either a direct or indirect bearing on health and safety or environmental protection.

II. The Department of Energy, its contractors and subcontractors, including the Department of Energy Generator Sites and the contractors operating the Sites, shall:

1. Provide the NMED with free, timely and unencumbered access to information and data relating to health, safety or environmental protection issues associated with the operations of the WIPP.
2. Provide the NMED with such preliminary reports relating to health, safety or environmental issues at the WIPP germane to the oversight of the WIPP by the NMED.
3. Provide the NMED with access to all meetings with regulatory agencies relating to health, safety or environmental issues at the WIPP. Written notification of such meetings shall be at least 2 weeks in advance.
4. Provide the NMED with access to all meetings with expert panels and peer review groups relating to health, safety or environmental issues at the WIPP. Written notification of such meetings shall be at least 2 weeks in advance.
5. Provide the NMED with at least one hard copy of all Department of Energy or Department of Energy Contractor reports that relate to the NMED oversight of the Waste Isolation Pilot Plant.
6. Provide the NMED access to ORPS and other routine reports on operational issues at the WIPP or Generator Sites that have a bearing on WIPP operations.
7. Provide the NMED with access to the WIPP Waste Information System (WWIS) ands such other information services relating to the WIPP operations or planning as may be determined from time to time by the NMED.

Oversight-management by overseeing the performance or operation of a person or group, watchful care
Monitoring-Periodic or continuous surveillance or testing to determine the level of compliance with statutory requirements

RE: Discharge Permit Modification, DP-831, Waste Isolation Pilot Plant (WIPP)

Dear Ms. Triay:

The New Mexico Environment Department (NMED) issues the enclosed Discharge Permit Modification, DP-831 to the Department of Energy Waste Isolation Pilot Plant (WIPP) pursuant to the New Mexico Water Quality Act (WQA), NMSA 1978§§74-6-17, and the New Mexico Water Quality Control Commission (WQCC) Regulations, 20.6.2 NMAC.

The Discharge Permit Modification contains terms and conditions that shall be complied with by WIPP and are enforceable by NMED pursuant to WQCC 20.6.2.3104, WQA, NMSA 1978 § 74-6-5 and §74-6-10. Issuance of this Discharge Permit Modification does not relieve WIPP of its responsibility to comply with the WQA, WQCC Regulations, or any other applicable federal, state and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

Pursuant to 20.6.2.3109.H.4 NMAC, this Discharge Permit Modification shall expire on **April 29, 2008**, the same day the Discharge Permit, DP-831 will automatically terminate. You must submit an application for renewal at least 120 days before the permit expiration date.

Sincerely,

Jerry Schoeppner, Chief
Ground Water Quality Bureau

NMED Carlsbad Field Office

GROUND WATER DISCHARGE PERMIT MODIFICATION
U.S. DEPARTMENT OF ENERGY, DP-831
WASTE ISOLATION PILOT PLANT (WIPP)

I. INTRODUCTION

The New Mexico Environment Department (NMED) issues this Modification to the Discharge Permit, DP-831, to U.S. Department of Energy (DOE) Waste Isolation Pilot Plant (WIPP) pursuant to the New Mexico Water Quality Act (WQA), NMSA 1978 §§74-6-1 through 74-6-17, and the New Mexico Water Quality Control Commission (WQCC) Regulations, 20.6.2 NMAC.

NMED's purpose in issuing this Discharge Permit Modification, and in imposing the requirements and conditions specified herein, is to control the discharge of water contaminants from the WIPP into ground and surface water, so as to protect ground and surface water for present and potential future use as domestic and agricultural water supply and other uses and protect public health. In issuing this Discharge Permit Modification, NMED has determined that the requirements of Section 20.6.2.3109.C NMAC have been met.

The activities which produce the discharge, the location of the discharge, and the quantity, quality and flow characteristics of the discharge were described in the Discharge Permit issued April 29, 2003, as follows:

> Up to 23,000 gallons per day of sewage effluent is discharged to a series of seven synthetically lined ponds for treatment and evaporation (facultative lagoon system). Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined evaporation cell (north evaporation cell). Up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources is discharged to a synthetically lined evaporation pond (H-19 evaporation pond). Up to 100 gallons per year of neutralized acid waste will also be discharged to the facultative lagoon system.

The Discharge Permit Modification to the WIPP wastewater disposal system is briefly described as follows:

> In addition to the daily discharge of 33,100 gallons per day of sewage effluent, brine and neutralized acid waste approved in the April 29, 2003 Discharge Permit Renewal, WIPP will be authorized to discharge up to 3,231,260 gallons per day of storm water runoff as a result of rainfall events that occur at the site. The runoff occurs from the plant facility and approximately 17 acres of excavated salt (salt piles) stored on the north side of the facility. The purpose for containing the storm water runoff is to minimize infitration into the subsurface, which has resulted in the accumulation of shallow subsurface water (SSW) below the WIPP facility. During the term of this permit additional salt storage capacity and associated storm water controls will be constructed immediately north of the existing salt pile. Storm water runoff from the Salt Storage Area (SSA) will be contained in the Salt Storage Extension Basin for evaporation. The remaining three basins will

collect storm water not specifically associated with the SSA, but from other areas around the WIPP facility.

The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. Regional ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3,920 milligrams per liter. The shallow subsurface water (SSW) below the site is at a depth of approximately 60 – 80 feet.

The WIPP Discharge Permit Modification consists of the materials submitted by the DOE dated October 30, 2002, April 24, 2003, and July 24, 2003. In addition, the discharge plan includes information and materials submitted as part of the original discharge plan approved on Janurary 16, 1992, amended on August 28, 1995, renewed on July 3, 1997, amended on June 12, 1998, amended on January 24, 2000, and renewed on April 29, 2003. The discharge shall be managed in accordance with the discharge plan as conditioned by the Discharge Permit approved April 29, 2003, and this Discharge Permit Modification.

Issuance of this Discharge Permit Modification does not relieve the DOE of its responsibility to comply with any conditions or requirements of the Discharge Permit, DP-831, approved April 29, 2003, the WQA, WQCC Regulations, any other applicable federal, state and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

The following abbreviations may be used in this permit modification:

Abbreviation	Explanation		Abbreviation	Explanation
DOE	Department of Energy		TDS	total dissolved solids
NMAC	New Mexico Administrative Code		WIPP	Waste Isolation Pilot Plant
NMED	New Mexico Environment Department		WQCC	Water Quality Control Commission

II. FINDINGS

In issuing this Discharge Permit Modification, NMED finds:

1. The DOE is discharging effluent or leachate from the WIPP facility so that such effluent or leachate may move directly or indirectly into ground water within the meaning of Section 20.6.2.3104 NMAC.

2. The DOE is discharging effluent or leachate from the WIPP facility so that such effluent or leachate may move into ground water of the State of New Mexico which has an existing concentration of 10,000 milligrams per liter or less of total dissolved solids within the meaning of Section 20.6.2.3101.A NMAC.

III. CONDITIONS

The following conditions of this Discharge Permit Modification shall be added to the requirements of the Discharge Permit renewal approved on April 29, 2003. The following conditions shall be complied with by the DOE and WIPP (permittee) and are enforceable by NMED:

OPERATIONS

1. The permittee is authorized to discharge up to 3,231,260 gallons per day of storm water runoff from the WIPP site to five synthetically lined retention basins for evaporation. [20.6.2.3104 NMAC]

Storm Water Controls:

2. The permittee shall install infiltration control measures, including synthetically lined impoundments, to mimimize infiltration of storm water runoff into the subsurface at the WIPP facility. The primary control structures include Evaporation Basin A, Pond 1, Pond 2, the Salt Storage Extension (SSE) (Cells A and B), the Salt Storage Extension Evaporation Basin, the Salt Pile Evaporation Pond (SPEP), and berms and ditches associated with these structures. The installation of the storm water control structures shall be in accordance with the application for discharge permit modification dated April 24, 2003, or in accordance with subsequent design and specification amendments subject to approval by NMED. The structures shall be completed according to the schedule dated July 24, 2003. Extensions may be granted per written request for good cause shown. [20.6.2.3109 NMAC]

MONITORING AND REPORTING

4. The permittee shall conduct the following monitoring, reporting, and other requirements listed below in accordance with the WQCC Regulations at 20.6.2.3107 NMAC and the monitoring plan submitted by the permittee dated July 25, 2003. A summary of monitoring requirements is attached to this permit as Table 1. A monitoring schedule is attached as Table 2. [20.6.2.3107 NMAC]

Sampling and Field Measurements:

5. Storm Water Collection Ponds – The permittee shall sample the SPEP, the SSE Evaporation Basin, Evaporation Basin A, Pond 1, and Pond 2 as follows:

   A. The permittee shall record the water depth to the nearest hundredth of a foot (0.01 ft), and the approximate volume of stormwater in each of the four storm water collection ponds once per year after a storm event where sufficient quantity of water has collected in the respective basins, during the same storm event in which water quality sampling is conducted (Condition 5B).

B. The permittee shall collect samples from each of the four storm water collection ponds once per year following a single storm event where water quantity has been measured (Condition 5A), and analyze for the water parameters listed in Conditions 7B and 7C below.

Analytical results and water level measurements shall be reported as required in Condition 9 below. [20.6.2.3107 NMAC]

6. Ground Water Monitoring Wells – The permittee shall sample the following monitoring wells and piezometers:

A. Monitoring Wells/Piezometers PZ-1, PZ-2, PZ-3, PZ-4, PZ-5, PZ-6, PZ-7, PZ-8, PZ-9, PZ-10, PZ-11, PZ-12, C-2505, C-2506, C-2507, C-2811 and WQSP-6A shall be sampled as follows:

1) The permittee shall record the depth to the water table to the nearest hundredth of a foot (0.01 ft) above msl, quarterly.

B. Monitoring Wells/Piezometers PZ-1, PZ-5, PZ-6, PZ-7, PZ-9, PZ-10, PZ-11, PZ-12, C-2507, C-2811 and WQSP-6A shall be sampled as follows:

1) The permittee shall collect samples from each well semi-annually and analyze the samples for the water parameters listed in Conditions 7A, 7B and 7C below.

Analytical results and water level measurements shall be reported as required in Condition 9 below. [20.6.2.3107 NMAC]

Analysis:

7. The permittee shall analyze samples of ground water and storm water for the parameters listed below. Samples of ground water from monitoring wells and piezometers shall be analyzed for dissolved concentrations of the analytes listed below. Samples of storm water shall exclude field parameters and shall be analyzed for dissolved and total concentrations of the analytes listed below. [20.6.2.3107 NMAC]

A. Field parameters (analysis to be performed in the field): pH, temperature and specific conductance.

B. General chemistry parameters: nitrate, sulfate, chloride, and total dissolved solids.

C. Trace metals: selenium, chromium

Methodology:

8. Unless otherwise approved in writing by NMED, the permittee shall conduct sampling

and analysis in accordance with the most recent edition of following documents:

A. American Public Health Association, *Standard Methods for the Examination of Water and Wastewater.*

B. U.S. Environmental Protection Agency, *Methods for Chemical Analysis of Water and Waste.*

C. U.S. Geological Survey, *Techniques for Water Resource Investigations of the U.S. Geological Survey.*

D. American Society for Testing and Materials, *Annual Book of ASTM Standards*, Part 31. Water.

E. U. S. Geological Survey, et al., *National Handbook of Recommended Methods for Water Data Acquisition.*

F. NMED Guidance, *Use of Low-Flow and Other Non-TradtionalSampling Techniques for RCRA Compliant Groundwater Monitoring.*

G. Surface water monitoring must also be conducted according to test procedures approved under Title 40 Code of Federal Regulations Part 136. [20.6.2.3107B NMAC]

Reporting:

9. The permittee shall submit to NMED a semi-annual report by the last day of January and July of each year. Reports shall use the following format:

A. A summary of all activities related to the discharge during the preceding 6 month period. Activities may include general operations, construction or demolition of structures, maintenance and repairs, water management, water quality and ground water level trends, and precipitation patterns.

B. A single table in a paper and electronic format (EXCEL spreadsheet) of water level measurements and water quality data with only those constituents analyzed and water levels measured during a single event shown in columns. Tabulated electrical conductivity shall include the measured field values and corrected values to 25 degrees Celsius. Monitoring sites shall be shown in rows. Values exceeding standards shall be bolded. Any constituent not analyzed for a particular site shall be shown as "NA", any site not sampled shall be shown as "NS" with an associated reason, and any site not measured for water levels shall be shown as "NM" with an associated reason.

C. Copies of the signed laboratory analyses sheet shall be provided semi-annually.

D. A potentiometric map for the WIPP facility area shall be submitted annually. The map shall incorporate the most recent water level data for all monitoring wells and piezometers installed in the shallow subsurface water (SSW). [20.6.2.3107 NMAC]

GENERAL TERMS AND CONDITIONS

10. In addition to any other requirements provided by law, approval of this Discharge Permit Modification is subject to the General Requirements as specified in the Discharge Permit approved on April 29, 2003. Refer to the Discharge Permit Renewal, DP-831, approved April 29, 2003, for specific information on the following General Requirements

    Monitoring and Reporting
    Record Keeping
    Inspection and Entry
    Duty to Provide Information
    Spills, Leaks and Other UnAuthorized Discharges
    Retention of Records
    Enforcement
    Modification and/or Amendments

Compliance with Other Laws:

11. Nothing in this Discharge Permit shall be construed in any way as relieving the permittee of its obligation to comply with all applicable federal, state, and local laws, regulations, permits or orders. [20.6.2 NMAC]

Right to Appeal:

12. The permittee may file a petition for hearing before the WQCC on this Discharge Permit Modification. Such petition shall be in writing to the WQCC within thirty (30) days of the receipt of this Discharge Permit Modification. Unless a timely petition for hearing is made, the decision of NMED shall be final. [74-6-5.N WQA]

Transfer of Permit:

13. Prior to any transfer of ownership, control, or possession of this permitted facility or any portion thereof, the permittee shall notify the proposed transferee in writing of the existence of this Discharge Permit and include a copy of this Discharge Permit with the notice. The permittee shall deliver or send by certified mail to NMED a copy of the notification and proof that such notification has been received by the proposed transferee. [20.6.2.3111 NMAC]

Term:

14. The term of this Discharge Permit Modification expires on **April 29, 2008,** the same day the Discharge Permit will automatically terminate. To renew the Discharge Permit, the permittee must submit an application for renewal at least 180 days before the termination date. [20.6.2.3109(H) NMAC, 74-6-5.H WQA]

ISSUED: December 22, 2003

EXPIRES: April 29, 2008

RE: Corrective Action Approval, DP-831, June
Pilot Plant

Dear Mr. Detwiler:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received the Written Notification and Corrective Action Report, submitted by the U.S. Department of Energy on June 8, 2004. The report addresses a discharge of domestic sewage at the Waste Isolation Pilot Plant (WIPP) that was discovered on June 3, 2004. The corrective action report is hereby approved for ground water related concerns pursuant to the New Mexico Water Quality Control Commission (WQCC) Regulations, Section 1203.A.6 NMAC.

The incident is briefly described as follows:

On June 2, 2004, during the grading and lining of an evaporation pond on the southwest side of the facility, construction crews using heavy equipment damaged a buried sewer line. The spill was discovered at 6:30 am on June 3, 2004. The top portion of the 8-inch sewer line was damaged allowing approximately 300 gallons of domestic sewage to be released into adjacent soils.

The corrective actions are summarized as follows:

The upstream manhole on the sewer line was blocked by sandbags to prevent further releases from the damaged pipe. Contractors using protective gear replaced an 81-foot length of pipe. Calcium hypochlorite was placed on the backfilled soil after repairs were complete.

If additional information becomes available indicating these corrective actions are inadequate, then additional actions may be required. Approval of this corrective action report does not relieve you of your responsibility to comply with any other applicable federal, state and/or local laws and regulations.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

Jerry Schoeppner, Chief
Ground Water Quality Bureau

Subject: Follow-Up Report Required By 20.6.2.1203 (3) NMAC And 15 Day Corrective Action Report Required by 20.6.2.1203 (6) NMAC for the June 2 and 3, 2004 Domestic Sewage Release at WIPP

Dear Mr. Marshall:

On June 3, 2004, the Department of Energy provided verbal notification of a release of domestic sewage from a broken sewer line at the WIPP Site. The purpose of this letter is to provide the seven-day follow-up report required by 20.6.2.1203 (3) NMAC and the 15-day corrective action report required by 20.6.2.1203 (6) NMAC.

The release was discovered at approximately 6:30 a.m. on June 3, 2004. Contractors responsible for grading and lining Evaporation Pond A on the southwest side of the facility discovered the leak. The sewer line had apparently been damaged on the afternoon of June 2, 2004 by heavy equipment that had been operating in the area supporting construction activities. No visible sign of leaking sewage was apparent until the following morning. The release posed no significant threat to the environment and every precaution was taken to protect construction personnel from exposure to raw sewage. All construction personnel involved in the repair of the sewer line were provided Hepatitis B and Tetanus shots. Additionally, response personnel wore Ty-Vek® coveralls, rubber boots and gloves. Calcium hypochlorite was added to the spill area as a disinfectant in accordance with your recommended corrective action.

The following information is provided as required by 20.6.2.1203 (3) and (6) NMAC:

1. Name, address, and telephone number of the person or persons in charge of the facility, as well as the owner and/or Operator of the facility:

Facility Owner:	United States Department of Energy
Person in Charge of the Facility:	R. P. Detwiler, Acting Manager Carlsbad Field Office
Address:	P.O Box 3090 Carlsbad, NM 88221
Phone Number:	505-234-7300
Facility Operator	United States Department of Energy
Responsible Individual:	George Basabilvazo
Address:	P.O Box 3090 Carlsbad, NM 88221
Phone Number:	505-234-8103

CBFO:OEC:HJP:JGW:04-0382:UFC:5486

2. Name and address of the Facility:

   Waste Isolation Pilot Plant
   26 miles E-SE of Carlsbad, NM.

3. Date, time and location of the discharge:

   Afternoon of June 2, 2004 through 3:50 pm June 3, 2004 (approximately 24-hours)

4. The estimated volume of the discharge:

   A conservative estimate of the volume of sewage released is 300 gallons based on a visual observation of the pooled sewage. The release occurred within the excavation of a newly constructed pond with highly compacted soil that was being prepared for the installation of a synthetic liner.

   Based on the totalizing sewage effluent flow meter an average of 148 gallons per hour was discharged over the 24-hour period that sewage was released. This equates to 3,562 gallons for the duration of the discharge. The majority of this water was not released to the environment but continued to flow through the portion of the sewer line that remained intact.

5. Any actions taken to mitigate immediate damage from the discharge:

   Upon discovery of the release, notifications were made and plans prepared for the repairs. The contractor responsible for the repairs had 8-inch pipe, fittings, and safety equipment delivered from Carlsbad, NM. Personnel began excavating the dirt covering the pipe. The affected pipe ran a length of 81 feet. One hundred feet of pipe was excavated to ensure all damaged pipe was replaced. Sandbags were placed in the upstream manhole to prevent the release of solids and minimize the sewage released while the new pipe was installed. By 3:50 p.m. on June 3, 2004, the new pipe was connected. Calcium hypochlorite was placed on the contaminated back-filled soil after repairs were complete.

Please advise us if you have any questions, or require any additional information. Please direct any inquiries to Mr. H. L. Plum, of my staff at (505) 234-7462.

Sincerely,

R. P. Detwiler, Acting Manager

Subject: Sewage Spill at the WIPP Site

Discussion:

WIPP called to report a spill that was discovered the morning of 6/3/04. It was believed to have occurred the day prior when heavy equipment being used to excavate Pond A accidentally crushed a sewer line. The line was an 8-inch concrete pipe that transferred sewage waste to the facultative lagoons from the WIPP site. Approximately 300 gallons spilled on the ground immediately surrounding the damaged pipe. Much of the spilled liquid eventually moved back into the pipe, which was caved in from above. Contractors were called in to repair the line in the afternoon of 6/3/04.

Conclusions:

A report will be sent detailing the characteristics of the spill and actions to mitigate and repair the damaged line.

Subject: Proposal to Store Well Development Water in the Domestic Wastewater Lagoons

Discussion:

A teleconference took place to discuss a proposal from WIPP to store development water from several wells in part of the facultative lagoon system at WIPP. The wells will be drilled into the Culebra Formation over the next several months. The development water will be primarily brine. WIPP wants to decommission three of the domestic facultative lagoons and - convert them to storage facilities for the brine that will be produced from the wells. The H-19 pond will also be used for this purpose. They want to begin this process soon, so we discussed WIPP obtaining a temporary permission for 120 days while the permit was being modified. I informed them that I was concerned with the apparent "shortcuts" they seemed to be taking to save costs for water storage. I also expressed my concerns for the integrity of the liners in the lagoon system. Since subsurface seepage is already a problem at the sight, I would like to see a full inspection of the liners in all of the lagoons prior to setting up the system they propose. I envisioned decommissioning one side, inspecting and repairing leaks, then switching the effluent to the repaired lagoons and repeating the process for the other side.

WIPP will be submitting requests for temporary permission and a permit modification.

RE: Disposal of Well Development Water at Controlled Recovery, Inc.

Dear Mr. Travis,

The U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) recently contacted the New Mexico Environment Department (NMED) concerning the ground water discharge permit for the Controlled Recovery, Inc. (CRI) landfarm facility. WIPP inquired whether the permit for CRI authorized the facility to receive water from the development of several monitoring wells being drilled at the WIPP facility.

CRI is authorized to receive well development water for disposal at their facility. However, due to the expected high TDS and chloride content, CRI is not allowed to land apply the water. The water must be evaporated in synthetically lined impoundments or steel tanks.

The discharge permit for CRI is currently in the process of being renewed. Final approval is expected by the end of the month. If you have any questions regarding this matter, please contact me at 505-827-0027.

Sincerely,

Clint Marshall, Hydrologist

Analysis of Observed Deviations from the Steady-State Model
of the Culebra Aquifer, Waste Isolation Pilot Plant

Lawrence E. Allen
Environmental Evaluation Group
Albuquerque, NM

Matthew K. Silva
Environmental Evaluation Group
Albuquerque, NM

ABSTRACT

The Waste Isolation Pilot Plant (WIPP) is a geologic repository for disposal of transuranic waste and is operated by the US Department of Energy (DOE). The repository is located at a depth of 655 m in the Permian age salt beds of the Salado Formation, 40 km east of Carlsbad, NM. The site began receiving waste in March 1999, following initial certification by the Environmental Protection Agency (EPA). The WIPP Land Withdrawal Act requires a recertification of the project every five years.

Observed increases in the monitoring well head values have raised concerns about the validity of the steady-state flow model used for performance assessment during the initial certification. The DOE is revisiting the modeling of the Culebra Member, and the Environmental Evaluation Group (EEG), in its oversight role, has begun an independent analysis of the flow and transport system and its ramifications on recertification.

INTRODUCTION

The Waste Isolation Pilot Plant (WIPP), a geologic repository for disposal of defense transuranic waste, was built and is operated by the US Department of Energy (DOE). The WIPP Land Withdrawal Act (LWA) required initial certification of compliance of the WIPP by the US Environmental Protection Agency (EPA) (LWA 1992). In addition, a recertification decision is required by the LWA every five years, dated from the initial receipt of waste. Recertification of compliance must consider new information resulting from operating experience of the facility and ongoing scientific investigation. The first recertification is due by March 2004.

The Culebra dolomite unit of the Rustler Formation is acknowledged as a likely pathway for breach of the WIPP repository. In the original WIPP Compliance Certification Application (CCA), the importance of the Culebra Aquifer to certification was noted, "Major emphasis is placed on the Culebra Member of the Rustler Formation because this is by far the most transmissive geologic layer in the disposal system" (DOE 1996).

The water level in the Culebra began increasing in April 1988 (Beauheim 1990; Silva 1996) and continues to rise. At the time of the CCA, water level increases in the vicinity of the WIPP were attributed to recovery in response to shaft sinking. Increases occurring to the north of the site were thought to be related to infiltration from potash recovery operations. The increases to the south were left unexplained (DOE 1996). However, even after recovery due to site construction is assumed to be completed, the levels have continued to increase.

Since the increasing water heads were thought to be short-lived, the modeling performed in support of the CCA assumed steady-state conditions and the aquifer was conceptualized as two-dimensional and non-leaky. However, the continued increases have forced the DOE to reconsider those assumptions for the first recertification of the WIPP. The DOE has identified several possible causes for these increases, but additional data and modeling is necessary in determining the source. It has become apparent that the time necessary for this work would likely push back resolution of this issue until after the first recertification date.

The Environmental Evaluation Group (EEG), in their role of providing independent technical oversight of the WIPP project on behalf of the State of New Mexico, has reviewed the work to date on resolving this issue and has conducted independent modeling analyses. To date, this has included: 1) a review of the hydrogeologic framework, 2) an analysis of the transmissivity regression model, 3) a review of the transmissivity field simulation, and 4) an assessment of the uncertainty associated with the simulation technique. Sandia National Laboratories (SNL) performed the original interpretations and analyses on behalf of the DOE.

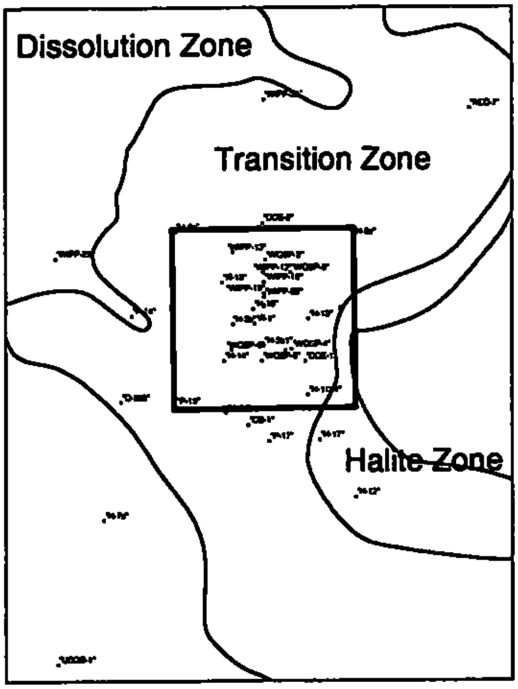
HYDROGEOLOGIC FRAMEWORK

The WIPP resides in the Salado Formation, approximately 655 m below the surface. Overlying the Salado Formation is the Ruster Formation, the most transmissive formation in the vicinity of the WIPP (Mercer and Gonzalez 1981). This Permian age formation consists of anhydrite, siltstone, mudstone, halite, and dolomite members: the Magenta and Culebra. The Culebra is the most transmissive unit located above the repository and has been the focus of much study because of its potential for transport of radionuclides if the repository were breached.

To the west of the WIPP is a large zone of Salado Formation dissolution. This dissolution fractured the various Rustler strata, resulting in increased hydraulic conductivity of the Culebra. East of the WIPP the halite is mostly intact, resulting in a broad area of low hydraulic conductivity. Interpretation of these boundaries in relation to the WIPP is shown in Figure 1. In addition, the depth to the Culebra increases to the east, with fracture apertures decreasing with the increasing overburden and the number of fractures decreasing with distance from the dissolution zone (Holt 2002). Thus the WIPP lies in a transition zone of variable transmissivity bounded by the high transmissivity dissolution zone on the west and the low transmissivity halite zone on the east.

Therefore, while the well-defined high and low transmissivity zones bounding the WIPP can be delineated through geological interpretation, the localized

Figure 1
Interpreted Geological Boundaries



areas of high and low transmissivity within the transitional zone cannot. Transmissivity in this zone is controlled by a complicated history of fracturing with associated gypsum precipitation and dissolution within the fractures. Well-interconnected fractures create high transmissivity zones (Holt 2002).

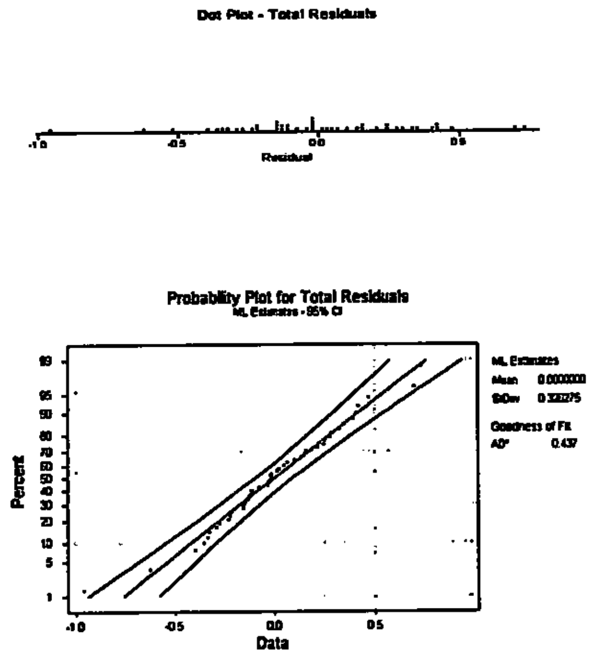
TRANSMISSIVITY REGRESSION MODEL

A regression model was developed by SNL for estimation of grid transmissivity values by regressing the log transform of transmissivity against depth from the surface to the Culebra (Holt 2002). This model considers three populations: 1) low transmissivity locations, 2) high transmissivity locations resulting from Salado dissolution, and 3) high transmissivity locations in the transition, or middle, zone caused by well-interconnected fractures. Data from 46 wells were used in this model. EEG assessed this model through an analysis of residuals.

While analysis of residuals does not result in a model necessarily being confirmed, it is a means for determining whether modeling assumptions appear to be violated (Draper and Smith 1981). Residuals of spatial data are further examined to ascertain the existence of spatial bias. This may include non-random zones of over- or under-estimation which may reflect poorly on a model's ability to represent local conditions. This may also highlight geological zones that have not been previously delineated or that are delineated improperly, e.g. boundary problems.

The mean of each of the residual populations is 0.000 m^2/sec. This would be expected from a regression model and desired as a first indicator of non-biasness. Figure 2 shows residual statistics for the various populations. The dot plots show relatively low spread with data generally concentrated about the mean while the probability plots suggest that the distributions of residuals are approximately normal. All of these statistics and plots show that the sub-populations are statistically "well behaved". This condition is generally referred to as conditional unbiasedness and is a first check on delineation of geological zones and assessment of local estimation (Isaaks and Srivastava 1989).

Figure 2
Residual Statistical Plots



Finally, the residuals were plotted and the positive versus negative values were delineated. It would be desirable for the spatial distribution of positive and negative values to be random. Spatial groupings of positive and negatives or groupings of high residuals may suggest poor local estimation or insufficient geological delineation. Some groupings of positives and negatives exist, which may indicate that local definition of zones is not satisfactory.

GEOSTATISTICAL SIMULATION

SNL designated a 0/1 indicator to represent low versus high transmissivity for each well location. Only wells located in the middle zone, between the dissolution zone on the west and the halite zone on the east, were used. Transmissivity was log-transformed (log T) for this analysis. Wells with a log T value greater than -5.4 were assigned a "1" and those less than -5.4 were assigned a "0". A variogram was then computed on these indicator transforms.

EEG conducted a cross validation analysis to check the robustness of the variogram model. In cross validation the measured log T value at a particular location is temporarily ignored and that location is estimated using ordinary kriging. As this is done for each well location, a distribution of errors, or residuals, is developed. This distribution can be analyzed both statistically and visually to determine the adequacy of the variogram function and kriging parameters for use in the simulation process.

The distribution of validation errors suggests global non-biasness. However, mapping of overestimation versus underestimation suggest systematic spatial bias. This bias probably results from unevenly spaced data and suggests poor local estimation, resulting in considerable uncertainty. The conditional simulation method used by SNL would be appropriate for capturing this uncertainty.

Using the indicator transformed data from the well locations and the variogram model, one hundred realizations of high/low zones were generated by SNL using sequential indicator simulation. These simulations were confined to the interpreted transition zone. Grid nodes were simulated on a 50 m spacing.

One hundred realizations of T-fields were then generated by the regression model using the high/low realizations, the interpreted salado and halite boundaries, and the depth to Culebra map.

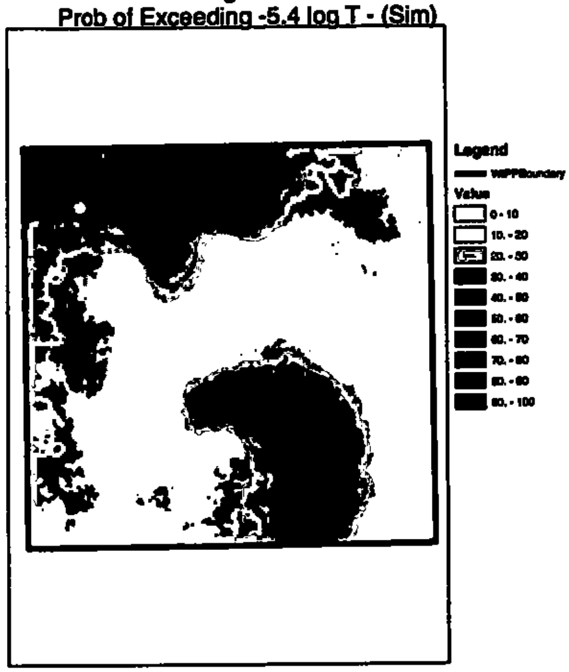
ASSESSMENT OF UNCERTAINTY

Uncertainty was assessed by EEG in two ways: 1) a probability map was constructed from the 100 SNL generated simulations, and 2) an alternative technique was used to estimate transmissivity for comparison to the simulated results.

Probability Mapping

Probability mapping is a means of visualizing multiple realizations on one map (Goovaerts 1997). At each simulated grid node, the probability of exceeding a given threshold is the proportion of simulated realization values above that threshold. Thus the 100 SNL realizations were post-processed and probabilities at each grid node were computed by EEG. The probability of exceeding the -5.4 log T threshold within the WIPP boundary is shown in Figure 3.

Figure 3
Prob of Exceeding -5.4 log T - (Sim)



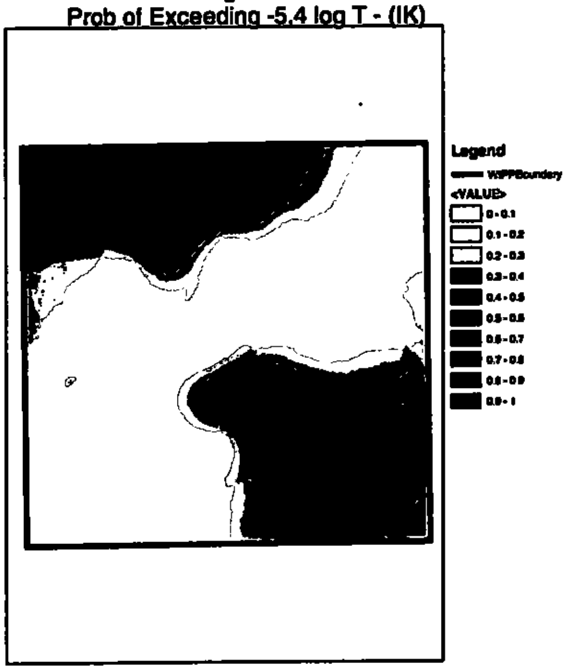
Multiple Indicator Kriging

Another means of assessing uncertainty is comparison of the simulated results with those generated by an appropriate estimation technique. EEG estimated non-transformed transmissivity using multiple indicator kriging, a non-parametric technique suitable for highly skewed distributions. This technique was applied as follows:

1) Nine threshold values were selected, dividing the distribution of transmissivities into deciles. These thresholds are: 1.58×10^{-7}, 1.99×10^{-7}, 2.51×10^{-7}, 3.16×10^{-7}, 6.31×10^{-7}, 1.0×10^{-6}, 3.98×10^{-6}, 1.26×10^{-5}, and 3.16×10^{-5} m^2/sec.
2) Indicator variograms were computed for the nine thresholds where a "0" was assigned for transmissivity values greater than or equal to the threshold, and a "1" for values less than the threshold.
3) Ordinary indicator kriging was used to generate cumulative indicator functions and compute the probability estimates for grid nodes, spaced at 50 m. The search parameters were the same as those used by SNL during conditional simulation.

A probability map was then generated from the local grid distributions for comparison to that from the SNL simulations. This map is shown in Figure 4. The probability map resulting from indicator kriging shows the same general trends as seen from the simulations. However, it is much smoother, extending the high and low zones into the areas of low data density. This method provides a reasonable check on the simulation method, but simulations provide a better characterization of uncertainty.

Figure 4
Prob of Exceeding -5.4 log T - (IK)



CONCLUSIONS

Development of geologically based T-fields using a well conceived hydrogeologic framework is a good first step towards the understanding of the hydrologic system and determining the source of increasing heads. This is important for evaluation of potential transport of radionuclides within the Culebra.

The results of the regression residual analysis do not contradict the assumptions of the SNL model. It appears that the model can satisfactorily estimate transmissivity at grid nodes, assuming proper geological delineation of the zones. The simulation technique used for generation of multiple transmissivity field realizations appears reasonable, generally agreeing with a multiple indicator kriging estimate of the transmissivity field.

Future work includes validation of calibrated transmissivity fields. This work could then be extended to a multi-layered hydrological model to assist in determining the source of increasing heads.

Subject: Estimated Schedule for Engineered Controls for Infiltration Project

Dear Mr. Marshall:

On September 16, 2003, several members of our management team presented, to you and Mr. Jerry Schoeppner, the status of the "Shallow Subsurface Water at WIPP" in regard to Water Budget Analysis Source Controls. Included in the presentation and discussion was our estimated completion of all engineered controls being December 2004. On November 6, 2003, you requested specific completion dates for each of the engineered controls. Our estimated completion dates are as follows:

SSE Pond	January 2004
Cell A	April 2004
Cell B	To be determined
Salt Pile Cover & Ditches	August 2004
Salt Pile Pond	September 2004
Basin A	September 2004
Pond 1	October 2004
Pond 2	November 2004

If you recall, WIPP originally provided an estimated completion date for Cell B in July of 2006. At our last meeting we discussed possibly accelerating that date. It now appears that budget constraints may not allow the planned accelerated completion of Cell B. Completion of Cell B is required for newly mined salt only after Cell A is filled with newly mined salt. We will let you know the schedule for construction of Cell B once that schedule is established.

We will keep you informed of any schedule changes, if any, and engineered control completion dates.

Sincerely,

David D. Emery
Site Environmental Compliance Manager

Notice is hereby given pursuant to 20.6.2.3108.G. NMAC, the following proposed ground water discharge permit applications have been proposed for approval or disapproval. To review the draft permit, please contact the Ground Water Quality Bureau office in Santa Fe. Prior to ruling on any proposed discharge permit or its modification, the NM Environment Department will allow thirty (30) days after the date of publication of this notice to receive written comments and during which a **public hearing may be requested** by any interested person including the applicant. Requests for public hearing shall set forth the reasons why the hearing should be held. A hearing will be held if the NM Environment Department determines that there is significant public interest. Requests for hearing should be submitted to the Ground Water Quality Bureau at the address below.

DP #	Facility/Applicant	Closest City	County	Notice	NMED Permit Contact
1402	Hidden Valley RV Park Robert Ponto, Owner 9505 Deneen, NW Albuquerque, NM 87114	Tijeras	Bernalillo	Hidden Valley RV Park, Robert Ponto, Owner, proposes to discharge up to 11,580 gallons per day of domestic waste. Primary contaminants associated with this type of discharge include nitrogen compounds. The facility is located in Tijeras in Section 7, T10N, R6E, Bernalillo County. Up to 11,580 gallons per day of wastewater will be discharged from the Hidden Valley RV Park to a sewerage system consisting of nine separate septic tank/leachfields. Ground water most likely to be affected is at a depth of approximately 173 feet and has a total dissolved solids concentration of approximately 908 milligrams per liter.	Kurt Vollbrecht
706	Rajen Dairy Randy Vander Dussen 948 CR O Clovis, NM 88101	Clovis	Curry	Rajen Dairy, Randy Vander Dussen, Owner, proposes to renew and modify the discharge permit for the discharge of dairy wastewater. The modification is to increase the discharge volume from 160,000 gallons per day to 200,000 gallons per day. Primary contaminants associated with this type of discharge include nitrogen compounds. The facility is located 4 miles west of Clovis in Sections 17 and 20, T02N, R35E, Curry County. Up to 200,000 gallons per day of dairy wastewater is discharged through two concrete solids separators to a clay-lined lagoon, then pumped through another solids separator before land application by center-pivot irrigation to 224 acres of irrigated cropland. Ground water most likely to be affected is at a depth of approximately 270 feet and has a total dissolved solids concentration of approximately 350 milligrams per liter.	Pamela Homer
831	Waste Isolation Pilot Plant	Carlsbad	Eddy	Waste Isolation Pilot Plant, Inez Triay, Manager, proposes to modify the discharge permit for the discharge of up to	Clint Marshall

	Dave Reber PO Box 3090 Carlsbad, NM 88221			3,264,360 gallons per day of domestic, industrial and mining waste. Primary contaminants associated with this type of discharge include nitrate, chloride and total dissolved solids. The facility is located 26 miles east of Carlsbad in Sections 20, 28 and 29, T22S, R31E, Eddy County. Up to 23,000 gallons per day of sewage effluent is discharged to a series of seven synthetically lined ponds for treatment and evaporation (facultative lagoon system). Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined evaporation cell (north evaporation cell). Up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources is discharged to a synthetically lined evaporation pond (H-19 evaporation pond). Up to 100 gallons per year of neutralized acid waste will also be discharged to the facultative lagoon system. The permit modification includes authorization to discharge up to 3,231,260 gallons per day of storm water runoff to one of five synthetically lined storm water retention basins for evaporation. The runoff originates from the plant facility and approximately 17 acres of excavated salt located on the north side of the facility. During the term of this permit additional salt storage and associated storm water controls will be constructed north of the existing salt storage area. Ground water most likely to be affected is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3,920 milligrams per liter.	
835	Elephant Butte State Park-North David Gatterman State Parks Division PO Box 1147 Santa Fe, NM 87505	Truth or Consequences	Sierra	Elephant Butte State Park-North, David Gatterman, Parks Engineer, proposes to renew and modify the Discharge Permit for the discharge of 5,375 gallons per day of domestic waste. Wastewater from a comfort station and camp host residence is discharged to 3 septic tank/leachfield systems; wastewater from a RV dump station and the Rock Canyon Marina, septic tank pumpings, and sludge from a package treatment plant is discharged to two septic tanks with effluent conveyed to synthetically lined lagoons with reed beds before discharge to a synthetically lined wetland system; vault and chemical toilet waste are	Gerald Knutson

				discharged to a concrete lined evaporation lagoon. Primary contaminants associated with this type of discharge include nitrogen compounds. The facilities are located approximately 4 to 11 miles from Truth or Consequences in Sections 24 and 36, T12S, R04W and Section 6, T12S, R03W, Sierra County. The modification consists of increasing the discharge from 2,000 gallons per day to 5,375 gallons per day, construction of 3 septic tank leachfield systems, and the construction of a concrete lined evaporation lagoon. Ground water most likely to be affected is at a depth of approximately 95 to 150 feet and has a total dissolved solids concentration of approximately 500 to 2,122 milligrams per liter.	
1151	Quality Inn At The Butte Gerald LaFont PO Box 996 Elephant Butte, NM 87935	Elephant Butte	Sierra	Quality Inn At The Butte, Gerald LaFont, Owner, proposes to renew and modify the discharge permit for the discharge of 6,730 gallons per day of domestic waste. Primary contaminants associated with this type of discharge include nitrogen compounds, dissolved solids, and chloride. The facility is located 3 miles from Elephant Butte in Section 14, T13S, R4W, Sierra County. The Quality Inn at the Butte hotel and restaurant discharges a total of 6,730 gallons per day of domestic wastewater into two septic tank/leachfield systems: 2,880 gallons per day from the hotel and 3,850 gallons per day from the restaurant facility. The owner proposes to replace the existing restaurant system with a grease trap, new septic tank, and a newly constructed leachfield. Ground water most likely to be affected is at a depth of approximately 135 feet and has a total dissolved solids concentration of approximately 400 milligrams per liter.	John Hall
1378	Ojo Caliente Mineral Springs Sherman Scott 8114 West Hwy 90 Broussard, LA 70518	Ojo Caliente	Taos	Ojo Caliente Mineral Springs, Sherman Scott, Owner, proposes to discharge up to 30,000 gallons per day of domestic waste. Primary contaminants associated with this type of discharge include nitrogen compounds. The facility is located in Ojo Caliente in Section 24, T24N, R8E, Taos County. Ojo Caliente Mineral Springs will discharge up to 30,000 gallons per day of domestic wastewater to a package treatment plant. Treated wastewater is then	Gerald Knutson

				conveyed to a leachfield for disposal. Ground water most likely to be affected is at a depth of approximately 5 feet and has a total dissolved solids concentration of approximately 1,700 milligrams per liter.	

Any interested person may obtain further information or request to be placed on a facility specific mailing list or request a copy of the proposed approval or disapproval of an application from the Ground Water Pollution Prevention Section of the NM Environment Department, telephone (505) 827-2900, and may submit written comments to the Ground Water Pollution Prevention Section, NM Environment Department, P.O. Box 26110, Santa Fe, NM 87502.

Subject: Comments on the Draft Permit for Discharge Plan Modification, DP-831, Waste Isolation Pilot Plant (WIPP)

Dear Mr. Marshall:

Thank you for the opportunity to review and comment on the Draft Discharge Plan Modification, DP-831 dated September 16, 2003. We have reviewed the Draft Discharge Permit Application for accuracy and completeness and have prepared the following comments for your consideration:

1. Section I, Introduction, Paragraph 4 states, "Storm water runoff at the WIPP site will be contained in one of five synthetically lined retention basins for evaporation." WIPP respectively requests this sentence be revised to state "Storm water runoff from the Salt Storage Area (SSA) will be contained in the Salt Storage Extension Basin for evaporation. The remaining basins will contain storm water not specifically associated with the SSA, but from other areas around the WIPP facility."

2. Section III. Conditions, Item 9.A.: The permittee assumes NMED's reference to water level trends is groundwater level trends. For clarification and since only one measurement of water levels in the retention basins is to be conducted once per year, please change water level trends to groundwater level trends.

3. Section III. Conditions, Item 5.a. Storm Water Collection Ponds states, "The Permittee shall record the water depth to the nearest hundredth of a foot (0.01 ft), and approximate volume of storm water in each of the five storm water collection ponds **once per year after each storm event** in which water quality sampling is conducted (Condition 5B)." Sampling of the "Storm Water Collection Ponds" will occur once per year following a single storm event where sufficient quantity of water has collected in the respective basins. It is not WIPP's intent to sample after every storm event or after a storm event where water has not sufficiently collected in the Storm Water Collection Ponds.

CBFO:OEC:DE:IW:03-3124:UFC:5486

Therefore, we respectfully request that this section (Item III.5.A) be revised to read, "The permittee shall record the water depth to the nearest hundredth of a foot (0.01 ft), and approximate volume of storm water in each of the five storm water collection ponds once per year following a storm event where sufficient quantity of water has collect in the respective basins, during the same event in which water quality sampling is conducted (Condition 5B)" or provide further clarification.

4. Section III, Conditions, Methodology, Item 8: This section states that, unless otherwise approved in writing by NMED, the permittee must conduct the sampling and analyses in accordance with the most recent edition of the following documents." The section lists the references found in 20.6.3107.B. NMAC. The permittees respectfully request that NMED's guidance *Use of Low-Flow and Other Non-Traditional Sampling Techniques for RCRA Compliant Groundwater Monitoring* be incorporated into the approved sampling and analytical techniques outlined in Item 8. The NMED Guidance is attached.

Again, we appreciate the opportunity to provide the enclosed comments. If you have any questions, or need additional information, please contact Mr. David Emery at (505) 234-7475.

Sincerely,

Inés Triay

RE: Draft Discharge Plan Modification, DP-831, Waste Isolation Pilot Plant (WIPP)

Dear Ms. Triay:

Please review the enclosed draft permit for Discharge Plan Modification, DP-831, Waste Isolation Pilot Plant (WIPP). The conditions in the draft permit should be reviewed for accuracy and completeness. Please pay special attention to Conditions 7 and 9, because they differ from the proposed actions in your application. Any comments, questions, or concerns should be directed towards Clint Marshall of the New Mexico Environment Department (NMED), Ground Water Quality Bureau (GWQB) at (505) 827-0027 before **October 15, 2003**. If no comments are received by this date, the NMED GWQB will issue a signed permit with conditions as written in the enclosed draft.

Sincerely,

Clint Marshall

GROUND WATER DISCHARGE PERMIT MODIFICATION
U.S. DEPARTMENT OF ENERGY, DP-831
WASTE ISOLATION PILOT PLANT (WIPP)
DRAFT

I. INTRODUCTION

The New Mexico Environment Department (NMED) issues this Modification to the Discharge Permit, DP-831, to U.S. Department of Energy (DOE) Waste Isolation Pilot Plant (WIPP) pursuant to the New Mexico Water Quality Act (WQA), NMSA 1978 §§74-6-1 through 74-6-17, and the New Mexico Water Quality Control Commission (WQCC) Regulations, 20.6.2 NMAC.

NMED's purpose in issuing this Discharge Permit Modification, and in imposing the requirements and conditions specified herein, is to control the discharge of water contaminants from the WIPP into ground and surface water, so as to protect ground and surface water for present and potential future use as domestic and agricultural water supply and other uses and protect public health. In issuing this Discharge Permit Modification, NMED has determined that the requirements of Section 20.6.2.3109.C NMAC have been met.

The activities which produce the discharge, the location of the discharge, and the quantity, quality and flow characteristics of the discharge were described in the Discharge Permit issued April 29, 2003, as follows:

> Up to 23,000 gallons per day of sewage effluent is discharged to a series of seven synthetically lined ponds for treatment and evaporation (facultative lagoon system). Up to 2,000 gallons per day of non-hazardous brine water is discharged to a synthetically lined evaporation cell (north evaporation cell). Up to 8,000 gallons per day of non-hazardous brine water generated from mine dewatering activities, pumping of groundwater wells, and from other non-hazardous sources is discharged to a synthetically lined evaporation pond (H-19 evaporation pond). Up to 100 gallons per year of neutralized acid waste will also be discharged to the facultative lagoon system.

The Discharge Permit Modification to the WIPP wastewater disposal system is briefly described as follows:

> In addition to the daily discharge of 33,100 gallons per day of sewage effluent, brine and neutralized acid waste approved in the April 29, 2003 Discharge Permit Renewal, WIPP will be authorized to discharge up to 3,231,260 gallons per day of storm water runoff as a result of rainfall events that occur at the site. The runoff occurs from the plant facility and approximately 17 acres of excavated salt (salt piles) stored on the north side of the facility. The purpose for containing the storm water runoff is to minimize infitration into the subsurface, which has resulted in the accumulation of shallow subsurface water (SSW) below the WIPP facility. During the term of this permit additional salt storage capacity and associated storm water controls will be contructed immediately north of the existing salt pile. Storm water runoff at the WIPP site will be contained in one of five synthetically lined retention basins for evaporation.

The facility is located approximately 26 miles east of Carlsbad in Sections 28 and 29, T22S, R31E, Eddy County. Regional ground water below the site is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3,920 milligrams per liter. The shallow subsurface water (SSW) below the site is at a depth of approximately 60 – 80 feet.

The WIPP Discharge Permit Modification consists of the materials submitted by the DOE dated October 30, 2002, April 24, 2003, and July 24, 2003. In addition, the discharge plan includes information and materials submitted as part of the original discharge plan approved on Janurary 16, 1992, amended on August 28, 1995, renewed on July 3, 1997, amended on June 12, 1998, amended on January 24, 2000, and renewed on April 29, 2003. The discharge shall be managed in accordance with the discharge plan as conditioned by the Discharge Permit approved April 29, 2003, and this Discharge Permit Modification.

Issuance of this Discharge Permit Modification does not relieve the DOE of its responsibility to comply with any conditions or requirements of the Discharge Permit, DP-831, approved April 29, 2003, the WQA, WQCC Regulations, any other applicable federal, state and/or local laws and regulations, such as zoning requirements and nuisance ordinances.

The following abbreviations may be used in this permit modification:

Abbreviation	Explanation	Abbreviation	Explanation
DOE	Department of Energy	TDS	total dissolved solids
NMAC	New Mexico Administrative Code	WIPP	Waste Isolation Pilot Plant
NMED	New Mexico Environment Department	WQCC	Water Quality Control Commission

II. FINDINGS

In issuing this Discharge Permit Modification, NMED finds:

1. The DOE is discharging effluent or leachate from the WIPP facility so that such effluent or leachate may move directly or indirectly into ground water within the meaning of Section 20.6.2.3104 NMAC.

2. The DOE is discharging effluent or leachate from the WIPP facility so that such effluent or leachate may move into ground water of the State of New Mexico which has an existing concentration of 10,000 milligrams per liter or less of total dissolved solids within the meaning of Section 20.6.2.3101.A NMAC.

3. The discharge from WIPP is not subject to any of the exemptions of Section 20.6.2.3105 NMAC.

III. CONDITIONS

The following conditions of this Discharge Permit Modification shall be added to the requirements of the Discharge Permit renewal approved on April 29, 2003. The following conditions shall be complied with by the DOE and WIPP (permittee) and are enforceable by NMED:

OPERATIONS

1. The permittee is authorized to discharge up to 3,231,260 gallons per day of storm water runoff from the WIPP site to five synthetically lined retention basins for evaporation. [20.6.2.3104 NMAC]

Storm Water Controls:

2. The permittee shall install infiltration control measures, including synthetically lined impoundments, to mimimize infiltration of storm water runoff into the subsurface at the WIPP facility. The primary control structures include Evaporation Basin A, Pond 1, Pond 2, the Salt Storage Extension (SSE) (Cells A and B), the Salt Storage Extension Evaporation Basin, the Salt Pile Evaporation Pond (SPEP), and berms and ditches associated with these structures. The installation of the storm water control structures shall be in accordance with the application for discharge permit modification dated April 24, 2003, or in accordance with subsequent design and specification amendments subject to approval by NMED. The structures shall be completed according to the schedule dated July 24, 2003. Extensions may be granted per written request for good cause shown. [20.6.2.3109 NMAC]

MONITORING AND REPORTING

4. The permittee shall conduct the following monitoring, reporting, and other requirements listed below in accordance with the WQCC Regulations at 20.6.2.3107 NMAC and the monitoring plan submitted by the permittee dated July 25, 2003. A summary of monitoring requirements is attached to this permit as Table 1. A monitoring schedule is attached as Table 2. [20.6.2.3107 NMAC]

Sampling and Field Measurements:

5. <u>Storm Water Collection Ponds</u> – The permittee shall sample the SPEP, the SSE Evaporation Basin, Evaporation Basin A, Pond 1, and Pond 2 as follows:

    A. The permittee shall record the water depth to the nearest hundredth of a foot (0.01 ft), and approximate volume of stormwater in each of the five storm water collection ponds once per year after each storm event in which water quality sampling is conducted (Condition 5B).

B. The permittee shall collect samples from the five storm water collection ponds once per year following a storm event and analyze for the water parameters listed in Conditions 7B and 7C below.

Analytical results and water level measurements shall be reported as required in Condition 9 below. [20.6.2.3107 NMAC]

6. Ground Water Monitoring Wells – The permittee shall sample the following monitoring wells and piezometers:

A. Monitoring Wells/Piezometers PZ-1, PZ-2, PZ-3, PZ-4, PZ-5, PZ-6, PZ-7, PZ-8, PZ-9, PZ-10, PZ-11, PZ-12, C-2505, C-2506, C-2507, C-2811 and WQSP-6A shall be sampled as follows:

1) The permittee shall record the depth to the water table to the nearest hundredth of a foot (0.01 ft) above msl, quarterly.

B. Monitoring Wells/Piezometers PZ-1, PZ-5, PZ-6, PZ-7, PZ-9, PZ-10, PZ-11, PZ-12, C-2507, C-2811 and WQSP-6A shall be sampled as follows:

1) The permittee shall collect samples from each well semi-annually and analyze the samples for the water parameters listed in Conditions 7A, 7B and 7C below.

Analytical results and water level measurements shall be reported as required in Condition 9 below. [20.6.2.3107 NMAC]

Analysis:

7. The permittee shall analyze samples of ground water and storm water for the parameters listed below. Samples of ground water from monitoring wells and piezometers shall be analyzed for dissolved concentrations of the analytes listed below. Samples of storm water shall exclude field parameters and shall be analyzed for dissolved and total concentrations of the analytes listed below. [20.6.2.3107 NMAC]

A. Field parameters (analysis to be performed in the field): pH, temperature and specific conductance.

B. General chemistry parameters: nitrate, sulfate, chloride, and total dissolved solids.

C. Trace metals: selenium, chromium

Methodology:

8. Unless otherwise approved in writing by NMED, the permittee shall conduct sampling and analysis in accordance with the most recent edition of following documents:

A. American Public Health Association, *Standard Methods for the Examination of Water and Wastewater.*

B. U.S. Environmental Protection Agency, *Methods for Chemical Analysis of Water and Waste.*

C. U.S. Geological Survey, *Techniques for Water Resource Investigations of the U.S. Geological Survey.*

D. American Society for Testing and Materials, *Annual Book of ASTM Standards,* Part 31. Water.

E. U. S. Geological Survey, et al., *National Handbook of Recommended Methods for Water Data Acquisition.*

F. Surface water monitoring must also be conducted according to test procedures approved under Title 40 Code of Federal Regulations Part 136. [20.6.2.3107B NMAC]

Reporting:

9. The permittee shall submit to NMED a semi-annual report by the last day of January and July of each year. Reports shall use the following format:

A. A summary of all activities related to the discharge during the preceding 6 month period. Activities may include general operations, construction or demolition of structures, maintenance and repairs, water management, water quality and water level trends, and precipitation patterns.

B. A single table in a paper and electronic format (EXCEL spreadsheet) of water level measurements and water quality data with only those constituents analyzed and water levels measured during a single event shown in columns. Tabulated electrical conductivity shall include the measured field values and corrected values to 25 degrees Celsius. Monitoring sites shall be shown in rows. Values exceeding standards shall be bolded. Any constituent not analyzed for a particular site shall be shown as "NA", any site not sampled shall be shown as "NS" with an associated reason, and any site not measured for water levels shall be shown as "NM" with an associated reason.

C. Copies of the signed laboratory analyses sheet shall be provided semi-annually.

D. A potentiometric map for the WIPP facility area shall be submitted annually. The map shall incorporate the most recent water level data for all monitoring wells and piezometers installed in the shallow subsurface water (SSW). [20.6.2.3107 NMAC]

GENERAL TERMS AND CONDITIONS

10. In addition to any other requirements provided by law, approval of this Discharge Permit Modification is subject to the General Requirements as specified in the Discharge Permit approved on April 29, 2003. Refer to the Discharge Permit Renewal, DP-831, approved April 29, 2003, for specific information on the following General Requirements

    Monitoring and Reporting
    Record Keeping
    Inspection and Entry
    Duty to Provide Information
    Spills, Leaks and Other UnAuthorized Discharges
    Retention of Records
    Enforcement
    Modification and/or Amendments

Compliance with Other Laws:

11. Nothing in this Discharge Permit shall be construed in any way as relieving the permittee of its obligation to comply with all applicable federal, state, and local laws, regulations, permits or orders. [20.6.2 NMAC]

Right to Appeal:

12. The permittee may file a petition for hearing before the WQCC on this Discharge Permit Modification. Such petition shall be in writing to the WQCC within thirty (30) days of the receipt of this Discharge Permit Modification. Unless a timely petition for hearing is made, the decision of NMED shall be final.[74-6-5.N WQA]

Transfer of Permit:

13. Prior to any transfer of ownership, control, or possession of this permitted facility or any portion thereof, the permittee shall notify the proposed transferee in writing of the existence of this Discharge Permit and include a copy of this Discharge Permit with the notice. The permittee shall deliver or send by certified mail to NMED a copy of the notification and proof that such notification has been received by the proposed transferee. [20.6.2.3111 NMAC]

Term:

14. The term of this Discharge Permit Modification expires on **April 29, 2008**, the same day the Discharge Permit will automatically terminate. To renew the Discharge Permit, the permittee must submit an application for renewal at least 180 days before the termination date. [20.6.2.3109(H) NMAC, 74-6-5.H WQA]

ISSUED: **Approval Date**
EXPIRES: April 29, 2008

Executive Summary

The water budget analysis of shallow subsurface water (SSW) underlying the central portion of the Waste Isolation Pilot Plant (WIPP) presents a comprehensive conceptual model of the SSW hydrologic characteristics. The water budget analysis was conducted for the U.S. Department of Energy (DOE) by Daniel B. Stephens & Associates, Inc. under contract to Portage Environmental — Carlsbad Field Office Technical Assistance Contractor. The water budget analysis is intended to support DOE efforts to ensure regulatory compliance at the WIPP and to provide information that will assist DOE decision-makers in determining the efficacy of proposed actions to address the SSW.

The objective of the water budget analysis was to quantify the SSW sources and consider the potential for migration and the effectiveness of planned controls. The water budget analyzed the important hydrologic processes controlling the SSW system and provided:

- An estimate of the volume of water contained within the perched zone
- Quantification of seepage inputs to the SSW from past and current practices
- A model of SSW accumulation, flow conditions, and potential long-term migration
- Determination of the effects of engineered seepage reduction measures that could be implemented at existing seepage sources

The water budget analysis focuses on the sources of water introduced to the subsurface as a result of site development at the WIPP. The SSW is considered to be anthropogenic, the result of a variety of water discharges and changes in site drainage that have occurred since on-site development of the WIPP began. Increases in recharge from the site have contributed to a saturated, perched zone within the Santa Rosa Sandstone Formation (Santa Rosa), with saturation typically found at depths of 40 to 60 feet below ground surface.

The water budget is a quantitative analysis of the primary inputs and losses of on-site water. The analyses include seepage estimates from five principal seepage sources within the WIPP surface facilities area: the Salt Storage Area, Salt Pile Evaporation Pond, Detention Basin A, and storm water retention Ponds 1 and 2. Since 1984, when the WIPP surface facilities were constructed, recharge of precipitation to the subsurface has increased because runoff from impervious surfaces is routed into retention ponds. Recharge from the Salt Storage Area occurs when precipitation falling on the salt pile infiltrates through the highly fractured surface. *

The water budget includes the following analyses:

- *Compilation of recorded discharges:* Records of past discharges were compiled to quantify the extent of discharges from activities such as drilling, shaft dewatering, water line purging, and sewage treatment.

- *Site drainage summary:* Storm water runoff calculations were completed to determine the volume of on-site storm water that drains to four storm water retention ponds, where seepage may contribute to the SSW.

- *Surface infiltration modeling:* Infiltration rates were modeled for the four storm water retention ponds and the Salt Storage Area. The model calculated evaporation and plant transpiration losses and the amount of recharge to the SSW.

- *Saturated flow modeling:* Saturated flow modeling was conducted to quantify recharge from the storm water retention ponds and Salt Storage Area and determine whether such recharge accounts for observed conditions in the SSW.

- *Long-term migration modeling:* The long-term SSW migration was modeled for a 100-year timeframe to evaluate whether the SSW has the potential to migrate to known groundwater resources. The potential for migration was examined both with and without the engineered controls planned by DOE to prevent seepage and reduce SSW migration.

The water budget results indicate that seepage from the five primary sources provide sufficient recharge to account for the observed SSW saturated lens and that the lens is expected to spread. *The water budget results quantify the following components of the SSW hydrologic system:

- The SSW saturated zone covers approximately 150 to 520 acres to a maximum saturated thickness exceeding 30 feet, and contains a total estimated volume of water in the range of 108 to 315 million gallons.

- Average annual precipitation on the 85-acre watershed surrounding the WIPP facilities area amounts to approximately 29.2 million gallons per year, and average annual storm water flow to the retention ponds and precipitation falling on the Salt Storage Area amounts to approximately 25.0 million gallons per year.

- Modeling by three independent methods produces seepage estimates in the range of 5.4 to 16.9 million gallons per year from the five primary seepage sources, which is equivalent to 18 to 58 percent of on-site precipitation.

- Records of discrete discharges from drilling and construction activities during the 1980s indicate that these discharges total approximately 6 million gallons, with evaporative losses further reducing the volume that these discharges may have contributed to the SSW.

- The estimated leakage from water lines providing input to the SSW is 0.22 million gallons per year, totaling approximately 4 million gallons of water line leakage since the WIPP facilities opened in 1984.

- Seepage into the Exhaust Shaft, which is a loss from the SSW, amounts to approximately 4 million gallons since seepage was detected in 1995.

The quantified water budget components are reasonably consistent, considering the uncertainties of the models and calculations. To develop a valid conceptual model of the SSW, multiple analysis methods were used to obtain a range of independent results, enhancing the reliability of the overall analysis.

The potential extent of long-term SSW migration was examined by expanding the saturated flow model domain to include the 16–square-mile WIPP land withdrawal area. A two-layer model was established, with the upper Layer 1 including the SSW perched lens in the Santa Rosa and the Gatuña Formations and the lower Layer 2 including the Dewey Lake Formation, which is the shallowest groundwater depth interval used for water supply near the WIPP boundary. The potential migration of SSW is a top-down process, with downward flow from the Santa Rosa moving vertically through the unsaturated upper Dewey Lake and laterally to areas where a natural water table exists in the middle Dewey Lake. The conceptual model is conservative in simulating all of the Dewey Lake recharge accumulating in a saturated lens, whereas a complex system of discontinuous saturated pathways in the predominantly unsaturated upper Dewey Lake may disperse the flow and lead to less migration. The rate of downward flow from the Santa Rosa to the Dewey Lake, controlled by the vertical hydraulic conductivity, was established by a model calibration phase that matched observed water levels for the 1996 to 2002 record. The calibrated model was then run for two predictive simulations until 2102, with seepage in Simulation 1 stopping at facility closure in 2035, and seepage in Simulation 2 stopping in 2006, after the implementation of engineered seepage controls.

The long-term migration model simulations indicate that the engineered seepage controls being planned by DOE will substantially reduce the extent of migration. The simulations predict that without seepage controls, the SSW has the potential to migrate over a 100-year time frame as far as the northern WIPP boundary and to the Dewey Lake saturated zone in the southwestern corner of the WIPP site near monitor well WQSP-6A. The predictive modeling results show that engineered seepage controls can reduce the SSW volume by more than half, from approximately 860 million gallons to 385 million gallons, and prevent migration from reaching the facility boundary.

1. Introduction

The water budget analysis presented in this report examines the sources and characteristics of the shallow subsurface water (SSW) underlying the central portion of the Waste Isolation Pilot Plant (WIPP) site near Carlsbad, New Mexico. The water budget builds on previous SSW investigations to develop a comprehensive conceptual model of the hydrogeologic conditions and flow regime. The water budget analysis was conducted on behalf of the U.S. Department of Energy (DOE) by Daniel B. Stephens & Associates, Inc. (DBS&A), under contract to Portage Environmental – Carlsbad Field Office Technical Assistance Contractor (CTAC).

1.1 Project Goals

The goal of the water budget analysis was to establish a conceptual model of the important hydrologic processes controlling the SSW hydrologic system. The water budget analysis provides:

- An estimate of the volume of water contained within the perched zone
- Quantification of seepage inputs to the SSW from past and current practices
- A model of SSW accumulation, flow conditions, and potential long-term migration
- Determination of the effects of engineered seepage controls that could be implemented at existing seepage sources

The purpose of this water budget analysis is to support DOE efforts to ensure regulatory compliance at the WIPP and to provide information that will assist DOE decision makers in determining the efficacy of proposed actions to address the SSW.

1.2 Water Budget Methodology

The concept of a water budget is to quantify the components of a closed hydrologic system. In principle, a hydrologic system can be described by a water budget that accounts for all inputs to and outputs from the system, with the difference being the change in water storage in the system.

The water budget analysis presented herein provides estimates of the primary water budget components, focusing on the sources of water introduced to the subsurface as a result of site development at the WIPP. The SSW is considered to be anthropogenic, the result of a variety of water discharges and changes in site drainage that have occurred since on-site development of the WIPP began in the 1980s. Increases in on-site recharge have contributed to a saturated, perched zone within the Santa Rosa Sandstone Formation, with saturation typically found at depths of 40 to 60 feet below ground surface (bgs). The water budget addresses only the SSW and not the deep regional groundwater systems that occur several hundred feet underground.

The primary water budget components for the SSW system include the following:

- On-site precipitation
- Infiltration below ground surface and recharge to the SSW
- Original water in the subsurface formations and overlying sediments at a moisture content less than saturation
- Downward leakage into the Dewey Lake Redbeds Formation
- Historical water discharges to surface lagoons from sources such as shaft dewatering brine, drilling fluids, showers, and water line flushing
- Leakage from on-site water and sewer lines
- Seepage into the Exhaust Shaft
- Evaporation
- Plant transpiration

The analysis builds on previous SSW site investigation activities that have been completed and considers the local conditions where the SSW has been detected and the potential for migration in the broader hydrogeologic regime. Within the WIPP surface facilities area, the increased recharge from site development was estimated from five principal seepage sources: the Salt Storage Area, Salt Pile Evaporation Pond, Detention Basin A, and storm water retention Ponds 1 and 2. The analyses performed for the water budget include:

- *Compilation of recorded discharges:* Records of past discharges were compiled to quantify the extent of discharges from activities such as drilling, shaft dewatering, water line purging, and sewage treatment.

- *Site drainage summary:* Storm water runoff calculations were completed to determine the volume of on-site storm water that drains to four storm water retention ponds that may contribute seepage to the SSW.

- *Surface infiltration modeling:* Infiltration rates were modeled for the four storm water retention ponds and the Salt Storage Area. The model results included calculated water losses to evaporation and plant transpiration and the amount of recharge to the SSW.

- *Saturated flow modeling:* Saturated flow modeling was conducted to quantify recharge from the storm water retention ponds and Salt Storage Area and to determine whether such recharge accounts for observed conditions in the SSW.

- *Long-term migration modeling:* The long-term SSW migration was modeled for a 100-year timeframe to evaluate whether the SSW has the potential to migrate to known groundwater resources. The potential for migration was examined both with and without the engineered controls planned by DOE to prevent seepage and reduce SSW migration.

The water budget analyses are described in detail in Sections 3 through 7 of this report.

The water budget is based on available data from historical records and previous site investigations. No new data were collected for the water budget, and as noted in this report, various uncertainties and data limitations were identified. Considering the uncertainties that exist, the water budget used multiple analysis approaches and, where necessary, reasonable assumptions, to develop ranges of expected results to support the development of a valid conceptual model of the SSW.

1.3 History of Shallow Subsurface Water at WIPP

Early exploratory drilling at the site (Sergent, Hauskins & Beckwith, 1979; Mercer, 1983) and geologic mapping of the WIPP Exhaust Shaft in 1984 and 1985 (Powers, 1995) did not detect saturated conditions in the Santa Rosa Sandstone Formation at the WIPP site prior to site development. Seepage into the Exhaust Shaft was first detected in 1995 (DOE, 2002), and subsurface investigations of the source of this seepage determined that a saturated zone had developed in the Santa Rosa underlying the WIPP surface facilities. The water budget analysis examines the occurrence of the SSW and the inputs to the system that have contributed to the perched zone where saturated conditions are observed.

2. Hydrologic Setting

The WIPP site is located in eastern Eddy County, New Mexico, in a remote area approximately 25 miles east of Carlsbad, New Mexico (Figure 1). The entire land withdrawal area for the WIPP site is 16 square miles, and the surface facilities area covers roughly 100 acres. A detailed site plan of the WIPP surface facilities is provided in Figure 2, and an aerial photograph of the WIPP surface facilities area from 2000 is provided in Figure 3.

2.1 Climate and Physiography

The WIPP site is located in a semiarid region of the U.S. desert southwest. The average annual precipitation for Carlsbad, New Mexico is 12.10 inches per year (in/yr), based on records beginning in 1948 for the Carlsbad Federal Aviation Administration (FAA) Airport. Annual evaporation from surface water exceeds 98 in/yr (Mercer, 1983). Native vegetation consists of mesquite, scrub oak, and other plants typical of the northern Chihuahuan Desert (Mercer, 1983). Surficial soils at the WIPP site are characterized by sand and dune sand deposits (Campbell et al., 1996).

Climatic data used in the water budget analyses were obtained from the Carlsbad FAA Airport weather station and an on-site weather station (Table 1). The detailed climatic data required for some analyses are available only for more recent years; therefore, data from various time frames, as noted in Table 1, were used in the water budget analysis.

Table 1. Precipitation Summary Statistics

Station	Start Date	End Date	Duration (years)	Annual Precipitation (inches)		
				Mean	Maximum	Minimum
Carlsbad FAA [a]	Jan-48	Dec-02	55	12.10	25.48	5.53
Carlsbad FAA [a]	Jan-84	Dec-02	19	14.40	25.48	5.82
WIPP station [b]	Jan-86	Dec-02	17	13.24	21.28	6.53
WIPP station [c, d]	Jan-96	Dec-02	7	12.54	23.91	7.72
WIPP station [c]	Jan-97	Dec-02	6	12.74	23.91	7.72

FAA = Federal Aviation Administration WIPP = Waste Isolation Pilot Plant

[a] Excludes years with more than five days missing in any month.

[b] Annual data reported by the National Oceanic and Atmospheric Administration (NOAA).

[c] Detailed electronic files with data in 15-minute intervals were available for 1997 through August 2002. Monthly precipitation totals for September 2002 through December 2002 were not available at the time the water budget analyses were initiated. Averages of the monthly total precipitation for September, October, November, and December were obtained from the WIPP site data from 1996 through 2001 and were substituted for missing data in 2002.

[d] Less detailed daily data were available from the WIPP station for 1996.

Figure 3

The long-term record of precipitation data from the Carlsbad FAA Airport is illustrated in Figure 4. As shown in this figure, precipitation was below normal until around 1970 and above normal from 1984 (the year that construction of the main WIPP facilities began) to 1992. Based on the long-term precipitation records available from the Carlsbad FAA Airport, from the initial development of the WIPP facilities in 1984 through 2002, the average annual precipitation has been 14.40 in/yr, approximately 19 percent above average (Table 1).

The climatic data input to the water budget models include daily records of precipitation, temperature, relative humidity, solar radiation, and wind speed. Detailed electronic files of climatic data from the on-site weather station at the WIPP, which provide the most reliable data set for the model, were available for the period from January 1997 to August 2002. The average annual precipitation for the seven-year period when SSW water level measurements were recorded (1996 through 2002) is 12.54 in/yr (Table 1). Precipitation was particularly high in 1997 (23.91 inches).

2.2 Surface Water and Drainage

The immediate area around the WIPP slopes gradually from the northeast to the southwest at approximately 1 percent. Surficial deposits, consisting of fine- to medium-grained dune sands known locally as the Mescalero sand, cover nearly the entire WIPP site (Mercer, 1983). No significant through-flowing streams or arroyos are present at the site (Mercer, 1983). On the north and east sides of the WIPP surface facilities (Figure 2), berms have been constructed to divert overland storm water flow and prevent runoff from reaching the site. Within the WIPP surface facilities area, surface water from on-site precipitation is routed to four storm water retention ponds, as described in Section 5.

2.3 Hydrogeologic Regime

The regional hydrogeologic regime in the area of the WIPP has been described by several investigators. Comprehensive reports by Hendrickson and Jones (1952) and Bachman (1984) describe the regional geologic setting. A more detailed description of the local hydrogeologic regime at the WIPP site is provided by Mercer (1983).

At the WIPP site, Powers (1995) reports the following stratigraphic column from geologic mapping of the WIPP Exhaust Shaft:

0 to 7.5 feet bgs	Quaternary dune sand
7.5 to 17 feet bgs	Mescalero caliche
17 to 34 feet bgs	Gatuña Formation
34 to 54 feet bgs	Santa Rosa Formation
54 to 546 feet bgs	Dewey Lake Formation
546 to 851 feet bgs	Rustler Formation
851 to 2,150(+) feet bgs	Salado Formation

The water budget focuses on the occurrence of SSW in the formations closer to the surface. This section describes the geologic units in these shallower formations, beginning with the Dewey Lake and the overlying geologic units.

The *Dewey Lake Redbeds Formation* (hereafter referred to as *Dewey Lake)*, which consists of alternating thin beds of siltstone and fine-grained sandstone, is the deepest formation examined in the water budget. This formation is absent in some areas due to erosion before Triassic time, but is as much as 560 feet thick in eastern Eddy County and western Lea County (Bachman, 1984), near the WIPP site. Drilling within the WIPP facilities area shows that the Dewey Lake is approximately 500 feet thick (Powers, 1995). The Dewey Lake dips gently eastward and also increases in thickness to the east (Mercer, 1983).

The Dewey Lake is at the base of the SSW, with saturated conditions found in an overlying perched zone. A siliceous layer in the upper Dewey Lake at the Santa Rosa/Dewey Lake contact (Intera, 1997a; Powers, 2003b) and a sulfate (gypsum) cementation zone in the lower Dewey Lake (Powers, 2003a) form zones of reduced permeability in the otherwise more permeable sandstone. During hydrogeologic investigations undertaken during the development of the WIPP, minor thin, discontinuous saturated zones were identified in the Dewey Lake (Mercer, 1983).

In this report, the terms upper, middle, and lower Dewey Lake are used to describe the stratigraphic position in the formation along with certain characteristics of the formation that relate to the occurrence of saturated conditions. Although these horizons are not strictly defined and their thicknesses vary, the terms upper, middle, and lower are useful for the water budget to describe the hydrologic conditions.

- The upper Dewey Lake consists of a thick, generally unsaturated section.

- The middle Dewey Lake is the interval immediately above the sulfate cementation change, where saturated conditions and a natural water table have been identified in limited areas.

- The lower Dewey Lake is below the sulfate cementation change, with predominantly unsaturated conditions and low permeabilities.

Within the WIPP site, monitor well WQSP-6A, located approximately 1.25 miles southwest of the surface facilities area, intersects water in the Dewey Lake. Well WQSP-6A is screened across an interval from 189 to 214 feet bgs and has a water level measured at approximately 165 feet bgs (Stensrud, 1995). At this location, the Dewey Lake Formation occurs from a depth of 35 to 410 feet bgs (U.S. DOE, 1996), which places the saturated horizon within the middle portion of the formation.

The Dewey Lake Formation generally does not yield a water supply to wells; however, in a localized area at the James Ranch (about 1 mile south of the WIPP site boundary in T23S, R31E, Sections 6 and 7), domestic and stock supply wells produce water from the middle Dewey Lake at depths of 94 to 212 feet bgs (Mercer, 1983).

The *Santa Rosa Sandstone Formation* (hereafter referred to as *Santa Rosa),* of Triassic age, unconformably overlies the Dewey Lake. The Santa Rosa consists of gray and red sandstone with lenses of shale and conglomerate (Hendrickson and Jones, 1952). The Santa Rosa can be 200 to 300 feet thick (Hendrickson and Jones, 1952), but due to erosion, it is absent to the west of the WIPP site (Mercer, 1983). Drilling within the WIPP facilities area (Intera, 1997a) shows that the Santa Rosa ranges in thickness from 16 to 39 feet in the area of the SSW.

Shallow water in the Santa Rosa sandstone is the focus of the water budget. Earlier hydrogeologic investigations show that the Santa Rosa was generally not water-bearing at the WIPP site; however, further east, in southwestern Lea County, the Santa Rosa serves as a principal aquifer (Nicholson and Clebsch, 1961). Saturation was detected in the lower part of the Santa Rosa in two test holes drilled approximately 3 miles northeast of the WIPP surface facilities (Mercer, 1983).

Water in the Santa Rosa is perched on the relatively impermeable underlying Dewey Lake redbeds. Small amounts of water may discharge downward into the Dewey Lake through fractures and along bedding planes. However, Nicholson and Clebsch (1961) indicate that downward flow into the Dewey Lake is evident only in areas where collapse features have created significant fracturing, which is not the case at the WIPP site.

The *Gatuña Formation* (hereafter referred to as *Gatuña*), of Pleistocene age, unconformably overlies the Santa Rosa at the WIPP site. This formation consists of silt, sand, and clay, and is discontinuous, with deposits in localized depressions (Hendrickson and Jones, 1952). Boring logs from on-site drilling by Sergent, Hauskins & Beckwith (1979) describe the Gatuña as predominantly sandstone with interbedded siltstone that is highly weathered, fractured, and moderately hard. Drilling within the WIPP facilities area shows that the Gatuña ranges in thickness from 19 to 31 feet (Intera, 1997a).

The Gatuña Formation is water-bearing in some areas, with saturation occurring in discontinuous perched zones. However, because of its erratic distribution, the Gatuña Formation has no known continuous saturated zone (Mercer, 1983). Drilling at the WIPP site, including 30 exploration borings drilled between 1978 and 1979 in the surface facilities area, did not identify any saturated zones in the Gatuña.

The *Mescalero Caliche* is an informal stratigraphic unit consisting of well lithified deposits of finely crystalline limestone (caliche) that developed below the surficial soils and in the upper portion of the Gatuña Formation (Mercer, 1983). Powers (2002) indicates that the caliche is generally well developed in the vicinity of the WIPP. The Mescalero Caliche is described in detail by Phillips (1987), who indicates that although the caliche is continuous and well lithified in some areas, it is often dissected by holes, fractures, and other discontinuities. The

Mescalero Caliche is typically between 2 and 10 feet thick, with the upper contact of the caliche between 5 and 10 feet bgs (Sergent, Hauskins & Beckwith, 1979).

2.3.1 Soils

Berino series soils make up the sandy, surficial soils at the WIPP site (Bachman, 1980). These soils are developed in reddish, noncalcareous, wind-worked deposits, generally about 3 feet in thickness. The Berino soils are classified as loamy fine sands with a sandy clay loam subsoil and are very susceptible to wind and water erosion, often forming hummocks or dunes.

2.3.2 Recharge in Native Soils

Under natural conditions, recharge rates through the native soils are extremely low, and little recharge to the Santa Rosa SSW zone is likely to occur in the vicinity of the WIPP site. Most precipitation falls on rangeland and is returned to the atmosphere through evapotranspiration. Hunter (1985) estimated an evapotranspiration rate of 96 percent for a broad water balance study area encompassing 2,000 square miles in Eddy and Lea Counties. A preliminary water balance estimate for a 400-square-mile area surrounding the WIPP site determined recharge rates of 0.5 to 2 percent of precipitation, or less than 0.25 in/yr (Hunter, 1985). A study by Campbell et al. (1996) determined recharge rates for the WIPP site based on stable isotopes in soil waters and chloride mass balance analysis. These investigators estimated recharge rates in surficial soils of only 0.06 to 0.6 percent of precipitation, or less than 0.08 in/yr.

The extremely low recharge rates that occur in native soils covered with desert vegetation indicate that natural recharge around the WIPP facilities area is likely an insignificant component of the SSW water budget. However, site development at the WIPP has altered the recharge conditions by focusing storm water in retention ponds and removing vegetation over large areas, thereby increasing recharge in comparison to natural conditions.

2.4 Previous On-Site Hydrogeologic and Soils Investigations

While many hydrogeologic investigations have been conducted at the WIPP site, this section describes only the more recent investigations that focus on the SSW. SSW investigations were initiated following the May 1995 detection of fluid seeping through cracks in the Exhaust Shaft concrete liner at depths of 50 to 80 feet bgs (Intera, 1996). The locations of monitor wells installed to investigate the SSW and shaft seepage are shown in Figure 2, and copies of well logs (Intera, 1996, 1997a) are provided in Appendix A. The investigations and ongoing monitoring of these wells provide the basis for our current understanding of the SSW conditions.

A series of SSW investigation activities was conducted by Intera in 1996 and 1997 (Intera 1996, 1997a, 1997b) including:

- Geophysical survey to identify saturated zones in the subsurface

- Drilling of 3 monitor wells (C-2505, C-2506, and C-2507; 4-inch-diameter)
- Drilling of 12 piezometers (PZ-01 through PZ-12, 2-inch-diameter)
- Pumping and slug tests to determine hydrologic properties of the saturated zone
- Sampling of the SSW for water quality analysis

(Hereafter, this report refers to the 3 C-series monitor wells and the 12 PZ-series piezometers collectively as *monitor wells.*)

During the investigation, a saturated zone ranging from 12 to 32 feet thick was encountered in the Santa Rosa in wells completed at depths ranging from 54 to 75 feet bgs. The well screens are predominantly in the saturated interval in the lower portion of the Santa Rosa, and the wells typically penetrate approximately 5 to 10 feet into the Dewey Lake. The Dewey Lake Formation was found to be dry in the interval penetrated, although one borehole (C-2507) was reported to have saturation within the upper 5 feet of the Dewey Lake (Intera, 1996). The easternmost piezometer, PZ-08, which is located approximately 0.25 mile east of the facilities area, did not intersect SSW, suggesting a limit on the saturated zone in this area; however, the full extent of the SSW was not determined.

Water quality analysis of samples from the monitor wells and piezometers indicated total dissolved solids (TDS) concentrations ranging from 3,700 to 155,000 milligrams per liter (mg/L) (Intera, 1997a). Pumping and slug tests showed saturated hydraulic conductivity (K_{sat}) values for the Santa Rosa sandstone of 2.42×10^{-6} to 5.48×10^{-3} centimeters per second (cm/s) (Intera, 1996, 1997a).

The monitor well and piezometer installations showed that the lower portion of the Santa Rosa contains a substantial saturated zone, the areal extent of which includes the entire WIPP surface facilities area. Based on a typical porosity range of 5 to 30 percent for sandstone, Intera (1997a) estimated a total volume of SSW between 20 to 120 million gallons. Intera (1997b) concluded that the increase in water level and gradient observed between October 1996 and March 1997 indicated a significant recharge source north of the Exhaust Shaft.

Continued water quality monitoring and water level measurements have been carried out by WIPP personnel from 1997 to present. The monitoring data used in the water budget include monthly water level and TDS measurements from the 12 PZ-series piezometers and the 3 C-series monitor wells.

Water recently encountered in the upper Dewey Lake at monitor well C-2811 may be interconnected with the SSW in the Santa Rosa, although the interconnection is uncertain (Powers, 2002). Shallow monitor well C-2811, drilled in March 2001 approximately 1,300 feet south of the nearest SSW monitoring location, PZ-12 (Figure 5), was completed in the upper Dewey Lake and intersected water at a depth of approximately 60 feet bgs (Powers, 2002). According to Powers (2002), the Dewey Lake encountered at C-2811 was not saturated during

Figure 5

drilling of earlier wells nearby. The thin zone of Santa Rosa, encountered from 35 to 45 feet bgs at the C-2811 location, was not water-bearing. The water quality from C-2811 is consistent with that of the SSW wells, with similar molar ratios (Powers, 2002). The TDS concentration in C-2811 was 2,630 mg/L, which is lower than the SSW wells, but follows the trend of decreasing TDS concentration toward the south.

Figures 6 to 8 show geologic cross sections through the SSW perched zone that are based on drilling logs from previous investigations (Appendix A). Cross section B-B′ (Figure 7) shows the relationship of the Santa Rosa, where the SSW is known to occur, and the shallow saturated zone encountered at well C-2811 in the predominantly unsaturated upper Dewey Lake. The saturated zone in the Dewey Lake at C-2811 is stratigraphically lower than the SSW occurring in the Santa Rosa to the north. The saturated zone at C-2811 is also both vertically and laterally distinct from the water at monitor well WQSP-6A, located about 1 mile southwest, where saturation occurs in the middle Dewey Lake (Section 2.4.3).

3. Characteristics of Shallow Subsurface Water

To estimate the quantity and source of recharge to the SSW, it was first necessary to determine the amount and characteristics of the water in the SSW lens. This section describes the initial assessment of water quantity and quality in the saturated lens, which provides the basis for the water budget analyses that follow.

3.1 Estimated Volume

The volume of SSW was estimated from the Santa Rosa saturated thickness measured in the on-site monitor wells (Figure 9). Water columns in the SSW monitor wells range from 4 to 34 feet thick in the Santa Rosa. The saturated thickness has been relatively constant since 1998.

The volume of SSW was calculated by estimating the area, average saturated thickness, porosity, and initial moisture conditions of the Santa Rosa Sandstone.

- The areal extent of the SSW (Figure 10) was estimated to be approximately 150 acres considering (1) the saturated thickness in the monitor wells, (2) the predominant direction of flow, and (3) the slope of the Santa Rosa/Dewey Lake contact.

- For the purpose of calculating the saturated volume, it was assumed that the Dewey Lake Redbeds Formation effectively represents an impermeable boundary beneath the Santa Rosa, giving an average saturated thickness of 16.6 feet, based on measurements made during October 1998 and October 2001.

- The only test data on the porosity of the Santa Rosa sandstone in the vicinity of the WIPP site are from a pumping test of a supply well in the Santa Rosa (Nicholson and Clebsch, 1961), which indicated an average 13 percent porosity. No test data on the Santa Rosa initial moisture content at the WIPP are available. Assuming this average 13 percent porosity and a residual moisture content of 3 percent, saturation in the SSW zone would be achieved when the remaining porosity of 10 percent is filled by additional water.

Thus, the calculated average volume of water needed to saturate the observed SSW is 83 million gallons. This amount represents only the addition of water to the SSW; adding the initial moisture content in the Santa Rosa Formation gives a total estimated SSW volume of 108 million gallons. This SSW volume estimate is based on information from on-site monitor wells and includes limited extrapolation beyond the perimeter of the monitor well network. A second estimate of the SSW volume based on MODFLOW saturated flow modeling is presented in Section 6.2.3.3.

3.2 Water Level Correction

Because of contrasting TDS values observed in the SSW, the measured water levels were corrected to account for water density differences. In cases where TDS concentrations were not measured during the same timeframe that water levels were measured, the first TDS concentration measured after the water level measurement was used in the correction.

3.3 Direction and Rate of Flow

A potentiometric surface contour map from October 2001 is presented in Figure 11. The contours are hand-drawn based on SSW monitor well water level measurements that have been corrected for density differences. In the northern portion of the site, limited well locations required interpretation to establish reasonable contours that consider the likely sources of significant recharge. In addition, monitor well PZ-04 was omitted from the potentiometric surface contours because measured water levels at this well have been anomalously low in relation to surrounding wells after dropping dramatically, by over 4 feet, during a one-week monitoring interval in 1997 (U.S. DOE, 2000). Omitting PZ-04 affects the water level contouring in only a localized area near the well.

The available water level data indicate that a water table mound exists near the Salt Pile Evaporation Pond and Salt Storage Area. The general SSW flow pattern suggests radial flow outward from the high point at PZ-07, with a predominantly eastward flow in the northern portion of the site and a predominantly southward flow in the southern portion. In the WIPP administrative area, where most SSW monitor wells are located, the SSW flows south and east from the apex of the water table mound. Monitor well PZ-11, located approximately 200 feet northwest of the Salt Pile Evaporation Pond, suggests a gradient to the north; however, the existing monitor well locations do not provide sufficient data to clearly demonstrate the gradient and extent of the SSW to the north of the water table mound.

The hydraulic gradient is variable, depending on the flow direction. Using the October 2001 contours (Figure 11) as a representative example, the typical hydraulic gradient beneath the WIPP administrative area is approximately 0.016 ft/ft toward the south. A typical SSW seepage velocity can then be calculated using an effective porosity of 10 percent and the geometric mean hydraulic conductivity (Intera, 1997a) of 1.5 feet per day (ft/d) for wells PZ-06, PZ-07, PZ-10, and PZ-12 (located in the central portion of the site where a relatively uniform southerly gradient is observed). The resulting seepage velocity is 0.24 ft/d, which represents a typical SSW flow velocity for current conditions.

3.4 Water Level Fluctuations

Water levels were observed to rise significantly in the SSW monitor wells during the first years of record, from 1996 to 1998. Since 1998, the water levels have remained fairly constant. A

Figure 11

time series analysis to examine water level trends for each of the SSW monitor wells was completed by plotting water level hydrographs along with precipitation records.

The SSW water levels appear to correlate with precipitation rates over the six-year period of record. The SSW monitor wells were installed in 1996, following a period of above average precipitation since 1984 (Figure 4). In the first year after installation of the wells (1997), when the total annual precipitation (23.91 in/yr) was nearly twice the average annual precipitation (13.24 in/yr at the WIPP weather station), SSW water levels increased sharply. In contrast, during the ensuing years (1998 to 2001), when the total annual precipitation was below the WIPP station average (Figure 4), observed water levels declined. These correlations are demonstrated in well PZ-07, located close to the Salt Pile Evaporation Pond, where the water level trends appear to be a result of high recharge rates during periods of high precipitation (Figure 12).

3.5 Water Quality

For the water budget analysis, DOE provided DBS&A up-to-date water quality monitoring data and TDS concentration contour maps for the years 1997 and 2000 (Figures 13 and 14, respectively). The highest TDS concentrations are found throughout the northern portion of the WIPP site, where much of the water encountered in the wells is classified as brine (TDS greater than 35,000 mg/L). Concentrations are much lower in the southern half of the site, but appear to be increasing over time. For example, the TDS concentration of PZ-12 was 3,140 mg/L in 1997, but increased to above 9,000 mg/L by 2000.

Time-series plots for each of the SSW monitor wells show distinct trends in the distribution of high TDS concentrations. In the vicinity of the Salt Storage Area, where TDS concentrations are most elevated, concentrations are steady or declining, consistent with the conceptual model for the SSW hydrologic characteristics. The observed water table mound, centered near the Salt Pile Evaporation Pond and Salt Storage Area, causes an outward radial flow from the mound's apex, with the high TDS plume spreading radially and increasing the TDS in wells at the periphery.

The DOE (2002) indicates that the composition of the Santa Rosa and overlying sediments does not provide a mechanism to produce naturally occurring water with the high salinities observed; thus the SSW is likely derived, at least in part, from anthropogenic saline sources.* Two potential sources of the saline zone within the SSW, the Salt Storage Area and Salt Pile Evaporation Pond, are close to the monitor wells with the highest TDS concentrations. In contrast, monitor wells near the storm water retention ponds, which are sources of fresh water recharge, exhibit the lowest TDS concentrations.

The halite (NaCl) contained in the Salt Storage Area is susceptible to dissolution by precipitation leaching through the salt. Dissolution is dependent on the rate of infiltration and the area of exposed mineral surfaces. Based on a halite solubility constant from Parkhurst (1995), water

saturated with halite contains 133,000 mg/L sodium and 205,000 mg/L chloride and has an approximate TDS concentration of 338,000 mg/L, depending on the exact composition of the crushed rock salt. Seepage that is near saturation with dissolved halite would have a TDS concentration approximately twice as high as the highest TDS concentration measured in the SSW. Thus, seepage from the Salt Storage Area provides a potential mechanism to generate the TDS concentrations observed in the monitor wells.

4. Operational Discharges and Losses

Numerous reports and documents describe the known and suspected water discharges and losses at the WIPP site. DBS&A compiled reported discharge rates, quantities, and sources, beginning with WIPP construction and continuing until the present. The operational discharges and water system leakage that may have contributed to the currently observed SSW are described in Sections 4.1 and 4.2, respectively. Operational-related losses from the SSW due to seepage into the Exhaust Shaft are described in Section 4.3.

4.1 Compilation of Historical Discharges

The record of historical water discharges at the WIPP site provides information on past flows of drilling fluids, fluids from shaft dewatering and water line purging, treated sewage effluent, and other discharges that occurred at various locations across the facility. Most historical discharges were not closely metered or measured, and for the water budget, discharge periods were estimated from available records to calculate total volumes. The sources, locations, and quantities of on-site discharges are summarized in Table 2.

The most significant historical discharges at the site occurred from the early to mid-1980s during drilling of the WIPP shafts, with the two largest sources of discharge being mine dewatering (1,300,000 gallons) and drilling of the Air Intake Shaft (770,000 gallons). Records from that time estimated the quantity of brine to be used during other drilling activities at more than 3 million gallons (U.S. DOE, 1980). This drilling fluid was discharged to a synthetically lined holding pond, and the amount of any release to the subsurface is uncertain. Other sources of operational discharges include flushing of the water supply pipeline (D'Appolonia Consulting Engineers, 1983), temporary showers for subsurface workers (U.S. DOE, 1980), and construction water from the Waste Handling Shaft (U.S. DOE, 1985).

The total volume of recorded on-site discharges to the ground surface is approximately 6 million gallons. Much of this was discharged into the Salt Pile Evaporation Pond, and a portion of the discharge was lost to evaporation. In comparison to the 108 million gallons of water estimated to be in the SSW saturated zone (Section 3.1), the volume of construction and operational discharges appears to provide only a minor contribution.

4.2 Estimate of Water Line Leakage

Leakage from water and sewer lines is a likely component of the overall water budget at the WIPP. Intera (1997b) indicates that several water line leaks were reported over a period of several months in 1996 and 1997. In addition to these identified leaks, a certain amount of leakage typically occurs in the underground piping network of most water systems.

Leakage rates from water systems are commonly estimated as a percentage of total use. A single water meter on the water system serving the WIPP facilities was put into service in

Table 2. Compilation of Historical Water Discharges

Source	Timeframe	Discharge: Location	Discharge: Rate[a] (gpd)	Discharge: Total Quantity[a] (gallons)	Reference
Mine dewatering[b]	August 1991 – December 1993	Salt pile evaporation pond	1,500[c]	1,280,000	U.S. DOE, 1991 NMED, 1993

Waste handling shaft construction and aquifer inflow	June 1981 – March 1982	Salt pile evaporation pond	17,000 – 20,000	250,000[e]	U.S. DOE, 1985

--- = Not available   gpd = Gallons per day

a Except as noted below, rates or quantities were obtained from references cited in last column.

b The timeframe for mine dewatering was taken from the DOE 1991 request for emergency permit and from a subsequent approval by New Mexico Environment Department (NMED) for a 60-day extension dated September 16, 1993.

c Only rates were given for these discharges; total volumes were calculated using the rates and the timeframe.

d Timeframe from *Geologic mapping of the air intake shaft at the Waste Isolation Pilot Plant* (Holt and Powers, 1990).

e Total quantity for waste handling shaft construction and aquifer inflow was reported; this figure was not based on rates.

October 2000. Since that time, flow meter readings show an average water use of 6,240,000 gallons per year for 2001 and 2002. Because the WIPP water system is relatively new, leakage was estimated based on a low leakage rate of 5 percent. Since this water leaks into shallow soils, it was assumed that approximately 50 percent is evaporated at ground surface and the remainder seeps downward to the SSW zone. Leakage for a separate fire-water system at the WIPP site was determined to be 15 gallons per hour in September 2002, based on pumping of the system makeup pump (Hedin, 2002).

Estimated water line leakage to the SSW is summarized in Table 3. An estimated seepage of 222,000 gallons per year from the combined systems provides a reasonable input volume to the SSW from this source. Thus, seepage from water lines since the WIPP facilities opened in 1984 is estimated to total approximately 4 million gallons.

Table 3. Estimate of Water Line Leakage Input to Shallow Subsurface Water

Source	Annual Flow (gallons)	Leakage Rate			
		Percent of System	Hourly (gallons)	Daily (gallons)	Annual (gallons)
Water supply system	6,240,000	5	36	855	312,000
Fire-water system	NA	NA	15	360	131,000
Total annual leakage					443,000
Annual seepage to SSW [a]					222,000

[a] Calculated as 50 percent of total leakage NA = Not available

4.3 Exhaust Shaft Seepage

Seepage into the Exhaust Shaft (Figure 2) from the SSW saturated zone was first detected in May 1995 (U.S. DOE, 2002), when a scheduled inspection found water emerging from small cracks in the concrete shaft liner. Video inspections of the shaft liner show that seepage through these cracks occurs principally at depths of approximately 50 and 80 feet bgs (U.S. DOE, 2002). Measurement of the seepage rate is complicated by the fact that much of the seepage into the shaft is lost to evaporation because of air flow of up to 425,000 cubic feet per minute in the Exhaust Shaft (U.S. DOE, 2002). Although the flow has not been directly measured, DOE (2002) estimates, based on visual observations and periodic measurements of water collected at the base of the Exhaust Shaft during times of low air flow, that seepage into the shaft is about 1 to 3 gallons per minute (gpm). A flow rate of this magnitude could represent a significant loss from the SSW in the range of 0.5 to 1.6 million gallons per year.

The rate of seepage into the Exhaust Shaft is uncertain, and seepage through cracks in the shaft liner may be increasing over time. Assuming that the Exhaust Shaft seepage has occurred at a rate of 1 gpm (0.5 million gallons per year) from 1995 to 2002, the estimated loss from SSW storage amounts to approximately 4 million gallons since the time seepage was first observed.

5. Storm Water Runoff

Storm water runoff, generated by on-site precipitation, is a major component of the water budget. Much of the precipitation within the WIPP surface facilities falls on impervious areas and is routed to shallow, unlined storm water retention ponds. This section examines total storm water flows, flow paths, and fate of storm water runoff to determine the contributions of storm water to the SSW system, using the storm water runoff as input to the seepage modeling analyses (Section 6).

The runoff calculations are based in part on the original site grading and drainage plans and engineering calculations completed for the WIPP facilities design in the early 1980s: This information was supplemented with new runoff calculations completed for the water budget that reflect the most recent topographic surveys and incorporate new infrastructure that has been added since the original design calculations.

5.1 On-Site Water Retention Facilities

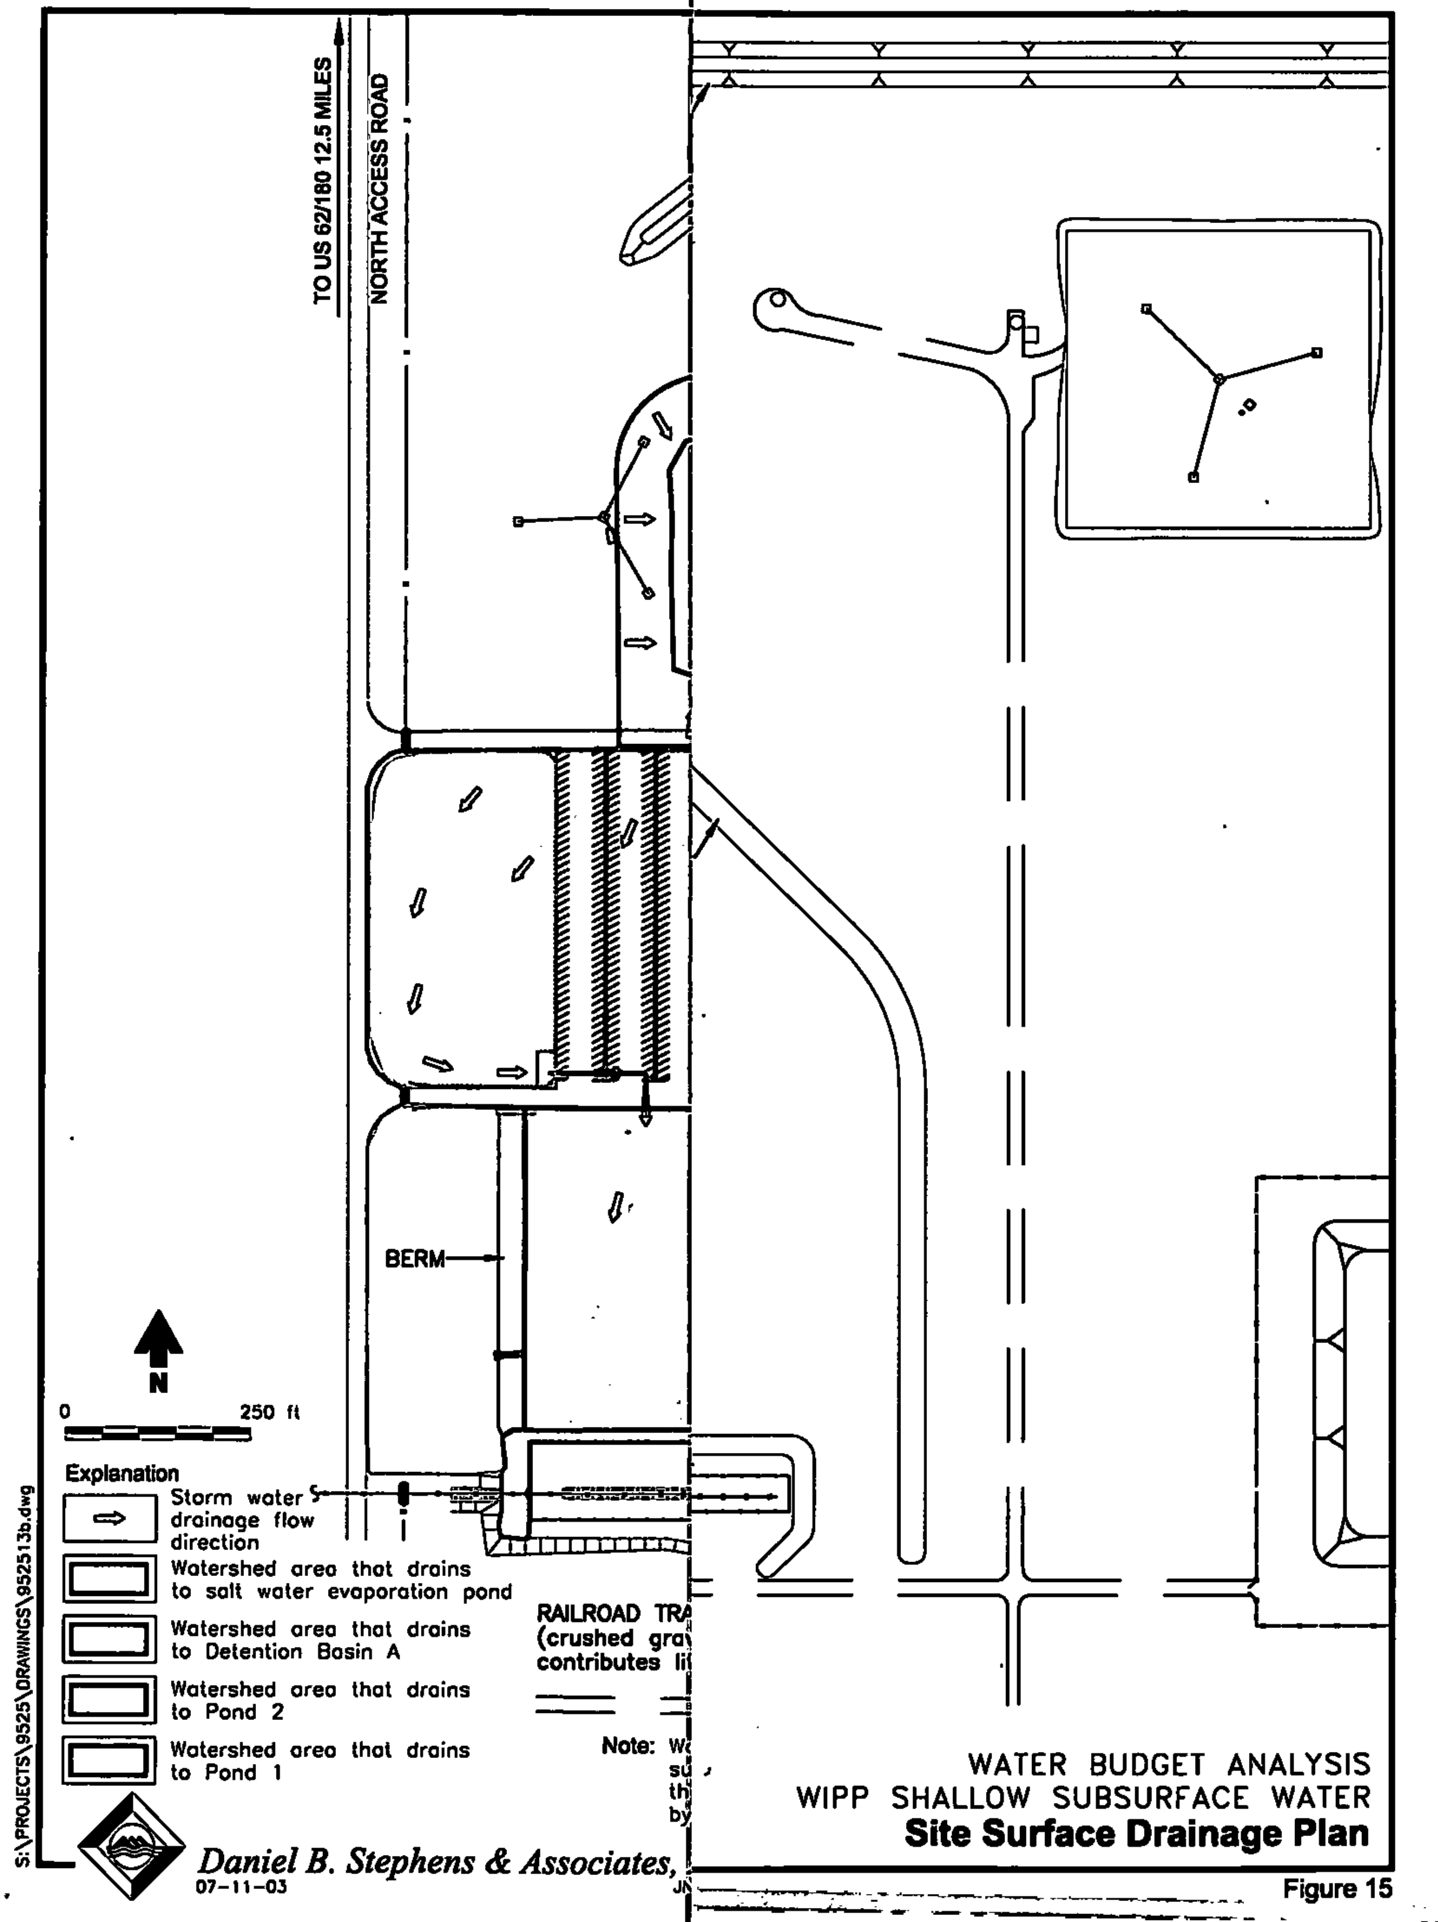
Surface water drainage at the WIPP site consists of four distinct watersheds that drain to four on-site, storm water retention ponds through a network of swales and culverts (Figure 15). The four ponds are:

- Salt Pile Evaporation Pond
- Detention Basin A
- Storm water retention Pond 1
- Storm water retention Pond 2

The areas of the ponds and watersheds, including the pervious and impervious areas, are summarized in Table 4. Figure 15 shows the ponds and their contributing watersheds. Three of the ponds receive relatively clean storm water from the surface facilities, while the Salt Pile Evaporation Pond receives runoff containing dissolved salt from the outer slopes of the Salt Storage Area. The largest watershed, located in the central portion of the facilities area, which includes the administrative area and parking area, drains to Detention Basin A. The southeast portion of the site drains to storm water retention Pond 2, while storm water retention Pond 1 collects a small amount of runoff from areas surrounding both Ponds 1 and 2.

The surface conditions of the watersheds range from relatively permeable bare ground to impermeable pavement and rooftops. Vegetation in the ponds is variable:

- Salt Pile Evaporation Pond: Sparse vegetation mainly in western half of pond
- Detention Basin A: Dense, well established vegetation
- Pond 1: No vegetation on caliche pond bottom
- Pond 2: No vegetation on caliche pond bottom



WATER BUDGET ANALYSIS
WIPP SHALLOW SUBSURFACE WATER
Site Surface Drainage Plan

Figure 15

Constructed berms to the north and east of the site prevent off-site surface water from running onto the WIPP site (Figure 15). Therefore, all of the storm water collected in the retention ponds is from on-site runoff.

Records regarding the design and construction of WIPP facilities indicate that the ponds were constructed between 1981 and 1984. The total capacity of the ponds is designed to handle the runoff from either a 100-year / 24-hour storm event (U.S. DOE, 1993) or two consecutive 10-year / 24-hour storms (Westinghouse, 1992). During 1993 to 1994, design improvements were completed on Detention Basin A and Ponds 1 and 2 to provide total storm water retention (Westinghouse, 1992).

Table 4. Summary of Watershed and Pond Areas

Pond	Pervious [a] Watershed Area		Impervious [b] Watershed Area		Entire Pond Area		Total Watershed Area	
	ft^2	acres	ft^2	acres	ft^2	acres	ft^2	acres
Salt Pile Evaporation Pond	724,393	16.6	0	0	158,024	3.63	882,417	20.3
Detention Basin A	502,172	11.5	890,778	20.4	249,956	5.74	1,642,906	37.7
Storm water retention Pond 1	119,793	2.75	16,615	0.38	21,818	0.50	158,226	3.63
Storm water retention Pond 2	98,643	2.26	222,328	5.10	32,416	0.74	353,387	8.11
Totals	1,445,001	33.1	1,129,721	25.9	462,214	10.61	3,036,936	69.7

[a] Pervious surfaces represent bare ground, gravel, and vegetated ground conditions.
[b] Impervious surfaces represent asphalt and concrete surfaces, and rooftops.
[c] Areas adjacent to the railroad tracks are excluded from the watersheds. Little runoff is expected from these gravel surfaces, which are level or in swales without an apparent discharge point.

5.2 Storm Water Runoff Calculations

For the water budget, runoff was estimated using the rational formula; a standard method that was also used for the original WIPP facility engineering design. Inasmuch as the purpose of the analysis was not to estimate peak discharge rates, but rather to estimate total runoff on a daily basis, a modified version of the rational formula was used (Wanielista et al., 1997).

Runoff was calculated using WIPP daily precipitation records from 1997 through 2002. Drainage flow paths for each watershed were determined from site topography, previous storm water calculations, and observations made during site visits. The irregular pond bottom grades were taken into account in the storm water calculations by determining the submerged area for average-size storms. Table 5 summarizes pond infiltration areas, total watershed areas, and rational method weighted average runoff coefficients used to calculate storm water runoff volumes.

Table 5. Summary of Runoff Calculation Input

Location	Pond Infiltration Area (ft^2)	Total Watershed Area (ft^2)	Total Watershed Area acres	Weighted Average Runoff Coefficient
Salt Pile Evaporation Pond	79,012	882,417	20.3	0.7507
Detention Basin A	70,222	1,642,906	37.7	0.8458
Pond 1	10,000	158,226	3.63	0.7954
Pond 2	15,624	353,387	8.11	0.9232

5.3 Discharges to Storm Water Ponds

Table 6 summarizes the total annual precipitation, runoff, and cumulative inches of storm water in each pond for the period of record from January 1997 through August 2002. The average annual precipitation rate for 1997 to 2001 is 12.7 in/yr, which translates to an average annual precipitation volume of approximately 29.2 million gallons over the 84.6-acre watershed, including the four storm water pond watersheds (24.0 million gallons of annual precipitation) and the 15-acre Salt Storage Area top deck (5.1 million gallons of annual precipitation).

The total combined runoff volume received at all four ponds for the period of record was 113.6 million gallons, and the average annual storm water runoff for 1997 to 2001 was 19.8 million gallons. The total runoff is divided among the four ponds as follows:

- Detention Basin A: 55.5 percent
- Salt Pile Evaporation Pond: 26.5 percent
- Pond 1: 5.0 percent
- Pond 2: 13.0 percent

Detention Basin A and the Salt Pile Evaporation Pond together capture more than 80 percent of storm water runoff. Detention Basin A alone captures more than half of the storm water runoff and therefore appears to be a primary source of seepage.

Table 6. Summary of Runoff Volumes

Year	Annual Precipitation (inches)	Volume of Runoff (gallons)					Cumulative Runoff Depth (inches)			
		Salt Water Evaporation Pond	Detention Basin A	Pond 1	Pond 2	Total	Salt Pile Evaporation Pond	Detention Basin A	Pond 1	Pond 2
1997	23.9	9,874,445	20,713,467	1,876,013	4,863,162	37,327,088	200	473	301	499
1998	7.7	3,188,120	6,687,669	605,700	1,570,149	12,051,639	65	153	97	161
1999	11.9	4,906,168	10,291,592	932,107	2,416,287	18,546,155	100	235	150	248

6. Storm Water Pond and Salt Pile Seepage

Local recharge to the SSW from potential sources of on-site seepage was analyzed using multiple calculation methods. Because impermeable surfaces cover much of the WIPP facilities area, seepage is expected to occur predominantly from the following five pervious areas, as shown on Figure 15:

- Salt Storage Area
- Salt Pile Evaporation Pond
- Detention Basin A
- Pond 1
- Pond 2

Using the calculated quantities of storm water runoff, the seepage rate was calculated for these five primary seepage sources. The calculation methods used for estimating local, focused recharge in these areas are independent approaches that can be cross-referenced to evaluate the reliability of the results. These methods include:

- *Surface infiltration model:* Calculates downward seepage based on hydraulic loading of precipitation and variably saturated flow processes in the soil/salt profile using UNSAT-H.

- *Saturated flow model:* Calculates seepage based on SSW hydrologic conditions and potentiometric surface of the saturated zone. Two types of saturated flow models were applied: (1) steady state (MODFLOW) and (2) transient flow (MODFLOW-SURFACT).

Multiple methods were used to evaluate seepage rates to provide a range of estimated results and corroboration of the general magnitude of seepage. Although the analyses were performed independently, they used many of the same input parameters to maintain consistency among the methods and ensure general reasonableness of results. The models were run with a range of input values during development, and sensitivity analyses were performed on input variables. The seepage rate estimates determined by these models were then used as input to a SSW flow model to examine long-term migration potential (Section 7). Details of the seepage analysis methods and results are described in Sections 6.1 and 6.2.

6.1 Surface Infiltration Modeling

Modeling of surface infiltration, the movement of precipitation from the ground surface to deep percolation, was conducted to estimate the volume of water contributing to SSW recharge from each of the five primary seepage sources. The UNSAT-H model (Fayer, 2000) was selected because it can consider variably saturated/unsaturated infiltration. The model accounts for the water budget losses of evaporation and transpiration and the seepage that contributes to the SSW. The UNSAT-H model can also determine the evapotranspiration losses and seepage inputs from sources with very different characteristics, such as those at the WIPP site.

Conceptually, surface infiltration occurs in cycles following storm events. Precipitation that falls on the Salt Storage Area can infiltrate below the salt pile surface through extensive fractures and dissolution channels (i.e., macropores) observed on the salt pile surface. In the storm water retention ponds, water collects to depths of a few inches to a few feet following storm events. Water levels in the basins decrease in response to combined losses of infiltration and evaporation, but ponded water may remain for days. Eventually, the ponded water will completely infiltrate and/or evaporate, and the soil in the basin will dry out as evapotranspiration and gravity drainage continue.

6.1.1 UNSAT-H Model

The UNSAT-H model uses a one-dimensional finite element version of Richard's equation to simulate infiltration in variably saturated media as a function of environmental conditions such as climate, soil type, and vegetation. The model was developed at Pacific Northwest National Laboratory (PNNL) and has been verified against analytical solutions and validated against lysimeter data by Fayer et al. (1992). More information about UNSAT-H is available from the DOE's PNNL (2002) web site.

Evapotranspiration losses from the soil profile are an important component of the water budget, and UNSAT-H provides a robust consideration of evapotranspiration. The model accounts for both downward and upward redistribution of moisture in the soil profile and changes in soil moisture storage. The model determines the seepage exiting the base of the model domain, which is assumed to migrate vertically downward and become recharge to the SSW.

6.1.2 Ponded Water Calculations

Storm water inputs to the retention ponds from the much larger watersheds result in accumulation of ponded water when storm water inflow exceeds the infiltration capacity of the ponds. To model seepage from the ponds, it was necessary to determine the depth of water (hydraulic head) in each pond after each precipitation event (the ponded water calculations did not apply to the Salt Storage Area, which receives only direct precipitation). Using the runoff volume and pond infiltration area, the depth of water in each pond was calculated for each day's runoff volume within the period of record. The ponding depth following precipitation events was calculated using the following input:

- Infiltration capacity of the soil in the pond bottom
- Weather data records from the WIPP weather station (1997 through September 2002)
- Storm water runoff calculated as described in Section 5

UNSAT-H simulated the evapotranspiration losses and infiltration of ponded water over a period of days. Calculations included daily time increments to ensure that evaporative losses were based on the actual climatic data for that day. This application of UNSAT-H produced negligible amounts of surface runoff from the ponds (3 percent of infiltration), which UNSAT-H shows as a minor mass-balance loss from the system.

6.1.3 UNSAT-H Input Data

UNSAT-H modeling was conducted for unconsolidated near-surface materials, including the Salt Storage Area and the first bedrock unit encountered, the Gatuña Formation. These materials were of four distinct types: crushed rock salt, unconsolidated sand, caliche, and the Gatuña Formation. The thickness of each unit and the four model profiles analyzed are depicted in Figures 16 and 17.

Inputs to the UNSAT-H model include climatological, soils, and vegetation data. Table 7 indicates the sources for these data, while Tables 8 and 9 indicate the data used for soil and vegetation parameters. No laboratory data are available for unsaturated flow parameters for WIPP soils or the crushed rock salt; therefore, the selected values in Table 8 are based on typical values for the general lithology of the materials.

Prior to each simulation, the weather data for 2000 were repeated for four years in UNSAT-H runs to allow the initial soil-water conditions in the model domain to attain a steady state with respect to typical climatic conditions. The model was then run for a five-year timeframe (1997 to 2001) to determine infiltration rates and evaporative losses.

6.1.4 UNSAT-H Modeling Results

In the UNSAT-H modeling results, infiltration represents the flux into the top surface of the model domain, and seepage represents the flux from the bottom of the model domain contributing recharge to the SSW. Bar graphs summarizing the complete water budget for each simulated profile are provided in Figures 18 and 19. UNSAT-H seepage results are summarized in Table 10 and shown in Figure 20 for the five years simulated (1997 to 2001).

The model results vary from year to year, depending on the amount of precipitation received, with seepage rates in 1997 (annual precipitation 23.91 inches) far exceeding subsequent years (Figures 18 and 19). Conversely, the amounts of water lost to evaporation and transpiration tend to change only modestly from year to year.

UNSAT-H Predicted Seepage Rates and Total Predicted Seepage

Daniel B. Stephens & Associates, Inc.
7-11-03 JN 9525

Figure 20

TVDR10-VDR-PROJECTS\9525\CorelDRAW10\952524b.CDR

Table 10 presents seepage in terms of inches of water that seep vertically downward and the total seepage volume from each source. The greatest amount of seepage is from Detention Basin A, which receives the most storm water. The Salt Storage Area is the next largest seepage source, due more to its large seepage area than its seepage rate.

The model predicts seepage rates to be relatively high, with seepage generally exceeding 50 percent of the water applied. The rates are high for two reasons: (1) the storm water retention ponds receive large inflows of water, which greatly exceed rates of evapotranspiration, and (2) areas without vegetation, such as Ponds 1 and 2 and the Salt Storage Area, have no loss to transpiration, and evaporative losses remove only a small percentage of the precipitation and ponded water. Seepage rates range from a low of approximately 5 to 12 in/yr for the Salt Storage Area to a high of approximately 70 to 370 in/yr for both Detention Basin A and Pond 2.

The total seepage volumes predicted by the UNSAT-H model show substantial annual inputs to the SSW. Average annual seepage rates range from 610,000 gallons per year for Pond 1 to 7,400,000 gallons per year for Detention Basin A. The seepage rates are estimated to average approximately 70 percent of the total water applied to the ponds and basins, after other losses that occur during storm water runoff.

6.2 Saturated Flow Modeling

Saturated flow modeling of the SSW was used to estimate areally distributed seepage rates that account for the water level elevations observed at the site. This approach determines seepage based on fundamental saturated flow principles. The seepage rates are estimated by determining the recharge to the SSW necessary to sustain the observed water table mound. The model focused on a limited area centered on the primary seepage sources and the portion of the SSW lens where hydrologic conditions have been most thoroughly characterized.

The code used to model SSW flow and seepage inputs was MODFLOW (McDonald and Harbaugh, 1988; Harbaugh and McDonald, 1996), a U.S. Geological Survey (USGS) quasi-three-dimensional finite-difference groundwater flow model that has been used previously for modeling of the SSW (Duke Engineering & Services, Inc., 1999). MODFLOW can simulate a wide variety of hydrologic features and processes, and is widely accepted by regulators.

For the water budget, steady-state and transient simulations were run to determine rates and distribution of seepage that contribute to the SSW. To better simulate fluctuating water table conditions, a MODFLOW variation, MODFLOW-SURFACT (Hydrogeologic, Inc., 1999) was used for the transient analyses. This variation is more adept at handling the complete drying and re-wetting of grid cells to simulate wetting front migration.

6.2.1 Conceptual Model and Model Domain

The model simulated SSW water table conditions under the influence of variable seepage inputs from the surface. Iterative model runs were conducted to determine seepage rates that match actual water levels observed in the SSW monitor wells.

6.2.1.1 Conceptual Model

The SSW was depicted as an unconfined perched zone with superimposed seepage contributing recharge to the water table. The only sources of recharge to the model are the Salt Storage Area, Salt Pile Evaporation Pond, Detention Basin A, and storm water retention Ponds 1 and 2. The model did not consider operational discharges from drilling and construction activities, water line leakage, or the SSW losses from seepage into the Exhaust Shaft, since these are apparently relatively small contributors in the SSW water budget (Section 4). In general, the inputs and losses omitted from the model are expected to be offsetting and thus are not likely to significantly impact the simulation of recharge from the primary seepage sources.

6.2.1.2 Model Domain

This analysis used a one-layer model simulating the saturated Santa Rosa perched zone above an impermeable Dewey Lake contact at the base of the model. Contours of the Santa Rosa/Dewey Lake contact were generated based on the reported contact elevation in boring logs from piezometers and monitor wells installed on-site (Figure 21). A no-flow boundary was assumed at the top of the Dewey Lake, because within the area where the SSW monitor wells were drilled, the Dewey Lake was found to be dry within 5 feet below the contact and little downward leakage appears to occur. The Santa Rosa pinchout to the west was also assumed to represent a no-flow boundary in the model. This boundary is based on boring logs (Sergent, Hauskins & Beckwith, 1979) that show the Santa Rosa to be absent approximately 1,500 feet southwest of the known limits of the SSW.

6.2.2 Steady-State Analysis

The objective of the steady-state MODFLOW simulation was to estimate the average recharge rate that sustains the water table mound in a near steady-state condition, based on monitor well hydrographs, which show relatively uniform water levels over the past five years.

6.2.2.1 Steady State Model Approach and Calibration

The recharge rate and its spatial distribution were varied in the steady-state MODFLOW model to simulate recharge that most closely replicated the observed shape of the SSW potentiometric surface. Recharge was applied to the Salt Pile Evaporation Pond, Salt Storage Area, Detention Basin A, and Ponds 1 and 2 (Figure 22). Based on the storm water runoff calculations (Section 5.1), recharge in Detention Basin A and the Salt Pile Evaporation Pond was applied to a portion of the ponds where the predominant seepage appears to occur. Recharge rates were varied during the calibration using iterative adjustments. To maintain the expected steady outflow near

Figure 22

the boundaries of the site, constant-head boundaries were placed at the estimated extent of the saturated area (Figure 23), based on the results of the calibrated transient model described in Section 6.2.3.

The spatial distribution of hydraulic conductivity of the Santa Rosa was estimated from several slug tests and pumping tests. As shown in Table 11, hydraulic conductivity values ranged from 0.007 to 15.5 ft/d. Several simulations were run using the two hydraulic conductivity zones shown in Table 11. However, the simulation that best represented observed water levels was a homogeneous hydraulic conductivity distribution using a calibrated value of 1 ft/d, which is close to the geometric mean of all the measurements (0.72 ft/d). While the calibrated hydraulic conductivity value differs significantly from some measurements at individual wells, it provides a good representation of the overall SSW flow field and observed water levels.

6.2.2.2 Steady-State Model Results

Figure 23 shows the simulated steady-state water level elevations in the Santa Rosa, and Table 12 presents the final calibrated recharge rates. The model reasonably predicts general flow directions and the steepening of the gradient to the east and south and provides reasonable estimates of recharge rates from the various seepage sources. However, the results do not represent a unique solution; simulation of other combinations of recharge rates may yield similar water level results.

The steady-state model predicts that seepage rates from the Salt Storage Area and Salt Pile Evaporation Pond dominate the seepage inputs to the SSW. This is due to the proximity of these seepage sources to the apex of the water table mound near monitor well PZ-7, in the northern portion of the observed SSW lens. At the southern edge of the site near monitor well PZ-12, the model tended to predict water levels higher than actual values, leading to relatively low predicted seepage rates for Detention Basin A and Ponds 1 and 2. A probable cause for this difference is that the field-measured hydraulic conductivity (5.98 ft/d) exceeds the values assigned to the model near this well, and the Santa Rosa/Dewey Lake contact slopes steeply southward at this location.

6.2.3 Transient Analysis

The objective of the transient analysis was to simulate the progressive saturation of the SSW due to increased recharge from the five primary seepage sources, beginning with the WIPP facilities development in 1981. The transient analysis considered variable recharge rates needed to simulate the observed water level hydrographs at the SSW monitor wells for the record available from 1996 to 2002. The results include seepage estimates for each source and estimates of the extent of the SSW saturated lens and volume in storage.

6.2.3.1 Transient Model Approach and Calibration

The transient analysis used MODFLOW-SURFACT to simulate saturated/unsaturated flow using the model's capabilities for re-wetting of dry cells to progressively saturate the SSW lens from initially unsaturated conditions. The transient model used a constant head boundary of 0.1 foot above the Santa Rosa/Dewey Lake contact on the north, east, and south borders of the model, with a "no-flow" boundary to the southwest, where the Santa Rosa pinches out. Recharge was applied at variable annual rates from 1981 to 2002 (Figure 24), beginning between 1981 and 1984 from the various seepage sources, based on records of construction of the various ponds and the Salt Storage Area.

The recharge rates at the four storm water ponds were established using a linear regression calculated between the annual precipitation rate and the recharge rate estimated from the unsaturated flow modeling (Section 6.1) and storm water runoff calculations (Section 5). Using the precipitation record from the WIPP weather station for 1991 through 2002 and from the Carlsbad FAA weather station for 1981 through 1990, the recharge to the SSW was estimated from the linear regressions. The recharge rates for the Salt Storage Area were initially set as a given percentage of precipitation and then adjusted until simulated hydrographs were in agreement with observed hydrographs during the 1996 to 2002 record.

The transient model used two hydraulic conductivity zones set at 1.7 ft/d for Zone 1 and 0.017 ft/d for Zone 2 (Table 11, Figure 25). The lower hydraulic conductivity zone (Zone 2) surrounds PZ-01, PZ-02, and PZ-05 (Table 11) and was also extended around PZ-08 because the dry condition in this well may be due to a lower hydraulic conductivity that inhibits the wetting front advance.

The transient model requires the storage parameter specific yield, defined as the ratio of the volume of water that drains from saturated rock due to gravity to the total volume of rock (Fetter, 1993). A uniform specific yield of 0.1 was assigned to the entire model, based on an estimated 0.13 porosity (Nicholson and Clebsch, 1961) and an assumed 0.03 residual water content.

6.2.3.2 Transient Model Results

Results of the MODFLOW transient analysis are illustrated in Figures 26 and 27, which show the simulated potentiometric surface contours and saturated thickness contours, respectively. Comparison of the simulated water level fluctuations with the observed hydrographs for each SSW monitor well shows that the simulation tracked the observed conditions favorably at most wells, with the more significant differences occurring primarily at wells with particularly high or low hydraulic conductivities based on field test results.

The recharge rates for the retention ponds were constrained by the storm water flow calculations (Section 5), which specify relative amounts of flow to each pond. Recharge rates are variable from year to year, based on long-term precipitation records, with seepage of storm water partitioned among the primary seepage sources.

Figure 27

Table 13 shows the estimated recharge rates from the transient model calibration. The transient model demonstrates that, using reasonable recharge rates, combined recharge from the five primary sources could have created the observed SSW saturated zone in the timeframe since the WIPP site was first developed. The model shows that the saturated zone is areally extensive and provides a reasonable simulation of the increasing SSW water levels over time. The seepage rates predicted by the transient model are not necessarily a unique solution, and it is possible that other combinations of parameters would provide similar results.

Table 13. Final Calibrated Recharge Rates, Transient Model

Location	Calibrated Recharge Rate[a] (in/yr) Average	Minimum Annual	Maximum Annual	Average Volume (gal/yr)

Pond 2	79.3	32.6	149.7	740,000

[a] Recharge rate statistics calculated for years when recharge was applied (1981 through 2002 for Salt Pile Evaporation Pond; 1984 through 2002 for all others).

in/yr = Inches per year
gal/yr= Gallons per year

6.2.3.3 SSW Volume Estimate

The simulated saturated thickness contours presented in Figure 27 provide a basis to estimate the total volume of the SSW saturated zone. The MODFLOW-SURFACT transient analysis predicts a seepage input to the SSW of 242 million gallons from 1981 to 2002. Since this input represents only seepage and does not include the initial moisture content in the Santa Rosa Formation, which is assumed to be 0.03 (based on a porosity of 0.13), the total SSW volume is estimated to be 315 million gallons.

The transient analysis projects saturation over a broad 520-acre area extending beyond the SSW monitor wells, and the estimated SSW volume is thus far higher than the estimate of 108 million gallons presented in Section 3.1, which is based more directly on the SSW saturated zone observed in on-site monitor wells. The higher SSW volume estimate from the transient analysis, however, is dependent on projecting information on the Santa Rosa's hydraulic properties considerably beyond the area where data are available, leading to added uncertainty with this estimate.

WATER BUDGET ANALYSIS
WIPP SHALLOW SUBSURFACE WATER
Long-Term Migration Model Domain Base Map

Daniel B. Stephens & Associates, Inc.
7-11-03 12:40PM JN 9525

Figure 28

7.1.1 Conceptual Model

The conceptual model depicts potential migration of the SSW perched lens that has been identified in the Santa Rosa by previous site investigations. An upper Layer 1 includes the Santa Rosa and, where the Santa Rosa pinches out, the Gatuña, with lateral flow of the perched lens above the Dewey Lake contact. The deeper Dewey Lake is modeled as Layer 2, with downward vertical leakage providing recharge that creates a second saturated lens in the Dewey Lake. The potential migration of SSW is a top-down process, with downward flow from the Santa Rosa moving vertically through the unsaturated upper Dewey Lake and laterally to areas where a natural water table exists in the middle Dewey Lake. The saturated horizon in the middle Dewey Lake is the shallowest groundwater depth interval used for water supply near the WIPP boundary, with wells south of the boundary producing from depths of 100 to 200 feet bgs.

Downward flow from the Santa Rosa to the Dewey Lake depends on the low-permeability siliceous layer at the contact and the sulfate cementation change in the lower Dewey Lake. Downward leakage in the upper Dewey Lake is modeled using a uniform vertical hydraulic conductivity, although the downward leakage is likely to occur in a complex system of fractures and permeable zones that create a heterogeneous flow field. The conceptual model represents a conservative approach in that it routes all of the Dewey Lake recharge to accumulate in a single layer as a saturated lens in the middle Dewey Lake, whereas a complex system of discontinuous saturated pathways in the predominantly unsaturated upper Dewey Lake may disperse the flow and lead to less migration.

The predictive simulations follow a timeline for WIPP operations that is based on input provided by DOE (2003a, 2003b). DOE is pursuing implementation by 2004 of engineered seepage controls, which will include covering the Salt Storage Area and lining the storm water ponds, to virtually eliminate the sources of increased seepage, including the apparent sources of saline seepage. The WIPP operating period is planned to extend until 2035. The water budget assumes that after site decommissioning, the site will be restored in a way that eliminates the sources of enhanced seepage. The long-term model was run for an initial calibration stage from 1981 to 2002 and a 100-year migration stage from 2003 through 2102, well beyond facility closure.

7.1.2 Model Domain

The model domain encompasses the formations where SSW has been identified and where it may potentially migrate. The domain includes the one-layer MODFLOW-SURFACT saturated flow model described in Section 6.2, which includes formation contacts developed from results of drilling near the primary seepage sources. The domain is expanded for the long-term migration model based on the structural contours and reported hydrologic characteristics of the Santa Rosa, Gatuña, and Dewey Lake Formations.

The top of Layer 1 is at ground surface, and the bottom is defined by structural contours of the top of the Dewey Lake from the WIPP Compliance Certification Application (U.S. DOE, 1996), merged with the updated contours from the PZ- and C-series wells (Figure 29). The bottom of Layer 2 was defined by the transition from carbonate to sulfate cementation in the Dewey Lake, where gypsum fracture infilling is reported to reduce porosity and permeability (Powers, 2003a). Saturated conditions are found above the cementation change in the middle Dewey Lake in the southwest corner of the WIPP site, near monitor well WQSP-6A. The conceptual model assumes the accumulation and migration of a saturated lens above the cementation change, as a conservative approach to examine the potential for SSW migration to reach naturally occurring groundwater. The elevation contours of the uppermost reported sulfate cementation are based on Powers (1997) (Figure 30), although this report suggests some uncertainty with regard to interpretation of the contours. At the boundary of the model domain, no-flow boundary conditions were set at the perimeters of Layers 1 and 2, and a no-flow boundary condition was set at the base of Layer 2. Figure 31 illustrates a cross-section of the stratigraphic boundaries that control SSW migration within the model domain.

Downward leakage from Layer 1 to Layer 2 is limited by a siliceous layer at the Santa Rosa/Dewey Lake contact, identified during drilling of the PZ- and C-series wells (Intera, 1997a; Powers, 2003b). The SSW is perched above the siliceous layer, but the layer's extent and continuity are uncertain. The model domain includes a 1-foot-thick low-permeability layer over the entire Santa Rosa/Dewey Lake contact. The vertical hydraulic conductivity of the siliceous layer is a key model calibration parameter; derived from the seepage rates estimated in Section 6 and the observed thickness of the SSW saturated lens. The low-permeability layer is absent where the Gatuña overlies the Dewey Lake.

Seepage into the Exhaust Shaft is simulated in the model as a well, where water is lost from the SSW system. The model allows seepage to continue at a constant rate until facility closure in 2035. Based on estimates reported by DOE (2002), the seepage rate was set at 1 gpm, which is conservative in retaining the most SSW storage.

The long-term migration model domain and boundary conditions are illustrated in Figure 32. This figure uses an extreme vertical exaggeration as a conceptual illustration of the model components. The actual thickness of the two-layer model is highly variable, ranging from 70 to 500 feet thick across the site. This variability is primarily a result of the irregular surface of the uppermost reported sulfate cementation change contours (Figure 30), which varies by more than 400 feet in elevation at the base of Layer 2. Layer 2 generally thins toward the northeast corner of the site and thickens in the northwest and southwest corners of the site. Layer 1, consisting of the Santa Rosa and Gatuña, is up to 270 feet thick in the eastern portion of the site, but is absent in the western portion of the site, where these formations have been removed by erosion and the Dewey Lake is covered only by thin, surficial soils.

7.2 Long-Term Migration Model Approach and Calibration

The long-term migration model was used to simulate a variety of scenarios using transient MODFLOW-SURFACT simulations. The model was run for a calibration phase (1981 to 2002) and a predictive phase (2003 through 2102). Model calibration involved a series of iterative input parameter adjustments until a close match was obtained between simulated and observed water levels.

7.2.1 Input Parameters

Recharge to the SSW was applied from the Salt Storage Area, Salt Pile Evaporation Pond, Detention Basin A, and Ponds 1 and 2. The very low recharge rate from desert soils across the WIPP site (Section 2.3.2) was not included in the model.

A range of seepage rates was estimated by surface infiltration unsaturated flow modeling using UNSAT-H and saturated flow modeling using MODFLOW (Section 6). The highest seepage rates were predicted by UNSAT-H; therefore, to take the most conservative approach for long-term migration modeling, seepage rates were based on the UNSAT-H model results presented in Section 6.1. The UNSAT-H results gave a linear regression relating seepage to precipitation, and the recharge to the MODFLOW-SURFACT long-term migration model was calculated based on the recorded precipitation for 1981 through 2002. The predictive scenarios calculated seepage based on the average annual precipitation of 13.24 inches from the NOAA WIPP weather station record for 1986 through 2002.

Hydrologic parameters representative of the Santa Rosa, Dewey Lake, and Gatuña Formations were reviewed and compiled from available data and reports for the WIPP site, as well as from other regional literature. Geometric mean hydraulic conductivities were calculated for the Dewey Lake (0.68 ft/d) and Gatuña Formations (1.0 ft/d), and the Santa Rosa is modeled with two hydraulic conductivity zones (1.7 and 0.017 ft/d [Figure 33), consistent with the transient saturated flow model presented in Section 6.2.3.

The vertical hydraulic conductivity must restrict downward seepage sufficiently to simulate SSW accumulation. The siliceous layer at the Santa Rosa/Dewey Lake contact has a vertical hydraulic conductivity several orders of magnitude lower than the horizontal hydraulic conductivities of either formation. The vertical hydraulic conductivity for this contact was established in the model calibration stage, based on seepage rate estimates for 1981 to 2002 (Section 6) and observed hydrographs during the 1996 to 2002 record. The calibration gave a vertical hydraulic conductivity for the siliceous layer of 4×10^{-7} ft/d to provide a close match with the observed hydrographs in the PZ- and C-series wells.

The vertical hydraulic conductivities of the Gatuña and Dewey Lake Formations were estimated as 10 percent of the horizontal hydraulic conductivity based on Domenico and Schwarz (1998), who provide representative values for horizontal and vertical hydraulic conductivities in different

In sandstone, representative ratios of horizontal to vertical hydraulic conductivity (K_h/K_v) are in the range of 2 to 10, with a maximum ratio of 1,000. The Gatuña and Dewey Lake were assigned vertical hydraulic conductivities of 0.1 and 0.68 ft/d, respectively, which do not lead to any perched conditions where the Gatuña directly overlies the Dewey Lake.

7.2.2 Predictive Simulations

The long-term migration model was used in two predictive simulations to evaluate the effects of engineered seepage controls to limit SSW migration over a 100-year timeframe. This evaluation assumes that the engineered seepage controls, including lining of storm water ponds and channels and covering the Salt Storage Area, will be effective in eliminating seepage from fresh and saline sources that exceeds the very low seepage rates that occur under natural conditions. The following timelines were established for the two predictive simulations.

- *Simulation 1:* SSW migration without seepage controls
  - Seepage continues for the WIPP operating period to 2035.
  - Seepage stops in 2036 and thereafter.
  - SSW migration is simulated through 2102.

- *Simulation 2:* SSW migration with engineered seepage controls
  - Engineered seepage controls are implemented by the end of 2004.
  - Transient drainage continues in 2005, providing continued seepage at constant rates.
  - Seepage stops in 2006 and thereafter.
  - SSW migration is simulated through 2102.

Under each simulation, seepage and SSW accumulation begins in 1981, with seepage rates varying annually based on actual precipitation records. The model is calibrated to match observed conditions in 2002, after which the predictive simulations project SSW migration over 100 years. Both simulations allow seepage into the Exhaust Shaft beginning in 1995 and continuing at a constant rate until final closure is completed in 2035 or until the region around the Exhaust Shaft can no longer sustain the specified 1-gpm flow.

7.3 Long-Term Migration Model Results

The results of the long-term migration model predictive simulations are presented in a series of figures (Figure 34 through 37) that show the extent of the SSW in the Santa Rosa and Gatuña (Layer 1) and the Dewey Lake (Layer 2). These figures illustrate the saturated thickness in each of the two layers in saturated lenses at the bottom of each layer, overlying the low-permeability cementation zones that define the bottom of each layer in the model domain.

Figures 34 and 35 show the saturated thickness in each of the two layers for 2002, at the start of the predictive simulations. These figures illustrate the calibrated model condition that simulates the observed SSW water levels, with a saturated thickness of up to 30 feet in the

Santa Rosa. The model predicts that downward leakage to the Dewey Lake has begun to develop a saturated lens in the middle Dewey Lake. Although the two-layer model simulates saturation at the base of Layer 2 in the middle Dewey Lake, the results suggest a potential for the SSW to extend to monitor well C-2811, where saturation occurs in the upper Dewey Lake.

Figure 36 shows the potential extent of SSW migration without seepage controls (Simulation 1). After 100 years, the model predicts that Layer 1 will drain downward to the Dewey Lake, and the saturated lens in the Santa Rosa will not be sustained. The SSW is predicted to migrate in the middle Dewey Lake in a general radial pattern, with flow strongly influenced by the formation contours used to set up the model domain (Figures 29, 30, and 33). If seepage from the surface continues, the saturated zone in the Dewey Lake is predicted to cover an area of approximately 4.4 square miles, with a saturated thickness above the sulfate cementation change surface exceeding 20 feet. The saturated lens contributed by the surface seepage is projected to migrate as far as monitor well WQSP-6A to the south, where naturally occurring saturated conditions exist, and to just reach the WIPP land withdrawal boundary to the north.

Figure 37 shows the potential extent of the SSW with implementation of engineered seepage controls (Simulation 2). After 100 years, the model predicts that Layer 1 will again become unsaturated, with downward drainage forming a saturated lens in the Dewey Lake. With the engineered seepage controls stopping recharge, however, the extent of the SSW lens in the Dewey Lake is significantly less than in Simulation 1. The saturated zone still covers approximately 3.5 square miles, but the saturated thickness is reduced by about half, to just over 10 feet. The northern extent of migration is maintained within the WIPP land withdrawal boundary. The southern extent of migration continues to reach monitor well WQSP-6A, but the saturated thickness of the SSW reaching the naturally occurring saturated zone is diminished by about half.

The predictive simulations show that seepage losses into the Exhaust Shaft are reduced when engineered seepage controls are implemented to prevent SSW recharge from the surface. Simulation 1, with continued recharge, shows seepage to the Exhaust Shaft continuing at a steady rate of 1 gpm up to 2035. Simulation 2, with the engineered seepage controls to prevent SSW recharge, shows that seepage to the Exhaust Shaft is not sustained at 1 gpm after 2008, and in the model, seepage is stopped for the remaining years of the simulation. The reduced seepage into the Exhaust Shaft is a result of declining water levels in the SSW lens in the Santa Rosa as the lens spreads laterally and leaks downward into the Dewey Lake. This large-scale model domain does not provide the detailed analysis of Exhaust Shaft seepage necessary to reach definitive conclusions about seepage improvements; however, the modeling results suggest that the engineered seepage controls will reduce seepage into the Exhaust Shaft.

Figure 38 shows the expected reduction in the Dewey Lake saturated lens that is created by the engineered seepage controls. The saturated thickness is reduced by as much as 12 feet, and a substantial improvement in the extent of migration is expected near the northern WIPP land withdrawal boundary.

Figure 38

The long-term migration model results are summarized in Table 14.

Table 14. Summary of Long-Term Migration Model Predictive Simulations

Simulation Result	Total Seepage Volume (millions of gallons)		
	Simulation 1 Continued Seepage	Simulation 2 Engineered Seepage Controls	Net Improvement [a]
Calibration Stage (1981-2002)			
Seepage volume	328	328	---
Volume lost to Exhaust Shaft	4	4	---
Volume in SSW storage	323	323	---
Predictive Stage (1981-2102)			
Seepage volume	882	392	490
Volume lost to Exhaust Shaft	22	7	15
Volume in SSW storage	861	385	475

[a] Simulation 1 volume minus Simulation 2 volume

The long-term migration model predicts that downward leakage to the Dewey Lake will continue, and the SSW saturated zone will continue to spread laterally. However, the predictive simulations indicate that implementation of engineered seepage controls will reduce the volume in storage by approximately 55 percent and significantly reduce the extent of saturation over the 100-year timeframe considered.

8. Summary and Conclusions

The SSW water budget for the WIPP provides information on the occurrence of shallow saturated conditions beneath the WIPP facilities area and the effects of site development on subsurface recharge. Through a quantitative analysis of the primary inputs to and losses of on-site water, the water budget examines each input and loss on a local scale and considers the potential for SSW migration in the context of the regional hydrogeologic setting.

The water budget was completed to support DOE regulatory compliance at the WIPP. Existing data and information were compiled and analyzed, but no new field data were gathered as part of the project. Certain data limitations were identified; however, existing data are sufficient to assemble a reasonable representation of the SSW water budget.

8.1 Principal Findings

The water budget used multiple analysis approaches to obtain a range of independent results that enhance the reliability of the overall analysis. The analyses focused on estimates of seepage from five principal seepage sources within the WIPP surface facilities area: the Salt Storage Area, Salt Pile Evaporation Pond, Detention Basin A, and storm water retention Ponds 1 and 2.

Since 1981, when construction of the WIPP surface facilities began, recharge of precipitation to the subsurface has increased, largely because approximately 26 acres developed for the WIPP surface facilities have been covered with impervious surfaces. Under pre-development conditions, precipitation falling on rangeland was predominantly lost to evaporation and plant uptake and transpiration, with only a small fraction (less than 1 percent) contributing to deep recharge. However, due to site development, storm water runoff is now routed to retention ponds, where focused runoff infiltrates over an area of approximately 10 acres. Another recharge source is the Salt Storage Area, where precipitation falling on the salt pile infiltrates through the highly fractured surface.

The greatest component of the water budget is precipitation that falls on-site, and based on the average annual precipitation rate, precipitation on the 85-acre watershed surrounding the WIPP facilities area amounts to approximately 29.2 million gallons per year. The resulting average annual storm water flow to the retention ponds, plus precipitation falling on the Salt Storage Area, amounts to approximately 25.0 million gallons per year. Since 1984, when the WIPP facilities were constructed, precipitation rates have exceeded the long-term average by 19 percent, with precipitation on the 85-acre watershed amounting to approximately 33 million gallons per year. Less than a year after the SSW monitor wells were installed in 1996, higher-than-normal precipitation in 1997 exceeded the long-term annual average by 98 percent, and a corresponding water level rise was observed in the SSW monitor wells. The relatively high precipitation experienced since 1984, along with the focusing of runoff in retention ponds, has resulted in significant recharge to the Santa Rosa.

On a regional basis, shallow water at depths less than 100 to 200 feet bgs is a common occurrence, and to the east of the WIPP site, the Santa Rosa Sandstone is an important aquifer. The Dewey Lake Redbeds Formation is also an aquifer that provides water supply locally from limited saturated horizons. At the time that the WIPP shafts were drilled, the Santa Rosa and Dewey Lake were unsaturated in the WIPP facilities area. Although the initial moisture content in the Santa Rosa and Dewey Lake prior to WIPP development is unknown, the increased seepage from WIPP development has contributed sufficient recharge to reach saturation and create a perched water lens 40 to 60 feet bgs in the Santa Rosa.

8.1.1 Shallow Subsurface Water Volume Estimate

The total volume of water in the SSW zone was estimated by two methods, providing a likely range of the SSW volume added to the saturated portion of the Santa Rosa. The first, based on the saturated zone observed in on-site monitor wells, yields an estimated SSW volume of 108 million gallons, covering approximately 150 acres at an average saturated thickness of 16.6 feet. The second, based on the MODFLOW transient analysis, yields an estimated SSW volume of 315 million gallons, covering approximately 520 acres with a saturated thickness from 1 to 31 feet. However, the SSW characteristics available for the estimations are limited. Certain aspects of the SSW volume estimate are reasonably well understood, including the (1) water table surface, (2) base configuration of the Santa Rosa, and (3) area where water is present in 14 of the 15 SSW monitor wells. Key uncertainties include the porosity and initial moisture content of the Santa Rosa Sandstone and the undefined limits of the SSW.

8.1.2 Operational Shallow Subsurface Water Inputs and Losses

Inputs to the SSW from on-site operational discharges were estimated from available records. Discrete discharges from drilling and construction activities since WIPP construction began in 1981 amount to approximately 6 million gallons, with evaporative losses further reducing the volume these discharges may have contributed to the SSW. The estimated leakage from water lines is approximately 0.22 million gallons per year, a total of approximately 4 million gallons since the WIPP facilities opened in 1984. These operational discharges represent a relatively small contribution to the total SSW volume.

Seepage into the Exhaust Shaft, first observed in 1995, represents a loss from the SSW; however, the seepage rate has not been directly measured. Current seepage rates may constitute a significant loss, having been estimated at rates of 0.5 to 1.6 million gallons per year (U.S. DOE, 2002). The Exhaust Shaft seepage is affected by the condition of the concrete shaft liner and the SSW hydraulic head, which suggests that seepage rates may have been lower in the past.

8.1.3 Shallow Subsurface Water Recharge Modeling

For the water budget, seepage providing recharge to the SSW was modeled using three independent methods to produce a range of seepage estimates for cross-comparison. The results are summarized in Table 15.

Table 15. Summary of Seepage Modeling Results

Location	Total Precipitation [a] (M gal/yr)	Total Storm Water [a] (M gal/yr)	Seepage Volume (M gal/yr)		
			UNSAT-H Simulation [b]	Steady-State MODFLOW Simulation	Transient MODFLOW Simulation [c]
Salt Storage Area	5.1	5.1	4.7	3.5	4.2
Salt Pile Evaporation Pond	7.0	5.2	2.5	1.4	3.0
Detention Basin A	13.0	11.0	7.4	0.39	3.2
Pond 1	1.3	1.0	0.61	0.06	0.28
Pond 2	2.8	2.6	1.7	0.08	0.74
Total	29.2	25.0	16.9	5.4	11.4
Estimated total seepage for 1984 to 2002			320	100	220

M gal/yr = Million gallons per year

[a] Volume represents the average over the years 1997 through 2002. For the Salt Storage Area, it includes direct precipitation onto the top deck. For the storm water ponds, it includes storm water runoff from the watershed and direct precipitation to the pond.

[b] Volume represents the average over the years 1997 through 2001.

[c] Volume represents the average over the years 1981 through 2002.

The UNSAT-H model, which uses a physically based approach to consider near-surface infiltration processes, predicts the highest seepage rates. The steady-state MODFLOW simulation predicts the lowest seepage rates, and the transient MODFLOW simulation predicts intermediate seepage rates. The MODFLOW simulations use SSW water levels and hydraulic testing data to determine the seepage inputs that would create the observed water levels. The MODFLOW simulations provide a reasonable, but non-unique solution; other combinations of seepage inputs may yield similar water level results.

The seepage modeling results are reasonably consistent, considering the uncertainties of each approach. All the models showed total annual seepage rates of several million gallons per year. Recharge to the SSW is estimated to be between 18 and 58 percent of the on-site precipitation. Together, the seepage volumes from the five primary seepage sources are sufficient to have contributed the volume of water necessary to create the SSW saturated zone. Although uncertainties exist in the SSW volume and seepage rates estimated for the five primary sources, it is clear that increased seepage resulting from the WIPP site development contributes significant recharge to the SSW.

8.2 Predictive Simulations

Predictive modeling simulations were used to evaluate the potential extent of long-term SSW migration and the effects of engineered controls to prevent discharges from the primary seepage sources, including the apparent sources of saline seepage. The predictive simulations used a transient saturated/unsaturated flow model that was first calibrated to match observed SSW conditions. Following calibration, the model was run in a predictive mode to evaluate (1) the potential long-term SSW migration for a 100-year timeframe and (2) the effectiveness of engineered seepage control measures in reducing SSW migration. The potential migration of SSW is a top-down process, with downward flow from the Santa Rosa moving vertically through the unsaturated upper Dewey Lake and laterally to areas where a natural water table exists in the middle Dewey Lake. The predictive simulations represent a complex hydrogeologic system as a two-layer model, which is conservative in considering the potential extent of long-term SSW migration, because all recharge to the Dewey Lake is routed to a single layer, whereas the actual heterogeneous flow field in the unsaturated upper Dewey Lake may disperse the flow and lead to less migration.

The predictive simulations examined the downward leakage from the Santa Rosa to the Dewey Lake across the low-permeability siliceous layer observed at the contact. The vertical hydraulic conductivity was established by calibrating the model to a vertical hydraulic conductivity that limits downward flow, such that SSW accumulates in the Santa Rosa perched lens as a result of seepage inputs and water level hydrographs are matched in the SSW monitor wells. The calibration was based on the highest seepage rate estimates for 1981 to 2002 and observed water level hydrographs for the 1996 to 2002 period of record. Given the calibrated vertical hydraulic conductivity, current seepage rates cause an increase in the SSW volume and water levels; however, with a cessation of anthropogenic seepage, either after engineered seepage controls are implemented (2004) or after the WIPP operating period ends (2035), downward leakage is predicted to drain the SSW from the Santa Rosa to the Dewey Lake. The 100-year predictive simulations suggest that the Santa Rosa will become unsaturated and the saturated lens in the Dewey Lake will expand laterally.

The long-term migration model, although preliminary, predicts that over a 100-year timeframe, the SSW has the potential to migrate as far as the northern boundary of the WIPP land withdrawal area. The results also show that within 100 years, SSW migration has the potential to reach monitor well WQSP-6A, where naturally occurring groundwater may be encountered. The model predicts sufficient potential for SSW migration, such that water currently present at monitor well C-2811 may be interconnected with the SSW lens.

The long-term migration model indicates that the engineered seepage controls being planned by DOE will substantially reduce the extent of SSW migration. The predictive simulations show that implementation of engineered seepage controls will reduce the volume of water in the SSW by more than half, from approximately 860 million gallons to 385 million gallons, and reduce migration to prevent the SSW from reaching the northern facility boundary, maintaining the saturated lens within the site.

Santa Fe, NM 87502

Dear Mr. Marshall:

This is to confirm the meeting scheduled for September 16, 2003 at 10:00am to brief you and your associates on:

(1) Status of the Infiltration Control Project and
(2) Water Budget Study Report

The planned attendance from the Waste Isolation Pilot Plant (WIPP) include: Keith Gordon, Dale Bignell, Lokesh Chaturvedi and David Emery.

We look forward to sharing our progress with you and your associates.

Sincerely,

David Emery
Site Environmental Compliance Manager

Subject: Completed Public Notice Requirements

Dear Ms. Leavitt:

In response to your letter dated June 13, 2003, WIPP has completed your requested Public Notice requirements for the Discharge Plan 831 (DP–831) modification application as required under discharge permit public notice requirements of 20.6.2.3108.A.1 NMAC.

On June 24, 2003 the public notices (copies enclosed) were published in the Carlsbad Current Argus newspaper in Section A and Hobbs-News Sun in Local 2. A sign of a synopsis of the public notice, in English and Spanish, was placed at the entrance of the WIPP facility. A photograph of the poster and an affidavit of sign posting are enclosed with this letter. The sign was in place for a period of 30 days as of July 24, 2003.

If you have any questions regarding these actions, please contact Mr. David Emery at (505) 234-7475.

Sincerely,

Inés Triay

AFFIDAVIT OF SIGN POSTING, DP- *831* AUG 0 5 2003

I certify, under penalty of law, that I fulfilled the ground water Discharge Permit public notice requirements of 20.6.2.3108.A.1 NMAC. I prominently posted a synopsis of the public notice (prepared by NMED), in English and in Spanish, at a conspicuous public location, approved by NMED, at or near the proposed facility for 30 days. I am aware that there are significant penalties for false certification including the possibility of fines. I have included a payment of $15.00 for the poster (If public notice option 1 or 2 was selected).

Public Notice

DP-831
U. S. Department of Energy Waste Isolation Pilot Plant

DP-831, the U.S. Department of Energy's Waste Isolation Pilot Plant, proposes to modify its discharge permit to discharge up to 3,264,360 gallons per day of domestic and industrial wastewater and storm water runoff from mined rock salt tailings at its federal facility for disposing of defense generated transuranic radioactive waste.

Potential contaminants from this type of discharge include dissolved solids, chloride and nitrogen compounds. The groundwater most likely to be affected is at a depth of nearly 608 feet and has a total dissolved solids concentration of approximately 3920 milligrams per liter. The facility is located 26 miles southeast of Carlsbad, New Mexico, Section 20, T22S, R31E, in Eddy County.

Information in this public notice was provided by the applicant and will be verified by the New Mexico Environment Department (NMED) during the permit application review process. The NMED will accept comments and statements of interest regarding the application and create a facility-specific mailing list for persons who wish to receive future notices regarding this application. Comments and statements of interest should be sent to:

Clinton Marshall
DP-831
Ground Water Quality Bureau
P.O. Box 26110

Subject: Additional Information for DP-831 Modification Application

Dear Mr. Marshall:

In response to your June 25, 2003 letter, WIPP is submitting the enclosed *WIPP Shallow Subsurface Water and Evaporation Basin Monitoring Plan* and schedule for completion of the infiltration controls.

The monitoring plan includes measurement of the surface elevation from all the shallow subsurface water (SSW) piezometers and monitoring wells on a quarterly basis. Also included is a sampling and analysis program for select SSW piezometers and wells and a sampling and analysis program for the Salt Pile Evaporation Pond (SPEP), Salt Storage Extension (SSE) Evaporation Basin, and Evaporation Basins A and B. There are currently no shallow monitoring wells north of the Salt Storage Area or future location of the SSE; therefore, an upgradient well is not included in the monitoring plan.

The enclosed schedule identifies major milestones for the installation of infiltration controls. Currently, we are in the process of contractor acquisition for this project. As the contracting process advances we will provide additional updates as necessary.

If you have any questions regarding the enclosed application, please contact Mr. Dave Emery at (505) 234-7475.

Sincerely,

Dr. Inés R. Triay for
Manager

WIPP Shallow Subsurface Water and Evaporation Basin Monitoring Plan

1.0 INTRODUCTION

On April 29, 2003 a Discharge Plan modification application for Discharge Permit 831 (DP-831) was submitted to the New Mexico Environment Department (NMED) Ground Water Quality Bureau (GWQB). The application covers activities associated with salt storage operations at the Waste Isolation Pilot Plant (WIPP) site. As part of the application, infiltration control measures were proposed to the GWQB to limit discharges to the subsurface. This monitoring plan describes the sampling procedures and frequency for monitoring discharges to the subsurface and to the evaporation basins associated with infiltration control measures.

Figure 1 shows the WIPP layout, locations of wells, and existing surface water retention basins. This plan will become effective upon issuance of the DP-831 permit modification.

2.0 WATER SURFACE ELEVATION MONITORING

Shallow subsurface water (SSW) monitoring will be performed in selected shallow piezometers and wells to determine spatial and temporal elevation changes. Data will be used for groundwater flow direction and flow rate estimates. Data will be presented semiannually to GWQB within 120 days of monitoring and sample collection.

2.1. Monitoring Network and Data Collection Frequency

Seventeen SSW wells will be monitored. These SSW wells were selected based on the spatial distribution that will provide adequate coverage of flow conditions in the SSW beneath and adjacent to the WIPP facility. For collection of SSW elevations, all piezometers and wells will be measured on a quarterly basis. These include all wells presented in Figure 1 and WQSP-6A (a Hazardous Waste Facility Permit [WIPP Hazardous Waste Facility Permit (HWFP) State of New Mexico, 1999, Hazardous Waste Facility Proposed Final Permit, EPA No. 4890139088] well) to the southwest of the WIPP site.

2.2. Surface Elevation Monitoring Methodology

To obtain an accurate SSW surface elevation measurement, a calibrated water-level measuring device is lowered into a well or piezometer and the depth to water recorded from a known reference point. When using an electrical conductance probe, the depth to water is determined by reading the appropriate measurement markings on the embossed measuring tape when the audible signal is activated at the surface. WIPP procedures specify the methods to be used in obtaining water surface elevation measurements.

2.3. Water Surface Elevation Records and Document Control

The data management process for SSW surface elevation measurements begins with completion of the field data sheets. Date, time, tape measurement, equipment identification number, calibration due date, initials of the field personnel, and equipment/comments are recorded on the field data sheets. If, for some reason, a measurement is not possible (e.g., a test is under way that prevents entry to the well bore), a notation as to why the measurement was not taken will be recorded in the comment section of the field data sheet.

The data are used to calculate SSW surface elevation relative to the mean sea level. The SSW elevations are adjusted to equivalent freshwater heads when pressure density measurements are available.

An electronic database will be maintained for all SSW surface elevation data. Data will be appended into a yearly file. Upon verification of the data, it will be appended into the project database file. A copy of the current project database (through December of the preceding year) will be maintained at the facility.

3.0 WATER QUALITY SAMPLING

Semiannual water quality samples will be obtained from the specified SSW well network and analyzed as described in Section 3.1 below. Laboratory data will be used to identify spatial and temporal changes in SSW chemistry beneath and adjacent to the WIPP site. Results will be presented semiannually to GWQB within 120 days of sample collection.

3.1. Sampling Network

The SSW wells to be sampled were selected based on the spatial distribution that will provide adequate coverage of chemical characteristics in the SSW beneath and adjacent to the WIPP site. The network was selected based on the variable flow direction, the isopach of the contact between the Santa Rosa and Dewey Lake Redbeds Formations, and localized recharge areas at the facility (i.e., evaporation basins). Based on this analysis, the network of eleven piezometers/wells for sampling includes piezometers PZ-1, PZ-5, PZ-6, PZ-7, PZ-9, PZ-10, PZ-11, and PZ-12; monitoring wells C-2507, C-2811 (Figure 1); and Water Quality Sampling Program (WQSP) WQSP-6A to the southwest of the WIPP site. Although well WQSP-6A is a part of this monitoring network, it is sampled and analyzed under a different monitoring program plan at WIPP (WQSP) as part of the Hazardous Waste Facility Permit; however, the sampling parameters include those needed to satisfy this monitoring plan.

3.2. Sampling Frequency and Schedule

Sampling of the SSW monitoring network has historically been performed annually. Due to DP-831 requirements, the wells/piezometers will be sampled and analyzed semi-annually. The sampling intervals will be performed during June and December, with the first round of sampling to be performed in June 2004.

3.3. Sampling Methodology

The method to be used on the SSW wells for sampling is the low-flow technique (http://www.nmev.state.nm.us/HWB/data/11-7low-flow%20final.pdf). Using this technique the amount of drawdown during well purging will be minimized through use of a submersible variable speed pump. Attached to the discharge line of the pump assembly will be an inline flow through cell where indicator parameters will be evaluated using an *in situ* multi-meter, which is capable of simultaneous analysis of pH, conductivity, and temperature. Indicator parameters will be taken at least every five minutes during purging until the results stabilize within ±10%. Specific emphasis will be placed on minimizing drawdown during the purging event by monitoring the water levels in 5-minute intervals. Samples will be collected directly from the discharge line into the specific containers. For wells not conducive to low-flow sampling (i.e., pumping rates too low), three well volumes will be purged to establish stabilized formation water for sampling.

4.0 EVAPORATION BASIN MONITORING

Evaporation basin water sampling and analysis will occur at the Salt Pile Evaporation Pond (SPEP), Salt Storage Extension (SSE), Evaporation Basin A, Pond 1, and Pond 2 to quantify chemical constituents, if any, in surface runoff water (Figure 1). Figure 1 presents Ponds 1 and 2 which were proposed to be combined in the DP-831 modification application. However, the hundred percent design indicates the capacity of the independent ponds is adequate and there is no need to combine them. Analytical data will be reported in the semiannual DP-831 reports to NMED GWQB.

4.1. Sampling Frequency and Locations

Water samples will be obtained from the SPEP, SSE, Evaporation Basin A, Pond 1, and Pond 2 once per year following a storm event where sufficient quantity of water has collected in the respective basins. Samples will be obtained from the edge of the basins at a low elevation point where the water has predominantly been contained. Sampling will commence upon issuance of the DP-831 modification permit. Sampling of the SSE will commence upon completion of the source control construction activities.

4.2. Sampling Methodology

A representative sample of the water collected in the evaporation basins will be obtained for laboratory analysis. Individual samples will be collected by submersing the sample container below the water surface and filling it to the appropriate volume. This may be performed by using a sampling boom with the container attached, or by hand grab sampling at the edge of the water body in the evaporation basin. Care will be taken to avoid obtaining a sample in areas of high algae growth. Additionally, care will be taken to minimize disturbance of bottom sediments. If sediments are inadvertently disturbed, samples will be obtained outside of the area of sediment plume. All applicable WIPP procedures will be adhered to when performing sample collection.

5.0 SAMPLE MANAGEMENT AND ANALYSIS

5.1. Sample Preservation, Tracking, Packaging, and Transportation

Some of the chemical constituents to be analyzed in the SSW monitoring program require preservation and special handling techniques. Samples requiring acidification will be as specified by the standard method of treatment required for the particular parameter suite. Samples will be preserved in accordance with standard methods for the examination of water and wastewater.

The laboratory receiving the samples will prescribe the type, the container material type, and the required sample volumes that will be collected. This information will be recorded on the sample checklist for use by field personnel when samples are being collected. Environmental Protection Agency (EPA) protocol will be followed for sample container type, volume, and preservative requirements.

The sample tracking system at WIPP uses uniquely numbered chain-of-custody (CofC) forms and request for analysis (RFA) forms. The primary consideration for storage or transportation is that samples shall be analyzed within the prescribed holding times for the parameters of interest. WIPP procedures provide protocol that ensures proper sample tracking.

Insulated shipping containers packaged with crushed ice or reusable ice packs will be used to keep the samples cool during transport to the contract laboratory.

5.2. Sample Documentation and Custody

To ensure the integrity of samples from the time of collection through the reporting date, sample collection, handling, and custody will be documented on a CofC form. Sample custody and documentation for SSW sampling and analysis activities are detailed in WIPP procedures. These procedures will be strictly followed throughout the course of sample collection and analysis.

Standardized forms used to document samples will include sample identification numbers, sample labels, custody tape, the sample tracking logbooks, and the RFA and CofC forms.

5.3. Laboratory Analysis and Analytical Parameters

Analyses of samples will be performed by a commercial laboratory using methods that are consistent with EPA recommended procedures. Table 1 presents the analytical parameters for the SSW well sampling program. Table 2 presents the analytical parameters for the evaporation basin sampling program.

RE: Request for Additional Information, DP-831, Waste Isolation Pilot Plant

Dear Ms. Triay:

The New Mexico Environment Department (NMED) is in receipt of the discharge permit modification application dated April 24, 2003 for the above referenced facility. The application proposes the discharge of up to 3,264,360 gallons per day of domestic and industrial wastewater, and storm water runoff from mine tailings.

NMED has reviewed the application in accordance with the New Mexico Water Quality Control Commission Regulations (20.6.2 NMAC). The following additional information is necessary, pursuant to Section 20.6.2.3106 NMAC, in order for NMED to complete its technical evaluation of the application:

1. Item 4B of your discharge plan modification application lists total dissolved solids (TDS) as the only contaminant associated facility's proposed salt pile storm water runoff collection and evaporation system. Please note that chloride and sulfate are also potential contaminants and will be included required analytes in your monitoring requirements as described below. Addtionally, past laboratory analyses of some wells have shown that chromium and selenium concentrations exceed Water Quality Control Commission (WQCC) ground water numerical standards. These analytes will also be included in the monitoring requirements.

2. Your application for discharge permit modification did not specify a ground water monitoring plan. Discharges to the subsurface are occurring at the facility, therefore a ground water monitoring plan will be required as part of your permit modification. Please

submit a monitoring plan that, at a minimum, includes semi-annual water quality sampling and quarterly water level measurements of select wells or piezometers that will provide adequate coverage of ground water conditions in the shallow subsurface water (SSW) beneath and adjacent to the facility. The plan must include selected wells and/or piezometers onsite, C-2811, WQSP-6A (Dewey Lake Formation), and, if possible, a monitoring well upgradient of the salt pile extension (SSE). Samples must be analyzed, at a minimum, for total dissolved solids, chloride, sulfate, selenium, chromium and nitrate-nitrogen. Ground water monitoring conducted as a requirement for other regulatory agencies may be used to meet this permit requirement provided the data is timely and appropriate.

3. Pursuant to 20.6.2.3107 NMAC, discharges to the Salt Pile Evaporation Pond (SPEP), the Salt Storage Extension (SSE) Evaporation Basin, and Evaporation Basins A and B must be sampled on a periodic basis and analyzed for the constituents listed in Item 2 above. Please submit a monitoring plan that outlines the sampling procedures and frequency for monitoring discharges to these basins. Sampling events should take place immediately after storm events and should be conducted, at a minimum, annually.

4. Please provide a schedule for completion of the storm water controls described in Attachment A, Design Basis Summary in your application. The schedule should include estimated start dates, if applicable, and completion dates of the major tasks outlined in the application.

Please submit the requested information within 30 days of the date of this letter. Your cooperation is appreciated. If you have any questions, you may reach me at 505-827-0027.

Sincerely,

Clint Marshall

RE: Administrative Completeness Determination and Applicant's Public Notice Requirements, DP-831, Waste Isolation Pilot Plant

Dear Discharge Permit Applicant:

The New Mexico Environment Department Ground Water Quality Bureau (NMED-GWQB) received a Ground Water Discharge Permit Application from you on 4/29/03. The NMED has determined that your application is administratively complete according to the New Mexico Water Quality Control Commission (WQCC) Regulations of 20.6.2.3106 NMAC.

Within 30 days of submitting your Discharge Permit Application, you must provide notice to neighboring properties using one of three public notice options listed in 20.6.2.3108 NMAC. You selected public notice option # 2. The instructions and materials needed to complete the selected public notice option are attached to this correspondence.

If you have any questions please call the GWQB at (505) 827-2900.

Sincerely,

Diana D. Sandoval

for: Marcy Leavitt, Chief
Ground Water Quality Bureau

Public Notice 1
DP-831

DP-831, Waste Isolation Pilot Plant, Inez Triay, Manager, proposes to modify the discharge permit for the discharge of up to 3,264,360 gallons per day of domestic and industrial wastewater, and storm water runoff from mine tailings from a federal nuclear waste storage facility. Potential contaminants from this type of discharge include dissolved solids, chloride and nitrogen compounds. The facility is located at 26 miles SE of Carlsbad; Carlsbad, NM 88221, in Section 20, T22S, R31E, Eddy County. Ground water most likely to be affected is at a depth of approximately 608 feet and has a total dissolved solids concentration of approximately 3920 milligrams per liter.

Information in this public notice was provided by the applicant and will be verified by NMED during the permit application review process. The New Mexico Environment Department will accept comments and statements of interest regarding the application and will create a facility specific mailing list for persons who wish to receive future notices. Comments and statements of interest should be sent to Clinton Marshall, DP-831, Ground Water Quality Bureau, P.O. Box 26110, Santa Fe, NM 87502. For additional information, please call (505) 827-2900.

Public Notice

DP-831
U. S. Department of Energy Waste Isolation Pilot Plant

DP-831, the U.S. Department of Energy's Waste Isolation Pilot Plant, proposes to modify its discharge permit to discharge up to 3,264,360 gallons per day of domestic and industrial wastewater and storm water runoff from mined rock salt tailings at its federal facility for disposing of defense generated transuranic radioactive waste.

Potential contaminants from this type of discharge include dissolved solids, chloride and nitrogen compounds. The groundwater most likely to be affected is at a depth of nearly 608 feet and has a total dissolved solids concentration of approximately 3920 milligrams per liter. The facility is located 26 miles southeast of Carlsbad, New Mexico, Section 20, T22S, R31E, in Eddy County.

Information in this public notice was provided by the applicant and will be verified by the New Mexico Environment Department (NMED) during the permit application review process. The NMED will accept comments and statements of interest regarding the application and create a facility-specific mailing list for persons who wish to receive future notices regarding this application. Ms. M. A. Menetrey, Program Manager
Mining Environmental Compliance Section
New Mexico Environment Department
P.O. Box 26110
Santa Fe, NM 87505

Subject: Discharge Plan 831 Modification Application

Dear Ms. Menetrey:

In response to the December 30, 2002 letter from Ms. Marcy Leavitt, of the New Mexico Environment Department (NMED) Ground Water Quality Bureau (GWQB), to Dr. Inés Triay, of the Waste Isolation Pilot Plant (WIPP), Carlsbad Field Office (CBFO), WIPP is submitting a discharge plan (DP) application modification for the mining operations at WIPP. The CBFO, pursuant to Section 20.6.2.3106.B of the Water Quality Control Commission Regulations, will be requesting temporary permission to discharge an additional 120 days under a separate letter.

The purpose of the enclosed application is to modify the existing DP-831 to cover discharge associated with the salt storage operations at WIPP. The application includes plans and specifications of facility operations not addressed in previous DP-831 applications and renewals. Where applicable, the DP-831 modification application refers to previous submittals to the GWQB, in lieu of submitting this information again. Additionally, the modification application refers to specific sections in the Notice of Intent (NOI) submitted to the GWQB on October 30, 2002 (WIPP NOI 2002). Excerpts from the NOI have been included as attachments to the modification application where appropriate.

As explained at the April 1, 2003 briefing between representatives of the WIPP and the GWQB, WIPP's approach to the modification application involves aggressive source, infiltration, and migration reduction and control measures. The design of the source control measures has been amended to include extension of a synthetically lined salt storage area, a new double lined Salt Storage Extension basin, single synthetically lined salt pile basin, Evaporation Basin A, Evaporation Basin B, and capping the existing salt pile. This approach is expected to eliminate solute and water infiltration and reduce the hydraulic head of the shallow subsurface water.

The DP-831 modification application includes associated figures and attachments. Attachment A includes the design basis and specifications for the system conveyance, collection, treatment, and distribution systems. Attachments B and D contain specific excerpts from the NOI delivered to the GWQB in October 2002. Attachment C includes recent water level measurements for the WIPP site. Attachment E contains specific responses to questions posed in the December 31, 2002 letter from NMED GWQB to the WIPP. Attachment E also contains figures requested in the GWQB's December 31, 2002 letter.

APR 25 2003

If you have any questions regarding the enclosed application, please contact David Emery of my staff at (505) 234-7475.

Sincerely,

Inés Triay

Dr. Inés R. Triay
Manager

GROUND WATER DISCHARGE PERMIT APPLICATION

Enclosed is a Ground Water Discharge Permit Application Form (Form) and checklist. Section 20.6.2.3104 NMAC of the NM Water Quality Control Commission Regulations (20.6.2 NMAC) requires that any person proposing to discharge effluent or leachate so that it may move directly or indirectly into ground water must have an approved discharge permit, unless a specific exemption is provided for in the Regulations. The enclosed Form is a general guideline for use by applicants to ensure that an application is complete and provides all of the information required by sections 20.6.2.3106, 20.6.2.3107, 20.6.2.3108, and 20.6.2.3109 NMAC.

Mail **three complete copies** of your application with a **$100 filing fee** check made payable to the New Mexico Environment Department (NMED) at the address below:

Maura Hanning, Program Manager
Ground Water Pollution Prevention Section
NM Environment Department
P. O. Box 26110
Santa Fe, NM 87502

Pursuant to Regulation 20.6.2.3108 NMAC, NMED will, within thirty (30) days of deeming the application administratively complete, publish a public notice and allow 30 days for public comment before taking final action on a discharge permit. A public hearing will be held if NMED determines that there is significant public interest. It takes approximately180 days to process a complete application and issue a discharge permit if no public hearing is held.

All applications must be accompanied by a filing fee of $100. **An additional fee will be assessed prior to permit issuance** to cover the estimated cost to the NMED for investigation, and, issuance of the permit. **Permit fees are listed in the Regulation 20.6.2.3114 NMAC.**

If you have any questions about this discharge permit application, call the Ground Water Pollution Prevention Section at 505-827-2900

COMPLETION CHECKLIST

✓		All portions of the Ground Water Discharge Permit Application Form have been addressed. (The application will not be considered complete if there are omissions, which will delay publication of the public notice and issuance of the permit.)
✓		Submitter has included operational, monitoring, contingency, and closure plans that are appropriate for the proposed treatment and disposal system, and meet the site-specific conditions for the proposed facility.
✓		Plans and specifications for the entire effluent or leachate conveyance, collection, treatment, distribution, and disposal system have been included as required by Regulation 20.6.2.1202 NMAC. For septic tank/leachfield systems, designs should be consistent with NMED's guidelines for Plans and Specifications for Discharge Permit Applications Using Septic Tank/Leachfields.
✓		The application has been signed and dated by the responsible party, generally the owner or lessee.
✓		If your facility site includes an archeological site on the State Register of Cultural Properties or National Register of Historic Places, the State Historic Preservation Office has the authority to require an archeological or historical study prior to NMED taking final action on your discharge permit.
✓		Four maps have been included: **1)** area United States Geological Survey (USGS) topographic map that includes the location of the facility and all of the information required in the application item 7.b, **2)** local road map clearly defining the location of the facility and the route to get to the facility, **3)** detailed site map that includes all discharge locations (lagoons, leachfields, land application areas, outfalls...), all water supply and monitoring wells, all water courses on the property and all buildings and **4)** United States Department of Agriculture (USDA) soils map. **Note: Previously submitted with DP-831 applications and renewals.**
✓		Three copies of all required information have been enclosed.
		A filing fee check in the amount of $100, has been enclosed, made payable to the NM Environment Department at the address on page 1. **Note: Funding for this modification application has been submitted under separate cover with request for Temporary Permission to Discharge for Additional 120 Days.**
✓		The SUMMARY OF APPLICANT'S PUBLIC NOTICE REQUIREMENTS has been reviewed and the option for Public Notice Has been selected on the application page 3.

ADMINISTRATIVE COMPLETENESS

To be deemed administratively complete for publication of a public notice, the following information must be provided. [20.6.2.3106, 20.6.2.3108 NMAC]

Review the SUMMARY OF APPLICANT'S PUBLIC NOTICE REQUIREMENTS (attached) to select an option below.

☐ Public Notice Option 1 ☑ Public Notice Option 2 ☐ Public Notice Option 3

1. **Name of the proposed discharger and facility** [20.6.2.3106, 20.6.2.3108.C.1 NMAC]:

Type of facility or operation (dairy, municipal wwtp, mining, school, etc.):

The Waste Isolation Pilot Plant (WIPP) is currently permitted to discharge into synthetically lined systems at the facility as defined in Discharge Permit (DP) 831. These permitted WIPP facilities include the facultative lagoon system and the H-19 evaporation pond. The facultative lagoon system is made up of seven synthetically lined ponds (two settling, two finishing, and three evaporation ponds, A, B, C) for treatment of sewage effluent, neutralized acid, and non-hazardous brine water. The H-19 evaporation pond receives non-hazardous brine water for treatment.

The purpose of this application is to modify the existing DP-831 permit to cover the discharge associated with the salt storage operations at WIPP, as described in the October 30, 2002 Notice of Intent. The following is a description of the facility and current salt storage operations.

The Waste Isolation Pilot Plant (WIPP) is a hazardous and radioactive waste disposal facility operated by the U.S. Department of Energy (DOE). It is designed, permitted, and operated for the receipt of defense generated TRU and TRU mixed waste. The WIPP is constructed in a bedded salt deposit 2150 feet beneath the earth's surface. Hazardous Waste Disposal Units are excavated in the bedded salt as permitted by the New Mexico Environment Department (NMED) with the issuance of Hazardous Waste Facility Permit (HWFP) #NM4890139088-TSDF, October 27, 1999. The excavated salt is stored on the surface for authorized disposition at closing of the WIPP. This pile, or salt pile (SP), is approximately 17 acres in size and has an associated salt pile evaporation pond (SPEP) that is approximately 3.5 acres. The SP is surrounded with ditches that divert runoff from the SP to the SPEP (referred to as the Salt Pile Runoff Ditches (SPRD). The SP, SPRD, and SPEP are the subject of this application (Figure 1). All of these units (SP, SPRD, SPEP) are collectively defined as the Salt Storage Area (SSA). The current design and operation of the SSA are described in Section 3.0, page 2, of the October 30, 2002 Notice of Intent (WIPP NOI 2002).

	Name	Address*	City	State	Zip	Telephone & Fax
Facility*	Waste Isolation Pilot Plant	26 miles E-SE of Carlsbad, NM	Carlsbad	NM	88221	505-234-7200

*For the facility address, enter physical address- not mailing address.

2. <u>Locations of the Discharges</u> [20.6.2.3106.C.2 and 20.6.3108.C.2 NMAC]:

List the locations of the discharges covered by this permit. Add rows as necessary to include all discharge locations. Sections should be described to the nearest ¼ of a ¼ of a ¼ section (please see attachment).

Discharge Location (lagoons, leachfields, land application areas, outfalls, etc.)	County	Township	Range	Section	Latitude	Longitude
Salt Storage Area	**Eddy**	**22S**	**31E**	**SE, NW, SW 20**	**32°22'27"N**	**103°47'45"W**

3. **Brief Description of Discharge** [20.6.2.3108.C.3 NMAC]:

Briefly describe the activities which produce the discharge(s) including the treatment and disposal methods. Attach additional pages as necessary.

The SP and SPEP were constructed in 1984. The current configuration and operation of the SP/SPEP is generally described in Section 3.0, page 2, of the October 30, 2002 Notice of Intent (WIPP NOI 2002). The SP area is approximately 17 acres and the SPEP area is approximately 3.5 acres as shown in Figure 1 attached to this application. The discharge from the SP to the SPEP is associated with precipitation events.

Storm water samples collected from the SPRD (these ditches have also been referred to as the SP "moat") and SPEP in 1997 showed total dissolved solids (TDS) concentrations of 9,320 mg/L and 2,630 mg/L, respectively (WIPP NOI 2002, Attachment 4).

Source control activities were described in Section 5.0 of the October 30, 2002 NOI and preliminary design specifications were included in Attachment 10. Source control activities continue to focus on prevention of water infiltration, and dissolution of solutes (salt) to the subsurface.

See Design Basis Summary with Drawings 1-12 (included as Attachment A), which describes the proposed source control design for the SSA.

4. Discharge Characteristics [20.6.2.3106.C.1 and 20.6.2.3108.C.4 NMAC]:

4.a. Quantity:

Peak design discharge rate* in gallons per day (gpd) (design capacity of the treatment and disposal system):	**SPEP: 432,000 cubic feet (cf)** **SSE: 251,000 cf**
Average discharge rate on annual basis in gpd (actual flow):	**SPEP: 178,886 cf** **SSE: 87,643 cf**
Methods used to meter or calculate discharge volume:	**See Attachment A, Appendix A.1**

*Peak design discharge rate is the maximum volume of wastewater the system was designed to treat on a daily basis. This is generally based on the capacity of the different components of the system (size of lagoons, volume of tanks, etc.)

4.b. Quality: Add rows as necessary to include all contaminants and toxic pollutants.

Contaminant(s) or Toxic Pollutant(s) generally associated with facility type (contaminants of concern are listed in 20.6.2.7. and 20.6.2.3103 NMAC)	**Influent Concentration (mg/L)**	**Effluent Concentration (mg/L)**
Total Dissolved Solids (TDS)	**2,630 mg/L and 9,320 mg/L [1]**	**NA**

1 **Concentrations represent analytical results of storm water samples obtained in 1997 from the SPEP and SPRDs (WIPP NOI, 2002, Page 3). Excerpts from the WIPP 2002 NOI and associated references are attached to this application (Attachment B)**

4.c. Flow Characteristics:

Number of days per week discharge occurs:	**7 days [1]**
Number of months per year discharge occurs (specify months):	**12 months [1]**
Is flow continuous or intermittent:	**Intermittent**

1 **Flow is associated with precipitation and is intermittent, but could occur on any day of the week or month of the year.**

5. <u>Ground Water Conditions</u> [20.6.2.3106.C.3 and 20.6.2.3108.C.5 NMAC]:

Sources for this information may be the New Mexico State Engineers Office, NMED, GWPPS web site (www.nmenv.state.nm.us), and USGS reports. If you do not have a TDS value, take a sample from the nearest well to the discharge location and submit the results from the analysis.

Depth to ground water below the discharge site:	**608 feet [1 & 2]**
Flow direction of ground water below the site:	**West**
Flow gradient of ground water below the site:	**0.0026 feet/feet**
Reference* or source for depth, direction and gradient:	**See footnote below [1]**

[1] The closest groundwater below the SSA occurs in the Magenta Member of the Rustler Formation at approximately 608 feet below ground surface (bgs). Due to pressure in the formation, water levels measured in wells completed in the Magenta rise to the potentiometric surface, approximately 315 feet bgs at the discharge site. The hydraulic gradient was generated from depth to water measurements from wells completed in the Magenta Member (H-10a, H-6c) near the discharge site (Figure 2). Underneath the SSA, the potentiometric surface is interpolated to be approximately 315 feet bgs. Depth to water measurements were obtained during January 2003 (See attachment C to this application).

[2] In accordance with NMAC 20.6.2.3106 (c) (3), which states "Depth to and TDS concentration of the ground water most likely to be affected by the discharge,", and as described in Section 4.4.2 of the October 30, 2002 NOI, natural Dewey Lake Redbeds groundwater exists in well WQSP-6A approximately 6,600 feet southwest of the SSA, and approximately 167 feet below ground surface at the WQSP-6A location. Natural Dewey Lake Groundwater does not exist beneath the SSA. TDS values measured in WQSP-6A have consistently remained stable at approximately 4,000 mg/L (WIPP 2002 NOI Section 4.4.2 and Table 2)

* If determined from well logs, please provide photocopies of well logs with application. If depth is derived from a report, include copies of appropriate pages and complete reference to report including author, title, and publication date.

Total Dissolved Solids (TDS) concentration (mg/L) of ground water below the site:	**Ranges from 4,600 to 24,600 mg/l [1]**
Reference or source for TDS:	**WIPP Compliance Certification Application, Appendix USDW.3.3.3 [1]**

[1] TDS concentrations for Magenta wells were reported in the Title 40 CFR 191 Compliance Certification Application (CCA) for the Waste Isolation Pilot Plant. The values for TDS ranged from 4,600 mg/l in well H-06c to 24,600 mg/l in well H-04c. Well H-06c is located in the northwest quadrant on the border of the Land Withdrawal Act (LWA) boundary while well H-04c is located on the southwest quadrant of the LWA boundary (Figure 2).

TDS concentrations in Natural Dewey Lake Redbeds groundwater have ranged from 3,800 mg/L to 4550 mg/L (WIPP 2002 NOI, Table 2). This natural groundwater in the Dewey Lake does not exist beneath the discharge site as discussed above.

TECHNICAL ADEQUACY

To be deemed technically adequate for purposes of issuing the discharge permit, the following information must be provided [20.6.2.3106, 20.6.2.3107, 20.6.2.3109 NMAC]. Operational, monitoring, contingency, and closure plans must be submitted and must be appropriate for the proposed treatment and disposal type and meet the site specific conditions for the proposed facility.

6. **Permit Plans** [20.6.2.3106.C.7, 20.6.2.3107.A, and 20.6.2.3109.C NMAC]:

6.a. **Operational Plan** [20.6.2.3106.C.7 and 20.6.2.3109.C NMAC]:

The operational plan must describe how the system(s) for conveyance, collection, treatment, distribution, and disposal of wastewaters or other discharges will be constructed, operated, inspected, and maintained. The operational plan must demonstrate that ground water standards will not be exceeded.

6.a.i. In the following table, identify all proposed conveyance, collection, treatment distribution, and disposal units included in the operational plan. Add rows as necessary to include all units.

Treatment/Storage/ or Disposal Unit **Treatment units** (lagoon, mechanical treatment plant, manure separator, clarifier, etc.) **Disposal Units** (land application area, leachfield, evaporative lagoon, leachstockpile, etc.)	**Construction Material**	**Volumetric Capacity*/Area*** (gallons or cubic yards/ acres)
See design plans and specifications in Attachment A to this application	**See design plans and specifications in Attachment A to this application**	**See Attachment A to this application**

*Volumetric Capacity must be provided for all tanks, chambers, and impoundments or other storage units.
*Area must be provided for all land application areas, leachfields or other area features.

6.a.ii. Describe in detail the operational plan, including all conveyance, collection, treatment, distribution and disposal systems. Attach additional pages as necessary:

The current configuration and operation of the SP/SPEP is generally described in Section 3.0, page 2, of the October 30, 2002 Notice of Intent (WIPP NOI 2002). The description of the proposed design conveyance, collection, and treatment systems for the SSA is included in the Design Basis Summary in Attachment A to this application.

6.a.iii. Describe the operations and maintenance plan that will be followed to ensure the system is maintained as described. At a minimum the plan must include monthly inspections of all wastewater treatment and disposal units. Attach additional pages as necessary.

The current configuration and operation of the SP/SPEP is generally described in Section 3.0, page 2, of the October 30, 2002 Notice of Intent (WIPP NOI 2002). The SSA will be inspected monthly, and following severe rainstorms, for damage and impediments to water flow. Inspections will include, but are not limited to, identification of liner wear, erosion, animal damage, vehicular damage, buildup of salt, soil, debris, and/or vegetation, that may impede designed water flow. Upon identification of unusual operation or defects in the system, corrective action will be initiated to correct any discrepancies or deteriorating conditions.

6.b. Monitoring Plan [20.6.2.3106.C.5 and 20.6.2.3107.A.1-9 NMAC]:

The monitoring plan must describe how the facility will be monitored to ensure that the discharge will not adversely impact ground water quality. The plan must include all monitoring locations (effluent sampling, monitoring wells, lagoons, soil sampling, plant tissue analysis, etc.). Monitoring locations must be included on the facility map.

6.b.i. Monitoring Locations. In the following tables, identify all monitoring locations. Add additional rows as necessary to include all monitoring locations.

Flow, Effluent and Ground Water Monitoring

Monitoring Location	Lat	Long	Elevation	Sampling Frequency per year	Reporting Frequency per year	Water or Soil Contaminant Type (please refer to 20.6.2.7.uu, and 20.6.3103 NMAC)
NA	NA	NA	NA	NA	NA	NA

*Identify the sampling locations as designated or named by the facility.

Soil, Plant Tissue and Other Sampling

Monitoring Location*	Lat	Long	Sampling Frequency per year	Reporting Frequency per year	Water or Soil Contaminant Type
Land application area soil sampling	N/A	N/A	N/A	N/A	N/A
Land application area plant tissue analysis	N/A	N/A	N/A	N/A	N/A
Other	N/A	N/A	N/A	N/A	N/A

N/A: Not Applicable

6.b.ii. Describe in detail the sampling protocols that will be used for sample collection at all monitoring locations. Attach additional pages as necessary.

As described in the WIPP October 2002 NOI (WIPP NOI 2002, Section 6.2), water level monitoring and water quality sampling for the SSW beneath the WIPP surface facilities will continue in the shallow monitoring wells and piezometers under the current schedule. Currently, the water quality sampling plan (WQSP) wells (including WQSP-6A) are sampled semi-annually and water levels measured monthly in accordance with the HWFP. The piezometer network is sampled annually and water levels are obtained monthly. This will continue until such time as the results from the Site Investigation Work Plan suggests that the monitoring be adjusted (WIPP NOI 2002, Attachment 11). Currently, the water levels in the shallow monitoring wells and piezometers are measured once per month. Water quality samples are obtained and analyzed once per year from these sample locations.

The protocol for the 16 SSW wells and piezometers will follow low-flow sampling techniques as described in the New Mexico Environment Department (NMED) guidance titled *Use of Low-Flow and Other Non-Traditional Sampling Techniques for RCRA Compliant Monitoring.* Purging for these wells will consist of low flow pumping of the well such that the decrease in hydraulic head is equivalent to the rate at which water is removed from the well. Purged water will be routed through Tygon™, or similar type, tubing into an approved flow-through cell, where serial samples will be obtained. Field indicator parameter sampling will be performed with a multi-meter instrument capable of measuring dynamic, in situ changes in pH, specific conductance, temperature, and dissolved oxygen. Final samples will be obtained after indicator parameters have stabilized over three consecutive readings spaced a minimum of five minutes apart. SSW samples will be analyzed for parameters listed in the Table 1 of the WIPP 2002 NOI and Attachment D of this application

6.b.iii. Standard Monitoring Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

☐ All monitoring wells will be installed according to NMED Monitoring Well Construction and Abandonment Guidelines (copy enclosed)

☑ All monitoring wells (if 3 or more monitoring wells are on site) will be surveyed to a common permanent benchmark and that the survey will be submitted to the NMED, GWQB within 60 days of installation of all monitoring wells. Survey data will include northing, easting, and elevation to the nearest hundredth of a foot. One of the wells may be used as the benchmark.

☑ This facility will measure the depth to ground water in each monitoring well to the nearest hundredth of a foot prior to purging and sampling, and that three well volumes will be purged from each monitoring well prior to sample collection.

☐ This facility will complete land application data sheets (LADS, copy enclosed) documenting the amount of nitrogen applied to each land application area if applicable. The LADS will incorporate the wastewater volume and analytical results of the wastewater testing to determine total nitrogen applied to each field. **Not Applicable**

6.c. Contingency Plan [20.6.2.3107.A.10 NMAC]:

The contingency plan must describe the actions to be taken if Regulation 20.6.2.3103 NMAC ground water standards are exceeded or if toxic pollutants are present (20.6.2.7.uu) as a result of discharges regulated under the proposed permit, and to cope with failure of the discharge permit or system.

6.c.i. Standard Contingency Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

☐ This Facility will comply with the following contingency language:

In the event that monitoring indicates ground water standards are violated or may be violated during the term of the discharge permit or upon post closure monitoring, this facility will collect a confirmation sample from the monitoring wells within 15 days to confirm the initial sampling results. Upon confirmation of contamination, all ground water monitoring will be conducted monthly and a corrective action plan will be submitted to the NMED. The corrective action plan will include a site investigation to define the source, nature and extent of ground water contamination, and a proposed abatement option; and a schedule for implementation. The site investigation and abatement option must be consistent with the requirements and provisions of Regulations 20.6.2.4101, 20.6.2.4103, 20.6.2.4106.E, 20.6.2.4107, and 20.6.2.4112 NMAC. The corrective action plan will be submitted to NMED for approval within 30 days of confirmation of ground water contamination, and will be initiated within 30 days of NMED approval. **See note below.**

Note: The October 30, 2002 NOI describes the planned site investigation activities to assess the lens of shallow subsurface water (WIPP NOI 2002, Section 6 and Attachment 11).

☑ This facility will comply with the following contingency language:

In the event of a spill or release that is not as prescribed in the approved discharge permit, this facility will take immediate corrective action to contain or mitigate the damage caused by the discharge and will initiate the notifications and corrective actions as required by Regulation 20.6.2.1203 NMAC. Within 24 hours discovery of the incident, this facility will verbally notify NMED and provide the information outlined in Regulation 20.6.2.1203.A.1. NMAC. Within 7 days of discovering the incident, this facility will submit a written verifying the oral notification and providing any additional pertinent information or changes. Within 15 days of the incident, this facility will submit a corrective action plan describing actions taken and/or to be taken to remedy the impact of the unauthorized discharge.

6.c.ii. Specific Contingency Plan:

Describe any additional specific corrective actions or contingencies that will be taken to cope with failure of the discharge system: Attach additional pages as necessary.

Specific contingency planning includes monthly inspection and repair of the SSA system liners as necessary, containment and investigation of all spills and releases. In the event of a tear in a liner that results in a release to the environment, an effluent spill or unauthorized discharge, the Ground Water Quality Bureau will be notified pursuant to the standard permit condition 6.c.i. The Permitee will assess damages and attempt to isolate any discharge, and corrective measures will be implemented immediately.

6.d. Closure Plan [20.6.2.3107.A.11 NMAC]:

The closure plan must describe the closure actions to be taken to prevent Regulation 20.6.2.3103 NMAC ground water standards from being exceeded, or the introduction of a toxic pollutant in ground water after cessation of operations. At a minimum, the closure plan must include a description of closure measures, post closure monitoring plans, and financial assurance (if required by NMED).

6.d.i. Specific Closure Plan: Describe the specific closure activities to ensure that ground water quality will be protected after cessation of operations. The plan shall include plugging, removal, and/or filling of all conveyance, collection, treatment, distribution and disposal features in order to prevent future discharges at the facility. The plan must also describe how all liquid and solid wastes will be removed and disposed of according to local, state, and federal laws. The plan must also describe how disturbed areas will be backfilled to blend with the original surface topography to prevent future ponding and to prevent a discharge at the facility from occurring after the cessation of operations. Attach additional pages as necessary.

The closure plan dated December 16, 1996 will be implemented when the facility is decommissioned. The plan includes the pumping or evaporation of all wastewater ponds, removal of all solids, and recontouring and revegetation of the site. In addition, all basin liners will be removed or perforated upon closure of the site. This will be performed to comply with Section 20.6.2.3107.A.11 NMAC.

6.d.ii. Standard Closure Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

This facility will comply with the following closure requirements:

☑ The discharger will notify NMED at least 30 days prior to cessation of operations and will provide a schedule for implementation of the closure plan.

☐ This facility will conduct post closure monitoring at the frequency and locations prescribed under the active permit for a period approved by NMED. If Regulation 20.6.2.3103 NMAC ground water standards are violated or toxic pollutants are present during post closure monitoring, this facility will implement the contingency plan required in the active permit.

☑ All monitoring wells will be plugged and abandoned in accordance with NMED Monitoring Well Construction and Abandonment Guidelines once NMED has agreed in writing that post closure ground water monitoring may cease.

☑ Once NMED has approved all closure activities, this facility will submit a letter requesting termination of the discharge permit.

TECHNICAL SUPPORT

The following information must be submitted as required by Regulation 20.6.2.3106, and 20.6.2.3109 NMAC.

7. **Other Discharge Locations** [20.6.2.3106.C.2 NMAC]:

7.a. List the locations of any other discharges at this facility not covered by this permit but permitted under the New Mexico Liquid Waste Disposal Regulations, Hazardous Waste Management Regulations, Federal Clean Water Act (NPDES), and any un-permitted discharges. Add rows as necessary to include all other discharge locations.

Discharge Type (septic tank/leachfields; surface water discharges, etc.)	**Permit Identification**	**Discharge Location Description**
Facultative Lagoon System and evaporation facility	**DP-831**	**23,000 gpd of sewage effluent and 2,000 gpd of non-hazardous brine**
H-19 Evaporation Pond	**DP-831**	**8,000 gpd non-hazardous brine water to north evaporation cell**

7.b. **Area Map:** On the appropriate United States Geological Survey (USGS) 7.5 minute topographic quadrangle map, identify the location of all water supply wells, injection wells, seeps, springs, bodies of water, and watercourses within one mile of the outside perimeter of the discharge site.

As described in Section 8 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, previous applications, renewals, and modifications, there are no water supply wells, injections wells, seeps, springs, bodies of water, or watercourses within one mile of the outside perimeter of the discharge site.

8. **Flooding Potential** [20.6.2.3106.C.4 NMAC]:

8.a. Describe the flooding potential of the discharge site based on the latest Federal Emergency Management Agency flood plain map or site specific analysis:

As described in Section 12 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, the flooding potential of the WIPP facility is considered minimal since the general ground elevation in the vicinity of the surface facilities is approximately 400 feet above the 100 year floodplain of the Pecos River, which is the closest river to the facility. The potential for flash flooding is considered minimal because of the high percolation rate of the surrounding sand dunes and the flood protection berms (see Section 8.b of this application).

Source for Information: **WIPP DP-831 Renewal Permit Application, December 16, 1996**

8.b. Describe the methods used to control flooding, run-on and run-off at the discharge site (berms, diversion channels, etc.):

As described in the October 30, 2002 Notice of Intent, a berm exists along the north side of the SP/SPEP facility and is contoured such that rainfall will be diverted around the berm to the west, and around the SPEP (WIPP NOI 2002, Attachment 2). This berm will be relocated as a result of the Salt Storage Extension (SSE), however the integrity will be retained. See the description of the berm in the Design Basis Summary and specifications in Attachment A to this Application.

9. **Geologic and Soil Information** [20.6.2.3106.5 NMAC]:

9.a. **Lithology:** Describe the lithology and thickness of each geologic unit below the discharge site and indicate which units bear water. This information may be obtained from a driller's log or geologic report. Include photocopies of all well logs with the application. Add rows as necessary to include all units.

The geologic units below the discharge site (SP/SPEP area) are described in the October 30, 2002 Notice of Intent (WIPP NOI 2002, Section 4.0, and NOI Attachments 3,4,5,6,7, and 11). These descriptions include lithology, thickness, and hydrogeologic properties of the unit below the discharge site.

Source for Information: **October 30, 2002 Notice of Intent (WIPP NOI 2002, Section 4.0, and Attachments 3, 4, 5, 6, 7, and 11)**

9.b. **Soil Map:** Attach a copy of the United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) soil survey map and descriptive information for soil(s) associated with the discharge site.

Previously provided in Attachment 9 of the WIPP Discharge Plan DP 831 Renewal Application, dated December 16, 1996.

10. Signatures:

Owner: I certify that I am the legal owner of the property in which all discharges will occur. I certify that I am knowledgeable about the information contained in this application, and believe the information is true, complete and accurate.

Print Name: Ines Triay

Signature: Ines Triay   Date 6-23-03

Responsible Party* (if property is leased or operated by someone other than the owner):

I certify that I am knowledgeable about the information contained in this application, and believe the information is true, complete and accurate.

Print Name: Bruce Lilly

Signature: Bruce Lilly   Date 6-23-03

* Enclose a signed copy of the lease agreement between the responsible party and the owner of the property on which the proposed discharge will occur. Lease agreement should be valid for the duration of the discharge permit or until the discharge permit is modified to reflect a new lessee.

1.0 PROJECT OBJECTIVES

Historical stormwater management practices may have contributed to Shallow Subsurface Water (SSW) conditions beneath the WIPP site. Storage of mined salt in the Salt Pile (SP) is likely responsible for elevated total dissolved solids (TDS) in the SSW. Infiltration of salt contact water has occurred through the SP and its associated run-off control systems:

- The Salt Pile Run-Off Ditches (SPRD's)
- The Salt Pile Evaporation Pond (SPEP)

Stormwater run-off exclusive of the Salt Storage Area (which includes the SP, SPRD's, and SPEP) is currently collected and managed in three unlined detention basins. This run-off mostly from the roofs and paved areas, may represent a third of the stormwater that is available to recharge the SSW.

The purposes of the proposed infiltration control systems are to:

1. Eliminate the potential for future salt infiltration .
2. Control and Evaporate nearly 100% of the site's stormwater run-off .

The priorities are to address the greatest potential contributors of TDS first; and stormwater second. As shown on **Table A.1**, the controls associated with the Salt Storage Area (SSA) and SPEP will address 100% of the salt infiltration; and an estimated 60% of the recharge. The current Salt Pile will be reshaped and capped with a geomembrane liner, with an additional 2' thickness of vegetative soils to protect the liner and stabilize the cap (Section 2.1). The SPRD's and SPEP will also be lined with high-density polyethylene (HDPE) to minimize surface water infiltration. This will be the first priority in the implementation sequence.

TABLE A.1

INFILTRATION CONTROL PRIORITIES

	Estimated Contribution (% of total)[1]	
	TDS	**Water**
1. Salt Storage Area • Salt Pile • Salt Pile Run-Off Ditches	>90%	>35%
2. Salt Pile Evaporation Pond	<10%	>25%
3. Salt Storage Extension • Cells A & B • Salt Storage Extension Basin	100% (future)	<5%
4. Stormwater Controls		
• Evaporation Basin A	0	>25%
• Evaporation Basin B	0	<10%

[1]From DBSA, March 2003

Discontinued use of the current SP will require the development of new salt storage facilities. The new 15 acre± Salt Storage Extension (SSE) will include lined salt storage cells; and a double lined contact water evaporation basin (the SSE). The SSE will be constructed concurrent with the SP capping activities, and will control 100% of potential salt infiltration from future storage practices.

The remaining stormwater will be routed to lined evaporation basins that are designed to maintain zero discharge. Currently Basin A will be enlarged and lined with HDPE geomembrane. Currently Ponds 1 and 2 will be combined into a single lined unit Evaporation Basin B.

The infiltration controls consist of layered geosynthetic and soil systems designed to minimize infiltration. Because the SSE Basin will be the only unit that will continue to store and evaporate salt contact water, it is equipped with a double liner and leak detection system. The SSE cells have a floor drainage system designed to minimize fluid head (pressure) on the liner. The geosynthetic and soil liners and caps proposed in this design:

- Comply with applicable NMED regulations and guidelines.
- Consist of proven materials and conventional construction technologies.
- Have a demonstrated track record of performance in similar arid applications.
- Will, when completed, control nearly 100% of potential future salt infiltration; and over 95% of potential stormwater contributions.

Table A.2 provides a summary of the estimated sizes, capacities, and materials required for each infiltration control unit. The Conceptual Design Drawings (**Appendix A.2**) provides details on the dimensions and materials for the proposed installations.

TABLE A.2
Capacity/Materials Summary

(5) Estimated

2.0 SALT STORAGE AREA (SSA)

The Salt Storage Area (SSA) currently consists of approximately 35 acres that is a relatively independent drainage basin extending along the north perimeter of the WIPP site. The SSA consists of four primary drainage elements (see **Drawing 2**):

- The Salt Pile (SP) – 16.8 acres ±
- The Salt Pile Evaporation Pond (SPEP) – 3.5 acres ±
- The Salt Pile Run-off Ditches (SPRD's) – 1.5 acres ±
- Tributary areas (including some north parking lot run-off) – 13.2 acres ±

This design integrates discontinued use of the current SP in conjunction with development of a new lined salt storage unit (the Salt Storage Extension, **Section 3.0**). The other primary SSA systems (SPEP, SPRD's) will be lined with 60 mil HDPE geomembranes to prevent future infiltration of water.

Construction of the SSA infiltration control systems would involve the phased installations designed to address the most significant sources of salt and water first:

- Reshaping the SP with mined salt
- Capping the SP
- Installing Cell A of the new lined Salt Storage Extension
- Lining the new SSE Basin
- Lining the SPEP and associated ditches (east, south and northwest SPRD's)

2.1 Salt Pile (SP)

The first priority is to recontour the SP to prepare it for cap installation. A cut/fill approach is planned to reduce the sideslopes from about 1.5:1 to 3:1. This will extend the toe of the slope outward approximately 25'. The north sideslope of the SP will be regraded first to facilitate construction of the Salt Storage Extension.

Mined salt from ongoing operations will be used to shape the crown to a minimum 2% slope. This includes bringing the southwest lobe up to prevailing grade, and backfilling the ramp. In some limited circumstances, native soil may be used for reshaping the SP crown and sideslopes.

The SP cap system will be installed incrementally as the reshaping and base preparation is completed for individual segments. The cap configuration includes a 16 oz. geotextile cushion at the salt contact; with a 60 mil geomembrane above it. Textured HDPE will be used on the 3:1 sideslopes, and smooth 60 mil HDPE is planned for the crown. The geosynthetic layers will be anchored at the crest and toe of slope.

The north sideslope will be the first SP segment to be capped. The 60 mil textured HDPE geomembrane will also serve as the south sidewall liner for the Salt Storage Cells. This segment will include a geonet/geotextile layer that will serve both as a cushion for future salt placement; and as a drainage layer for water collection (see **Section 3.1**)

With the exception of the north sideslope, a min. 24" thick protective soil layer will be placed over the entire SP cap. It is planned that this process will proceed incrementally following cap installation over individual segments. Vegetative cover, consisting of hardy native grasses, will be added and maintained.

2.2 Salt Pile Run-off Ditches (SPRD's)

New SPRD's will be installed along the east, south, and north part of the west perimeters. All north drainage will be directed to the SSE Basin, and the south part of the west slope drains directly to the SPEP. The ditches are designed to manage the 25-year, 24-hour storm event (see **Appendix A.1**).

The toe of the regraded SP will extend out about 25' from its current position. A relatively horizontal bench about 20' wide will be installed between the toe of the SP slope and the inside edge of the adjacent SPRD.

The SPRD's will be lined with 60 mil (smooth) HDPE geomembrane after base preparation to a design slope 0.5%. The ditches are designed to accommodate the standard geomembrane roll width (22' –23') so that seams will only be necessary every 400'±. The sideslope liner will be extended across the bench to tie in with the inside SPRD anchor. Because of the extension of the toe and addition of the bench, the prior ditch areas will be regraded and covered with the new liner system.

2.3 Salt Pile Evaporation Pond (SPEP)

After the SP is capped and the SPRD's are lined, the SPEP will receive clean stormwater only. The current footprint will be reshaped to accommodate the new watershed dimensions (e.g., eliminate north SP run-off; and the extension of the west SP footprint) (**Section 2.1**). The SPEP floor and sidewalls will be compacted with a "level" floor and 3:1 sideslopes. A single 60 mil (smooth) HDPE liner will be placed and anchored at the perimeters. Ballast or anchors will be deployed to resist uplift.

The SPEP is sized to detain and evaporate the design storm event (see **Appendix A.1**).

3.0 SALT STORAGE EXTENSION (SSE)

The Salt Storage Extension consists of two primary units:

- The Salt Storage Cells (A & B)
- The Salt Storage Extension Evaporation Basin

The Salt Storage Extension includes approximately 11.4 acres of lined salt storage capacity designed to receive up to 600,000 tons of mined salt (i.e., Panels 4– 8). The Salt Storage Extension is contiguous with the north slope of the SP, and is subdivided into Cell A and Cell B. The storage cells include a geomembrane liner; geonet cushion/drainage system; protective layer; and fluid collection piping. The collection system conveys any stormwater infiltrating through the stored salt by gravity to the Salt Storage Evaporation Basin. The SSE Basin will have a double liner with a leak detection system, and is sized to detain and evaporate the design storm. This is the only drainage element that will be receiving salt water contact run-off after the project is completed.

Installation of salt storage capacity is currently designed in two increments which are hydraulically connected. Cell A, which is west and downgradient, would be constructed first. Cell B involves extending the liner and water collection system upgradient (east) to the east limit of the SP. The boundary between Cells A & B can be selected based on incremental construction costs vs. capacity developed.

Construction of the Salt Storage Extension Cells and Evaporation Basin includes four primary components:

- Lining the north sideslope of the SP (see **Section 2.2**).
- Relocating the stormwater diversion berm.
- Earthmoving – including Basin excavation and Cell A base preparation.
- Installing liners and related systems in the Basin and Cell A.

Lining the north sideslope of the SP is discussed in **Section 2.1** This approach minimizes the footprint of the SSE by taking advantage of the "wedge" of airspace available between the SP and the new cells.

Simultaneous with sideslope preparation, the existing stormwater diversion berm must be relocated approximately 400' north of its current position. An access zone approximately 50' wide is provided at the east end of Cell B, where the berm will extend north approximately 400' before it turns west. The new berm is approximately 8' high with 3:1 sideslopes, and serves the same stormwater diversion purpose as the existing berm. The new berm will be a structural element for the Salt Storage Cell liner system, where the north edge of liner will be anchored. A construction berm approximately 8' high is planned as the downgradient perimeter for Cell A. The berms will be constructed in horizontal lifts and subjected to conventional soil compaction and construction quality assurance standards (e.g., 90% Standard Proctor).

3.1 Cells A & B

Cell A includes a permanent berm along the west (downgradient) perimeter; and a temporary berm at the (upgradient) Cell B interface. Once at final design elevation, the soil in the floor and sidewalls of the Basin will be compacted. The fill soil placed as the foundation for Cell A will be placed in horizontal lifts and compacted.

The liner system for the new SSE Cells will be installed over the prepared subgrade in the floor area. On the north and east, it will be anchored at the top of the relocated stormwater diversion berm. On the south side, it will be anchored with the north SP sideslope cap to create a continuous impervious surface. On the west perimeter, the liner will be tied to the adjacent east sidewall liner of the SSE. The Cell A & Cell B liner configuration consists of the following layers, in ascending order:

- Compacted soil subbase (compacted sand on south slope)
- 60 mil (smooth) HDPE liner (textured on sideslopes)
- Collection system piping
- 200 mil geonet cushion/drainage layer
- 8 oz. geotextile filter fabric
- 2′ thick protective material layer (salt or soil)

Cells A & B are equipped with a continuous perforated pipe that slopes up at 1% from west to east to facilitate water collection off the liner to minimize head (i.e., water pressure). The pipe is enveloped in aggregrate, and daylights into the SSE Basin to allow gravity flow. A pipe boot is specified at the penetration of the west berm. Pipe cleanout capability is provided by a temporary riser at the upgradient terminus of Cell A; and a permanent cleanout riser at the east of Cell B.

3.2 SSE Basin

The new Salt Storage Extension Evaporation Basin has an estimated footprint of 1.6 acres with an average depth of 5′. The excavated soil (15,000 $yd^3 \pm$) will be used as fill and compacted to prepare Cell A to its design base grades.

Once the earthwork is complete, the prescribed liner systems will be installed in both the Basin and Cell A. Because the SSE Basin is the only unit that will manage salt water drainage in the future, it is equipped with a double liner system. The liner configuration, in ascending order, includes:

- Compacted soil subbase
- 60 mil (smooth) HDPE secondary liner
- 200 mil geonet leak detection layer
- 60 mil (smooth) HDPE primary liner

The leak detection layer will drain to a sump with an inclined riser to allow for future inspection and monitoring. Ballast or anchors will be deployed to resist uplift. No salt will be stored in the SSE until the Basin is complete.

4.0 STORMWATER CONTROLS

Future stormwater infiltration will be managed by lining the SPEP and Evaporation Basins A & B with 60 mil HDPE geomembranes. This will be the first priority in the implementation sequence. The watersheds for Basins A & B consist primarily of covered/paved surface and lined drainageways with culverts. Both basins will be sized to detain and evaporate the design storm event.

4.1 Evaporation Basin A

Basin A will be reshaped to accommodate the evaporation rate for the design storm; and to allow liner installation. Sidewalls will be prepared to maximum 3:1 sideslopes and compacted. The geomembrane liner system will be anchored at the perimeters, and uplift will be addressed with ballast or floor anchors.

4.2 Evaporation Basin B

Existing Ponds 1 & 2 may be combined into a single Evaporation Basin (Basin "B") designed to manage run-off from both watersheds. This unit will receive clean stormwater run-off only, and be lined consistent with the SPEP and Evaporation Basin A plans.

A.1.1 – 25-yr, 24-hr Storm Event

A.1.2 – Average Annual Climate Data

Appendix A.1.1 – 25-yr, 24-hr Storm Event

DESIGN BASIS
WIPP INFILTRATION CONTROLS – CONCEPTUAL DESIGN
SPEP and SSE BASIN CAPACITY ANALYSIS
25-YEAR, 24-HOUR PEAK STORM EVENT

Objective:

The objective of this calculation is to determine if the Salt Pile Evaporation Pond (SPEP) and the Salt Storage Evaporation (SSE) Basin have the capacity to contain the runoff from their respective watersheds due to a 25-Year, 24-Hour storm event.

Data:

1. Design Storm: 25-Year, 24-Hour Storm Event

   Reference: New Mexico State Highway and Transportation Department, Drainage Manual, Volume 1, Hydrology, 1995

   25-Year, 24-Hour Storm Event Depth = 3.90 inches

2. SSA Drainage Area

   Reference: WIPP Infiltration Controls Conceptual Design, Gordon Environmental, Inc., March 31, 2003 [Drawing 12]

   Drainage Area ~ 27.5 acres

3. SSE Basin Drainage Area

   Reference: WIPP Infiltration Controls Conceptual Design, Gordon Environmental, Inc., March 31, 2003 [Drawing 12]

   Drainage Area ~ 10.4 acres

4. SPEP Capacity:

   Length of Pond: 425 feet (+/-)
   Width of Pond: 360 feet (+/-)
   Total Depth of Pond = 4 feet (+/-)
   Freeboard = 1 foot

   Pond Capacity = Calculated using Prismoid Equation Excel Worksheet (see **Attachment 1**).

   Pond Capacity = 438,000 ft^3

5. SSE Basin Capacity:

   Length of Basin: 265 feet (+/-)
   Width of Basin: 260 feet (+/-)
   Total Depth of Basin = 5 feet (+/-)
   Freeboard = 1 foot

Basin Capacity ~ Calculated using Prismoid Equation Excel Worksheet (see **Attachment 2**).

Basin Capacity ~251,000 ft^3

Calculation

1. SSA Drainage Basin Runoff Volume

   Assume 100% Runoff (i.e., 0 inches of infiltration) for the entire 27.5 acre basin.

   Volume of Runoff = [27.5 acres] x [43,560 sf/acre] x [3.90 in/12 in/ft] ~ **390,000 ft^3**

2. SSE Drainage Basin Runoff Volume

   Assume 100% Runoff (i.e., 0 inches of infiltration) for the entire 10.4 acre basin.

   Volume of Runoff = [10.4 acres] x [43,560 sf/acre] x [3.90 in/12 in/ft] ~ **147,500 ft^3**

Results

1. The SPEP has more than adequate capacity to store the 25-year, 24-hour storm event runoff without using the available freeboard.

2. The SSE Basin has more than adequate capacity to store the 25-year, 24-hour storm event runoff without using the available freeboard.

Appendix A.1.2 – Average Annual Climate Data

WIPP INFILTRATION CONTROLS - CONCEPTUAL DESIGN
EVAPORATION BASIN POTENTIAL
PERFORMANCE BASED ON AVERAGE ANNUAL CLIMATIC DATA

OBJECTIVE:

The purpose of this study was to determine the evaporation potential for the Salt Pile Evaporation Pond (SPEP) and Salt Storage Extension (SSE) Basin to determine if the capacity is adequate to manage the anticipated runoff from the SPEP watershed based on average monthly precipitation and evaporation data.

1.0 CLIMATIC DATA

WIPP is located in southeast New Mexico near Carlsbad, New Mexico. WIPP averages 15 inches of normal precipitation annually (Reference: Western Region Climatic Center, (www.wrcc.dri.edu) 1961-1990 Monthly Climate Summary, Waste Isolation Pilot Plant, New Mexico (299569)) and the dry climate provides a high pan evaporation rate, averaging in excess of 90-inches per year (Reference: Western Region Climatic Center, (www.wrcc.dri.edu) Evaporation Table for the Western United States, Monthly Average Pan Evaporation, Lake Avalon, New Mexico)). Given these two climatic conditions, evaporation is proven to be an effective means for reduction in runoff volumes after collection by the pond. The mean temperature, average rainfall and average evaporation rates by month are provided in **Table A.1.2-1**

TABLE A.1.2-1

AVERAGE MONTHLY TEMPERATURE, PRECIPITATION AND EVAPORATION DEPTHS FOR THE WASTE ISOLATION PILOT PLANT AND VICINITY

Month	Mean Temperature[1] (° F)	Average Precipitation (inches)	Average Evaporation (inches)
January	45.0	0.38	0.0
February	49.7	0.39	0.0
March	55.4	0.29	0.0
April	64.5	0.62	12.36
May	74.1	1.41	14.31
June	81.6	1.95	15.16
July	83.6	2.22	14.14
August	81.6	1.85	12.33
September	75.2	1.85	9.25
October	65.4	0.76	7.26
November	52.5	0.33	0.0
December	44.9	0.85	0.0
Average Annual		**12.90**	**84.81**

Note: 1. Evaporation potential (inches) is assumed to occur above a base temperature ~ 65°F.

2.0 SPEP EVAPORATION POTENTIAL

The dimensions of the SPEP were determined from the WIPP Infiltration Controls Conceptual Design Drawings and are:

- Top of Pond Length = 425 feet (+/-)
- Top of Pond Width = 360 feet (+/-)
- Depth = 4 feet (+/-)
- Sideslopes = 3H:1V

This configuration provides approximately 154,000 ft^2 (See **Attachment 1**) of area for evaporation assuming the pond is allowed a maximum 3-foot of water with a 1-foot freeboard. **Table A.1.2-2** presents the mass balance for the SPEP and assumes the installation and vegetation of the planned 2-foot soil cap over the entire salt pile (18.8 Acres).

The results in **Tale A.1.2-2** indicate that the evaporation pond system will reach a steady state mass balance at the end of the 2nd year of operation from which the same amount of collected stormwater (94,235 ft^3) remains in December of each operating year. This mass balance is based on average monthly values for precipitation and evaporation and will vary depending on wet as well as dryer years.

3.0 SSE BASIN EVAPORATION POTENTIAL

The dimensions of the SSE Basin were determined from the WIPP Infiltration Controls Conceptual Design Drawings and are:

- Top of Pond Length = 265 feet (+/-)
- Top of Pond Width = 260 feet (+/-)
- Depth = 5 feet (+/-)
- Sideslopes = 3H:1V

This configuration provides approximately 70,000 ft^2 (See **Attachment 2**) of area for evaporation assuming the pond is allowed a maximum 4-foot of water with a 1-foot freeboard. **Table A.1.2-3** presents the mass balance for the SSE Basin and assumes 100% runoff of precipitation over the SSE 10.4 (+/-) acreage.

The results in **Table A.1.2-3** indicate that the evaporation pond system will reach a steady state mass balance at the end of the 2nd year of operation from which the same amount of collected stormwater (47,626 ft^3) remains in December of each operating year. This mass balance is based on average monthly values for precipitation and evaporation and will vary depending on wet as well as dryer years.

Notice of Intent

Waste Isolation Pilot Plant
Carlsbad, New Mexico

October 30, 2002

having a slope of 10 percent extends into and divides the pile into two sections (east and west) that are approximately equal in area. Mine safety regulations require that a small berm (about 3 to 4 feet in height) be maintained at the top of the SP to prevent trucks from backing over the edge of the pile during unloading, and there are about 13 acres within the berm.

The SPEP receives run-off from a watershed that includes areas in addition to those in the original design calculations (349,920 cubic feet design requirement, see April 1983 NOI in Attachment 1). The run-off entering the SPEP consists of storm water from portions of the plant site and parking lot and run-off generated from the SP side slopes (approximately 4 acres of surface area) and access ramp. Also, a portion of the plant site run-off is diverted from the south through culverts that feed into the SPEP rather than being directed off-site. The 13 acres within the SP berm do not normally drain to the evaporation pond, and most precipitation either infiltrates or evaporates from the SP surface.

The SPEP capacity is approximately twice the design volume because the actual berm height is 7 feet compared to 3 feet in the original design. Ditches designed to divert storm water from a small area north of the SPEP are not operating at full capacity. There is also minor side slope erosion on the SP and within the run-off ditches, and some accumulation of sediment in the SPEP. However, the erosion, accumulation of sediment, and additional run-off into the SPEP are offset by the over-sized capacity of the SPEP.

Infiltration of water into the SP and SPEP will vary, depending on the intensity of rain and the condition of the ground surface. Actual infiltration on the SP surface depends on rainfall intensity and duration, the age of the salt, the condition of the surface as a result of prior rains, and atmospheric conditions. Field observations indicate that a portion of direct rainfall will penetrate the SP surface, and that subsequent evaporation will be minimal.

Storm water samples collected from the SPEP and SP run-off ditches (these ditches have also been referred to as the SP "moat") in 1997 showed total dissolved solids (TDS) concentrations of 2,630 mg/L and 9,320 mg/L, respectively (see report at Attachment 4).

4.0 Shallow Hydrogeology at the WIPP Site

4.1 Introduction

Shallow subsurface water occurs beneath the WIPP site at a depth of less than 100 feet below ground surface (bgs) at the contact between the lower Santa Rosa Formation and the upper Dewey Lake Formation. This SSW yields generally less than 1 gallon per minute in monitoring wells and piezometers and contains high concentrations of TDS and chlorides. The origin of this water is believed to be primarily from anthropogenic causes, with some contribution from natural sources. The SSW occurs not only under the WIPP site surface facilities but also to the south as indicated by the recent encounter in drillhole C-2737 about a half mile south of the Waste Shaft (Powers, 2002a, see Attachment 8). Figure 1 is a map of the WIPP site showing the location of this drillhole (which was completed as Well C-2737).

Well C-2737 monitors units of the deeper Rustler Formation, and was drilled to replace monitoring Well H-1, which has been plugged and abandoned. Well H-1 monitored water levels within the Culebra and Magenta Dolomite Members of the Rustler Formation. Well H-1, originally drilled and completed in 1978, was replaced because its steel casing was deteriorating and the water level data it was providing on the Magenta Member were suspect. During the

APPENDIX 2

Composition and Origin of Groundwater at the Santa Rosa/Dewey Lake Contact

2.0 Analytical Results for Groundwater and Surface-Water Samples

Appendix A contains analytical results for monitoring-well samples collected from September 1996 through October 1997 and piezometer-well samples collected from July 1997 through October 1997. However, analytical results on monitoring-well samples collected in September of 1996 are not used in the geochemical analysis presented in Section 3.0 because these samples were collected during well development and contained abundant sediment. Therefore, six rounds of data are available for the 3 monitoring wells and three rounds of data are available for 11 of the 12 piezometer wells. Piezometer well PZ-08 is dry and was not sampled. Abundant sediment in PZ-01 shut down the pump and a sample could not be collected during the first-round event. PZ-01 was developed further and a water sample was obtained during the second- and third-round event. The cation and anion charge balance of the samples is good (i.e., within ± 5 %) with the exception of five samples. An assessment of data quality is provided in Appendix A.

A single round of surface-water samples was collected on July 31 and August 1, 1997 after a large thunderstorm event. Surface-water samples were collected from seven locations: a drainage ditch west of the Support Building, Retention Basins A, B, and C, the moat around the salt pile, the salt pile evaporation pond, and the SE corner of the site within the fenced area (Figure 1). The highest TDS values were measured in samples from the salt pile evaporation pond and moat (2,630 to 9,320 mg/L; Appendix A), and the lowest TDS values were recorded for water collected from the retention basins (100 to 165 mg/L; Appendix A). Surface waters collected from the retention basin have excess positive charge balance (i.e., greater than 5 %). Additional details on data quality are provided in Appendix A.

Table A-1 in Appendix A provides a summary of simple statistics for all parameters analyzed. Simple statistics were calculated using reported detection limit values, unless the reported detection limit was greater than reported analyte concentrations. For example, February 1997 results for boron at monitoring well C2505 were reported as less than 1 milligram per liter (mg/L) but in May 1997 were reported as 0.27 mg/L (Table A-1,

ATTACHMENT E

The December 31, 2002 letter from C. Marshall of the GWQB to I. Triay of WIPP, requested the following items:

1. "*NMED recommends that a subsurface geologic map be constructed at the unconformity that extends from the top of the Santa Rosa Formation along the base of the Gatuna Formation. This map should aid in understanding the relationship between the SSW and the extent of the Santa Rosa Formation*".

   A map showing the elevation of the erosional base of the Gatuna Formation is attached to this DP Application (Figure E1).

2. *An isopach map of the Santa Rosa Formation may also be helpful*".

   An isopach map of the Santa Rosa Formation is attached to this DP Application (Figure E2).

3. "*Please provide an updated potentiometric map reflecting the most recent water level measurements for the SSW*".

   A potentiometric surface map depicting recent water level data is attached to this DP Application (Figure E3).

4. "*...a more detailed analysis and discussion, as well as an updated TDS isoconcentration map would be helpful in explaining the high TDS concentrations in and around PZ-9 and PZ-3*".

   An updated TDS isoconcentration map is attached to this application (Figure E4). The analytical results used to generate this map were from samples obtained during December 2002. The current hydrologic conceptual model for the anthropogenic subsurface water (SSWa) was developed based on the potentiometric surface map.

   Focused recharge to the SSWa has occurred through the salt pile (SP) and salt pile evaporation pond (SPEP). Recharge has occurred through precipitation and through historical discharges (WIPP NOI 2002) in the vicinity of the SPEP and SP, creating a mound of water where vertical movement is impeded by cementation changes at the Santa Rosa Formation and Dewey Lake Redbeds Formation contact. Flow from this area is believed to be multidirectional.

   TDS concentrations generally decrease in a radial direction from the SPEP and SP. Piezometer PZ-9 is close to the SP and the TDS concentration is high in this well and compared to the other locations. Additionally, it appears that wells located predominantly down gradient, but immediately adjacent to focused "clean" recharge sources, are being diluted more than others away from such focused recharge points. For example, PZ-10 is near the storm water detention basin and exhibits a low TDS concentration. TDS concentrations for PZ-3 during this latest round of sampling indicated a significant decrease when compared to previous sampling rounds, but remains among the greatest TDS, along with wells nearest the SP (PZ-7, PZ-5, PZ-6). This follows the trend of decreased TDS as a function of distance from the SP/SPEP.

5. "*It is noted that the TDS concentrations in the Barn Well are significantly lower than those in the Ranch Well. If possible, please provide an explanation for this difference*".

   Locally the TDS concentration in the Dewey Lake Redbeds Formation is highly variable due to isolated occurrence of saturation and limited recharge and mixing of freshwater.

   As noted in Section 2.5.2 of the October 30, 2002 WIPP NOI, TDS concentrations are higher in the Ranch Well than the Barn Well. The Ranch Well is located on the J.C. Mill Ranch adjacent to the ranch corral and used only to water livestock. The corral is actively used for containment of livestock. The Mills Ranch also maintains livestock drinkers and water holding tanks, supplied by the Ranch Well, near the corral. The well is reported to be over 50 years of age (personal communication with Dennis Powers). The Barn Well provides water for domestic uses (WIPP CCA, Appendix USDW).

Subject: Proposal for Inspection of WIPP Sewage Lagoon System

Dear Mr. Marshall:

The purpose of this letter is to provide you our proposal for inspection of the Waste Isolation Pilot Plant (WIPP) Sewage Lagoon Liner Systems using electronic methods. During your inspection of the WIPP Site on August 11, 2004, you requested that the Department of Energy (DOE) provide you with a plan for inspecting the geo-membrane liners of each of the seven lagoons that comprise the WIPP Sewage Lagoon System.

DOE proposes that the WIPP Management and Operating Contractor, Washington TRU Solutions (WTS) place a contract with a service provider capable of providing professional engineering services which uses electronic leak location detection methods to locate leaks in geo-membrane lined facilities. Literature is provided as Enclosure 1 that discusses this process. In addition to this work, WTS will collect sample coupons of membrane liner that is above the water line from each of the seven lagoons. These coupons will be subjected to laboratory testing to determine its condition and to evaluate the ability of the geo-membrane to continue to perform its intended function.

The WIPP sewage treatment facility is located on the southwest side of the WIPP Site and is surrounded by a chain-link fence topped by out riggers to discourage intrusion. The primary function of the WIPP sewage lagoon system is to provide for the collection and treatment of sewage effluent from WIPP facilities. Collection of the sanitary waste is through a buried gravity flow system. The influent to the sewage lagoon system is treated in one of two parallel trains, each consisting of one primary settling pond and one polishing pond. The polishing ponds discharge to a common evaporation pond (Evaporation Pond A). Two additional ponds (Evaporation Pond B and Evaporation Pond C) provide for additional capacity as needed to evaporate effluent from Pond A. See Figure 1 enclosed for an illustration of the layout of the seven ponds. The sewage lagoon system is designed to meet applicable American Society of Civil Engineers and the Water Pollution Control Federation design criteria and WIPP maintains operators certified in accordance with 20.7.4.20 NMAC.

The stabilization lagoons and evaporation ponds are approximately 6 feet and 7 feet deep, respectively, with a 3:1 slope. The two primary settling cells and the two polishing cells are lined with a single 30 millimeter Hypalon™ liner. The three effluent evaporation ponds are lined with a single medium density polyethylene liner. The liners

CBFO:AMO:HLP:VW:05-0231:UFC:5486

for the original two settling ponds and two polishing ponds were constructed in 1985 with liners installed on 4-6 inches of sand over compacted caliche. Evaporation Pond A was originally lined only with compacted caliche. In 1992, a synthetic liner was installed in Evaporation Pond A and Evaporation Ponds B & C were constructed with liners installed on 4-6 inches of bentonite over compacted caliche.

WTS conducts a visual inspection of the sewage lagoon and evaporation pond liners weekly; however, only the exposed portion of the liner is visually inspected. During your inspection on August 11, 2004, you expressed concern that this may not be sufficient to determine if leaks from the lagoons have occurred. You requested that DOE provide you a plan to inspect the lagoons for leaks in approximately 6 months from the date of inspection.

DOE has reviewed several approaches, including the removal of all liquid and sludges from the lagoons to allow inspection of the geomembrane liners. It is our understanding that this is both an arduous task and frequently does not find all leaks present. There is the further concern that the process of sludge removal may cause damage to the geomembrane liner. DOE has determined that a process for geomembrane liner leak detection called the electrical leak location method has been used successfully in New Mexico in nearby municipal landfills. Information available indicates this is a dependable method for determining leaks beneath the surface in lagoons and landfills where the synthetic liners are covered and not readily inspectable. The process is nondestructive and does not present hazards to the geomembrane liners as may occur from more aggressive inspections requiring removal of water and sludges. The process utilizes electrical paths through leaks in a geomembrane liner and meets ASTM Standard. D-6747-04, *Standard Guide for Selection of Techniques for Electrical Detection of Potential Leak Paths in Geomembranes.*

In the leak detection process, a voltage is applied to an electrode placed in the soil or water covering the liner and to an electrode placed in the earth ground. The liner serves as an electrical insulator; therefore, if there are leaks in the liner, the imposed current produces localized anomalous areas of high current density near the leaks. Electrical measurements are then made on the soil or in the water to locate these points of current flow through the leaks (see Figure 2 enclosed). The precision of the process can be as close as 1" from the actual leak, dependent on conditions present. This method of leak detection has recently been used at other locations in southern New Mexico and several DOE facilities around the country.

The information obtained will be used to determine whether any leaks in the liners are present, if the liner materials are repairable, or that replacement is needed. Subject to vendor availability and the concurrence of your office, WIPP proposes to conduct the leak tests and laboratory analyses during calendar year 2005. DOE will notify the New Mexico Environment Department (NMED) of the dates work is to be performed. Should NMED have interest in observing this work, you presence is welcome.

CBFO:AMO:HLP:VW:05-0231:UFC:5486

A report of the integrity of the liners, any immediate action that is planned to be taken, and future actions required to maintain the sewage lagoon system will be provided to the NMED within 90 days of the contractor's report.

Your approval of this proposal would be appreciated. We will proceed with the procurement of a contractor to perform the evaluation of the sewage lagoon liners on receipt of this approval.

If you have any questions pertaining to this subject, please contact Mr. Jody Plum at (505) 234-7462.

Sincerely,

Inés Triay

Geomembrane Liner Leak Detection for Landfills, and Surface Impoundments

QUALITY CONTROL / QUALITY ASSURANCE
ASTM STANDARD D-6747 TESTING

An International Company Specializing in Electrical Leak Location Surveys of Geomembrane Liners

Cutting Holes for Testing?

or

Testing for Holes and Cuts?

Do you have it backwards?

The industry is changing the erroneous rationale of focusing on testing seams that almost never fail in service while ignoring actual holes in the geomembranes.

The electrical leak location method is a powerful tool used to detect electrical paths through leaks in a geomembrane liner. A voltage is applied to an electrode placed in the soil or water covering the liner and to an electrode placed in the leak detection zone for double-lined systems or connected to earth ground for single-lined systems. Because the geomembrane liner is an electrical insulator, current will flow only through leaks in the liner. This current produces localized anomalous areas of high current density near the leaks. Electrical measurements are then made on the soil or in the water to locate these points of current flow through the leaks.

The electrical leak location method is suitable for liquid impoundments and tanks, as well as pre-service inspection of solid waste landfills. Electrical leak location surveys are conducted on the primary or secondary geomembrane liners with water or soil covering the liner. Surveys with soil on the liner are important to detect leaks caused by machinery used to emplace the soil cover.

With the proper implementation of equipment and survey procedures the electrical leak location method can easily detect and locate 0.001 square inch (0.6 square mm) leaks in liners covered with water and 0.01 square inch (6 square mm) leaks in liners covered with 2 feet (600mm) of soil. The amplitude of the leak signal is proportional to the amount of electrical current flowing through the leak in the liner. LLSI maximizes this current by using a high voltage power supply that can provide up to 300 volts DC, depending on the current requirement.

An electrical leak location survey of the soil-covered geomembrane of a newly constructed landfill is a very cost effective method for finding leaks that occur while placing a protective soil cover over the geomembrane liner. Damage caused by heavy machinery while installing earth materials on geomembranes is the most significant cause of damage to geomembranes. The method has a distinct advantage because the testing is done after the final construction and after the geomembrane liner has been subjected to construction and loading activity.

Surveys with soil on the liner are conducted by making point-by-point electrical measurements on the soil. The data is recorded in a portable data acquisition logger and then downloaded to a portable computer for processing and data analysis. When a suspect area is indicated in the processed data, manual measurements are taken to further localize the leak. *Click image to see larger size*

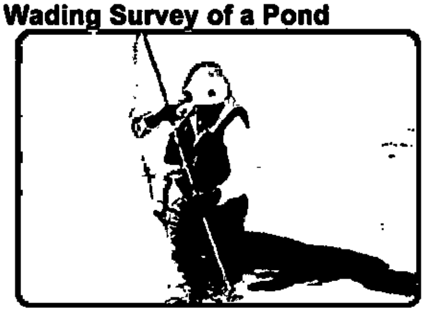
Geomembrane leak location surveys of surface impoundments and tanks can be conducted with water covering the geomembrane. Surveys are conducted using a probe while wading or standing on the side slopes, or using a sensor that is towed across the impoundment.

Wading Survey Mode

For the wading survey mode the survey personnel wade in the water and systematically scan the submerged liner to locate any leaks. For this method a water depth of between six and 30 inches (150 and 750 mm) is required. Temporary survey lanes are established across the bottom and are scanned with overlapping coverage. The liner field seams that can be located are double-checked. When detected, leaks are located to within one inch (25 mm) or less and immediately marked. The side slopes can be surveyed with deeper water using a long probe that is systematically scanned along the side slopes.

Wading Survey of a Pond



Towed Probe Survey Mode

If the water in the geomembrane lined pond, impoundment, or tank is too deep or the water in the pond is unsuitable for personnel to wade, then the towed probe survey mode is used. While standing on the top of the side slopes, survey personnel systematically pull the probe back and forth across the bottom of the pond along temporary survey lines. When detected, the distances to the leaks are immediately marked on the liner of the closer side slope.

Bare Liner Surveys

To avoid the logistics of flooding the geomembrane with water, the exposed geomembrane can be tested for leaks using a water puddle test. This test is used on geomembranes that are in direct contact with the supporting sub-grade or a GCL.

The bare liner test is to detect electrical current flowing through a hole in the geomembrane liner using a small amount of water that is temporarily placed in contact with the liner using a squeegee. One output of an LLSI power supply is connected to earth ground or the GCL and the second output is connected to the scanning sensor through an LLSI electronic leak detection unit. When the water in the leak contacts earth ground or the gcl, a circuit is established and the electrical current will increase. The LLSI electronic leak detector unit converts the increase in the current to an audible tone indicating the presence of leak.

GENERAL

- Tests are performed by an independent testing company for an objective evaluation
- Proven technology that has been successfully used for more than 18 years.
- Strongly encouraged or required by state regulatory agencies.
- Does not require specialty, sole source liner

FOR LANDFILLS

- Tests after protective sand or gravel is put on the liner to detect leaks caused by heavy equipment
- Tests double wedge welded seams

FOR SURFACE IMPOUNDMENTS AND TANKS

- Test under hydrostatic load to detect leaks caused by loading
- Does not require emptying or cleaning the facility
- Tests double wedge welded seams

FOR BARE GEOMEMBRANES

- Does not require flooding with water
- Can be performed during construction

COMPARISON OF LEAK LOCATION SURVEY MODES

Survey Mode	Applications	Typical Sensitivity	Typical Accuracy	Advantages	Limitations
Wading Survey	Bottom of impoundments, sumps	0.001 square inch	1 inch	Most sensitive, tests under load, can be for in-service testing	Geomembrane must be flooded with water
Towed Sensor Survey	Impoundments with deep water or side slopes	0.001 square inch	24 inches	Deep or foul water surveys, can be for in-service testing	Accuracy of leak position, geomembrane must be flooded with water
Long Probe Survey	Side slopes of impoundments	0.001 square inch	2 inches	More accurate than towed survey	May require second mobilization
Surveys with Soil	Landfills, landfill caps, and heap leach pads	0.01 square inch	Half of thickness of soil cover, leaks are uncovered and exactly located	Detects leaks under soil, detects construction damage after high potential for damage is gone	Soil must have some moisture
Bare Liner Survey	Bare liners	0.001 square inch	Leaks are exactly located	Does not require flooding liner with water, can be done as construction progresses	Not as reliable for patches or tortuous leak paths, or for geomembranes with wrinkles, bridging, or desiccated subgrade
Electrical Leak Imaging and Monitoring System (ELIM)	Pre-installed monitoring system	0.1 to 1 percent of electrode spacing	10 percent of electrode spacing	Detects leaks under waste, continuous monitoring	Must be installed during liner installation, higher cost

Leak Location Services, Inc. (LLSI) provides worldwide professional services for locating leaks in geomembrane-lined facilities. We use a time-proven electrical leak location method that is very accurate and highly sensitive. LLSI has affiliate companies in the United Kingdom and Canada allowing leak location field crews to quickly mobilize to anywhere in the world.

The development of the leak location method began in 1980 and the method has been in commercial use since 1985. Leak location surveys are used for construction quality assurance or to solve a leakage problem in lined landfills, impoundments, or tanks. LLSI founders Daren L. Laine and Glenn T. Darilek, P.E. are the pioneers in the development and commercial application of the electrical leak location method. Using specialized equipment designed and built by LLSI, the highly qualified and trained staff provide unrivaled know-how and technical expertise to verify their integrity or solve a liner leakage problem.

Leak Location Services, Inc. worldwide experience includes projects completed in thirteen countries on five continents.

- **Key members in the technical and commercial application of the electrical leak location method since 1981.**
- **Published more than 25 technical papers about the leak location method and applications.**
- **Holds five patents on the method.**
- **Performs about 100 leak location surveys of a total of more than 17 million square feet every year.**
- **Surveyed more than 75 million square feet of geomembrane liner at over 500 project sites.**
- **HAZWOPER trained.**
- **Trained for confined space entry.**
- **MSHA trained.**

Carlsbad, New Mexico 88221
March 10, 2005

Mr. Steve Zappe, WIPP Project Leader
Hazardous Waste Permits Program
Hazardous Waste Bureau
New Mexico Environment Department
2905 E. Rodeo Park Dr., Bldg. 1
Santa Fe, New Mexico 87505-6303

Subject: Stained Soils Found in the Parking Area During Excavation for the TRUPACT Sun Shade Structure

Dear Mr. Zappe:

The purpose of this letter is to provide follow-up information concerning the stained soils noted during construction of the TRUPACT Sun Shade Structure (Enclosure 1). On February 14, 2005, the Department of Energy (DOE) and Washington TRU Solutions (WTS) notified you that stained soil had been found in two of the 15 footing excavations. These excavations are located within the Parking Area Unit (PAU) as described in the Waste Isolation Pilot Plant (WIPP) Hazardous Waste Facility Permit (HWFP) that is paved over the area of Solid Waste Management Unit (SWMU) 005a (Enclosure 2). This SWMU was a concrete batch plant operated during the construction of several buildings at the WIPP facility. SWMU 005a is characterized in Revision 3 of the WIPP RCRA Permit Application as follows:

> "The only releases at these sites consist of spillage that occurred during filling of the trucks and stockpiling materials. The material released was water mixed with concrete, sand, and gravel and is considered non-hazardous. In addition, trace amounts of non-RCRA regulated motor oil, grease, and diesel may have leaked from trucks during handling."

During the notification call, it was stated that an investigation of the stained soil, including sampling, would be conducted to determine if there were constituents of concern present. The soil and a small amount of liquid were sampled on February 15, 2005. The excavations were deepened and a geologic soil description was made on February 18, 2005. The following enclosures provide details of the investigative activities:

Enclosure 1	Engineering Figure of the TRUPACT Sun Shade Shelter Noting the Location of the Structure and Footings
Enclosure 2	Aerial Photograph Noting the Location of Solid Waste Management Unit 005a
Enclosure 3	Analytical Results for the Investigation
Enclosure 4	Analytical Discussion
Enclosure 5	Summary Description of Additional Excavated Soil

CBFO:AMO:HLP:GS:05-0228:UFC 5486.00

The sample analyses have indicated the contaminant is diesel fuel (Enclosure 3). Excavations indicate only a small area was contaminated (see Enclosure 4). The levels of diesel fuel are slightly elevated (see Enclosure 4) above the clean soil levels described in the Solid Waste Regulations NMED 20.9.1.708. Data and observations indicate the stained soil is stable. The information developed during the investigation shows the stained soil is not migrating (Enclosure 5). The diesel found was bound to the soils and obvious signs of degradation indicate the microbes in the soil and oxidation of the fuels were taking place. The natural attenuation process is expected to continue to reduce the diesel levels in the soil. Inspection of the excavations on subsequent days after the excavations showed the stained soil to be dramatically lighter in color and no odor was present.

No impact is expected to human health or the environment, due to the depth of the contamination and the fact that it is covered with a minimum of 6 inches of concrete and 4 inches of asphalt under the concrete. The footings measuring approximately 4 feet wide by 4 feet long by 4 feet deep will be filled with compacted gravel and concrete. There is no apparent migration of the contaminants and no receptors under the concrete and asphalt.

The location has been identified using the Global Positioning Satellite System and SWMU 005a has been noted in the HWFP. Solid Waste Management Unit 005a will be thoroughly evaluated at the decommissioning of the WIPP facility and closed per the HWFP Attachment I. Since this is a previously identified SWMU with non hazardous constituents and no human health or environmental receptors, no further actions are planned until site closure.

Per DOE's phone conversation with you on March 4, 2005, construction of the TRUPACT sun shade structure will resume.

If you have any questions, please contact me at (505) 234-7300.

Sincerely,

Inés Triay

Subject: Modification of Discharge Permit DP-831, Waste Isolation Pilot Plant

Dear Ms. Hanning:

Enclosed please find three (3) copies of the completed Discharge Plan Application and a $100.00 check for the filing fee for this modification of Discharge Plan DP-831 for the Waste Isolation Pilot Plant (WIPP).

The modification request is being submitted pursuant to the September 8, 2004 letter from the Ground Water Quality Bureau (GWQB) to R.P. Detwiler, Acting Manager, U.S. Department of Energy (DOE). The GWQB requested that the DOE submit, within 120 days of the date of the letter, a permit modification application that addresses "additional potential contamination sources at the WIPP facility" and that incorporates "all potential sources into a comprehensive closure plan." The DOE requested and was granted an extension to March 6, 2005 to submit its response.

If you have any questions or comments, please contact Mr. Jody Plum at (505) 234-7462.

Sincerely,

for Inés Triay
Acting Manager

[redacted]

Enclosed is a Ground Water Discharge Permit Application Form (Form) and checklist. Section 20.6.2.3104 NMAC of the NM Water Quality Control Commission Regulations (20.6.2 NMAC) requires that any person proposing to discharge effluent or leachate so that it may move directly or indirectly into ground water must have an approved discharge permit, unless a specific exemption is provided for in the Regulations. The enclosed Form is a general guideline for use by applicants to ensure that an application is complete and provides all of the information required by sections 20.6.2.3106, 20.6.2.3107, 20.6.2.3108, and 20.6.2.3109 NMAC.

Mail **three complete copies** of your application with a **$100 filing fee** check made payable to the New Mexico Environment Department (NMED) at the address below:

Maura Hanning, Program Manager
Ground Water Pollution Prevention Section
NM Environment Department
P. O. Box 26110
Santa Fe, NM 87502

Pursuant to Regulation 20.6.2.3108 NMAC, NMED will, within thirty (30) days of deeming the application administratively complete, publish a public notice and allow 30 days for public comment before taking final action on a discharge permit. A public hearing will be held if NMED determines that there is significant public interest. It takes approximately180 days to process a complete application and issue a discharge permit if no public hearing is held.

All applications must be accompanied by a filing fee of $100. **An additional fee will be assessed prior to permit issuance** to cover the estimated cost to the NMED for investigation, and, issuance of the permit. **Permit fees are listed in the Regulation 20.6.2.3114 NMAC.**

If you have any questions about this discharge permit application, call the Ground Water Pollution Prevention Section at 505-827-2900

COMPLETION CHECKLIST

☐		All portions of the Ground Water Discharge Permit Application Form have been addressed. (The application will not be considered complete if there are omissions, which will delay publication of the public notice and issuance of the permit.)
☐		Submitter has included operational, monitoring, contingency, and closure plans that are appropriate for the proposed treatment and disposal system, and meet the site-specific conditions for the proposed facility.
☐		Plans and specifications for the entire effluent or leachate conveyance, collection, treatment, distribution, and disposal system have been included as required by Regulation 20.6.2.1202 NMAC. For septic tank/leachfield systems, designs should be consistent with NMED's guidelines for Plans and Specifications for Discharge Permit Applications Using Septic Tank/Leachfields.
☐		The application has been signed and dated by the responsible party, generally the owner or lessee.
☐		If your facility site includes an archeological site on the State Register of Cultural Properties or National Register of Historic Places, the State Historic Preservation Office has the authority to require an archeological or historical study prior to NMED taking final action on your discharge permit.
☐		Four maps have been included: **1)** area United States Geological Survey (USGS) topographic map that includes the location of the facility and all of the information required in the application item 7.b, **2)** local road map clearly defining the location of the facility and the route to get to the facility, **3)** detailed site map that includes all discharge locations (lagoons, leachfields, land application areas, outfalls...), all water supply and monitoring wells, all water courses on the property and all buildings and **4)** United States Department of Agriculture (USDA) soils map.
☐		Three copies of all required information have been enclosed.
☐		A filing fee check in the amount of $100, has been enclosed, made payable to the NM Environment Department at the address on page 1.
☐		The SUMMARY OF APPLICANT'S PUBLIC NOTICE REQUIREMENTS has been reviewed and the option for Public Notice Has been selected on the application page 3.

MAR 08 2005

ADMINISTRATIVE COMPLETENESS

To be deemed administratively complete for publication of a public notice, the following information must be provided. [20.6.2.3106, 20.6.2.3108 NMAC]

Review the SUMMARY OF APPLICANT'S PUBLIC NOTICE REQUIREMENTS (attached) to select an option below.

☐ Public Notice Option 1 ☑ Public Notice Option 2 ☐ Public Notice Option 3

1. <u>**Name of the proposed discharger and facility**</u> [20.6.2.3106, 20.6.2.3108.C.1 NMAC]:

Type of facility or operation (dairy, municipal wwtp, mining, school, etc.): ____________________

The Waste Isolation Pilot Plant (WIPP) is a hazardous and radioactive waste disposal facility operated by the U.S. Department of Energy (DOE). It is designed, permitted, and operated for the receipt of defense generated TRU and TRU mixed waste. The WIPP is constructed in a bedded salt deposit 2150 feet beneath the earth's surface. Hazardous Waste Disposal Units are excavated in the bedded salt as permitted by the New Mexico Environment Department (NMED) with the issuance of Hazardous Waste Facility Permit (HWFP) #NM4890139088-TSDF, October 27, 1999. The WIPP is currently operating under Discharge Permit DP-831 as approved on April 29, 2003 and December 22, 2003.

The purpose of this application is to supplement the existing DP-831 permit with 1) the identification of additional potential contamination sources not identified in previous permit applications or modifications (see Additional Potential Contamination Sources (Tab 1), Table I, List of All Solid Waste Management Units (Tab 4) and Table II Solid Waste Management Units Not Previously Granted No Further Action (Tab 4), and 2) a closure plan (see Closure Plan for DP-831 Facility Components (Tab 2)).

*For the facility address, enter physical address- not mailing address.

2. Locations of the Discharges [20.6.2.3106.C.2 and 20.6.3108.C.2 NMAC]:

List the locations of the discharges covered by this permit. Add rows as necessary to include all discharge locations. Sections should be described to the nearest ¼ of a ¼ of a ¼ section (please see attachment).

Discharge Location (lagoons, leachfields, land application areas, outfalls, etc.)	**County**	**Township**	**Range**	**Section**	**Latitude**	**Longitude**
Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.						

3. Brief Description of Discharge [20.6.2.3108.C.3 NMAC]:

Briefly describe the activities which produce the discharge(s) including the treatment and disposal methods. Attach additional pages as necessary.

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2004.

4. Discharge Characteristics [20.6.2.3106.C.1 and 20.6.2.3108.C.4 NMAC]:

4.a. Quantity:

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

4.b. Quality: Add rows as necessary to include all contaminants and toxic pollutants.

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

4.c. Flow Characteristics:

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

5. <u>Ground Water Conditions</u> [20.6.2.3106.C.3 and 20.6.2.3108.C.5 NMAC]:

Sources for this information may be the New Mexico State Engineers Office, NMED, GWPPS web site (www.nmenv.state.nm.us), and USGS reports. If you do not have a TDS value, take a sample from the nearest well to the discharge location and submit the results from the analysis.

Depth to ground water below the discharge site:	**See DP-831 Permit Modification Application dated April 25, 2003.**
Flow direction of ground water below the site:	
Flow gradient of ground water below the site:	
Reference* or source for depth, direction and gradient:	

* If determined from well logs, please provide photocopies of well logs with application. If depth is derived from a report include copies of appropriate pages and complete reference to report including author, title, and publication date.

Total Dissolved Solids (TDS) concentration (mg/L) of ground water below the site:	**See DP-831 Permit Modification Application dated April 25, 2003.**
Reference or source for TDS:	

TECHNICAL ADEQUACY

To be deemed technically adequate, for purposes of issuing the discharge permit, the following information must be provided. [20.6.2.3106, 20.6.2.3107, 20.6.2.3109 NMAC]. Operational, monitoring, contingency, and closure plans must be submitted and must be appropriate for the proposed treatment and disposal type and meet the site specific conditions for the proposed facility.

6. <u>Permit Plans</u> [20.6.2.3106.C.7, 20.6.2.3107.A, and 20.6.2.3109.C NMAC]:

6.a. Operational Plan [20.6.2.3106.C.7 and 20.6.2.3109.C NMAC]:

The operational plan must describe how the system(s) for conveyance, collection, treatment, distribution, and disposal of wastewaters or other discharges will be constructed, operated, inspected, and maintained. The operational plan must demonstrate that ground water standards will not be exceeded.

6.a.i. In the following table, identify all proposed conveyance, collection, treatment distribution, and disposal units included in the operational plan. Add rows as necessary to include all units.

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

6.a.ii. Describe in detail the operational plan, including all conveyance, collection, treatment, distribution and disposal systems. Attach additional pages as necessary:

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

6.a.iii. Describe the operations and maintenance plan that will be followed to ensure the system is maintained as described. At a minimum the plan must include monthly inspections of all wastewater treatment and disposal units. Attach additional pages as necessary.

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

6.b. Monitoring Plan [20.6.2.3106.C.5 and 20.6.2.3107.A.1-9 NMAC]:

The monitoring plan must describe how the facility will be monitored to ensure the discharge will not adversely impact ground water quality. The plan must include all monitoring locations (effluent sampling, monitoring wells, lagoons, soil sampling, plant tissue analysis, etc.). Monitoring locations must be included on the facility map.

See DP-831 Additional Potential Contamination Sources, Tab 1

6.b.i. Monitoring Locations. In the following tables, identify all monitoring locations. Add additional rows as necessary to include all monitoring locations.

See DP-831 Additional Potential Contamination Sources, Tab 1

6.b.ii. Describe in detail the sampling protocols that will be used for sample collection at all monitoring locations. Attach additional pages as necessary.

See DP-831 Additional Potential Contamination Sources, Tab 1

6.b.iii. Standard Monitoring Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

See DP-831 Additional Potential Contamination Sources, Tab 1

6.c. Contingency Plan [20.6.2.3107.A.10 NMAC]:

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

6.c.i. Standard Contingency Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

6.c.ii. Specific Contingency Plan:

Describe any additional specific corrective actions or contingencies that will be taken to cope with failure of the discharge system: Attach additional pages as necessary.

Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003.

6.d. Closure Plan [20.6.2.3107.A.11 NMAC]:

The closure plan must describe the closure actions to be taken to prevent Regulation 20.6.2.3103 NMAC ground water standards from being exceeded, or the introduction of a toxic pollutant in ground water after cessation of operations. At a minimum, the closure plan must include a description of closure measures, post closure monitoring plans, and financial assurance (if required by NMED).[1]

See Closure Plan for DP-831 Facility Components, Tab 2

[1] Based on a letter from Tracy Hughes to Pete Domenici, Jr.,, dated January 31, 2005, the DOE is not required to submit financial assurance information for DP-831.

6.d.i. Specific Closure Plan: Describe the specific closure activities to ensure that ground water quality will be protected after cessation of operations. The plan shall include plugging, removal, and/or filling of all conveyance, collection, treatment, distribution and disposal features in order to prevent future discharges at the facility. The plan must also describe how all liquid and solid wastes will be removed and disposed of according to local, state, and federal laws. The plan must also describe how disturbed areas will be backfilled to blend with the original surface topography to prevent future ponding and to prevent a discharge at the facility from occurring after the cessation of operations. Attach additional pages as necessary.

6.d.ii. Standard Closure Requirements: The following paragraphs are standard permit conditions. Please read the condition and check the boxes that you will comply with as a condition of your permit.

This facility will comply with the following closure requirements:

☑ The discharger will notify NMED at least 30 days prior to cessation of operations and will provide a schedule for implementation of the closure plan.

☐ This facility will conduct post closure monitoring at the frequency and locations prescribed under the active permit for a period approved by NMED. If Regulation 20.6.2.3103 NMAC ground water standards are violated or toxic pollutants are present during post closure monitoring, this facility will implement the contingency plan required in the active permit.

☐ All monitoring wells will be plugged and abandoned in accordance with NMED Monitoring Well Construction and Abandonment Guidelines once NMED has agreed in writing that post closure ground water monitoring may cease.

☐ Once NMED has approved all closure activities, this facility will submit a letter requesting termination of the discharge permit.

TECHNICAL SUPPORT

The following information must be submitted as required by Regulation 20.6.2.3106, and 20.6.2.3109 NMAC.

7. **<u>Other Discharge Locations</u>** [20.6.2.3106.C.2 NMAC]:

7.a. List the locations of any other discharges at this facility not covered by this permit but permitted under the New Mexico Liquid Waste Disposal Regulations, Hazardous Waste Management Regulations, Federal Clean Water Act (NPDES), and any un-permitted discharges. Add rows as necessary to include all other discharge locations.

Discharge Type (septic tank/leachfields, surface water discharges, etc.)	Permit Identification	Discharge Location Description
Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 22, 2003 and Closure Plan for DP-831 Facility Components, Tab 2.		

7.b. Area Map: On the appropriate United States Geological Survey (USGS) 7.5 minute topographic quadrangle map, identify the location of all water supply wells, injections wells, seeps, springs, bodies of water, and watercourses within one mile of the outside perimeter of the discharge site.

As described in Section 8 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, previous applications, renewals, and modifications, there are no water supply wells, injections wells, seeps, springs, bodies of water, or watercourses within one mile of the outside perimeter of the discharge site.

8. **Flooding Potential** [20.6.2.3106.C.4 NMAC]:

8.a. Describe the flooding potential of the discharge site based on the latest Federal Emergency Management Agency flood plain map or site specific analysis:

Source for Information: **WIPP DP-831 Renewal Permit Application, December 16, 1996**

As described in Section 12 of the WIPP Discharge Plan DP-831 Renewal Permit Application, dated December 16, 1996, the flooding potential of the WIPP facility is considered minimal since the general ground elevation in the vicinity of the surface facilities is approximately 400 feet above the 100 year floodplain of the Pecos River, which is the closest river to the facility. The potential for flash flooding is considered minimal because of the high percolation rate of the surrounding sand dunes and the flood protection berms (see Section 8.b of this application).

8.b. Describe the methods used to control flooding, run-on and run-off at the discharge site (berms, diversion channels, etc.):

As described in the April 25, 2003, DP-831 Permit Modification Application and subsequent design drawings, a berm exists along the north side of the Salt Storage Extension (SSE) and is contoured such that rainfall is diverted around the WIPP surface facilities.

9. **Geologic and Soil Information** [20.6.2.3106.5 NMAC]:

9.a. Lithology: Describe the lithology and thickness of each geologic unit below the discharge site and indicate which units bear water. This information may be obtained from a driller's log or geologic report. Include photocopies of all well logs with the application. Add rows as necessary to include all units.

The geologic units below the discharge site (SP/SPEP area) are described in the October 30, 2002 Notice of Intent (WIPP NOI 2002, Section 4.0, and NOI Attachments 3,4,5,6,7, and 11). These descriptions include lithology, thickness, and hydrogeologic properties of the unit below the discharge site.

Source for Information: **October 30, 2002, Notice of Intent (WIPP NOI 2002, Section 4.0, and Attachments 3, 4, 5, 6, 7, and 11)**

9.b. Soil Map: Attach a copy of the United States Department of Agriculture (USDA) Natural Resources Conservation Service (NRCS) soil survey map and descriptive information for soil(s) associated with the discharge site.

Previously provided in Attachment 9 of the WIPP Discharge Plan DP 831 Renewal Application, dated December 16, 1996.

10. Signatures:

Owner: I certify that I am the legal owner of the property in which all discharges will occur. I certify that I am knowledgeable about the information contained in this application, and believe the information is true, complete and accurate.

Print Name: Kerry W. Watson
Authorized Agent of Owner, U.S. Department of Energy

Signature: Kerry W. Watson Date 3/4/2005

Responsible Party* (if property is leased or operated by someone other than the owner):

I certify that I am knowledgeable about the information contained in this application, and believe the information is true, complete and accurate.

Print Name: ______________________

Tab 1

DP-831 ADDITIONAL POTENTIAL CONTAMINATION SOURCES

The following information is being submitted as part of the Permit Modification Application, March 4, 2005 ("Permit Modification Application") and in response to the September 8, 2004, letter from the New Mexico Environment Department's (NMED) Ground Water Quality Bureau (GWQB) to R.P. Detwiler, Acting Manager, U.S. Department of Energy (DOE), Waste Isolation Pilot Plant (WIPP). The GWQB requested that the DOE submit, within 120 days of the date of the letter, a permit modification application that addresses "additional potential contamination sources at the WIPP facility." WIPP requested and was granted an extension to March 6, 2005, to submit the permit modification application. The additional "potential contamination sources" addressed include "all active and inactive salt storage areas and waste disposal areas located within the WIPP property boundary defined by the Land Withdrawal Act."

Other than the Salt Storage Area and the Site and Preliminary Design Validation (SPDV) pile, both discussed below, there are no additional salt storage areas. Additional piezometers are proposed for groundwater monitoring around the SPDV pile. Tables I and II (Tab 4) provide a summary of the Solid Waste Management Units (SWMUs) that are regulated by the NMED Hazardous Waste Bureau (HWB) pursuant to the WIPP Hazardous Waste Permit (HWFP). As discussed in the Closure Plan for DP-831 Facility Components (Tab 2), some of the SWMUs identified in Table I (Tab 4) have received "No Further Action" (NFA) determinations from the HWB. Additionally, with the exception of SWMU 004a (Portacamp), DOE has requested NFA decisions for all of the SWMUs listed in Table II (Tab 4). No additional groundwater monitoring is proposed for the additional SWMUs identified in Tables I and II (Tab 4) because no groundwater impacts are expected.

1. SALT STORAGE AREA

The salt storage operations at the WIPP facility were described in the October 30, 2002, Notice of Intent and in the April 24, 2003, DP-831 Modification Application. As explained, the WIPP is a hazardous and radioactive waste disposal facility operated by the DOE. It is designed, permitted and operated for the receipt of transuranic (TRU) and TRU mixed waste. The WIPP TRU waste disposal rooms are constructed in a bedded salt formation. At WIPP's closure, all permitted Hazardous Waste Disposal Units (HWDU) will have been excavated from the bedded salt layer 2150 feet beneath the earth's surface. The excavated salt is stored on the surface for authorized disposition at closing of WIPP. The disposition of the salt is discussed in the Closure Plan for DP-831 Facility Components (Tab 2). The salt pile is approximately 18.8 acres in size and has an associated salt pile evaporation pond that is approximately 3.0 acres. The salt pile is surrounded by ditches that divert runoff from the salt pile to the evaporation pond. The salt pile and associated evaporation pond and ditches were the subject of the April 24, 2003, DP-831 Modification Application. All of the components are collectively defined as the Salt Storage Area. The design and operation of the Salt Storage Area were described in Section 3.0, page 2, of the October 30, 2002, Notice of Intent.

Pursuant to the current conditions of DP-831, the following groundwater and storm water controls have been or are being implemented:

- Synthetic liner covering the Salt Pile;
- Placement of salt on a synthetically lined system with stormwater/leachate collection system (Salt Storage Extension System);
- One synthetically lined evaporation pond (Salt Storage Evaporation Basin) for the collection of salt contact water from Cell A of the Salt Storage Extension;
- Synthetically lined conveyance ditches around the Salt Pile, which discharge to the Salt Pile Evaporation Pond;
- Four synthetically lined storm water evaporation ponds (the Salt Pile Evaporation Pond, Evaporation Basin A, and Evaporation Basins 1 and 2), H-19 evaporation pond and seven sewage lagoon ponds;
- Storm water overland flow diversion berms;
- Salt placement procedures and active monitoring programs.

Monitoring of the shallow subsurface water is currently being performed at WIPP. The Shallow Subsurface Water (SSW) DP-831 monitoring and sampling network, set forth in the current DP-831, consists of water level monitoring on a quarterly basis and SSW sampling and analysis on a semi-annual basis.

2. SITE AND PRELIMINARY DESIGN VALIDATION (SPDV) PILE

The Site and Preliminary Design Validation Pile (SPDV pile) has been closed and fully remediated. The SPDV pile was created during the design validation phase of the WIPP for placement of construction materials resulting from the drilling of two 2,150 foot shafts and the underground excavation of connecting tunnels, exploratory tunnels, and four rooms. The materials in the SPDV pile include mined tailings interspersed with soil, rock, and debris from the construction of the shafts. The SPDV pile encompasses approximately 10 acres and ranges in height from 7 to 20 feet above ground. The volume is approximately 168,000 cubic yards, which includes an area beneath the pile where soil was excavated prior to tailings placement.

In 1995, the SPDV pile was characterized to determine the chemical nature of wastes within the pile and to support selection of reclamation alternatives. ("Characterization of the Site Preliminary Design Validation Salt Pile," Daniel B. Stephens & Associates, Inc., Jan. 5, 1996). The investigation determined that no remedial measures were required according to NMED guidelines. As a result of the study, stabilization and reclamation were recommended in order to prevent offsite transport of salt and brine solutions into the surrounding environment, and to blend the salt pile into the surrounding environment.

Reclamation activities completed in 1999 and 2000 at the SPDV pile included:

1) Re-contouring the SPDV pile to an estimated average of 15 feet above near ground surface elevation while maintaining the initial basal footprint situated on top of the undisturbed caliche.
2) Establishing a 4:1 horizontal to vertical slope ratio along the sides to deter veneer failure. The majority of the slopes are constructed at a three percent grade outward from the center crown to prevent ponding.
3) After contouring, the SPDV pile was capped with a Claymax geosynthetic clay liner encompassing nearly 319,000 square feet. The liner is on top of six inches of native material screened to a maximum of 3/4" in diameter.
4) After the liner was placed, a minimum of three feet of soil rooting medium consisting of 15% (by weight) 1/2" crushed rock was added to minimize wind erosion.
5) The entire reclaimed SPDV pile was seeded with shallow rooted plants, which have been successfully established.
6) The reclaimed SPDV is regularly inspected, monitored and maintained.

The reclaimed SPDV pile is unlikely to discharge to the groundwater due to the capping installed during reclamation and the fact that no brine liquid was added to the pile. The orientation of the reclaimed SPDV pile is primarily from north to south along the long axis.

Based on the general trend of the cementation change between the Santa Rosa and Dewey Lake formations, and the local topography surrounding the reclaimed SPDV pile, the assumed hydraulic gradient of a potential perched shallow water lens is to the south-southwest.

Because the existence of a perched zone at the location of the SPDV remains unclear, three additional piezometers are proposed for installation. The additional piezometers would be on the east side, the west side, and the south side of the reclaimed SPDV pile, as close to the reclaimed pile as possible without damaging the liner. The piezometers would be drilled to a point immediately beyond the cementation change at the Dewey Lake-Santa Rosa contact, where moisture, if present, would perch. The completion depths are estimated to be approximately 60 to 70 feet below ground surface. To the extent possible, drilling techniques will not involve fluids so that the moisture of drill cuttings and soil/rock samples can be monitored for evidence of infiltration into the subsurface from the reclaimed SPDV pile. The piezometers will be integrated into the current DP-831 monitoring and sampling program. Plans for the three additional piezometers will be submitted to the GWQB for review and approval prior to field work.

Tab 2

CLOSURE PLAN
FOR DP-831 FACILITY COMPONENTS

I. INTRODUCTION

The following Closure Plan is being submitted in response to the September 8, 2004, letter from the New Mexico Environment Department's Ground Water Quality Bureau (GWQB) to R.P. Detwiler, Acting Manager, U.S. Department of Energy (DOE), Waste Isolation Pilot Plant (WIPP). The GWQB requested that the DOE submit, within 120 days of the date of the letter, a permit modification application that addresses "additional potential contamination sources at the WIPP facility" and that incorporates "all potential sources into a comprehensive closure plan." The DOE requested and was granted an extension to March 6, 2005, to submit the permit modification application. The GWQB stated that the application "may reference current activities and existing documents, plans and specifications that apply towards final closure of facility components covered under DP-831." *Id.* at 3. As discussed below, the decommissioning and decontamination and final closure of the WIPP facility will be completed pursuant to the WIPP Hazardous Waste Facility Permit (HWFP) and applicable federal regulations and requirements. This Closure Plan references and incorporates existing plans and specifications for closure of the facility components that are or may be covered by DP-831.

II. BACKGROUND

The WIPP facility is a mined geologic repository in a deep salt formation. The WIPP Land Withdrawal Act (WIPP LWA), passed by Congress in 1992 and amended in 1996, authorizes the disposal of transuranic (TRU) waste at WIPP. (Pub. L. No. 102-579, 106 Stat. 4777 (1992) and Pub. L. No. 104-201, 110 Stat. 2851-2854 (1996)). The TRU waste disposed of at WIPP includes both "mixed waste" and "non-mixed waste." TRU mixed waste contains both radioactive materials and hazardous wastes. Hazardous wastes are defined and regulated pursuant to the Resource Conservation and Recovery Act (RCRA), 42 U.S.C. §6901 *et seq.* and the New Mexico Hazardous Waste Act (HWA), NMSA 1978 §74-4-1 *et seq.* TRU non-mixed waste does not contain hazardous waste.

The WIPP LWA grants the DOE authority over the WIPP facility and defines the regulatory authority of the United States Environmental Protection Agency (EPA). EPA has sole authority, through the certification and re-certification process, to determine if the WIPP facility complies with EPA's radioactive waste disposal standards set forth in 40 CFR Part 191, Subparts B and C, and Part 194. (WIPP LWA at §8). DOE submitted its initial Compliance Certification Application (CCA) in October, 1996. On May 18, 1998, EPA certified that WIPP will comply with 40 CFR Part 191, Parts B and C, as implemented by 40 CFR Part 194. (63 FR 27405). The CCA, approved by EPA, includes requirements for the decontamination, decommissioning and final closure of the WIPP facility. Compliance recertification applications are submitted to EPA every five years. (WIPP LWA at §8(f)).

NMED, pursuant to its authority to implement the Solid Waste Disposal Act, as amended by RCRA, 42 U.S.C. §6901 *et seq.*, has regulatory authority over the hazardous waste component of the TRU mixed-waste. (WIPP LWA at §9, stating that WIPP is required to comply with the Solid Waste Disposal Act).

The State of New Mexico has been authorized by EPA to implement a hazardous waste program in lieu of, but equivalent to, the federal program. NMSA §74-4-1 *et seq.*; 42 U.S.C. §6926; 50 FR 1515 (Jan. 11, 1985). NMED has the authority to regulate hazardous wastes and facilities for the treatment, storage and disposal of hazardous waste. Such facilities must receive a permit from NMED in order to operate in New Mexico. EPA has also authorized New Mexico to regulate the hazardous components of radioactive mixed waste managed in the state in a manner consistent with the federal RCRA program. (55 FR 28397, July 11, 1990). The HWA implemented RCRA in the State of New Mexico and required the Environmental Improvement Board to issue regulations consistent with RCRA. With a few exceptions, the New Mexico Hazardous Waste Management Regulations, 20.4.1.1. NMAC *et seq.*, adopt the RCRA regulations found at 40 CFR Parts 260 to 266, 268, 270 and 273. The Hazardous Waste Bureau (HWB) is responsible for implementing the State RCRA program.

In October, 1999, pursuant to the HWA and RCRA, the HWB issued WIPP a treatment, storage and disposal facility permit that authorized WIPP to accept TRU-mixed waste for storage and disposal. The WIPP HWFP provides all the conditions necessary for compliance with RCRA and for the safe management, storage, and disposal of TRU waste, including general waste information, waste analysis requirements, and closure requirements.

III. CLOSURE PLAN

The plan presented in this document is based on existing decontamination and decommissioning plans and closure plans developed pursuant to the HWFP, applicable federal regulations and requirements, and the current DP-831. A detailed closure plan will be prepared for the Environmental Protection Agency (EPA) final Compliance Recertification Application (CRA), which will be prepared during the final three years of the project, as WIPP operations approach completion.

The following sections of the HWFP contain closure plan requirements:

- Module II- General Facility Conditions; Section II.L – Closure
- Module III- Container Storage; Section III.H- Closure
- Module IV- Geologic Repository Disposal; Section IV.I- Closure
- Module VI- Post Closure Care Plan
- Permit Attachment I – Closure Plan
- Permit Attachment J – Post Closure Plan

HWFP Attachment I includes the facility closure plan and is attached at Tab 3.

The detailed closure plan to be developed as part of the final CRA will include design engineering, construction and decommissioning details, borrow source locations, cut and fill plans, final drainage plans, sampling and remediation plans, confirmation and verification plans, and closure monitoring plans.

As required by the HWFP, once operations at the WIPP facility are completed, the entire facility will undergo decontamination and decommissioning prior to final closure. The objective of decontamination and decommissioning activities at the WIPP facility "is to return the surface to as close to the pre-construction condition as reasonably possible, while protecting the health and safety of the public and the environment." Tab 3 at I-11.

The HWFP states as follows:

> In the preparation of its Final Environmental Impact Statement, the DOE committed to restore the site to as near to its original condition as is practicable. This involves removal of access roads, unneeded utilities, fences, and any other structures built by DOE to support WIPP operations. Provisions would be left for active post-closure controls of the site and for the installation of long-term makers and monuments for the purpose of permanently marking the location of the repository and waste. Permit Attachment J-1a(1) discusses the active and long-term controls proposed for the WIPP. Installation of borehole seals are anticipated to take twelve (12) months, shaft seals fifty-two (52) months, and final surface contouring eight (8) months.

Id. at I-18.

Decontamination includes "those activities which are performed to remove contamination from surfaces and equipment that are not intended to be disposed of at the WIPP facility." *Id.* at I-11. Decommissioning is "the process of removing equipment, facilities or surface areas from further use and closing the facility. Decommissioning is part of final facility closure only and will involve the removal of equipment, buildings, closure of the shafts, and establishing active and passive institutional controls for the facility." *Id.* HWFP Attachment I identifies and discusses the major activities required to be accomplished as part of decontamination and decommissioning. *Id.* at I-11 to I-19.

The foregoing requirements apply to all facility components that are or may be covered under DP-831. Specific components of the facility are addressed below. Section F discusses groundwater impacts and monitoring for the facility for both the operational phase and during closure.

A. <u>Facultative Lagoon System, H-19 Evaporation Pond, Salt Evaporation Ponds, and Storm Water Collection Ponds</u>

The closure plan for the facultative lagoon system and H-19 evaporation pond was included in the December 16, 1996, DP-831 Permit Renewal Application and in the June 5, 2002, DP-831 Renewal Application. The closure plan for the salt pile evaporation ponds and storm water collection ponds was included in the April 24, 2003, DP-831 Modification Application. The closure plan includes the synthetically lined conveyance ditches.

The December 16, 1996, DP-831 Permit Renewal Application, at Section 19, states as follows:

At the time the WIPP facility is decommissioned, the sewage facility and the evaporation ponds will be closed using closure plans discussed in the *Waste Isolation Pilot Plant Final Supplemental Environmental Impact Statement (SEIS)* (DOE/EIS 0026-FS, January, 1990). Although a detailed closure plan has not been completed, the SEIS states that all surface facilities will be decommissioned, all hazardous materials removed from the site, surface soils will be re-contoured to approximate original features, and native vegetation will be planted.

Closure plans for the sewage facility and evaporation ponds will specifically require that all lagoons and ponds will be pumped or evaporated and that all sludges be sampled to determine if hazardous constituents exist as defined by the Resource Conservation and Recovery Act (RCRA- 40 CFR 261). If hazardous constituents are detected, the sludges will be managed accordingly.

The June 5, 2002 DP-831 Permit Renewal Application, at 6.d, states as follows:

The standard permit conditions in 6.d.ii will be incorporated into the closure plan for the facultative lagoon system and evaporation facilities currently permitted under DP-831 and described in section 19 of the WIPP Discharge Plan Renewal Permit Application, dated December 16, 1996.

At the time the WIPP facility is decommissioned, the closure plan will specify the closure activities required to ensure that groundwater quality will be protected. These activities include the pumping or evaporation of all wastewater ponds, removal and disposal of all solids in accordance with applicable regulations, and contouring and revegetation of the site.

The April 24, 2003, DP-831 Modification Application states:

The closure plan dated December 16, 1996, will be implemented when the facility is decommissioned. The plan includes the pumping or evaporation of all wastewater ponds, removal of all solids, and recontouring and revegetation of the site. In addition, all basin liners will be removed or perforated upon closure of the site. This will be performed to comply with Section 20.6.2.3107.A.11 NMAC.

The closure plan set forth in the December 16, 1996, and the June 5, 2002, DP-831 Permit Renewal Applications and the April 24, 2003, DP-831 Modification Application are incorporated herein.

B. Active Salt Pile

The active salt pile and the salt pile storage area are described in Section 1 of the April 24, 2003, DP-831 Modification Application and in Section 3.0, page 2, of the October 30, 2002, Notice of Intent to Discharge. The salt pile will be disposed of in accordance with the requirements of the LWA, §4(b)(4) which states that "[t]he Secretary shall dispose of salt tailings extracted from the Withdrawal that the Secretary determines are not needed for backfill at WIPP. Disposition of such tailings shall be made under sections 2 and 3 of the Act of July 31, 1947 (30 U.S.C. 602, 602; commonly referred to as the 'Materials Act of 1947')." The final plan for the post-closure management and use of the area withdrawn under the LWA will be developed by the Secretary of the DOE in consultation with the Secretary of the Interior and the State of New Mexico. The plan will be submitted to Congress. (WIPP LWA §13). As required by Section 4(b)(1) of the LWA, Land Management Plan (DOE/WIPP 93-004) was developed in consultation with the Department of Interior and the State of New Mexico in 1994. The Land Management Plan was submitted to Congress and is reviewed and updated biennially. As part of the closure of the facility, a berm will be constructed around the perimeter of the closure area, which would include 70 hectares (175 acres). Exhibit B, 1990 FEIS at 3-15. As part of decommissioning, DOE will restore the areas occupied by the salt pile and "[a]ny salt remaining after the WIPP closure and construction of the berm would be sold or disposed of in accordance with the Materials Act of 1947." *Id.*

C. <u>Site and Preliminary Design Validation Pile</u>

The SPDV pile has been closed and fully remediated. The SPDV pile was created during the design validation phase of the WIPP for placement of construction materials resulting from the drilling of two 2,150 foot shafts and the underground excavation of connecting tunnels, exploratory tunnels, and four rooms. The materials in the SPDV pile include mined tailings interspersed with soil, rock, and debris from the construction of the shafts. The SPDV pile encompasses approximately 10 acres and ranges in height from 7 to 20 feet above ground. The volume is approximately 168,000 cubic yards, which includes an area beneath the pile where soil was excavated prior to tailings placement.

In 1995, the SPDV pile was characterized to determine the chemical nature of wastes within the pile and to support selection of reclamation alternatives. ("Characterization of the Site Preliminary Design Validation Salt Pile," Daniel B. Stephens & Associates, Inc., Jan. 5, 1996). The investigation determined that no remedial measures were required according to NMED guidelines. As a result of the study, stabilization and reclamation were recommended in order to prevent offsite transport of salt and brine solutions into the surrounding environment, and to blend the salt pile into the surrounding environment.

Reclamation activities completed in 1999 and 2000 at the SPDV pile included:

1) Re-contouring the SPDV pile to an estimated average of 15 feet above ground surface elevation while maintaining the initial basal footprint situated on top of the undisturbed caliche.
2) Establishing a 4:1 horizontal to vertical slope ratio along the sides to deter veneer failure. The majority of the slopes are constructed at a three percent grade outward from the center crown to prevent ponding.
3) After contouring, the SPDV pile was capped with a Claymax geosynthetic clay liner encompassing nearly 319,000 square feet. The liner is on top of six inches of native material screened to a maximum of 3/4" in diameter.
4) After the liner was placed, a minimum of three feet of soil rooting medium consisting of 15% (by weight) 1/2" crushed rock was added to minimize wind erosion.
5) The entire reclaimed SPDV pile was seeded with shallow rooted plants, which have been successfully established.
6) The reclaimed SPDV is regularly inspected, monitored and maintained.

The reclaimed SPDV pile is unlikely to discharge to the groundwater due to the capping installed during reclamation and the fact that no brine liquid was added to the pile. However, as set forth in DP-831 Additional Potential Contamination Sources (Tab 1), additional groundwater monitoring piezometers will be installed down gradient from the SPDV pile.

D. <u>Underground Hazardous Waste Disposal Units, the Underground Respository, the Waste Handling Building Unit, Parking Area Unit, and Boreholes.</u>

The Underground Hazardous Waste Disposal Units (HWDUs), the Repository, the Waste Handling Building (WHB) unit, and the Parking area unit will be closed pursuant to the requirements of HWFP Attachment I (Tab 3), HWFP Module II, Section II.L, HWFP Module III, Section III.H, and HWFP Module VI, Section VI.I. Post-closure groundwater monitoring will be conducted pursuant to HWFP Modules V and VI and HWFP Attachment L, the WIPP Groundwater Monitoring Plan. All boreholes will be closed pursuant to Table I-3 of HWFP Attachment I (Tab 3).

E. Other DP-831 Facility Components

DP-831 Additional Potential Contamination Sources (Tab 1) identifies "additional potential contamination sources at the WIPP facility." Tables I and II (Tab 4) provide a summary of the WIPP Solid Waste Management Units (SWMUs) included in the WIPP HWFP. Any facility components that have not been previously discussed in this Closure Plan will be closed pursuant to HWFP Attachment I (Tab 3), the FEIS and the final CRA that will be prepared during the final three years of the project.

As indicated in Table I (Tab 4), a number of the SWMUs have received a "no further action" (NFA) determination by the NMED Hazardous Waste Bureau (HWB), as set forth in the "Technical Support Document Exclusion/Inclusion of Solid Waste Management Units and Areas of Concern, Proposed Final Permit Module VII, Corrective Action for Solid Waste Management Units," NMED, June 25, 1999 ("June 25, 1999 Technical Support Document"). For the SWMUs identified in Table II (Tab 4), NMED requested further sampling and analysis, which was completed in August, 2002. In October, 2002, the "No Further Action Report (NFA) and Petition" was submitted to the HWB. Upon approval of the report by NMED, a permit modification request will be submitted to the HWB requesting that the SWMUs be removed from Module VII of the WIPP HWFP.

The DOE requests that the GWQB recognize and/or accept the NFA determinations made by the HWB in the June 25, 1999, Technical Support Document and any NFA determinations that will be made by the HWB, based on the DOE's October 2002, submittal to the HWB, or any subsequent submittals reviewed and addressed pursuant to applicable HWB regulations. The DOE further requests that the GWQB determine that the no further closure activity is required under DP-831 for the SWMUs that have received NFA determinations from the HWB.

F. Groundwater Impacts and Monitoring

a. Operational Phase: The following groundwater and storm water controls, as described in the current DP-831 and supporting documents, have been or are being implemented at the WIPP facility:

- Synthetic liner covering the Salt Pile;
- Placement of salt on a synthetically lined system with stormwater/leachate collection system (Salt Storage Extension System);
- One synthetically lined evaporation pond (Salt Storage Evaporation Basin) for the collection of salt contact water from Cell A of the Salt Storage Extension;
- Synthetically lined conveyance ditches around the Salt Pile, which discharge to the Salt Pile Evaporation Pond;
- Four synthetically lined storm water evaporation ponds (the Salt Pile Evaporation Pond, Evaporation Basin A, and Evaporation Basins 1 and 2), H-19 evaporation pond and seven sewage lagoon ponds;
- Storm water overland flow diversion berms;
- Salt placement procedures and active monitoring programs.

Monitoring of the shallow subsurface water is currently being performed at WIPP. The Shallow Subsurface Water (SSW) DP-831 monitoring and sampling network, set forth in the current DP-831, consists of water level monitoring on a quarterly basis and SSW sampling and analysis on a semi-annual basis.

Additional groundwater monitoring associated with the SPDV pile is proposed in DP-831 Additional Potential Contamination Sources (Tab 1) and will be incorporated in the existing SSW-DP-831. No groundwater impacts are expected from the Solid Waste Management Units (SWMUs) identified in Tables I and II (Tab 4) and no additional groundwater monitoring is proposed.

b. Closure: As required by the Standard Closure Requirement 6.d.ii, post closure groundwater monitoring for the WIPP facility will be conducted at the frequency and locations under the active permit for a period approved by NMED. If Regulation 20.6.2.3103 NMAC groundwater standards are violated or toxic pollutants are present during post closure monitoring, the WIPP will implement the contingency plan required in the active permit.

In addition to the SSW DP-831 monitoring and sampling, the WIPP facility conducts groundwater monitoring pursuant to the HWFP Attachment L, "WIPP Ground-Water Detection Monitoring Program Plan." As required by the HWFP,

> "Post-closure groundwater monitoring will involve a continuation of the monitoring plan in Permit Attachment L as described in Module V. The sampling frequency may be changed to biannually after final facility closure is complete by modification of the Permit as approved by the Secretary of the NMED in accordance with 20.4.1.901.B NMAC (incorporating 40 CFR §270.42). In addition, the final target analyte list specified in Permit Attachment L may be changed by permit modification based on final volume of waste."

ATTACHMENT I

CLOSURE PLAN

Introduction

This Permit Attachment contains the Closure Plan that describes the activities necessary to close the Waste Isolation Pilot Plant (**WIPP**) individual units and facility. Since the current plans for operations extend over several decades, the Permittees will periodically reapply for an operating permit in accordance with Title 20 of the New Mexico Administrative Code, Chapter 4, Part 1 (**20.4.1 NMAC**), Subpart 900 (incorporating 40 CFR §270.10(h)). Consequently, this Closure Plan describes several types of closures. The first type is panel closure, which occurs as underground hazardous waste disposal units (**HWDUs**) are filled. Final closure at the end of the Disposal Phase will entail "clean" closure of the two storage units on the surface and construction of the four shaft seal systems. Finally, in the event a new permit is not issued prior to expiration of an existing permit, a modification to this Closure Plan will be sought to perform contingency closure. Contingency closure defers the final closure of waste management facilities such as the Waste Handling Building Container Storage Unit (**WHB Unit**), the conveyances, the shafts, and the haulage ways because these will be needed to continue operations with non-mixed Transuranic (**TRU**) waste.

The hazardous waste management units (**HWMUs**) addressed in this Closure Plan include the aboveground HWMU in the WHB, the parking area HWMU, and Panels 1 through 8, each consisting of seven rooms. In addition, the disposal area access drifts shown as E-300, E-140, W-30, and W-170 between S-1600 and S-3650 on Figure I-1 may, at some time in the future, be needed for waste disposal. These access drifts, if used for disposal, are also subject to this Closure Plan.

This plan was submitted to the New Mexico Environment Department (**NMED**) and the U.S. Environmental Protection Agency (**EPA**) in accordance with 20.4.1.900 NMAC (incorporating 40 CFR §270.14(b)(13)). Closure at the panel level will include the construction of barriers to limit the emission of hazardous waste constituents from the panel into the mine ventilation air stream below levels that meet environmental performance standards[1] and to mitigate the impacts of methane buildup and deflagration that may be postulated for some closed panels. The Post-Closure Plan (Permit Attachment J) includes the implementation of institutional controls to limit

[1] The mechanism for air emissions prior to closure is different than the mechanism after closure. Prior to closure, volatile organic compounds (VOC) will diffuse through drum filters based on the concentration gradient between the disposal room and the drum headspace. These VOCs are swept away by the ventilation system, thereby maintaining a concentration gradient that is assumed to be constant. Hence, the VOCs in the ventilation stream are a function of the number of containers only. After closure, the panel air will reach an equilibrium concentration with the drum headspace and no more diffusion will occur. The only mechanism for release into the mine ventilation system is due to pressure that builds up in the closed panel. This pressure arises from the creep closure mechanism that is reducing the volume of the rooms and from the postulated generation of gas as the result of microbial degradation of organic matter in the waste. Consequently, the emissions after panel closure are a direct function of pressurization processes and rates within the panel.

access and groundwater monitoring to assess disposal system performance. Until final closure is complete and has been certified in accordance with 20.4.1.500 NMAC (incorporating 40 CFR §264.115), a copy of the approved Closure Plan and all approved revisions will be on file at the WIPP facility and will be available to the Secretary of the NMED or the EPA Region VI Administrator upon request.

I-1 Closure Plan

This Closure Plan is prepared in accordance with the requirements of 20.4.1.500 NMAC (incorporating 40 CFR §264 Subparts G, I, and X), Closure and Post-Closure, Use and Management of Containers, and Miscellaneous Units. The WIPP underground HWDUs, including Panels 1 through 8 and the disposal area access drifts, designated as Panels 9 and 10 on Figure I-1, will be closed to meet the performance standards in 20.4.1.500 NMAC (incorporating 40 CFR §264.601). The WIPP surface facilities, including Waste Handling Building Container Storage Unit and the Parking Area Container Storage Unit, will be closed in accordance with 20.4.1.500 NMAC (incorporating 40 CFR §264.178). For final facility closure, this plan also includes closure and sealing of the facility shafts in accordance with 20.4.1.500 NMAC (incorporating 40 CFR §264.601).

Following completion of waste emplacement in each underground HWDU, the HWDU will be closed. The Permittees will notify the NMED of the closure of each underground HWDU as specified in the schedule in Figure I-2. For the purpose of this Closure Plan, panel closure is defined as the process of rendering underground HWDUs in the repository inactive and closed according to the facility Closure Plan. The Post-Closure Plan (Permit Attachment J) addresses requirements for future monitoring that are deemed necessary for the post-closure period, including monitoring closed panels prior to final facility closure.

For the purposes of this Closure Plan, final facility closure is defined as closure that will occur when all waste disposal areas are filled or when the WIPP achieves its capacity of 6.2 million cubic feet (ft^3) (175,600 cubic meters (m^3)) of TRU waste. At final facility closure, the surface container storage areas will be closed, and equipment that can be decontaminated and used at other facilities will be cleaned and sent off site. Equipment that cannot be decontaminated plus any derived waste resulting from decontamination will be placed in the last open underground HWDU. Stockpiled salt may be placed in the underground; it may be used as the core material for the berm component of the permanent marker system; or it must be otherwise disposed of in accordance with Sections 2 and 3 of the Minerals Act of 1947 (30 U.S.C. §§602 and 603). In addition, shafts and boreholes which lie within the WIPP Site Boundary and penetrate the Salado will be plugged and sealed, and surface and subsurface facilities and equipment will be decontaminated and removed. Final facility closure will be completed to demonstrate compliance with the Closure Performance Standards contained in 20.4.1.500 NMAC (incorporating 40 CFR §264.111, 178, and 601).

In the event the Permittees fail to obtain an extension of the hazardous waste permit in accordance with 20.4.1.900 NMAC (incorporating 40 CFR §270.51) or fail to obtain a new permit in accordance with 20.4.1.900 NMAC (incorporating 40 CFR §270.10(h)), the Permittees will seek a modification to this Closure Plan in accordance with 20.4.1.900 NMAC (incorporating 40 CFR 270.42) to accommodate a contingency closure. Under contingency closure, storage units will undergo clean closure in accordance with 20.4.1.500 NMAC (incorporating 40 CFR

§264.178) waste handling equipment, shafts, and haulage ways will be inspected for hazardous waste residues (using, among other techniques, radiological surveys to indicate potential hazardous waste releases as described in Permit Attachment I3) and decontaminated as necessary, and underground HWDUs that contain radioactive mixed waste will be closed in accordance with the panel closure design described in this Closure Plan. Final facility closure, however, will be redefined and a request for a time extension for final closure will be requested. A copy of this Closure Plan will be maintained by the Permittees at the WIPP facility and at the Department of Energy (DOE) Carlsbad Field Office. The primary contact person at the WIPP facility is:

Manager, Carlsbad Field Office
U.S. Department of Energy
Waste Isolation Pilot Plant
P. O. Box 3090
Carlsbad, New Mexico 88221-3090
(505) 234-7300

I-1a Closure Performance Standard

The closure performance standard specified in 20.4.1.500 NMAC (incorporating 40 CFR §264.111), states that the closure shall be performed in a manner that minimizes the need for further maintenance; that minimizes, controls, or eliminates the escape of hazardous waste; and that conforms to the closure requirements of §264.178 and §264.601. These standards are discussed in the following paragraphs.

I-1a(1) Container Storage Units

Closure of the permitted container storage units (the Waste Handling Building Unit and Parking Area Unit) will be accomplished by removing all waste and waste residues. Indication of waste contamination will be based, among other techniques, on the use of radiological surveys as described in Permit Attachment I3. Radiological surveys use very sensitive radiation detection equipment to indicate if there has been a potential release of TRU mixed waste, including hazardous waste components, from a container. This allows the Permittees to indicate potential releases that are not detectable from visible evidence such as stains or discoloration. Visual inspection and operating records will also be used to identify areas where decontamination is necessary. Contaminated surfaces will be decontaminated until radioactivity is below free release limits[2]. Once surfaces are determined to be free of radioactive waste constituents, they will be tested for hazardous waste contamination. These surface decontamination activities will ensure the removal of waste residues to levels protective of human health and the environment. The facility is expected to require no decontamination at closure because any waste spilled or released during operations will be contained and removed immediately. Solid waste management units associated described in Permit Module VII will be subject to closure. In the event portions of these units which require decontamination cannot be decontaminated, these portions will be removed and the resultant wastes will be managed as appropriately.

[2] The free release criteria for items, equipment, and areas is < 20 dpm/100 cm^2 for alpha radioactivity and < 200 dpm/100 cm^2 for beta-gamma radioactivity.

Once the container storage units are decontaminated and certified by the Permittees to be clean, no further maintenance is required. The facilities and equipment in these units will be reused for other purposes as needed.

I-1a(2) Miscellaneous Unit

Post-closure migration of hazardous waste or hazardous waste constituents to ground or surface waters or to the atmosphere, above levels that will harm human health or the environment, will not occur due to facility engineering and the geological isolation of the unit. The engineering aspects of closure are centered on the use of panel closures on each of the underground HWDUs and final facility seals placed in the shafts. The design of the panel closure system is based on the criteria that the closure system for closed underground HWDUs will prevent migration of hazardous waste constituents in the air pathway in concentrations above health-based levels beyond the WIPP land withdrawal boundary during the thirty-five (35) year operational and facility closure period and to withstand any flammable gas deflagration that may occur prior to final facility closure.

Consistent with the definitions in 20.4.1.101 NMAC (incorporating 40 CFR §260.10), the process of panel closure is considered partial closure because it is a process of rendering a part of the repository inactive and closed according to the approved underground HWDU partial closure plan. Panel closure will be complete when the panel closure system is emplaced and operational, when that underground HWDU and related equipment and structures have been decontaminated (if necessary), and when the NMED has been notified of the closure.

Shaft seals are designed to provide effective barriers to the inward migration of ground water and the outward migration of gas and contaminated brine over two discrete time periods. Several components become effective immediately and are expected to function for one hundred (100) years. Other components become effective more slowly, but provide permanent isolation of the waste. The final shaft seal design is specified in Permit Attachment I2.

The facility will be finally closed (i.e., decontaminated and decommissioned) to minimize the need for continued maintenance. Protection of human health and the environment includes, but is not limited to:

- Prevention of any releases that may have adverse effects on human health or the environment due to the migration of waste constituents in the groundwater or in the subsurface environment [20.4.1.500 NMAC, incorporating 40 CFR §264.601(a)].

- Prevention of any releases that may have adverse effects on human health or the environment due to migration of waste constituents in surface water, in wetlands, or on the soil surface [20.4.1.500 NMAC, incorporating 40 CFR §264.601(b)].

- Prevention of any release that may have adverse effects on human health or the environment due to migration of waste constituents in the air [20.4.1.500 NMAC, incorporating 40 CFR §264.601(c)].

As part of final facility closure, surface recontouring and reclamation will establish a stable vegetative cover, and further surface maintenance will not be necessary to protect human health and the environment. Prior to cessation of active controls, monuments will be emplaced to serve as long-term site markers to discourage activities that would penetrate the facility or impair the ability of the salt formation to isolate the waste from the surface environment for at least 10,000 years. The Federal government will maintain administrative responsibility for the repository site in perpetuity and will limit future use of the area.

If, during panel or final facility closure activities, unexpected events require modification of this Closure Plan to demonstrate compliance with closure performance standards, a Closure Plan amendment will be submitted in accordance with 20.4.1.900 NMAC (incorporating 40 CFR §270.42).

I-1a(3) Post-Closure Care

The post-closure care period will begin after completion of the first panel closure and will continue for thirty (30) years after final facility closure. The post-closure care period may be shortened or lengthened at the discretion of the regulatory agency based on evidence that human health and the environment are being protected or that they are at risk. During the post-closure period, the WIPP shall be maintained in a manner that complies with the environmental performance standards in 20.4.1.500 NMAC (incorporating 40 CFR §264.601). Post-closure activities are described in Permit Attachment J.

I-1b Requirements

The Permit specifies a sequential process for the closure of individual HWMUs at the WIPP. Each underground HWDU will undergo panel closure when waste emplacement in that panel is complete. Following waste emplacement in each underground HWDU, construction-side ventilation will be terminated and waste-disposal-side ventilation will be established in the next underground HWDU to be used, and the underground HWDU containing the waste will be closed. The Permittees will notify the NMED of the closure of each of the underground HWDUs as they are sequentially filled on a HWDU-by-HWDU basis. The HWMUs in the WHB and in the parking area will be closed as part of final facility closure of the WIPP facility.

The Permittees will notify the Secretary of the NMED in writing at least sixty (60) days prior to the date on which closure activities are scheduled to begin.

I-1c Maximum Waste Inventory

The WIPP will receive no more than 6.2 million ft^3 (175,600 m^3) of TRU mixed waste. Excavations are mined as permitted when needed during operations to maintain a reserve of disposal areas. The amount of waste placed in each room is limited by structural and physical considerations of equipment and design. Waste volumes include waste received from off-site generator locations as well as derived waste from disposal and decontamination operations. Maximum waste volumes in the disposal panels are calculated as follows: for 100 percent 55-gallon drums--11,502 7-packs consisting of 80,514 drums and 591,800 ft^3 (16,760 m^3) of waste; for 100 percent standard waste boxes (**SWB**)--11,580 SWBs and 767,750 ft^3 (21,740 m^3) of waste. Since the waste can arrive in any combination of 7-packs and SWBs, a fixed volume is not set for each panel. Furthermore, the placement of backfill materials to modify chemical nature of brines over the long-term will likely result in fewer containers per panel as described in Permit Attachment M2. For planning purposes, a maximum achievable volume is used. This equates to 662,400 ft^3 (18,750 m^3) of contact handled (**CH**) TRU per panel. 81,000 containers were assumed in design calculations since, for air dispersion modeling, it is important to maximize the number of container vents through which volatile organic compounds (**VOC**) may be released. In reality, using the 40 percent-60 percent mix, there would be only 51,000 containers in a panel, containing 56,000 vents (2 vents per SWB).

The maximum extent of operations during the term of this permit is expected to be Panels 1 through 4 and Panels 9 and 10 as shown on Figure I-1, the WHB Container Storage Unit, and the Parking Area Container Storage Unit. Note that panels 4, 9, and 10 are scheduled for excavation only under this permit. If other waste management units are permitted during the Disposal Phase, this Closure Plan will be revised to include the additional waste management units. At any given time during disposal operations, it is possible that two rooms may be receiving waste for disposal at the same time. Underground HWDUs in which disposal has been completed (i.e., in which CH TRU mixed waste emplacement activities have ceased) will undergo panel closure.

I-1d Schedule for Closure

For the purpose of establishing a schedule for closure, an operating and closure period of no more than thirty-five (35) years (twenty-five (25) years for disposal operations and ten (10) years for closure) is assumed. This operating period may be extended or shortened depending on a number of factors, including the rate of waste approved for shipment to the WIPP facility and the schedules of TRU mixed waste generator sites, and future decommissioning activities.

I-1d(1) Schedule for Panel Closure

The anticipated schedule for the closure of the underground HWDUs known as Panels 2 through 8 is shown in Figure I-2. This schedule assumes there will be little contamination within the exhaust drift of the panel. The following assumptions are made in estimating the time that closure will be initiated at each underground HWDU: waste operations are assumed to begin in July 1998 for planning purposes; throughput for CH waste is 784 drums per week (7 pallets per day, 4 days per week, 28 drums per pallet); and the capacity of a panel is 81,000 drums. Under these assumptions, a minimum of 104 weeks is needed to emplace the waste. Allowing a 25 percent contingency for maintenance delays and time to transition from one room to another, it is estimated that a panel will be filled 2.5 years after emplacement is initiated. This means that underground HWDUs will be ready for closure according to the schedule in Table I-1. These dates are estimates for planning and permitting purposes. Actual dates may vary depending on the availability of waste from the generator sites. Waste availability at maximum throughput is not anticipated immediately as assumed here.

In the schedule in Figure I-2, notification of intent to close occurs thirty (30) days before placing the final waste in a panel. Once a panel is full, the Permittees will initially block ventilation through the panel as described in Permit Attachment M2 and then will assess the closure area for ground conditions and contamination so that a definitive schedule and closure design can be determined. If as the result of this assessment the Permittees determine that a panel closure cannot be emplaced in accordance with the schedule in this Closure Plan, a modification will be submitted requesting an extension to the time for closure.

The Permittees will initially block ventilation through Panel 1 as described in Permit Attachment M2 once Panel 1 is full to ensure continued protection of human health and the environment. The Permittees will then install the explosion isolation wall portion of the panel closure system that is described in Permit Attachment I1, Section 3.3.2, Explosion-and Construction-Isolation Walls. Construction of the explosion isolation wall will not exceed 180 days after the last receipt of waste in Panel 1. Final closure of Panel 1 will be completed as specified in this Permit no later than five years after completion of the explosion isolation wall.

I-1d(2) Schedule for Final Facility Closure

The Disposal Phase for the WIPP facility is expected to require a period of twenty-five (25) years beginning with the first receipt of TRU waste at the WIPP facility and followed by a period ranging from seven to ten (7-10) years for decontamination, decommissioning, and final closure. Assuming the first waste receipt occurs in July 1998, the Disposal Phase may extend until 2023, and so the latest expected year of final closure of the WIPP facility (i.e., date of final closure certification) would be 2033. If, as is currently projected, the WIPP facility is dismantled at closure, all surface and subsurface facilities (except the hot cell portion of the WHB, which will remain as an artifact of the Permanent Marker System [**PMS**]) will be disassembled and either salvaged or disposed in accordance with applicable standards. In addition, asphalt and crushed caliche that was used for paving will be removed, and the area will be recontoured and revegetated in accordance with a land management plan. A detailed closure schedule will be submitted in writing to the Secretary of the NMED, along with the notification of closure. Throughout the closure period, all necessary steps will be taken to prevent threats to human health and the environment in compliance with all applicable Resource Conservation and Recovery Act (**RCRA**) permit requirements. Figure I-3 presents the best estimate of a final facility closure schedule.

The schedule for final facility closure is considered to be a best estimate because closure of the facility is driven by policies and practices established for the decontamination, if necessary, and decommissioning of radioactively contaminated facilities. These required activities include extensive radiological contamination surveys and hazardous constituent surveys using, among other techniques, radiological surveys to indicate potential hazardous waste releases. Both types of surveys will be performed at all areas of the WIPP site where hazardous waste were managed. These surveys, along with historical radiological survey records, will provide the basis for release of structures, equipment, and components for disposal or decontamination for release off site. Specifications will be developed for each structure to be removed. A cost benefit analysis will be needed to evaluate decontamination options if extensive decontamination is necessary. Individual equipment surveys, structure surveys, and debris surveys will be required prior to disposition. Size-reduction techniques may be required to dispose of mixed or radioactive waste at the WIPP site. Current DOE policy, as reflected in the WIPP facility Safety Analysis Report (**SAR**) (DOE 1997), requires the preparation of a final decommissioning and decontamination (**D&D**) plan immediately prior to final facility closure. In this way, the specific conditions of the facility at the time D&D is initiated will be addressed. Section I-1e(2) provides a more detailed discussion of final facility closure activities.

Figure I-3 shows the schedule for the final facility closure consisting of decontamination, as needed, of the TRU waste-handling equipment, and of the aboveground equipment and facilities, including closure of surface HWMUs; decontamination of the shaft and haulage ways; disposal of decontamination derived wastes in the last open underground HWDU; and subsequent closure of this underground HWDU. Subsequent activities will include installation of repository shaft seals.

An overall schedule for final facility closure, showing currently scheduled dates for the start and end of final facility closure activities is shown in Table I-2. The dates assume a start up date of March 1999 and hazardous waste permit effective dates of September 1999, September 2009, and September 2019. Details for panel closures are shown on Table I-1.

I-1d(3) Extension for Closure Time

As indicated by the closure schedule presented in Figure I-3, the activities necessary to perform facility closure of the WIPP facility will require more than one hundred eighty (180) days to complete because of additional stringent requirements for managing radioactive materials. Therefore, the Permit provides an extension of the 180-day final closure requirement in accordance with 20.4.1.500 NMAC (incorporating 40 CFR §264.113). During the extended closure period, the Permittees will continue to demonstrate compliance with applicable permit requirements and will take all steps necessary to prevent threats to human health and the environment as a result of TRU mixed waste management at the WIPP facility including all of the applicable measures in Permit Attachment E (Preparedness and Prevention).

In addition, according to the schedules in Figure I-3, the final derived wastes that are generated as the result of decontamination activities will not be disposed of for sixteen (16) months after the initiation of final facility closure. In accordance with 20.4.1.500 NMAC (incorporating 40 CFR §264.113(a)), the Permit provides an extension of the 90-day limit to dispose of final derived waste resulting from the closure process. This provision is necessitated by the fact that the radioactive nature of the derived waste makes placement in the WIPP the best disposition, and the removal of these wastes will, by necessity, take longer than ninety (90) days in accordance with the closure schedules. During this extended period of time, the Permittees will take all steps necessary to prevent threats to human health and the environment, including compliance with all applicable permit requirements. These steps include all of the applicable preparedness and prevention measures in Permit Attachment E.

Finally, in the event the hazardous waste permit is not renewed as assumed in the schedule, the Permittees will submit a modification to the Closure Plan to implement a contingency closure that will allow the Permittees to continue to operate for the disposal of non-mixed TRU waste. This modification will include a request for an extension of the time for final facility closure. This modified Closure Plan will be submitted to the NMED for approval.

I-1d(4) Amendment of the Closure Plan

If it becomes necessary to amend the Closure Plan for the WIPP facility, the Permittees will submit, in accordance with 20.4.1.900 NMAC (incorporating 40 CFR §270.42), a written notification of or request for a permit modification describing any change in operation or facility design that affects the Closure Plan. The written notification or request will include a copy of the amended Closure Plan for approval by the NMED. The Permittees will submit a written notification of or request for a permit modification to authorize a change in the approved plan, if:

- There are changes in operating plans or in the waste management unit facility design that affect the Closure Plan
- There is a change in the expected year of closure
- Unexpected events occur during panel or final facility closure that require modification of the approved Closure Plan
- Changes in State or Federal laws affect the Closure Plan
- Permittees fail to obtain permits for continued operations as discussed above

The Permittees will submit a written request for a permit modification with a copy of the amended Closure Plan at least sixty (60) days prior to the proposed change in facility design or operation or within sixty (60) days of the occurrence of an unexpected event that affects the Closure Plan. If the unexpected event occurs during final closure, the permit modification will be requested within thirty (30) days of the occurrence. If the Secretary of the NMED requests a modification of the Closure Plan, a plan modified in accordance with the request will be submitted within sixty (60) days of notification or within thirty (30) days, if the change in facility condition occurs during final closure.

I-1e Closure Activities

Closure activities include those instituted for panel closure (i.e., closure of filled underground HWDUs), contingency closure (i.e., closure of surface HWMUs and decontamination of other waste handling areas), and final facility closure (i.e., closure of surface HWMUs, D&D of surface facilities and the areas surrounding the WHB, and placement of repository shaft seals). Panel closure systems will be emplaced to separate areas of the facility and to isolate panels. Permit Attachments I1 and I2 provide panel closure system and shaft seal designs. All closure activities will meet the applicable quality assurance (QA)/quality control (QC) program standards in place at the WIPP facility. Facility monitoring procedures in place during operations will remain in place through final closure, as applicable.

I-1e(1) Panel Closure

Following completion of waste emplacement in each underground HWDU, disposal-side ventilation will be established in the next panel to be used, and the panel containing the waste will be closed. A panel closure system will be emplaced in the panel access drifts, in accordance with the design in Permit Attachment I1 and the schedule in Figure I-2 and Table I-1. The panel closure system is designed to meet the following requirements that were established by the DOE for the design to comply with 20.4.1.500 NMAC (incorporating 40 CFR §264.601(a)):

- the panel closure system shall limit the migration of VOCs to the compliance point so that compliance is achieved by at least one order of magnitude

- the panel closure system shall consider potential flow of VOCs through the disturbed rock zone (DRZ) in addition to flow through closure components
- the panel closure system shall perform its intended functions under loads generated by creep closure of the tunnels
- the panel closure system shall perform its intended function under the conditions of a postulated methane explosion
- the nominal operational life of the closure system is thirty-five (35) years
- the panel closure system for each individual panel shall not require routine maintenance during its operational life
- the panel closure system shall address the most severe ground conditions expected in the waste disposal area
- the design class of the panel closure system shall be IIIb (which means that it is to be built to generally accepted national design and construction standards)
- the design and construction shall follow conventional mining practices
- structural analysis shall use data acquired from the WIPP underground
- materials shall be compatible with their emplacement environment and function
- treatment of surfaces in the closure areas shall be considered in the design
- thermal cracking of concrete shall be addressed
- during construction, a QA/QC program shall be established to verify material properties and construction practices
- construction of the panel closure system shall consider shaft and underground access and services for materials handling

The performance standard for air emissions from the WIPP facility is established in Module IV and Permit Attachment M2. Releases shall be below these limits for the facility to remain in compliance with standards to protect human health and the environment. The following panel closure design has been shown, through analysis, to meet these standards, if emplaced in accordance with the specifications in Permit Attachment I1.

The approved design for the panel closure system calls for a composite panel barrier system consisting of a rigid concrete plug with removal of the DRZ, and an explosion-isolation wall. The design basis for this closure is such that the migration of hazardous waste constituents from closed panels during the operational and closure period would result in concentrations well below health-based standards. The source term used as the design basis included the average concentrations of VOCs from CH waste containers as measured in headspace gases through

January 1995. The VOCs are assumed to have been released by diffusion through the container vents and are assumed to be in equilibrium with the air in the panel. Emissions from the closed panel occur at a rate determined by gas generation within the waste and creep closure of the panel.

Figures I-4 and I-5 show a diagram of the panel closure design and installation envelopes. Permit Attachment I1 provides the detailed design and the design analysis for the panel closure system. Although the permit application proposed several panel closure design options, depending on the gas generated by wastes and the age of the mined openings, the NMED and EPA determined that only the most robust design option (D) would be approved. This decision does not prevent the Permittees from continuing to collect data on the behavior of the wastes and mined openings, or proposing a modification to the Closure Plan in the future, using the available data to support a request for reconsideration of one or more of the original design options. If a design different from Option D as defined in Permit Attachment I1 is proposed, the appropriate permit modification will be sought.

I-1e(2) Decontamination and Decommissioning

Decontamination is defined as those activities which are performed to remove contamination from surfaces and equipment that are not intended to be disposed of at the WIPP facility. The policy at the WIPP will be to decontaminate as many areas as possible, consistent with radiation protection policy. Decontamination is part of all closure activities and is a necessary activity in the clean closure of the surface container management units. Decontamination determinations are based upon radiological and hazardous constituent surveys.

Decommissioning is the process of removing equipment, facilities, or surface areas from further use and closing the facility. Decommissioning is part of final facility closure only and will involve the removal of equipment, buildings, closure of the shafts, and establishing active and passive institutional controls for the facility. Passive institutional controls are not included in the Permit.

The objective of D&D activities at the WIPP facility is to return the surface to as close to the preconstruction condition as reasonably possible, while protecting the health and safety of the public and the environment. Major activities required to accomplish this objective include, but are not limited to the following:

1. Review of operational records for historical information on releases

2. Visual examination of surface structures for evidence of spills or releases

3. Performance of site contamination surveys

4. Decontamination, if necessary, of usable equipment, materials, and structures including surface facilities and areas surrounding the WHB.

5. Disposal of equipment/materials that cannot be decontaminated but that meet the treatment, storage, and disposal facility waste acceptance criteria (TSDF-WAC) in an underground HWDU

6. Emplacement of final panel closure system

7. Emplacement of shaft seals[3]

8. Regrading the surface to approximately original contours

9. Initiation of active controls

This Closure Plan will be amended prior to the initiation of closure activities to specify the methods to be used.

Health and Safety

Before final closure activities begin, health physics personnel will conduct a hazards survey of the unit(s) being closed. A release of radionuclides could also indicate a release of hazardous constituents. If radionuclides are not detected, sampling for hazardous constituents will still be performed if there is documentation or visible evidence that a spill or release has occurred. The purpose of the hazards survey will be to identify potential contamination concerns that may present hazards to workers during the closure activities and to specify any control measures necessary to reduce worker risk. This survey will provide the information necessary for the health physics personnel to identify worker qualifications, personal protective equipment (PPE), safety awareness, work permits, exposure control programs, and emergency coordination that will be required to perform closure related activities.

I-1e(2)(a) Determine the Extent of Contamination

The first activities performed as part of decontamination include those needed to determine the extent of any contamination that needs to be removed prior to decommissioning a facility. This includes activities 1 to 3 above and, as can be seen by the schedules in Figures I-3 and I-4 (Items B and C), these surveys are anticipated to take ten (10) months to perform, including obtaining the results of any sample analyses. The process of identifying areas that require decontamination include three sources of information. First, operating records will be reviewed to determine where contamination has previously been found as the result of historical releases and spills. Even though releases and spills will have been cleaned up at the time of occurrence, newer equipment and technology may allow further cleaning. Second, surfaces of facilities and structures will be examined visually for evidence of spills or releases. Finally, extensive detailed contamination surveys will be performed to document the level of cleanliness for all surface structures and equipment. If equipment or areas are identified as contaminated, the Permittees will notify NMED as specified in Permit Module I, and a plan and procedure(s) will be developed and implemented to address decontamination-related questions, including:

- Should the component be decontaminated or disposed of as waste?
- What is the most cost-effective method of decontaminating the component?

[3] For the purposes of planning, the conclusion of shaft sealing is used by the DOE as the end of closure activities and the beginning of the Post-Closure Care Period.

- Will the decontamination procedures adequately contain the contamination?

Radiological and hazardous constituent surveys will be used in determining the presence of hazardous waste and hazardous waste residues in areas where spills or releases have occurred. Radiological surveys are described in Permit Attachment I3. Once cleanup of the radioactivity has been completed, the surface will be sampled for hazardous constituents specified in Permit Attachment O to determine that they, too, have been cleaned up. Sampling and analysis protocols will be consistent with EPA's document SW-846 (EPA, 1996).

I-1e(2)(b) Decontamination Activities

Once the extent of contamination is known, decontamination activities will be planned and performed. Radiological control and the control of hazardous waste residues are the primary criteria used in the design of decontamination activities. Radiation control procedures require that careful planning and execution be used in decontamination activities to prevent the exposure of workers beyond applicable standards and to prevent the further spread of contamination. Careful control of entry, cleanup, and ventilation are vital components of radiation decontamination. The level of care mandated by DOE orders and occupational protection requirements results in closure activities that will exceed the one hundred eighty (180) days allowed in 20.4.1.500 NMAC (incorporating 40 CFR §264.113(b)). Decontamination activities are included as item 4 above and are shown on the schedules for contingency closure and final facility closure (Figures I-3 and I-4) as activities D, E, and F. These activities are anticipated to have a duration of twenty (20) months for both contingency closure and for final facility closure. The result of these activities is the clean closure of the surface container management units. Under contingency closure, the other areas that have been decontaminated will not be closed. Instead they will remain in use for continued waste management activities involving non-mixed waste. Under final facility closure, other areas that are decontaminated are eligible for closure.

The "Start Clean—Stay Clean" operating philosophy of the WIPP Project will provide for minimum need for decontamination. However, the need for decontamination techniques may arise.

Decontamination activities will be coordinated with closure activities so that areas that have been decontaminated will not be recontaminated. All waste resulting from decontamination activities will be surveyed and analyzed for the presence of radioactive contamination and hazardous constituents specified in Permit Attachment O. The waste will be characterized as hazardous, mixed, or radioactive and will be packaged and handled appropriately. Mixed and radioactive waste will be classified as TRU mixed waste managed in accordance with the applicable Permit requirements. Derived mixed waste collected during decontamination activities that are generated before repository shafts have been sealed will be emplaced in the facility, if appropriate, or will be managed together with decontamination derived waste collected after the underground is closed. This waste will be classified and shipped off site to an appropriate, permitted facility for treatment, if necessary, and for disposal.

Removal of Hazardous Waste Residues

Because of the type of waste management activities that will occur at the WIPP facility, waste residues that may be encountered during the operation of the facility and at closure may include derived waste. Derived wastes result from the management of the waste containers or may be collected as part of the closure activities (such as those during which wipes were used to sample the containers and equipment for potential radioactive contamination or those involving solidified decontamination solutions, the handling of equipment designated for disposal, and the handling of residues collected as a result of spill cleanup). Derived wastes collected during the operation and closure of the WIPP facility will be identified and managed as TRU mixed wastes. These wastes will be disposed in the active underground HWDU. D&D derived wastes and equipment designated for disposal will be placed in the last underground HWDU panel before closure of that unit.

Surface Container Storage Units

The procedures employed for waste receipt at the WIPP facility minimize the likelihood for any waste spillage to occur outside the WHB. TRU mixed waste is shipped to the WIPP facility in approved shipping containers (i.e., Contact Handled Packages) that are not opened until they are inside the WHB. Therefore, it is unlikely that soil in the Parking Area Unit or elsewhere in the vicinity of the WHB will become contaminated with TRU mixed waste constituents as a result of TRU mixed waste management activities. An evaluation of the soils in the vicinity of the WHB will only be necessary if a documented event resulting in a release has occurred outside the WHB.

The "Start Clean—Stay Clean" operating philosophy of the WIPP Project will minimize the need for decontamination of the WHB during decommissioning and closure. Procedures for opening shipping containers in the WHB limit the opportunity for waste spillage.

Should the need for decontamination of the WHB arise, the following methods may be employed, as appropriate, for the hazardous constituent/contaminant type and extent:

- Chemical cleaning (e.g., water, mild detergent cleanser, and polyvinyl alcohol)
- Nonchemical cleaning (e.g., sandblasting, grinding, high-pressure water spray, scabbler pistons and needle scalers, ice-blast technology, dry-ice blasting)
- Removal of contaminated components such as pipe and ductwork

Waste generated as a result of WHB decontamination activities will be managed as derived waste in accordance with applicable permit requirements and will be emplaced in the last open underground HWDU for disposal.

Waste Handling Equipment and

The waste hoist conveyance and associated waste handling equipment will be decontaminated to background or be disposed as derived waste as part of both contingency and final facility closure. Procedures for detection and sampling will be as described above. Equipment cleanup will be as above using chemical or nonchemical techniques.

Personnel Decontamination

PPE worn by personnel performing closure activities in areas determined to be contaminated will be disposed of appropriately. Disposable PPE used in such areas will be placed into containers and managed as TRU mixed waste. Non-disposable PPE will be decontaminated, if possible. Non-disposable PPE that cannot be decontaminated will be managed as TRU mixed waste.

In accordance with DOE policy, TRU mixed waste PPE will be considered to be contaminated with all of the hazardous waste constituents contained in the containers that have been managed within the unit being closed. Wastes collected as a result of closure activities and that may be contaminated with radioactive and hazardous constituents will be considered TRU mixed wastes. These wastes will be managed as derived wastes, as described in Permit Attachment M2. Such waste, collected as the result of closure of the WIPP facility, will be disposed of in the final open underground HWDU.

Cleanup Criteria

Radiation decontamination will be less than or equal to the following levels, or to whatever lesser levels that may be established by DOE Order at the time of cleanup:

Contamination Type	Loose[4]	Fixed plus removable
alpha contamination (α)	20 dpm/100 cm^2	500 dpm/100 cm^2
beta-gamma contamination (β-γ)	200 dpm/100 cm^2	1000 dpm/100 cm^2

Hazardous waste decontamination will be conducted in accordance with standards in 20.4.1.500 NMAC (incorporating 40 CFR §264) or as incorporated into the Permit.

Final Contamination Sampling and Quality Assurance

Verification samples will be analyzed by an approved laboratory that has been qualified by the DOE according to a written program with strict criteria. The QA requirements of EPA/SW-846, "Test Methods for Evaluating Solid Waste" (EPA, 1986), will be met for hazardous constituent sampling and analyses.

[4] The unit "dpm" stands for "disintegration per minute" and is the rate of emission by radioactive material as determined by correcting the counts per minute observed by an appropriate detector for background, efficiency, and geometric factors associated with the instrumentation.

Quality Assurance/Quality Control

Because decisions about closure activities may be based, in part, on analyses of samples of potentially contaminated surfaces and media, a program to ensure reliability of analytical data is essential. Data reliability will be ensured by following a QA/QC program that mandates adequate precision and accuracy of laboratory analyses. Field documentation will be used to document the conditions under which each sample is collected. The documented QA/QC program in place at the WIPP facility will meet applicable RCRA QA requirements.

Field blanks and duplicate samples will be collected in the field to determine potential errors introduced in the data from sample collection and handling activities. To determine the potential for cross-contamination, rinsate blanks (consisting of rinsate from decontaminated sampling equipment) will be collected and analyzed. At least one rinsate blank will be collected for every 20 field samples. Duplicate samples will be collected at a frequency of one duplicate sample for every ten field samples. In no case will less than one rinsate blank or duplicate sample be collected for a field-sampling effort. These blank and duplicate samples will be identified and treated as separate samples. Acceptance criteria for QA/QC hazardous constituent sample analyses will adhere to the most recent version of EPA SW-846 or other applicable EPA guidance.

I-1e(2)(c) Dismantling

Final facility closure will include dismantling of structures on the surface and in the underground. These are items 6 and 7 above and are represented as Activity G in the final facility closure schedule in Figure I-4. During dismantling, priority will be given to contaminated structures and equipment that cannot be decontaminated to assure these are properly disposed of in the remaining open underground HWDU in a timely manner. All such facilities and equipment are expected to be removed and disposed of sixteen (16) months after the initiation of closure. Dismantling of the balance of the facility, including those structures and equipment that are not included in the application and are not used for TRU mixed waste management, is anticipated to take an additional sixty-six (66) months. It should be noted that the placement of D&D waste into the final underground HWDU may, by necessity, involve the placement of uncontainerized bulk materials such as concrete components, building framing, structural members, disassembled or partially disassembled equipment, or containerized materials in non-standard waste boxes. Such placement will only occur if it can be shown that it is protective of human health and the environment and all items are described in an amendment to the Closure Plan. Identification of bulk items is not possible at this time since their size and quantity will depend on the extent of non-removable contamination.

I-1e(2)(d) Closure of Open Underground HWDU

The closure of the final underground HWDU is shown by Activity H in Figure I-3. This closure will be consistent with the description in Section I-1e(1) and the design in Permit Attachment I1. Detailed closure schedules for underground HWDUs are given in Figure I-2 and Table I-1.

I-1e(2)(e) Final Facility Closure

Final facility closure includes several activities designed to assure both the short-term isolation of the waste and the long-term integrity of the disposal system. These include the placement of plugs in boreholes that penetrate the salt and the placement of the repository sealing system. In addition, the surface will be returned to as near its original condition as practicable, and will be readied for the construction of markers and monuments that will provide permanent marking of the repository location and contents.

Figure I-6 identifies where ten existing boreholes overlie the proximate area of the repository footprint. Of these identified boreholes in Figure I-6, all but ERDA-9 are terminated hundreds of feet above the repository horizon. Only ERDA-9, which is accounted for in long-term performance modeling, is drilled through the repository horizon, near the WIPP excavations.

To mitigate the potential for migration beyond the repository horizon, the DOE has specified that borehole seals be designed to limit the volume of water that could be introduced to the repository from the overlying water-bearing zones and to limit the volume of contaminated brine released from the repository to the surface or water-bearing zones.

Borehole plugging activities have been underway since the 1970s, from the early days of the development of the WIPP facility. Early in the exploratory phase of the project, a number of boreholes were sunk in Lea and Eddy counties. After the WIPP site was situated in its current location, an evaluation of all vertical penetrations was made by Christensen and Peterson (1981).

As an initial criterion, any borehole that connects a fluid-producing zone with the repository horizon becomes a plugging candidate.

Grout plugging procedures are routinely performed in standard oil-field operations; however, quantitative measurements of plug performance are rarely obtained. The Bell Canyon Test reported by Christensen and Peterson (1981) was a field test demonstration of the use of cementitious plugging materials and modification of existing industrial emplacement techniques to suit repository plugging requirements. Cement emplacement technology was found to be "generally adequate to satisfy repository plugging requirements." Christensen and Peterson (1981) also report "that grouts can be effective in sealing boreholes, if proper care is exercised in matching physical properties of the local rock with grout mixtures. Further, the reduction in fluid flow provided by even limited length plugs is far in excess of that required by bounding safety assessments for the WIPP." The governing regulations for plugging and/or abandonment of boreholes are summarized in Table I-3.

The proposed repository sealing system design will prevent water from entering the repository and will prevent gases or brines from migrating out of the repository. The proposed design includes the following subsystems and associated principal functions:

- Near-surface: to prevent subsidence at and around the shafts

- Rustler Formation: to prevent subsidence at and around the shafts and to ensure compliance with Federal and State of New Mexico groundwater protection requirements

- Salado Formation: to prevent transporting hazardous waste constituents beyond the point of compliance specified in Permit Module V

The repository sealing system will consist of natural and engineered barriers within the WIPP repository that will withstand forces expected to be present because of rock creep, hydraulic pressure, and probable collapses in the repository and will meet the closure requirements of 20.4.1.500 NMAC (incorporating 40 CFR §264.601 and §264.111). Permit Attachment I2 presents the final repository sealing system design.

Once shaft sealing is completed, the Permittees will consider closure complete and will provide the NMED with a certification of such within sixty (60) days.

I-1e(2)(f) Final Contouring and Revegetation

In the preparation of its Final Environmental Impact Statement (DOE, 1980), the DOE committed to restore the site to as near to its original condition as is practicable. This involves removal of access roads, unneeded utilities, fences, and any other structures built by the DOE to support WIPP operations. Provisions would be left for active post-closure controls of the site and for the installation of long-term markers and monuments for the purpose of permanently marking the location of the repository and waste. Permit Attachment J-1a(1) discusses the active and long-term controls proposed for the WIPP. Installation of borehole seals are anticipated to take twelve (12) months, shaft seals fifty-two (52) months, and final surface contouring eight (8) months.

I-1e(2)(g) Closure, Monuments, and Records

A record of the WIPP Project shall be listed in the public domain in accordance with the requirements of 20.4.1.500 NMAC (incorporating 40 CFR §264.116). Active access controls will be employed for at least the first one hundred (100) years after final facility closure. In addition, a passive control system consisting of monuments or markers will be erected at the site to inform future generations of the location of the WIPP repository (see "Permanent Marker Conceptual Design Report" [DOE, 1995b]).

This Permit requires only a thirty (30) year post-closure period. This is the maximum post-closure time frame allowed in an initial Permit for any facility, as specified in 20.4.1.500 NMAC (incorporating 40 CFR §264.117(a)). The Secretary of the NMED may shorten or extend the post-closure care period at any time in the future prior to completion of the original post-closure period (30 years after the completion of construction of the shaft seals). The Permanent Marker Conceptual Design Report and other provisions during the first 100 years after closure are addressed under another Federal regulatory program.

Closure of the WIPP facility will contribute to the following:

- Prevention of the intrusion of fluids into the repository by sealing the shafts

- Prevention of human intrusion after closure
- Minimization of future physical and environmental surveillance

Detailed records shall be filed with local, State, and Federal government agencies to ensure that the location of the WIPP facility is easily determined and that appropriate notifications and restrictions are given to anyone who applies to drill in the area. This information, together with land survey data, will be on record with the U.S. Geological Survey and other agencies. The Federal government will maintain permanent administrative authority over those aspects of land management assigned by law. Details of post-closure activities are in Permit Attachment J.

I-1e(3) Performance of the Closed Facility

20.4.1.500 NMAC (incorporating 40 CFR §264.601) requires that a miscellaneous unit be closed in a manner that protects human health and the environment. The RCRA Part B permit application addressed the expected performance of the closed facility during the thirty (30) year post closure period. Groundwater monitoring will provide information on the performance of the closed facility during the post-closure care period, as specified in Section J-1a(2) (Monitoring) of Permit Attachment J.

The principal barriers to the movement of hazardous constituents from the facility or the movement of waters into the facility are the halite of the Salado Formation (natural barrier) and the repository seals (engineered barrier). Data and calculations that support this discussion were presented in the permit application. The majority of the calculations performed for the repository are focused on long-term performance and making predictions of performance over 10,000 years. In the short term, the repository is reaching a steady state configuration where the hypothetical brine inflow rate is affected by the increasing pressure in the repository due to gas generation and creep closure. These three phenomena are related in the numerical modeling performed to support the permit application. The modeling parameters, assumptions and methodology were described in detail in the permit application.

I-2 Notices Required for Disposal Facilities

I-2a Certification of Closure

Within sixty (60) days after completion of closure activities for a HWMU (i.e., for each storage unit and each disposal unit), the Permittees will submit to the Secretary of the NMED a certification that the unit (and, after completion of final closure, the facility) has been closed in accordance with the specifications of this Closure Plan. The certification will be signed by the Permittees and by an independent New Mexico registered professional engineer. Documentation supporting the independent registered engineer's certification will be furnished to the Secretary of the NMED with the certification.

I-2b Survey Plat

Within sixty (60) days of completion of closure activities for each underground HWDU, and no later than the submission of the certification of closure of each underground HWDU, the Permittees will submit to the Secretary of the NMED a survey plat indicating the location and dimensions of hazardous waste disposal units with respect to permanently surveyed benchmarks. The plat will be prepared and certified by a professional land surveyor and will contain a prominently displayed note that states the Permittees' obligation to restrict disturbance of the hazardous waste disposal unit. In addition, the land records in the Eddy County Courthouse, Carlsbad, New Mexico, will be updated through filing of the final survey plats.

TABLES

(This page intentionally blank)

TABLE I-1
ANTICIPATED EARLIEST CLOSURE DATES FOR THE UNDERGROUND HWDUs

HWDU	OPERATIONS START	OPERATIONS END	CLOSURE START	CLOSURE END
PANEL 1	3/99	2/03	3/03	9/03 SEE NOTE 5
PANEL 2	1/02	7/04	8/04	12/05
PANEL 3	7/04	1/07	2/07	6/07
PANEL 4	1/07	7/09	8/09	12/10
PANEL 5	7/09	1/12	2/12	6/12
PANEL 6	1/12	7/14	8/14	12/15
PANEL 7	7/14	1/17	2/17	6/17
PANEL 8	1/17	7/19	8/19	12/20
PANEL 9	7/19	1/22	2/22	SEE NOTE 4
PANEL 10	1/22	7/24	8/24	SEE NOTE 4

NOTE 1: Only Panels 1 to 3 will be closed under the permit covered by this application. Closure schedules for Panels 4 through 10 are projected assuming new permits will be issued in 2009 and 2019.

NOTE 2: The point of closure start is defined as sixty (60) days following notification to the NMED of closure.

NOTE 3: The point of closure end is defined as one hundred eighty (180) days following placement of final waste in the panel.

NOTE 4: The time to close these areas may be extended depending on the nature and extent of the disturbed rock zone. The excavations that constitute these panels will have been opened for as many as forty (40) years so that the preparation for closure may take longer than the time allotted in Figure I-2. If this extension is needed, it will be requested as an amendment to the Closure Plan.

NOTE 5: The anticipated closure end date for Panel 1 is for installation of the 12-foot explosion isolation wall. Final closure of Panel 1 will be completed as specified in this Permit no later than five years after completion of the explosion isolation wall.

TABLE I-2
ANTICIPATED OVERALL SCHEDULE FOR CLOSURE ACTIVITIES

ACTIVITY	FINAL FACILITY CLOSURE	
	START	STOP
Notify NMED of Intent to Close WIPP (or to Implement Contingency Closure)	August 2024	N/A
Perform Contamination Surveys in both Surface Storage Areas	August 2024	February 2025
Sample Analysis	October 2024	May 2025
Decontamination as Necessary of both Surface Storage Areas	April 2025	November 2025
Final Contamination Surveys of both Surface Storage Areas	December 2025	July 2026
Sample Analysis	April 2026	November 2026
Prepare and Submit Container Management Unit Closure Certification	December 2026	March 2027
Dispose of Closure-Derived Waste	September 2024	November 2025
Closure of Open Underground HWDU panel	December 2025*	July 2026
Install Borehole Seals	August 2026	July 2027
Install Repository Seals	April 2027	July 2031
Recontour and Revegetate	August 2031	March 2032
Prepare and Submit Final (Contingency) Closure Certification	August 2031	March 2032
Post-closure Monitoring	May 2032	N/A

N/A--Not Applicable
Refer to Figures I-3 and I-4 for precise activity titles.

*This assumes the final waste is placed in this unit in November 2025 and notification of closure for this HWDU is submitted to the NMED in October 2025.

TABLE I-3
GOVERNING REGULATIONS FOR BOREHOLE ABANDONMENT

Federal or State Land	Type of Well or Borehole	Governing Regulation	Summary of Requirements
Both	Groundwater Surveillance	State and Federal regulation in effect at time of abandonment	Monitor wells no longer in use shall be plugged in such a manner as to preclude migration of surface runoff or groundwater along the length of the well. Where possible, this shall be accomplished by removing the well casing and pumping expanding cement from the bottom to the top of the well. If the casing cannot be removed, the casing shall be ripped or perforated along its entire length if possible, and grouted. Filling with bentonite pellets from the bottom to the top is an acceptable alternative to pressure grouting.
Federal	Oil and Gas Wells	43 CFR Part 3160, §§ 3162.3-4	The operator shall promptly plug and abandon, in accordance with a plan first approved in writing or prescribed by the authorized officer.
Federal	Potash	43 CFR Part 3590, § 3593.1	(b) Surface boreholes for development or holes for prospecting shall be abandoned to the satisfaction of the authorizing officer by cementing and/or casing or by other methods approved in advance by the authorized officer. The holes shall also be abandoned in a manner to protect the surface and not endanger any present or future underground operation, any deposit of oil, gas, or other mineral substances, or any aquifer.
State	Oil and Gas Well Outside the Oil-Potash Area	State of New Mexico, Oil Conservation Division, Rule 202 (eff. 3-1-91)	B. Plugging (1) Prior to abandonment, the well shall be plugged in a manner to permanently confine all oil, gas, and water in the separate strata where they were originally found. This can be accomplished by using mud-laden fluid, cement, and plugs singly or in combination as approved by the Division on the notice of intention to plug. (2) The exact location of plugged and abandoned wells shall be marked by the operator with a steel marker not less than four inches (4") in diameter, set in cement, and extending at least four feet (4') above mean ground level. The metal of the marker shall be permanently engraved, welded, or stamped with the operator name, lease name, and well number and location, including unit letter, section, township, and range.
State	Oil and Gas Wells Inside the Oil-Potash Area	State of New Mexico, Oil Conservation Division, Order No. R-111-P (eff. 4-21-88)	F. Plugging and Abandonment of Wells (1) All existing and future wells that are drilled within the potash area, shall be plugged in accordance with the general rules established by the Division. A solid cement plug shall be provided through the salt section and any water-bearing horizon to prevent liquids or gases from entering the hole above or below the salt selection. It shall have suitable proportions—but no greater than three (3) percent of calcium chloride by weight—of cement considered to be the desired mixture when possible.

List of All Solid Waste Management Units

	Unit Type	Unit Description	Chemicals Deposited in the Unit	Status	Impacts to Groundwater
001 a - ab	MUD Pits	These mud pits were used for settling drill cuttings out of the drilling fluids being used in drilling holes to support hydrologic testing and monitoring, potash evaluation, and drilling for hydrocarbons.	Sodium and potassium chloride saturated brine; starch; bentonite gel; diesel fuel; drill cuttings; metal cuttings; grease; hydraulic fluid; motor oil.	The mud pits are no longer in use. NFA granted in 1999.* NFA Petition was submitted in Oct. 2002 for the removal of the remaining mud pits listed in Table II.	None. No GW present and engineering controls limit migration potential.
002 a - d	Mine Tailings and Top Soil Storage Areas	A total of four areas ranging in size from 3 to 15 acres used for mine tailings and topsoil storage.	Mined rock (principally salt); topsoil; traces of hydraulic oil; motor oil; diesel fuel; and scrap steel.	The two salt storage piles (002a,b) are inactive. The two top soil piles (002c,d) are active.	Engineering controls are in place per DP-831 for the salt storage piles. No impacts to groundwater are expected from the top soil storage areas.
003 a - b	Landfills	Two landfills used for disposal of construction debris.	Foundation excavation soils; concrete; scrap wood; and metal.	003b is active. 003a is inactive.	None. No GW present and no hazardous materials or liquids have been placed in CD landfill.

Table I

	Unit Type	Unit Description	Chemicals Deposited in the Unit	Status	Impacts to Groundwater
004 a - c	Storage Yards	Three storage yard areas used for storage of construction and maintenance materials, wastewater, and used oils or materials that can be reclaimed or recycled.	Water contaminated with motor oil, hydraulic oil, and diesel fuel; used hydraulic oil, motor oil, antifreeze, glycol-based oils, chemical grout; used lead acid batteries; scrap metal. Used hydrocarbons are collected in containers for future recycling.	004a is active. 004b is inactive & closed. 004c is inactive & closed.	None. Only portacamp (004a) is active; i.e., not granted NFA Status. No hazardous wastes are stored in 004a & any products stored in that area are stored in sealed containers and on secondary containment. There are no records of hazardous materials releases in 004a.
005 a - c	Concrete Batch Plants	Three areas were used as temporary locations for concrete batch plants.	Concrete; trace amounts of motor oil and grease.	Inactive and closed. NFA granted in 1999*.	None. Concrete plants are closed. No hazardous constituents were present in these locations.
006 a - b	Holding Ponds	Two ponds used to hold brine drilling fluid from the drilling of the salt handling and waste handling shafts.	Saturated brine; bentonite; drill cuttings; hydraulic oil and grease.	Inactive and closed. NFA granted in 1999*.	None. No hazardous constituents were present.
007 a - c	Evaporation Ponds	Three ponds used for the evaporation of water.	Water; soap; non hazardous cleaning solutions; oil; unsaturated salt brine.	Two Inactive and closed. NFA granted in 1999*. 007b NFA requested in the October 2002 Petition.	None. Two inactive ponds are closed. Engineering controls will be put in place for the other evaporation pond.

Table I

	Unit Type	Unit Description	Chemicals Deposited in the Unit	Status	Impacts to Groundwater
008 a - r	Surface Satellite Accumulation Areas	Ten hazardous waste or used petroleum product satellite accumulation areas; two hazardous waste staging areas. All hazardous wastes were kept in steel containers and managed as hazardous waste.	Non-radioactive, site-generated wastes, collected in containers including spent solvents, aerosol cans, oily rages, expired chemicals, and paint products.	Inactive and closed . NFA Granted in 1999*.	None. No hazardous constituents were released. No contaminant migration to GW due to engineered controls. Waste was managed appropriately.
009 a - l	Underground Satellite Accumulation Areas	Ten hazardous waste or used petroleum product satellite accumulation areas.	Non-radioactive, site-generated wastes, including spent solvents, aerosol cans, oily rages, used oils, spent lead acid batteries, grout, and cement. Hazardous waste and used petroleum products are collected in containers.	Nine of ten closed. All granted NFA in 1999*.	None. No usable groundwater occurs within the repository horizon (Salado Formation).
010 a - e	Shaft Sumps	An area at the bottom of each of the four WIPP shafts that collected construction debris or accumulated brine.	Welding residue; scrap wood and metal; salt; Class C cement; chem-seal; bentonite; grease and oil; cement and chem grout; Rustler formation brine; washwater.	Two active (010b,c) and NFA was request in October 2002. Three inactive (010a,d,e) granted NFA in 1999*.	None. No usable groundwater occurs within the repository horizon (Salado Formation).
011 a - e	Sewage Treatment Facility	Only five of the seven sewage treatment lagoons were listed in the RFA.	Sanitary waste; neutralized film developer (tested non-hazardous), and oil.	Active	None. No known usable GW under the sewage lagoons. Analysis indicates no hazardous constituents. Engineering controls in place including liners and inspections.

Table I

	Unit Type	Unit Description	Chemicals Deposited in the Unit	Status	Impacts to Groundwater
012	Non-hazardous Solid Waste Collections Bins	Twenty portable bins used for solid waste collection.	Non-hazardous solid waste including non liquid sanitary waste and industrial waste.	Active	None. Administrative controls insure no hazardous constituents in bins. Engineering controls prevent release of any constituents.
013	TRU Mixed Waste Management Units	Areas where transuranic (TRU) mixed waste was managed during the Disposal Phase. Includes contact and remote handled TRU waste, including areas in the Waste Handling Building and Disposal Panels 1 through 8 in the underground. Waste will be in approved containers**.	Radioactive mixed waste consisting of TRU waste that is co-contaminated by various listed hazardous or characteristic waste consisting mostly of metals.	Active	None. No hazardous releases. No liquids accepted, and there have been no air releases. In addition, engineering controls, impermeable concrete, inspections, and spill prevention control procedures are in place.

RE: Response to Notice of Intent to Discharge Storm Water from SWIC Ponds 1, 2 and A to the Ground, DP-831, Waste Isolation Pilot Plant

Dear Dr. Triay:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received a Notice of Intent (NOI), submitted by the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) dated March 4, 2005. Excessive precipitation in the area has caused further delay in lining Storm Water Infiltration Control (SWIC) Pond A and discharge of storm water to the environment is requested to manage storm water at the WIPP site. In accordance with 20.6.2.1201 NMAC, the NOI requests the following discharges to occur.

1. Approximately 200,000 gallons of storm water will be discharged from the SWIC Pond A to SWIC Ponds 1 and 2, or to the ground. Storm water discharge from SWIC Pond A to SWIC Ponds 1 and 2 is necessary to allow completion of construction activities for synthetically lining this facility as required under DP-831.

2. Approximately 600,000 gallons of storm water will be discharged from SWIC Ponds 1 and 2 to the ground adjacent to these facilities. Discharge of storm water from these ponds is necessary to create storage capacity for future rain events and prevent damage to these facilities.

Samples of the storm water to be discharged were obtained and analyzed for pH, Specific Gravity, Specific Conductance, Bicarbonate, Chloride, Divalent Cations, Iron, Calcium, Sulfide and Potassium.

Based on the presently available information in your letter, dated March 7, 2005, a discharge permit is not being required for the discharges described above`. A discharge permit is not being required because the discharges conform to the numerical ground water standards in 20.6.2.3103 NMAC and do not contain any toxic pollutants as defined in 20.6.2.1101.TT NMAC, and therefore are exempt from the discharge permit requirement under 20.6.2.3105.A NMAC.

If at some time in the future WIPP intends to change the amount, the character, or location of the discharges so that they will not be as described, or if observation or monitoring shows that the discharges are threatening ground water quality, you must file a new request for exemption with the NMED.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

William C. Olson, Chief
Ground Water Quality Bureau

Subject: Notice of Intent to Discharge

Dear Mr. Marshall:

This letter is to confirm the information provided to you on March 1, 2005 during a teleconference with Mr. H. L. Plum, U.S. Department of Energy (DOE) and Mr. Stewart Jones, Washington TRU Solutions (WTS). There were discussions explaining the need for an extension of scheduled construction activities to emplace a liner in Storm Water Infiltration Control (SWIC) Pond A, and the discharge of storm water from Waste Isolation Pilot Plant (WIPP) SWIC Ponds 1, 2 and A.

Mr. Plum reported that excessive precipitation has continued to be recorded at the WIPP since the notifications submitted January 31 and February 2, 2005. Due to the additional storm water being collected, SWIC Pond 1 is at capacity and SWIC Pond 2 will be at or near capacity if predicted precipitation events occur March 4-7, 2005. Storm water that has collected in SWIC Pond A due to additional precipitation has caused further delay in construction activities even with the relief previously provided by the New Mexico Environment Department (NMED) after the Notification of Intent submitted February 2, 2005. He informed you that the number of precipitation events and the amount of rainfall resulting from these events is above the average expected for the WIPP site upon which the construction schedules were determined and SWIC capacities determined.

The excess volume of storm water collected requires DOE to provide a Notification of Intent to Discharge to NMED of the need to discharge storm water from the SWIC Ponds 1, 2 and A. This request is to allow the pumping and dispersal of excess storm water that has collected in SWIC Ponds 1, 2 and A to alternative locations for beneficial use of the water in the environment adjacent to these facilities. This is needed to prevent damage to SWIC Ponds 1 and 2 by exceeding their design capacity and to expedite the completion of construction activities for emplacement of liner material in SWIC Pond A.

CBFO:AMO:HLP:VW:05-0227:UFC:5487

Since the discussion of March 1, 2005, a review of options to prevent the collection of storm water in SWIC Pond A in the event of additional precipitation events have occurred. Engineers have determined that continued diversion of storm water from entering the storm water culverts on the east side of SWIC Pond A is appropriate and that this water will be diverted to SWIC Pond 2. Storm water collected from the parking lot north of SWIC Pond A that would normally pass through culverts on the north side of this facility will be diverted to the same location as storm water that has been and will be pumped from SWIC Pond A. With these actions, only rainfall falling on the surface of SWIC Pond A will affect the construction activities underway. SWIC Pond A has a surface area of 6.39 acres and the effect of additional precipitation events are expected to be limited. It is anticipated that this action will allow the soils in this facility to dry and allow work to resume in a minimum of 2 weeks of the date of approval of this request, unless the volume of precipitation is so large as to overwhelm measures described to control storm water collection.

It was concurred that discharge of these waters to the environment for beneficial reuse could be possible. You also stated that water samples must be collected and analyzed and this information forwarded with a formal written request as required by 20.6.2.1200 NMAC, Notice of Intent to Discharge to NMED. It was stressed that the collection of water samples must occur and this action completed prior to any such discharge occurring from a regulated site. NMED would review the information received in the notification and provide written determination of its decision by return mail. Both parties agreed that this re-use of collected storm water, when water quality had not been degraded, was appropriate in arid environments. DOE did discuss the sampling protocol to be used for this storm water. You agreed that, due to the fact that previous sampling and analysis events had determined this water to be of good quality, that DOE could limit analysis to the parameters that could be completed by site laboratory facilities. These parameters and field analytical results for the ponds are found in response to question 4 below. The storm water samples did not indicate presence of contaminants above levels of concern.

It was further discussed that WIPP's Discharge Permit (DP)- 831 contained a condition that construction activities to reshape and emplace an impermeable liner in SWIC Pond A would be completed by January 2005. Due to the unusually large number of precipitation events that occurred in September and October 2004 and the large volume of storm water collected in SWIC Pond A, the DOE did request an extension to complete construction to April 2005 by letter to NMED of November 12, 2004. NMED approved this extension November 18, 2004. As discussed above, continued delay of construction activities has occurred. Rather than requesting another date for construction activities to be completed in the future, you suggested that DOE provide a monthly status update of construction progress. DOE concurred that this would be an acceptable. DOE would like to suggest that this information be included in our current monthly report to NMED on freeboard remaining in the WIPP Sewage Lagoons permitted in DP-831.

CBFO:AMO:HLP:VW:05-0227:UFC:5487

DOE's oral and written notices are provided to NMED under 20.6.2.1201 NMAC.

(3) The location of the discharge;

Name	County	Township	Range	Section	Latitude	Longitude
Pond A	Eddy	22S	31E	SE ¼ of the SW ¼ of the SE ¼ of Section 20	N32, 22 Minutes, 19.9 Seconds	W103, 47 Minutes, 51.9 Seconds
Pond 1	Eddy	22S	31E	SW1/4 of the SE1/4 of the SE1/4 of Section 20	N 32 degrees, 22 minutes, 13.6' seconds	W 103, 47 minutes, 39.4 seconds
Pond 2	Eddy	22S	31E	SE1/4 of the SE1/4 of the SE1/4 of Section 20	N 32 degrees, 22 minutes, 13.7 seconds	W103 degrees, 47 minutes, 34.3 seconds

(4) An estimate of the concentration of water contaminates in the discharge; and add type of results;

Parameter	**Pond A Results**	**Pond 1 Results**	**Pond 2 Results**
Ph	8.20	8.19	7.58
Specific Gravity @ 21° C	1.002	1.002	1.002
Specific Conductance @ 25° C	556	602	168
Bicarbonate of Alkalinity HCO_3	115.2	83.3	47.7
Chloride mg/l	103	132	22
Divalent Cations meq/l	0.5	0.7	1.1
Fe (total)	0.07	0.03	0.00
Calcium mg/l	9.0	14.0	21
Sulfide mg/l	0.0	12.0	7.0
Potassium mg/l	1.0	2.0	2.0

CBFO:AMO:HLP:VW:05-0227:UFC:5487

(5) The quantity of the discharge.
Approximately 200,000 gallons of storm water may be discharged from SWIC Pond A to SWIC Ponds 1 and 2 and/or directly to the environment. Approximately 600,000 gallons of storm water will be pumped from SWIC Ponds 1 and 2, and dispersed to the environment adjacent to these facilities for beneficial use of the water by the environment. Approximately 800,000 gallons of storm water will be managed by these activities.

If you have any questions regarding this notification, please contact Mr. Jody Plum at (505) 234-7462.

Sincerely,

for

Inés Triay
Acting Manager

Subject: Notification of the February 2005 Freebaord Levels For the Sewage Lagoons and the H-19 Evaporation Pond

Dear Mr. Marshall:

Your letter dated December 28, 2004, approving the corrective actions proposed by the Waste Isolation Pilot Plant (WIPP) for the loss of freeboard in the sewage lagoons and the H-19 evaporation pond requires us to notify you of the freeboard levels in each pond by the last day of each month. As requested, here are the freeboard levels for February 2005.

Area	February 15, 2005
Settling Pond 1A	21 inches
Polishing Pond 1B	21 inches
Settling Pond 2A	20 inches
Settling Pond 2B	18 inches
Evaporation Pond A	18 inches
Evaporation Pond B	20 inches
Evaporation Pond C	20 inches
H-19 Evaporation Pond	22 inches

If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

Ines R. Triay

RE: Corrective Action Approval, DP-831, Discharge of Storm Water from SWIC Ponds 1, 2 and A, Waste Isolation Pilot Plant

Dear Dr. Triay:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received a Written Notification and Corrective Action Report, submitted by the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) dated January 31, 2005. The report addresses the discharge of storm water from Storm Water Infiltration Control (SWIC) Ponds 1, 2 and A located at the WIPP. Pursuant to Section 20.6.2.1203.A(7) NMAC, the corrective action is hereby approved.

Heavy rains occurred at the WIPP site from August through December 2004. Construction activities were also in progress during this time to prepare SWIC Ponds 1, 2 and A for liner installation. Large volumes of storm water collected in the ponds as a result of the rainfall. WIPP construction personnel made a decision to pump the storm water to the ground to allow construction activities to continue. An estimated 7,000,000 to 14,000,000 gallons of storm water was discharged from SWIC Ponds 1, 2 and A from September through December 2004.

When WIPP regulatory oversight personnel learned of the discharge, the activity was stopped immediately. Samples of the storm water were collected and analyzed for volatiles, semivolatiles, total dissolved solids, total petroleum hydrocarbons (TPH), nitrate, sulfate, chloride, total dissolved solids (TDS), total suspended solids, metals and pH. The samples did not exceed Water Quality Contol Commission (WQCC) ground water standards for any of the analytes tested, therefore no additional corrective actions are proposed.

If additional information becomes available indicating these corrective actions are inadequate, then additional actions may be required. Approval of this corrective action report does not relieve you of your responsibility to comply with any other applicable federal, state and/or local laws and regulations.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

William C. Olson, Chief
Ground Water Quality Bureau

Harold Runnels Building, Room N2250
1190 St. Francis Drive
Santa Fe, NM 87501

Subject: Notice of Intent to Discharge

Dear Mr. Marshall:

The purpose of this letter is to confirm the information provided by Mr. H. L. Plum, U.S. Department of Energy (DOE) to Mr. Clint Marshall, New Mexico Environment Department (NMED), January 31, 2005. Mr. Plum reported the need to discharge storm water from the Waste Isolation Pilot Plant (WIPP) Storm Water Infiltration Control (SWIC) Pond A to SWIC Ponds 1 and/or 2. This action is being requested to allow the pumping of excess storm water that has collected in SWIC Pond A to alternative locations to allow the completion of construction activities for emplacement of liner materials in SWIC Pond A. DOE's oral and written notices are provided to NMED under 20.6.2.1201 NMAC.

During this conversation, Mr. Plum also indicated a need to dispose of water in the near future from the WIPP Fire Water Tank to SWIC Ponds 1 and/or 2, or Pond A if construction activities to line this facility have been completed, to allow needed preventive maintenance activities to occur. Further site maintenance activities that occur throughout the year require the testing of fire hydrants. This water will be allowed to collect in site drainage and disposed in SWIC Ponds A, 1, 2 and/or the Salt Pile Evaporation Pond.

(1) Name of the person making the discharge;
Dr. Ines Triay, Manager

(2) The address of the person making the discharge;
U.S. Department of Energy
Carlsbad Field Office
P.O. Box 3090
4021 National Parks Highway
Carlsbad, NM 88221
(505) 234-7303

(3) The location of the discharge;

Name	County	Township	Range	Section	Latitude	Longitude
Pond A	Eddy	22S	31E	SE ¼ of the SW ¼ of the SE ¼ of Section 20	N32, 22 Minutes, 19.9 Seconds	W103, 47 Minutes, 51.9 Seconds

(4) An estimate of the concentration of water contaminants in the discharge; and None believed to be present.

(5) The quantity of the discharge.
A combined total of approximately 270,000 gallons of water will be discharge to SWIC Ponds A, 1, 2, and/or Salt Pile Evaporation Pond. It is estimated that approximately 200,000 gallons of storm water and approximately 70,000 gallons of potable water will be disposed in these ponds by these activities.

On February 1, 2005, Mr. Plum and Mr. Marshall discussed the potential future need to discharge water from the SWIC Ponds 1, 2 and A, and/or the Salt Pile Evaporation Pond to the environment. These ponds are designed and operated to capture storm water runoff and site generated potable water discharges from maintenance activities such as maintenance of fire hydrants and water storage tanks.

Mr. Marshall concurred that discharge of these waters to the environment could be possible. He stated that water samples must be collected and analyzed and this information forwarded with a formal written request as required by 20.6.2.1200 NMAC, Notice of Intent to Discharge to NMED. Mr. Marshall stressed that the collection of water samples must occur and this action completed prior to any such discharge occurring from a regulated site. NMED would review the information received in the notification and provide written determination of its decision by return mail. Both agreed that this re-use of collected storm water and potable water, when water quality had not been degraded, was appropriate in arid environments.

If you have any questions regarding this notification, please contact Mr. Plum at (505) 234-7462.

Sincerely,

Ines Triay

Dr. Ines R. Triay
Acting Manager

Subject: Notice of Discharge-Removal

Dear Mr. Marshall:

The purpose of this letter is to confirm the information provided by Mr. H. L. Plum, U. S. Department of Energy (DOE) to Mr. Clint Marshall, New Mexico Environment Department (NMED), January 25, 2005. Mr. Plum reported the discharge of water from the Waste Isolation Pilot Plant (WIPP) Storm Water Infiltration Control Ponds 1, 2, and A as described in Discharge Plan-831 (DP-831), as amended, issued by the New Mexico Environment Department, December 22, 2003. DOE's oral and written notices are being provided to NMED under 20.6.2.1203 NMAC. A. (1).

(a) Name, address, and telephone number of the person or persons in charge of the facility:
Dr. Inės Triay, Acting Manager
U. S. Department of Energy
Carlsbad Field Office
P.O. Box 3090
4021 National Parks Highway
Carlsbad, NM 88221
(505) 234-7303

(b) Name and address of the facility (Discharge Locations):
Waste Isolation Pilot Plant
26 miles East-Southeast of Carlsbad, New Mexico, Eddy County

Name	County	Township	Range	Section	Latitude	Longitude
Pond 1	Eddy	22S	31E	SW1/4 of the SE1/4 of the SE1/4 of Section 20	N32°, 22 Minutes, 13.6 Seconds	W103°, 47 Minutes, 39.4 Seconds
Pond 2	Eddy	22S	31E	SE1/4 of the SE1/4 of the SE1/4 of section 20	N32°, 22 Minutes, 13.7 Seconds	W103°, 47 Minutes, 34.3 Seconds
Pond A	Eddy	22S	31E	SE1/4 of the SW1/4 of the SE1/4 of section 20	N32°, 22 Minutes, 19.9 Seconds	W103°, 47 Minutes, 51.9 Seconds

CBFO:AMO:HLP:VW:05-0203:UFC:5487

(c) The date, location, and duration of the discharge:
September 1, 2004 through December 31, 2004
(periodic discharges over an estimated 25 days)

(d) The source and cause of the discharge:
The DOE has been constructing lined ponds to retain storm water runoff as required by DP-831 (as amended December 22, 2003). Unusual and heavy rainfall occurred at the WIPP site August 2004 though December 2004. Total rainfall at the WIPP facility during this period was 13.57 inches. The surface drainage area to the three ponds, including the surface area of each pond is 49.4 acres (enclosure 1). The Storm Water Infiltration Control Ponds 1, 2, and A were not lined at the time these rainfall events occurred, but construction activities, including the reshaping of earthwork required prior to emplacement of pond liners, had begun. Due to the large volume of water collected in Storm Water Infiltration Control Ponds 1, 2, and A, as a result of the unusually heavy rainfall events, construction activities were halted. This halt in construction activities was caused by the large volume of water that had been collected in the ponds that did not allow the use of heavy earth moving equipment to prepare the pond for installation of liner material. Construction activities could not resume until the ponds dried and equipment could again enter the ponds to complete grading and compacting activities.

Excessive rain, beginning in August 2004, continued to hamper construction activities through December 2004. To facilitate resumption of construction activities, a decision to pump this storm water from each of these three ponds to the ground was made as part of construction activities necessary to complete the project (Enclosure 1).

Lining of Storm Water Infiltration Control Ponds 1 and 2 was completed on January 23, 2005, and these lined ponds are now in service at WIPP. Pond A continues to retain water and a separate Notification of Intent to Discharge from Pond A to Pond(s) 1 and 2 is being prepared and will be submitted to NMED in the near future.

(e) A description of the discharge, including its chemical composition:
The water discharged consisted of storm water rainfall that had been collected on the surface of 49.4 acres. Approximately 42.42 acres are covered with asphalt or packed soil and some 6.98 acres are storm water pond surface. Grab samples were collected from the storm water ponds on October 7, 2004 (enclosure 1). The protocols used for the collection of grab samples and the analytical results are enclosures 2, 3, and 4 of this notification. The analytical data (enclosure 5) shows there were no contaminants of concern above regulatory limits.

(f) The estimated volume of the discharge:
7,000,000 to 14,000,000 gallons of storm water were discharged from Storm Water Infiltration Control Ponds 1, 2, and A between September 1, 2004 and December 31, 2004.

CBFO:AMO:HLP:VW:05-0203:UFC:5487

(g) Any actions taken to mitigate immediate damage from the discharge.

All pumping activities were stopped on December 31, 2004. There was no damage to the soil surface where discharge occurred. The analytical data, enclosure 5, shows there were no contaminants of concern above regulatory limits. No damage from these discharges of storm water has been determined and no further action is planned to be initiated as a result of these discharges. There is no known harm to human health or the environment from these discharges.

Action has been taken to assure all contractors working on projects regulated by DP-831 know to report any changes in construction or operations to DOE prior to initiation of any changes occurring.

If you have any questions regarding the above information, please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

Inés Triay

PRE-JOB SAMPLING PLAN

Date: October 7, 2004
Purpose: Environmental Sampling
PPE: Level D, Nitrile Gloves, Lab Coats, Steel Toe Shoes Safety Glasses
Safety Concerns: No eating or drinking while sampling. Be conscious of cross contamination of samples. Observe general safety measures. Pond liners and other surfaces may be slippery or unstable due to recent storms. Exercise extreme caution on these surfaces.
Lab Destination: Trace Analysis Laboratory
PO #: 402560 Budget Number: W125010601
Lab Contact: Mike Able Phone Number: 800-378-1296
Lab Address: 6701 Aberdeen Avenue, Suite 9, Lubbock, TX 79424

GENERAL INFORMATION:

Sample Location:	**Storm Water Evaporation Pond (South of Parking Lot)**
Sample Parameters:	**Total Volatiles**
Preservative:	**pH<2 with Hydrochloric Acid, chill 4 C**
Sample Equipment/Bottles:	(2) 40-mL amber glass VOA vials, plastic dipper, pH strips, Sampling Bag, paper towels.
SAMPLE COLLECTION:	**Total Volatiles** Collect sample from pond using plastic dipper. Collect sample into (2) 40-mL amber glass VOA vials. No air bubbles. Collect extra sample in an additional glass bottle to ensure that no air bubbles are present after preservation. Preserve after collection to pH<2 with Hydrochloric Acid. Chill 4° C.
Sample Location:	**Storm Water Evaporation Pond (South of Parking Lot)**
Sample Parameters:	**Total Organic Carbon**
Preservative:	**pH<2 with Sulfuric Acid, chill 4 C**
Sample Equipment/Bottles:	(2) 40-mL amber glass VOA vials, plastic dipper, pH strips, Sampling Bag, paper towels.
SAMPLE COLLECTION:	**Total Organic Carbon** Collect sample from pond using plastic dipper. Collect sample into (2) 40-mL amber glass VOA vials. No air bubbles. Collect extra sample in an additional glass bottle to ensure that no air bubbles are present after preservation. Preserve after collection to pH<2 with Sulfuric Acid. Chill 4° C.
Sample Location:	**Storm Water Evaporation Pond (South of Parking Lot)**
Sample Parameters:	**Total Semi-Volatiles**
Preservative:	**Chill 4 C**
Sample Equipment/Bottles:	(1) 1-L amber glass bottle, plastic dipper, Sampling Bag, paper towels.
SAMPLE COLLECTION:	**Total Semi-Volatiles** Collect sample from pond using plastic dipper. Collect sample into (1) 1-L amber glass bottle. No air bubbles. Chill 4° C.

1.0 INTRODUCTION [1]

1.1 Project Description

This Quality Assurance Project Plan (QAPjP) states the quality assurance (QA) requirements for the Waste Isolation Pilot Plant (WIPP) Site Effluent and Hazardous Materials Sampling Program, which is established in WP 02-EC.06, WIPP Site Effluent and Hazardous Materials Sampling Plan. Throughout the rest of this document, the WIPP Site Effluent and Hazardous Materials Sampling Plan will be referred to as the "sampling plan."

The sampling plan outlines the processes for sampling and analyzing various media at the WIPP site. For the purpose of this plan, the WIPP site is defined as the area within the fenced boundary, the underground, the 16 sections as defined by the Land Withdrawal Act, the Skeen-Whitlock Building offices, and any additional Department of Energy leased property used for the operation of WIPP.

This plan applies to nonroutine sampling that is not specified by an established monitoring procedure. The scope of this plan includes the following environmental data operations, as defined in WP 13-1, Washington TRU Solutions LLC (WTS) Quality Assurance Program Description (QAPD):

- Underground Storage Tank Leaks
- Hazardous and Mixed Waste Characterization
- Site Effluent
- Spill Response
- Contaminated Soil
- Contaminated Debris
- Used Oil
- Site Investigation
- Site Remediation
- Solid Waste Management Units
- Waste Handling Building Sumps
- WIPP Site Drinking Water

This plan satisfies the requirement for planning and managing these activities in accordance with an approved QAPjP.

1.2 Sampling Team

The WIPP Sampling Team is responsible for performing sampling activities in accordance with the sampling plan and this QAPjP. The team consists of a team coordinator and sampling technicians. The team coordinator is responsible for evaluating sampling situations and media that may be encountered, and to determine the sampling technique, container, preservative, and analyses of the sample to be taken, in accordance with the sampling plan or after consultation with appropriate groups on site. The team coordinator does not always have to be present for the actual sampling activity. Once the sampling activity has been coordinated and a sampling plan generated, the sampling technicians may complete the sampling and shipping process.

The sampling team will perform field parameter tests, such as pH, temperature and conductivity if appropriate, during sample collection to help determine the required analyses and preservatives. The members of the sampling team will have the required training to perform these tests.

The members of the sampling team will be trained in accordance with the Resource Conservation and Recovery Act (RCRA), and either ST-01, Sampling Team Qualification Card, or STA-01, Sampling Team Assistant Qualification Card, and will be part of the RCRA training matrix. It is recommended that the sampling team members be certified by the State of New Mexico Environment Department in Water Supply Regulations in order to perform lead and copper sampling for drinking water. Additionally, it is recommended that sampling team members attend a U.S. Environmental Protection Agency (EPA) approved, or equivalent, sampling course that includes proper sampling techniques and sampling quality control management.

The development and management of the contract with the analytical laboratory will be the responsibility of the sampling team. The team will initiate the review cycle of the results and prepare a final report of the sampling activity.

In the event of a spill, only qualified sampling team members may be called out to support the Emergency Response Team. The Facility Shift Manager will make the determination to activate the sampling team, per the applicable WIPP procedure. In the event of a TRU waste spill, the sampling team shall be available to take samples of the spill area. These samples shall be taken after the area has been decontaminated, and may be analyzed for total metals, total semi-volatiles, total volatiles, or beryllium to verify that cleanup has been effectively completed.

1.2.1 Site Environmental Compliance

The Site Environmental Compliance (SEC) Section will be responsible for providing regulatory oversight of sampling programs and for providing interpretation of regulatory changes that could impact sampling programs.

1.2.2 Industrial Safety and Hygiene

The Industrial Safety and Hygiene Section will be responsible for determining the type of personal protective equipment to be used for sampling or in the event of spill cleanup.

1.2.3 Shipping Coordination

Shipping Coordination shall assist in the shipment of any hazardous samples to ensure that the proper Department of Transportation regulations for packaging and shipping are met.

1.2.4 Quality Assurance

The QA Department is responsible for conducting independent assessments of the sampling and analysis program, in accordance with the WTS QAPD. QA uses a graded approach to determine the frequency of assessments based on program risk. QA will also ensure that the proposed contract laboratory meets the requirements for the Qualified Suppliers List (QSL).

1.2.5 Business Management

The Procurement section is responsible for placement of the analytical laboratory subcontract and the administration of subcontract activities.

The Warehouse is responsible for processing the shipping authorization.

1.2.6 Contract Laboratory

The contract laboratory will.be responsible for performing the analyses of the samples, reporting the results, and having an analytical Quality Assurance/Quality Control (QA/QC) program in place, as specified in the subcontract statement of work.

2.0 TECHNICAL SPECIFICATIONS

2.1 Project Data Quality Objectives

As required by the WTS QAPD, the following criteria for data quality are established.

2.1.1 Data Quality Objectives for Precision, Accuracy, and Lower Limits of Detection

The specifications for precision, accuracy, and lower limits of detection for each analyte are in accordance with SW-846, Test Methods for Evaluating Solid Waste, Physical/Chemical Methods. The Data Quality Objectives (DQOs) established by the EPA Contract Laboratory Program Statement of Work will be incorporated as part of the statement of work for the contract with the analytical laboratory.

Table 1.0 provides the test methods, accuracy and precision recovery ranges, required reporting limits, and the completeness percent required for groundwater and soil/ sediment media. Sample media does not always include groundwater or soil/sediment. Due to the diverse media sample under the sampling plan, a graded approach to QA/QC of the data quality objectives is taken based on the users determination of tolerable error in the results. The estimated method reporting limits or quantitation limits listed in Table 1.0 provide guidance and may not always be achievable in all sample media due to matrix interference. A graded approach to QA/QC bases the level of managerial controls applied to an item or work according to the intended use of the results and the degree of confidence needed in the quality of the results.

2.1.2 DQO for Representativeness

The sampling plan identifies the guidelines for ensuring that representative samples are collected. A random grid method or other techniques, as specified by SW-846, will be used whenever necessary.

2.1.3 DQO for Completeness

The sampling team will, in all cases, ensure that all documentation associated with sampling is complete. SEC and QA will review the program periodically to ensure that sampling activities fulfill the QA requirements established in this plan.

2.1.4 DQO for Comparability

To ensure comparability with other WIPP activities, units for reporting analyte concentrations are to be expressed in mg/L, µg/L, mg/kg, or ppb, or as appropriate.

2.2 Sampling Procedures

2.2.1 Effluent, Discharge, or Spill Sampling Procedures

If nonemergency sampling is required, the sampling team will collect samples as required by the sampling plan.

The sampling methods and tools for sampling different media and situations are suggested in Table 1, Sampling Equipment for Particular Materials, of the sampling plan. This sampling will be performed on an "as needed" basis. The sampling plan is designed to provide general guidelines for sampling situations not identified in specific procedures. The sampling plan presents suggested methods and tools for sampling different media, ~~but the sampling team coordinator will~~ make the determination of which method will be utilized according to the situation.

The type of preservative method and the containers used are defined in the sampling plan. It is necessary to ensure that the correct preservative methods are used for the analyses to be performed. Table 2, Containers, Preservatives, and Holding Times, of the sampling plan outlines the preservative methods. The analytical laboratory will aid in the selection of preservatives if a situation arises where the preservative method is not included in Table 2 of the sampling plan. Preservatives are to be kept in appropriate storage facilities, in accordance with applicable WIPP procedures, when not in use.

The maximum hold times and storage specifications for each sample type are defined in Table 2 of the sampling plan.

The sampling plan lists recommended analyses for different sample types in Table 4. In the event that the minimum analyses are not sufficient, it is the responsibility of the sampling team coordinator, in consultation with other applicable groups, to determine which analyses are needed. If additional analyses are to be performed, it will be the responsibility of the sampling team to state these analyses on the Request for Analysis Form.

The data packages produced from sample analyses will be reviewed, as appropriate, by the following groups:

- SEC
- Environmental Monitoring and Hydrology
- QA

The review process is outlined in the sampling plan.

2.2.2 Solid Waste Characterization Sampling Procedures

Sampling for the characterization of solid waste will be performed according to the sampling plan, unless the material can be characterized using generator knowledge. The sampling team coordinator or cognizant individual will determine the sampling method, container, preservative, and analyses to be performed, in accordance with the sampling plan and in consultation with other applicable groups.

Verification of the effectiveness of the removal of hazardous materials from a spill shall be obtained by collecting samples and sending them to the contract laboratory for analysis. Analytical results shall provide the necessary documentation that any residual contamination from a spill of TRU-mixed waste has been effectively removed.

Samples taken from the sumps in the Waste Handling Building shall be analyzed for hazardous constituents, gross alpha, and gross beta/gamma based on process knowledge. For unidentifiable materials, the sampling containers, amounts, and preservatives are specified in Table 2 of the sampling plan.

2.3 Sample Documentation, Handling, and Shipping

Shipping of samples will be performed through the Warehouse per WIPP shipping procedures. Shipping Coordination will determine if the sample meets the definition of a hazardous material upon review of the shipping authorization request. If the sample is a determined to be a hazardous material, Shipping Coordination shall provide packaging, labeling, and required documentation in accordance with the applicable WIPP procedure. Samples determined to be nonhazardous by Shipping Coordination shall be packaged for shipping by the Sampling Team.

Transportation of all samples shall be arranged by the Warehouse.

2.4 Sample Custody

Chain-of-Custody and Request for Analysis forms specified by the sampling plan will be used to document sample custody. The forms have provisions for maintaining positive identification of the sample from collection through analysis. The carrier is not required to sign for custody of the sample. The shipping documents tendered with the shipment will document their custody.

2.5 Equipment Calibration and Maintenance

The instrumentation used for field parameter testing by the sampling team will be under the control of the WIPP Metrology Office as part of the Monitoring and Data Collection Recall System. Calibration/comparison checks of field equipment are part of the specific procedures for the field equipment. The calibration of all instruments used for field measurements will be verified before each use. All field measurement equipment will be calibrated by a QSL certified calibration laboratory according to manufacturer's specifications. The Sampling Team will verify that the standards have not expired prior to use.

Calibration and maintenance of analytical equipment used by the contracted laboratory is addressed by the laboratory contract.

2.6 Analytical Methods

A list of analytical methods acceptable for each constituent is included in Table 3 of the sampling plan. The subcontracted laboratory will be responsible for specifying analytical methods and for justifying deviations from suggested methods in the contract quotation.

2.7 Data Reduction, Validation, and Reporting

Laboratory results are to be reviewed against previously specified DQOs. The primary responsibility of drawing conclusions from the analyses and compiling the report belongs to SEC and the sampling team coordinator, although the data may go through a review cycle designated in the sampling plan.

If any discrepancies are found in the analytical results, the laboratory shall be contacted by the designated representative to obtain any additional information that could resolve these discrepancies. No discrepancies shall remain unresolved; use the guidance of EPA 540/R-99/008 and/or EPA 540R-94/013 540-R-01-008 to determine data acceptability. Use the appropriate data qualifiers for data that is not fully compliant. A description of the reasons for data qualification and the qualification that is applied to the data shall be documented on Attachment 1 of the sampling plan.

2.8 Internal Quality Control Checks

Field duplicates will be collected and analyzed for every matrix in a batch, or a frequency of one duplicate per every ten samples whenever appropriate. Compliance type sampling will require blanks and duplicates, whereas characterization sampling may not require blanks and duplicates. The collection and analysis of blanks and duplicates for characterization samples will be determined by the sampling team coordinator.

In the event that samples must be stored overnight before shipment, the following procedure will be followed:

- Samples will be maintained in a locked, temperature-controlled area.
- Access will be restricted to authorized personnel only.

2.9 Performance and System Audit Requirements

The successful bidders of the analytical laboratory contracts for the sample analyses are required to be included on the QSL for analytical services. The laboratory's QA program must be reviewed and approved in accordance with applicable WIPP procedures in order to be included on the WTS QSL. After the bid is awarded, an additional surveillance or source inspection may be performed by SEC and QA personnel while analytical work is in progress.

2.10 Preventive Maintenance

Routine preventive maintenance records of field analytical equipment will be subject to review as part of the Environmental Assessment Program. Since most analyses are performed by a contracted analytical laboratory, the preventive maintenance records for the contracted laboratory will be addressed in the subcontract statement of work.

2.11 Corrective Action

In cases where deviations from accepted practices are determined, the contract laboratory shall follow all requirements of WIPP procedures addressing Corrective Action Programs.

2.12 QA Reports to Management

An assessment of the Site Effluent and Hazardous Materials Sampling Program will be conducted and reported to SEC management by the QA Department. Scheduling of these assessments will be determined by the QA Department.

2.13 Specific Routine Procedures Used to Assess Data Quality

The quality of the contract analyses will be determined by comparing the duplicate analysis in each batch of ten samples to the previously established limit for precision in the DQOs. Accuracy will be determined by the submission of a calibration check for each analyte against a known standard concentration of the analyte (laboratory control standard, matrix spike, or matrix spike duplicate on a submitted sample that is designated as the matrix spike sample) within the range of analysis by the contract laboratory.

2.14 Disposition of Nonconforming Samples

Samples collected by the WIPP Sampling Team are normally intended for waste characterization prior to disposal rather than for compliance-related monitoring. In the unusual event that a sample is identified by the contract laboratory as a nonconforming sample (e.g., a sample has exceeded the holding time for a specific test), another sample shall be collected and submitted to the contract laboratory for analysis. If another sample cannot be collected, discussions between the lab manager and the sampling team coordinator may be held indicating that the test be run on the sample as received. Any impact on the test results shall be noted and the discussion shall be documented and included as part of the analytical file.

3.0 DEFINITIONS

Accuracy - The degree of agreement of a measurement (or, an average of measurements of the same thing), X, with an accepted reference or true value, T, usually expressed as the difference between the two values, X-T, or the difference as a percentage of the reference or true value, 100(X-T)/T, and sometimes expressed as a ratio, X/T. Accuracy is a measure of the bias in a system.

Assessment/Verification - The act of reviewing, inspecting, testing, checking, conducting surveillances, auditing, or otherwise determining and documenting whether items, processes, or services meet specified requirements. The terms "assessment" and "verification," as used in the WTS QAPD, are synonymous; their use is determined by who is performing the work. Assessments are performed by or for senior management. Verifications are performed by the line organization.

Audit - A planned and documented activity performed to determine by investigation, examination, or evaluation of the objective evidence, the adequacy of, and compliance with, established procedures, instructions, drawings, manuals, specifications, codes, and standards or other applicable requirements, and the effectiveness of implementation.

Comparability - Expresses the confidence with which one data set can be compared to another.

Completeness - For determination of data quality, a measure of the amount of valid data obtained from a measurement system compared to the amount that was expected to be obtained under normal conditions.

Complete Record - A document is considered a complete record when the record is stamped, initialed, signed, and dated, or otherwise validated.

Data Validation - A systematic process for reviewing a body of data against a set of criteria to provide assurance that the data are adequate for their intended use.

Data Quality Objective - The totality of features and characteristics of data that bears on the data's ability to satisfy a given purpose. The characteristics of major importance are accuracy, precision, completeness, representativeness, and comparability.

Document - Recorded information that describes, defines, specifies, reports, certifies, requires, or provides data or results.

Environmental Data Operations - Compliance activities associated with collection and analysis of environmental samples, including data reduction, handling, reporting, and records management.

Inspection - An examination or measurement to verify whether an item or process meets specified requirements.

Major Measurement Parameter - Datum point or set of data collected or reported for environmental compliance, and specified in a DQO.

Monitoring and Data Collection Equipment - Devices, systems, or equipment used for collection of data or control of processes.

Nonconformance - A deficiency in characteristic or record that renders the quality of an item or sample unacceptable or indeterminate.

Precision - A measure of agreement between comparable data gathered or developed under similar conditions expressed in terms of a standard deviation.

Procurement Document - Purchase requisitions, purchase orders, drawings, contracts, specifications, or instructions used to define requirements for purchase.

QA Record - A completed and validated document that furnishes objective evidence of the quality of items or activities affecting quality.

Quality - The degree to which an item or process meets or exceeds the user's requirements and expectations.

Quality Assurance - Actions that provide confidence that quality is achieved. Comprises all planned or systematic actions necessary to provide adequate confidence that a component, system, structure, or facility will perform satisfactorily in service; or the total integrated program for ensuring the reliability of monitoring and measurement data.

Quality Assurance Plan - Subtier QA implementation documents that are limited in scope and that usually contain more detail than the QAPD. QAPjPs are examples of QA plans.

Quality Assurance Program Description - A description of the overall program established by WTS to implement QA requirements and guidance, such as American Society of Mechanical Engineers (ASME) Nuclear Quality Assurance (NQA)-1-1989, EPA QA/G-5, and 10 *Code of Federal Regulations* (CFR) 71, Subpart H. The QAPD assigns responsibilities and authorities, defines policies and requirements, and provides for the performance and assessment of work.

Quality Control - Comprises all those QA actions related to the physical characteristics of components, systems, or structures that provide a means to control and measure the quality of a component, system, or structure to predetermined requirements.

Records Management - The systematic control over the creation, maintenance, retention, protection, and preservation of records.

Representativeness - The degree to which data accurately and precisely represent a characteristic of a population, parameter variations at a sampling point, a process condition, or environmental condition.

Supplier - Any individual or organization that furnishes items or services in accordance with a procurement document. An all-inclusive term used in place of any of the following: vendor, seller, contractor, fabricator, consultant, and their subtier levels.

Surveillance - The act of monitoring, observing, or witnessing to verify whether an item or activity conforms to specified requirements.

Temporary Storage - For records, temporary storage is accomplished in accordance with ASME NQA-1-1989, Supplemental Requirement 17S-1, Section 4.4.3. Temporary storage is required for managing active records prior to the submittal to the records holding facilities.

Validation - An activity that demonstrates that an item, process, or set of data satisfies specified requirements of the user. For records, to certify the content of a document as authentic and complete (certification of document validity is indicated by the date and signature or initials of authorized individuals).

WIPP	Waste Isolation Pilot Plant

1.0 INTRODUCTION

This document describes the environmental sampling activities for effluent, hazardous, transuranic (TRU)-mixed, and PCB (polychlorinated biphenyl)-containing TRU-mixed waste at the Waste Isolation Pilot Plant (WIPP) site that do not fall under an existing monitoring program. Rather than maintaining a separate plan for each specific area, or specific procedures, this plan contains guidelines incorporating all of the environmental sampling into one sampling plan, and provides one document identifying sampling protocol, suggested analytical parameters, and quality assurance requirements. This plan does not apply to radioactive areas, personnel monitoring, or industrial hygiene sampling. Specific sampling protocols are contained in WP 02-EC1001, Characterization Sampling, Shipping, and Documentation.

Throughout this document, the WIPP Site Effluent and Hazardous Materials Sampling Plan will be referred to as the "plan" and "TRU-mixed and PCB-containing TRU-mixed waste" will be referred to as "TRU-mixed waste."

The purpose of this plan is to provide a guide for all types of effluent, hazardous, and TRU-mixed waste sampling at the WIPP site. Any site effluent or hazardous material sampling activity not addressed by an established monitoring program will fall under this plan. The areas of interest are as follows:

- Underground storage tanks
- Hazardous and TRU-mixed waste characterization
- Site effluent
- Spill response
- Contaminated soils
- Contaminated debris
- Used oils
- Site environmental investigations
- Site remediations
- Solid waste management units (SWMUs)
- Waste Handling Building sumps
- WIPP site drinking water

This plan outlines methods for sampling, containers to use, preservation techniques, sample labeling and documentation, sample custody, suggested analyses, data review, and validation.

Each sampling area is addressed differently. There are separate requirements and different regulations for different types of samples and different sample media. The intent of this plan is to allow the flexibility to sample each situation using the best possible method for the given situation.

The Quality Assurance Project Plan for WIPP Site Effluent and Hazardous Material Sampling, WP 02-EC.05, addresses the quality assurance/quality control measures to be taken when using this plan.

2.0 PERSONNEL [1]

The sampling team will be the primary group responsible for the implementation of this plan. This sampling team will consist of at least two sampling personnel, one of which may be the team coordinator.

The team coordinator will serve as the Quality Assurance Officer, whose responsibilities will include determining the validity of the sample collected. This is done by verifying that the sampling technique, preservation, containment, and shipping are adequate to ensure a representative sample that will produce valid data.

The team coordinator will be the member of the team to determine the type of sampling technique to be used. If additional consultation with other groups on-site is needed, it is up to the team coordinator to make those contacts. The team coordinator will review all documentation and data after the process is complete.

The team coordinator will be responsible for scheduling the sampling activities, coordinating safety reviews, and preliminary surveys when necessary.

In order to prevent spills or cross-contamination, two people are essential for sampling activities. It is a good practice to have at least two additional people available to serve as backups in a hazardous situation. The sampling personnel are responsible for maintaining two sampling logbooks in accordance with Section 4.2 of this plan.

Each member of the team will be trained according to the requirements of the Resource Conservation and Recovery Act (RCRA), and will be part of the RCRA training matrix on-site. It is recommended that a New Mexico Environment Department or U.S. Environmental Protection Agency (EPA) approved, or equivalent, sampling course that includes proper sampling techniques and sampling quality control management be attended by each member of the team. All members of the team will complete ST-01, WIPP Sampling Team Qualification Card, and the prerequisite training identified on the card, prior to performing sampling tasks without the direct supervision of a qualified person. All sampling team personnel responding to hazardous materials incidents will be trained in accordance with Title 29 *Code of Federal Regulations* (CFR) §1910.120, "Hazardous Waste Operations and Emergency Response."

All sampling team assistants will complete STA-01, WIPP Sampling Team Assistant Qualification Card, and the prerequisite training identified on the card.

3.0 SAMPLING ACTIVITIES

3.1 Communication

Prior to leaving for off-site sampling activities, Site Environmental Compliance (SEC) sampling personnel will sign out from their designated work locations to indicate their off-site sampling location. The SEC sampling team coordinator will make arrangements to have an effective, two-way communication device at the sampling location. The communication device must be fully operational for the entire sampling event. The device must be able to send and receive messages from all locations where sampling activities will be conducted (e.g., if a cell phone is used, the battery must be fully charged and the phone must be able to access a service area during the entire sampling event). Notification of emergencies shall be made directly to the Central Monitoring Room by the sampling team. The equipment will be maintained in the presence of the sampling team while performing off-site activities.

3.2 Sampling Protocol

Sampling protocols may vary according to each waste stream. Each waste stream shall be evaluated independently.

3.2.1 Underground Storage Tanks [2]

The WIPP site has two underground storage tanks for diesel and unleaded fuel. These tanks are equipped with leak detection devices that will alarm if a leak occurs. If a leak occurs, sufficient core soil samples to determine the spread or location of the leaking fuel are required. More information about the underground storage tanks is included in WP 04-GC1605, Operation of Surface Fuel Station Storage Tanks.

3.2.2 Hazardous and TRU-Mixed Waste Characterization [3]

Most hazardous waste determinations at the site can be made by Material Safety Data Sheets (MSDSs) or information from the WIPP Waste Information System. In some instances, sampling is required.

In the event a hazardous or TRU-mixed waste sample must be collected from a radiological area, a plan will be developed jointly by Operational Health Physics and the sampling team. The plan shall be covered by a Radiological Work Permit and must address beryllium exposure in accordance with WP 12-IH.02-9, WIPP Industrial Hygiene Program - Beryllium Exposure Prevention Program. In accordance with this plan and WP 02-EC1001, all appropriate sampling protocols shall be followed.

Verification of the effectiveness of the removal of hazardous materials from a TRU-mixed waste spill shall be obtained by collecting samples of the swipes and sending them to the contract laboratory for analysis. Analytical results shall provide the necessary documentation that any residual contamination from a spill of TRU-mixed waste has been effectively removed.

The sampling team coordinator will select analytical parameters for samples taken from the fire suppression sumps in the Waste Handling Building. The selection of analytical parameters for these samples shall be based on process knowledge and may include hazardous constituents, beryllium, gross alpha, and gross beta/gamma.

3.2.3 Spill Response [1]

The sampling team will be on-call to the Facility Shift Manager (FSM) in the event of a spill. Sampling team members trained to the EPA's Emergency Response to Hazardous Materials, or equivalent, may be called upon to support the Emergency Response Team for sampling spill incidents. If the FSM determines that a sample must be collected, the sampling team will be contacted to sample the spill. Only qualified personnel will respond to emergency incidents. Hazardous material responses and analyses will be conducted in accordance with 29 CFR §1910.120.

In the event of a spill of hazardous or TRU-mixed waste in a radiological area, the sampling team may be called to collect a sample after radiological cleanup has been completed. Operational Health Physics will survey the known or suspected TRU mixed waste spill and SEC, in conjunction with Industrial Hygiene, shall determine whether sampling for hazardous materials is needed. If sampling is indicated, then all activities shall be covered under a Radiological Work Permit. Sampling protocols and procedures shall be in accordance with WP 02-EC1001 and this sampling plan.

3.2.4 Used Oils [4,5]

The WIPP site recycles used oils. Prior to being sent to an off-site recycling facility, the oils must be characterized to demonstrate that they are nonhazardous and meet the recycling requirements of 40 CFR Part 279. The oils are evaluated to determine if they meet the recycling requirements of 40 CFR Part 279. Process knowledge or sampling data may be used to meet these characterization requirements.

3.2.5 Solid Waste Management Units [6]

Sampling of SWMUs and Areas of Concern (AOCs) will be completed as needed in accordance with the WIPP Sampling and Analysis Plan (SAP) for Solid Waste Management Units and Areas of Concern. The SWMUs and AOCs are identified in both the SAP and the WIPP Hazardous Waste Facility Permit.

3.2.6 Contaminated Soils

Due to the remoteness of many areas at the site, there is the possibility of site soils being contaminated by an unknown substance. In this event, soil samples will be collected by the sampling team to identify possible contaminants, the extent of contamination, and the course of remediation. Additionally, samples of site soils may be collected by the sampling team to verify the completion of remediation from spills of petroleum products, hazardous materials, or hazardous waste.

3.2.7 Contaminated Debris [7]

Debris is defined in 40 CFR §268.2 as "solid material exceeding a 60mm particle size that is intended for disposal and that is a manufactured object; or plant or animal matter; or natural geologic material." Since this covers a large range of materials, sampling will be performed as needed on a case-by-case basis.

3.2.8 Site Remediations [8]

Samples to determine the levels of contaminants in an area to be remediated, or samples to determine if remediation technologies used were sufficient, will be the responsibility of the sampling team. If possible, a follow-up sample of a remediated area will be taken within 72 hours of the initial cleanup to determine if sufficient remediation was performed.

3.2.9 Site Investigations

In the event that site investigations are required to verify compliance with various permits or to locate contaminated areas, samples will be collected in accordance with this plan.

3.2.10 WIPP Site Drinking Water

The sampling team shall perform triennial lead and copper sampling of the WIPP site drinking water. Sampling support may also occur on an as-needed basis to confirm that the site drinking water meets the water supply regulations established by the state of New Mexico.

The sampling team will collect all samples in accordance with established procedures for sampling site drinking water for lead, copper, chlorine, and total coliform. Only sampling team members currently certified by the state of New Mexico to collect compliance samples may participate in the collection of water samples for lead and copper analysis. In accordance with 20.7.10 NMAC, sampling certification is not required for persons performing only microbiological or turbidity samples.

3.3 Sampling Devices

This plan addresses a variety of media that may be sampled by sampling team members. Due to various media and constituents being analyzed, there are many methods for sample collection.

Care should be exercised to ensure that representative samples are taken from all areas of concern. Representative samples should be taken at different locations or depths encompassing the entire population of the concerned media. When appropriate, the EPA suggests that either grab or composite samples be collected. A grab sample is an individual sample collected from a single location at a specific time. Composite samples consist of discrete grab samples mixed together to characterize the average composition for any one day.

The different types of sampling devices are presented in Table 1, along with the appropriate media for each sampling device. In some situations, combinations or variations of these sampling tools may be needed. The final decision on which sampling devices to be used will be made by the team coordinator.

3.3.1 Coliwasa

A coliwasa is a glass, plastic, or metal tube with a tapered stopper at the bottom. The stopper is released; the instrument is inserted into the material; and the stopper is retracted, holding the sample inside the tube. The coliwasa is used when sampling drummed or containerized substances.

3.3.2 Weighted Bottle

A weighted bottle is used to sample from the bottom of a vessel. This sampler consists of a glass or plastic bottle, a stopper, a sinker, and a line to raise, lower, and pull out the stopper. The bottle is lowered into the vessel and the stopper pulled when the bottle reaches the bottom of the vessel.

3.3.3 Dipper

A dipper is a beaker or similar container attached to a telescoping pole, so that samples from different locations can be collected by a person standing in one location. This apparatus is used primarily for surface sampling.

3.3.4 Liquid Thief

A liquid thief is a glass tube used for sampling from containers with small openings. When inserted into the liquid, the sampler places his or her thumb over the top opening, holding the liquid in the tube until it can be transferred to the sample container.

3.3.5 Solid Thief

A solid thief is a tool that consists of two metal cylinders (usually stainless steel or brass), one inside the other, with slot openings in both tubes. The outer tube is pointed so that it can be driven into the material to be sampled. The instrument is closed (slots in tubes not lined up and the opening is blocked) when it enters the material, then the tubes are turned so that the slots are aligned and material can enter. The tool is closed before it is withdrawn from the material.

3.3.6 Trier

A trier is a metal tube, cut in half lengthwise and pointed at one end. It is used in a similar fashion to the thief but it cannot encapsulate the sample drawn.

3.3.7 Auger

An auger is used for hard or packed samples. It has spiral blades and a central shaft. It is used in a rotating motion, much like a drill, to loosen the material so that it can be scooped or shoveled.

3.3.8 Scoops and Trowels

Scoops and trowels are either metal or plastic hand tools used to dig or move material. The amount of sample needed will determine which one of these similar devices will be used.

3.3.9 Soil Sampler

A soil sampler is a stainless steel device used to collect small soil samples. This is primarily used when analyzing soils for volatile constituents.

3.3.10 Peristaltic Pump

The peristaltic pump is the only mechanical tool listed and will mechanically pull a sample. This pump could decrease the sampling time when large samples are needed.

3.3.11 Tool Decontamination

When possible, the sampling team will use disposable tools. New tools will be used for each sampling event. Disposable equipment must be kept clean and free of contamination prior to sampling.

In order to prevent sample contamination, nondisposable tools may require cleaning before they are used to collect a sample. After sampling activities are complete, the tools must again be cleaned to remove any residual material. Deionized water or an appropriate detergent may be used to perform the cleanings. Wash water should be collected in a container and evaluated to determine if it must be disposed of as hazardous waste. Pre- and post-sampling wash water may be collected in the same container.

If decontamination of the sampling tools is not possible or practical, the tools may be discarded at the discretion of the team coordinator. If applicable, the tools will be discarded as hazardous waste. When tools are used for sampling a TRU-mixed waste in a radiological area, they shall be disposed of appropriately.

3.3.12 Maintaining Sampling Equipment

Sampling tools and other equipment must be kept in a controlled area, preferably locked, in order to maintain the integrity of the tools and to prevent sample cross-contamination. If instruments are used for field parameter testing, they will be calibrated periodically. Control and calibration of these instruments (if applicable) will be the responsibility of the WIPP Metrology Office. When applicable, field measurements will be verified by specifying them as parameters requested for analysis by the contract laboratory.

SEC must maintain a database of Monitoring and Data Collection (M&DC) equipment. The database must contain the following information:

- Accuracy specifications or location of the specifications for each piece of M&DC
- Calibration records
- Location of operating manuals and/or operating instructions for using each M&DC
- Records that reconcile "Out-of-Tolerance," damaged, or expired M&DC calibration conditions
- "As found" vendor calibrations

In addition, the following shall be performed:

- Store all Certifications of Calibration and data in fire proof cabinets, until transfer in accordance with the applicable Records Inventory and Disposition Schedule.
- Check each piece of M&DC for a current calibration label before use.
- Tag, segregate, or otherwise control equipment with expired calibration labels to prevent its use until it has been recalibrated.
- Store M&DC so that the equipment will not be subjected to extremes outside the manufacturer's recommendation for temperature, humidity, vibration, electromagnetic interference, dust and accidental damage.

3.4 Quality Assurance Samples

3.4.1 Field Duplicates and Blanks

Field duplicates will be collected at specified frequencies and are employed to document precision. The precision resulting from field duplicates is a function of the variance of waste composition, the variance of sampling technique, and the variance of the analytical technique. Duplicates will be collected in the same manner as samples. When a duplicate sample is drawn, the technique, location, and amount should be identical to the corresponding sample. Documentation and identification of duplicate samples and split or subdivided samples shall reference the sample identification of the original sample.

Equipment rinseates will be collected at specified frequencies and will vary according to the probability of contamination or cross-contamination. Equipment rinseates are analyzed to detect any contamination from the equipment, cross-contamination from previously collected samples, or conditions during the sampling activity. Rinseates are conducted by using deionized or reagent water.

The sampling team will collect field duplicates and rinseates as instructed by the team coordinator. As a best management practice, one out of every ten samples will be a field duplicate and/or equipment rinseate.

3.4.2 Disposition of Nonconforming Samples

The WIPP Sampling Team's samples are normally collected for waste characterization prior to disposal versus a compliance related monitoring program. In the unusual event that a sample is identified by the contract laboratory as a nonconforming sample (i.e., a sample has exceeded the holding time for a specific test) another sample shall be taken of the media and submitted to the contract laboratory for analysis. If another sample cannot be taken, discussions between the lab manager and the sampling team coordinator may be held indicating that the test be run on the sample as received. Any impact on the test results shall be noted and the discussion shall be documented and included as part of the analytical file.

3.5 Sample Containers

Each type of sample must be contained in a specific way, suitable for the type of substance being sampled. The types of sampling containers for each type of sample are listed in Table 2.

Special care must be taken to ensure the outside of the containers are not contaminated with the sampled substance. This could cause cross-contamination between samples and pose a health risk.

3.6 Sample Preservation

Samples shall be preserved as applicable immediately following collection. The different preservation techniques used are listed in Table 2. The contract laboratory and the sampling team coordinator will determine the applicability of sample preservation for samples that are not compliance regulated or samples containing high ionic strength brine water.

Preservatives should be stored in proper chemical lockers. Care should be taken not to store incompatible chemicals in the same locker. Guidelines for the handling and storage of the preservative chemicals are available in the hazardous materials management plan or from the Industrial Hygienist.

4.0 SAMPLE DOCUMENTATION

4.1 Sample Numbers

A sample number will be assigned to each sample collected. The format for the sample numbers is as follows:

- "WST" (WIPP Sampling Team), followed by
- The last two digits of the current year, followed by
- Three-digit sequential numbering starting with "001"

Example: WST-03-032

The first available sequential number will be determined by examining the field logbook.

Equipment rinseates and duplicates will be numbered in the same way as other samples. A notation should be made in the field logbook to identify samples as equipment rinseates or duplicates, as appropriate.

4.2 Sample Logbooks

Two logbooks will be maintained for all sampling team activities. The logbooks will include all samples taken by the team. The samples will be logged by the sample number. One logbook will be the sample tracking logbook and the other will be the field logbook. Both log books are considered quality records and shall be stored in locked fireproof cabinets at the end of each work day. Only copies of the logbook entries may be taken off-site, unless the sample team members are using the field logbook during a sampling activity. The logbooks will include the information specified in WP 02-EC1001.

In addition to this information, a detailed description of how the sample was collected should be recorded in the field logbook, including the in situ orientation of the sample, where appropriate.

The team coordinator is responsible for reviewing the logbooks for accuracy and completeness periodically. The team coordinator should document the reviews with initials or signature and date.

4.3 Container Identification

The sample container must be labeled with the information specified in WP 02-EC1001.

Sample identification shall be maintained through final disposition of the sample.

Care shall be taken to ensure that sample identification does not compromise or cross-contaminate the sample. If physical markings are used, they shall not be obliterated or hidden by surface treatments or sample preparation unless other means of identification are substituted.

4.4 Tamper-Proof Seals

After the sample has been collected, the container must be sealed to resist tampering. Sample bottles are sealed by wrapping sealing tape or electrical tape around the lid and the neck of the container. A custody seal shall be placed over the tape so that it will break if the container is opened. The custody seal must be placed on the container before the sample leaves the sample location. The custody seal should contain the information specified in WP 02-EC1001.

4.5 Sample Custody

4.5.1 Sample Chain-of-Custody Forms

Sample Chain-of-Custody (COC) forms must be generated for every sample collected. A sample team member will initiate the COC form by filling in the required information. Information required to be on the COC form when the samples are shipped to the contract lab includes:

- Unique COC number (preprinted on the COC form)
- Sample number
- Sample location and description
- Date and time collected
- Sample type
- Container type
- Sampling program (i.e., WIPP Sampling Team)
- Names of sampling team members involved in the sampling event
- Name of the laboratory being used for analysis

In addition, there must be space to document the condition of the samples upon receipt at the laboratory and an area to be used to document changes in sample custody.

An example of a COC form is maintained as Attachment 2, to WP 02-EM3001, Administrative Processes for Environmental Monitoring and Hydrology Processes. This is an example form only. There is not a required format for a COC form, if the form being used contains the required information.

A sample is considered to be in a person's custody if it is in their physical possession, is in the their view, or they have prevented tampering of the sample by securing it. Changes of sample custody must be documented on the COC form. The custody is exchanged by the current custodian signing to release custody, and the new custodian signing to receive custody. The signatures should be accompanied by a date and time of transfer and an indication of each person's employer.

When samples are being shipped, the carrier is not required to sign for custody of the sample. The shipping documentation will be proof of custody until the samples are received at the analytical laboratory.

4.5.2 Request for Analysis

A Request for Analysis (RFA) form should accompany the sample COC form when the samples are shipped for analysis. A sample team member will initiate the RFA form by filling in the required information for both the sample collection and the requested analyses. Information required to be on the RFA form includes:

- Sample number
- Sample type
- Sample quantity
- Preservative (if applicable)
- Required testing program
- Special Instructions (if applicable)
- Sampling program
- Purchase order number
- Date of shipment
- Name of the laboratory being used for analysis
- Name of the laboratory contact
- Address to send the laboratory report to
- Date the laboratory report is due
- Name of the project contact
- Project contact's phone number

In addition, there must be space to document any known sample hazards and instructions for sample disposal. The preprinted number on the COC form should be written on the upper right-hand side of the RFA form.

An example of an RFA form is maintained as Attachment 3 to WP 02-EM3001. This is an example form only. There is not a required format for an RFA form, if the form being used contains the required information.

The original copy of the COC and RFA forms will be sent to the contracted laboratory and all remaining copies shall be part of the documentation packet. Instructions to the laboratory will be sent with the forms. The original copies will be sent back with the data report. (An example of instructions for the analytical laboratory is included in Attachment 2, Instructions to the Contract Analytical Laboratory.) All other copies are filed in the custody records for tracking purposes.

5.0 SAFETY

5.1 Material Safety Data Sheets [3]

MSDSs and/or process knowledge will be the main source of safety information when approaching a sampling activity. The MSDS contains information that will be used when deciding the appropriate sample container and how the material should be sampled. The MSDS also contains information on the necessary personal protective equipment (PPE) when required.

5.2 Industrial Hygiene

When an MSDS is not available, or the substance to be sampled is of unknown composition, the Industrial Hygienist will be responsible for determining the safest way to sample the substance and the PPE that is required. If the Industrial Hygienist, is absent, a Certified Safety Professional will make the determination. Examples of the levels of PPE are included in Attachment 3, Personal Protective Equipment.

5.3 Personal Protective Equipment [8]

Personal protective equipment that becomes saturated due to spillage or splashes during sampling, shall be evaluated for disposal via the Request for Disposal process outlined in WP 02-RC3108, Request for Disposal. Noncontaminated PPE shall be disposed of as nonhazardous waste.

All PPE and sampling equipment used while sampling TRU-mixed waste shall be disposed of as site-derived waste.

5.4 General Safety and Sample Integrity [3]

Safety of the sampling activity shall be evaluated before sampling commences. When there are unknown materials, all appropriate precautions should be taken. Sample collectors shall avoid contact with any of the media being sampled. Training will be provided to ensure the safety of the sampling activities, but every situation is different and shall be approached with caution.

Safety goggles and rubber gloves are required when handling preservatives. MSDSs must be current and readily available.

Sample integrity is an issue closely related to safety. If the sample is taken in a sloppy or inconsistent manner, the sample will not provide valid data, and will require resampling.

In addition to hazards posed by materials to be sampled, there are other dangers that may be encountered. The area around the WIPP site is undeveloped and contains many tripping and falling hazards, as well as buried electric and gas lines, animals, and insects that could be harmful to the sampling team members. All persons involved in sampling activities shall be aware of the sampling location's surroundings. If necessary, samplers shall have surveys conducted to map locations of buried lines. Adverse weather conditions pose additional hazards to sampling team members. Samplers should plan sampling activities so that weather conditions such as extreme heat, lightning, and high winds do not pose a threat to the health and safety of the sampling team members.

Even when the utmost care is taken, an emergency situation can occur as a result of an unanticipated explosion, electrical hazard, fall, or exposure to a hazardous substance. To minimize the impact of an emergency, sampling personnel should be aware of basic first aid and have immediate access to a first aid kit.

Before personnel function as part of the sampling team, they will have a medical examination in accordance with the requirements in WP 15-HS.02, WIPP Occupational Health Program. The initial examination includes:

- Spirometry
- Basic Physical Examination
- Complete Blood Count
- Urinalysis
- Chest X-ray (optional)
- Respirator Medical Evaluation Questionnaire

The examination will document the initial quality of a sampling team member's health and ensure the maintenance of good health. Annual examinations, in accordance with WP 15-HS.02, will be performed if the individual remains on the sampling team. Unscheduled medical examinations should be performed in the event of an accident, illness, exposure, or suspected exposure to toxic materials. Personnel will not participate in further sampling team activities until cleared by the medical director.

6.0 ANALYSES

6.1 Field General Chemistry Analyses

General field parameters, such as pH, temperature, and conductivity, may be performed in the field by the sampling personnel. If it is not possible to perform these tests when the sample is taken, the analyses must be performed as soon as possible. These tests will aid in determining how the sample is contained, preserved, and analyzed. If a sample is of unknown composition, the characteristics of the material give the sampler an idea of what the composition might be, making it easier to determine the analyses needed to be conducted by the analytical laboratory. The forms generated by the corresponding field test procedures will be maintained with the sample logbook or the applicable data report file.

6.1.1 pH Measurement

In most cases, the pH will be measured by the contract laboratory. For purposes of shipping, pH may be measured in the field using pH strips. As required, the pH of a substance may be measured per WP 02-EM1005, Groundwater Serial Sample Analysis, or applicable instrument instructions, using calibrated equipment. The pH can be measured only if the sample media is aqueous or multiphase with the aqueous part of the sample media being at least 20 percent of the total volume. This procedure also includes a calibration of the pH meter and electrode.

6.1.2 Temperature Measurement

When it is necessary to determine the temperature of a substance, it will be measured per WP 02-EM1005 or the applicable instrument instructions.

6.1.3 Conductivity Analysis

When it is necessary to determine the conductivity of a solution, it will be measured per WP 02-EM1005 or the applicable instrument instructions.

6.2 Qualitative and Quantitative Analyses

There are minimum analyses that must be performed on certain types of samples. In some cases, only characterization will be required, and in other cases, a qualitative and quantitative analysis will be needed. The minimum analyses are listed in Table 4. If additional analyses are needed, they must be specified on the RFA form sent with the sample.

The contracted analytical laboratory will be responsible for providing the results to the qualitative and quantitative analyses, according to their contract. For each parameter of interest, there are suggested methods of analysis. The suggested methods are listed in Table 3. The contracted laboratory will specify which analysis will be performed, and present the deviations from this analysis for approval at the time of contract placement.

7.0 TRANSPORTATION [9, 10]

7.1 Shipment of Samples for Laboratory Analysis

Samples being transported to a laboratory for the purpose of testing to determine their characteristics or composition are exempted from RCRA regulations under 40 CFR §261.4(d), "Exclusions." However, sample shipment shall be coordinated with Shipping Coordination to ensure that the applicable U.S. Department of Transportation regulations for packaging and shipping have been met. Verification of this process shall be indicated by a signature from a designated Shipping Coordination representative on the Shipping Authorization form in accordance with WP 15-PM3525.

8.0 DATA PACKAGE REVIEW [11]

The data package for the sampling activity will consist of the following:

- Data summary report
- Analytical narrative
- Sample custody papers
- RFA form

- Copies of the general chemistry results
- Analytical equipment calibration data
- Analytical equipment calibration check data
- Analytical equipment control charts (if appropriate)
- Equipment rinseates analysis data (if appropriate)
- Duplicate analysis data (if appropriate)

The data package will be reviewed by the sampling team coordinator. The sampling team coordinator may also request the data package be reviewed by additional SEC, Environmental Monitoring and Hydrology, or Quality Assurance personnel.

SEC will review the data package for validity and compliance with the sampling plan. If responding to a spill or release, SEC will also look at the levels of contaminants found, determine whether the quantities are reportable, and whether or not the levels warrant further action. If levels are reportable, SEC must respond according to WP 02-EC3506, Environmental Incident Reporting, and contact the Facility Manager per the requirements of the applicable WIPP procedure for reporting occurrences in accordance with DOE Order 231.1A, *Environment, Safety, and Health Reporting.*

If necessary, the sampling team coordinator may request that Quality Assurance review the data package validity.

The review will be documented on Attachment 1, Review Form for Sample Analysis Data Package. After all reviews are completed, the data package will be validated by the sampling team coordinator.

9.0 RECORDS

Records generated by this plan are:

- COC form
- RFA form
- Data packages
- Field logbook
- Sample tracking logbook
- Review form for sample analysis data package

Table 1 - Sampling Equipment for Particular Materials

Solid Samplers		
Samplers	**Application**	**Limitations**
Solid Thief (Grain Sampler)	Powdered or granular solids.	Maximum sampling depth approximately 6 feet. Grains may be approximately the size of a kernel of corn. Limited application for sampling moist or sticky solids.
Sampling Trier	Preferred when powdered or granular materials are moist or sticky. Soft or loosened soil samples.	Maximum sampling depth approximately 2 feet. Difficult to retain core sample of very dry granular materials.
Trowel or Scoop	Dry, granular or powdered material or surface soil collection. Material consisting of large particles.	Maximum sampling depth approximately 3 inches. Difficult to obtain reproducible mass of samples.
Soil Auger	Soil samples 3 inches or deeper.	Maximum sampling depth approximately 6 feet. Cutting diameter up to 8 inches.
Waste Pile Sampler	Waste piles and granular or powdered material.	Maximum sampling depth approximately 6 feet. Unable to sample solid material with dimensions greater than half the diameter of the sampling tube.
Coliwasa	Liquids, sludges, and slurries in drums, vacuum trucks, barrels, and similar containers.	Maximum sampling depth approximately 5 feet.
Liquid Thief	Use with containers that have smaller openings. Liquids, sludges, slurries, immiscible phases, and sediments.	Maximum sampling depth to about 3 feet. With immiscible phases, problems keeping sample in tube due to loss of surface tension.
Soil Sampler	Use for collecting small samples of soil for analysis of volatile constituents.	Maximum sampling depth approximately 2 inches.
Peristaltic Pump	Variable speed collection, depending on pump head type. Used for both composite samples and individual samples.	Difficult to obtain representative sample with immiscible phases. Vacuum in tubing may cause out-gassing of organics.
Dipper	Liquids and sludges from surface of ponds, lagoons, or similar reservoirs.	Maximum length about 12 feet. Loss of sample when transferring to sample container.
Weighted Bottle	Storage tanks, deep wells, sumps or other containers too deep for coliwasa. Multiple depth sampling.	Difficult to use with viscous liquids. Must be aware of chemical compatibility with weight sinker and line or frame.

Table 2 - Containers, Preservatives, and Holding Times

Name	Amount	Container	Preservation	Max Hold
Cyanide	1L	P,G	≤4°C, if oxidizing agents present add 5 ml 0.1N $NaAsO_2$ per L or .06 g ascorbic acid per L; adjust pH to 12 with NaOH	14 days
Hydrogen ion pH	25 ml	P,G	None	24 hours
Nitrate/Nitrite	100ml	P	≤4°C, H_2SO_4 to pH<2	28 days
Nitrate	1L	P,G	≤4°C	48 hours
Metals	1L	P,G	HNO_3 to pH<2	6 months
Dissolved Metals	1L	P	≤4°C	6 months
Oil and Grease	100 ml	G	≤4°C	28 days
Organic Carbon TOC	15 ml (4)	P,G	≤4°C	28 days
Volatiles	40 ml (2)	G, Teflon	≤4°C, 4 drops HCl	14 days
Semivolatiles	2L	AG	≤4°C	7 days
Pesticides	½ gal	AG	≤4°C	7 days
Phenols	500 ml	G	≤4°C, H_2SO_4 to pH<2	28 days
Total Suspended Solids TSS	1L	AG	HNO_3 to pH<2	180 days
TCLP Metals	1L	P	None	6 months
TCLP Semivolatiles	1L	G	None	7 days
TCLP Volatiles	40 ml (2)/250ml/125ml	WMG/Septum Lid	None	14 days
BTEX	250ml	WMG/Septum Lid	25 drops (2.5 ml HCL) ≤4°C	14 days
BOD	1L	P	≤4°C	48 hours

To Contract Analytical Laboratory:

Please relinquish custody on the Chain-of-Custody form by signing and dating on the next appropriate line and return original with the sample analyses data to:

Washington Regulatory and Environmental Services
Sampling Team Coordinator's Name MS 486-06
WIPP Site/Jal Highway
32 miles SE of Carlsbad
Carlsbad, NM 88220

Attachment 3 - Personal Protective Equipment

There are four levels of personal protective equipment that are used when approaching a hazardous material. These levels are as follows:

A - Full-positive pressure suit
- Full-face piece self-contained breathing apparatus (SCBA) or positive pressure supplied air respirator with escape SCBA
- Totally encapsulated chemical protective suit
- Inner and outer chemical resistant gloves
- Hard hat (if appropriate)
- Chemical resistant steel toe boots

B - Positive pressure suit
- Full-face piece SCBA or positive pressure supplied air respirator with escape SCBA
- Hooded chemical resistant clothing
- Inner and outer chemical resistant gloves
- Chemical resistant steel toe boots
- Disposable boot covers

C - Full-face or half-mask air purifying respirator
- Hooded chemical resistant clothing
- Inner and outer chemical resistant gloves
- Steel toe boots
- Disposable boot covers

D - Work uniform
- Steel toe boots
- Safety glasses
- Work gloves (if appropriate)
- Hard hat (if appropriate)

The level of personal protective equipment to be used will be determined by the MSDS or the Industrial Hygienist.

These results represent only the samples received in the laboratory. The Quality Control Report is generated on a batch basis. All information contained in this report is for the analytical batch(es) in which your sample(s) were analyzed.

This report consists of a total of 38 pages and shall not be reproduced except in its entirety, without written approval of TraceAnalysis, Inc.

January 27, 2005

Mr. Clint Marshall
Ground Water Quality Bureau
New Mexico Environment Department
P.O. Box 26110
Santa Fe, New Mexico 87502

RECEIVED
FEB 04 2005

Subject: Notification of the December 2004 and January 2005 Freeboard Levels for the Sewage Lagoons and the H-19 Evaporation Pond

Dear Mr. Marshall:

Your letter dated December 28, 2004, approving the corrective actions proposed by the Waste Isolation Pilot Plant (WIPP) for the loss of freeboard in the sewage lagoons and H-19 requires us to notify you of the freeboard levels in each pond by the last day of each month. The freeboard levels for December 2004 and January 2005 were as follows:

Area	December 31, 2004	January 16, 2005
Settling Pond 1A	20 inches	20 inches
Polishing Pond 1B	20 inches	20 inches
Settling Pond 2A	21 inches	18 inches
Settling Pond 2B	19 inches	17 inches
Evaporation Pond A	20 inches	25 inches
Evaporation Pond B	29 inches	27 inches
Evaporation Pond C	29 inches	27 inches
H-19	22 inches	22 inches

During the week of January 17, 2005, the sewage lagoons were configured to allow the ponds with the least freeboard, Ponds 2A and 2B, to drain into Pond A.

If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

for Inés Triay
Acting Manager

Notice is hereby given pursuant to 20.6.2.3108 NMAC, the following Ground Water Discharge Permit applications have been proposed for approval. To request additional information or to obtain a copy of a draft permit, contact the Ground Water Quality Bureau in Santa Fe at (505) 827-2900. Draft permits may also be viewed on-line at www.nmenv.state.nm.us/gwb/New%20Pages/public_notice.htm

NOTE – If viewing by WEB - Click on facility name to review a copy of the draft permit.

DP #	Facility/Applicant	Closest City	County	Notice	NMED Permit Contact
929	Former Texaco Bulk Fuels Terminal Gary Jacobson, Environmental Manager Chevron Environmental Management Inc. 4800 Fournace Pl, E534A Bellaire, TX 77401	Albuquerque	Bernalillo	Former Texaco Bulk Fuels Terminal, Gary Jacobson, Environmental Manager, proposes to renew the Discharge Permit for the discharge of up to 213,120 gallons per day of treated ground water from a remediation system into five injection wells. Potential contaminants associated with this type of discharge include organic compounds. The facility is located at 3209 Broadway Boulevard SE, Albuquerque, in Section 32, T10N, R03E, Bernalillo County. Ground water beneath the site is at a depth of approximately 20 feet and has a total dissolved solids concentration of approximately 1,470 milligrams per liter.	Naomi Davidson
1178	Indian Hills/Canyon Auto Remediation Site James Davis, Chief NMED Petroleum Storage Tank Bureau 2044 Galisteo St. Santa Fe, NM 87505	Tijeras	Bernalillo	Indian Hills/Canyon Auto Remediation Site, James Davis, Chief of Petroleum Storage Tank Bureau, proposes to discharge up to 10,800 gallons per day of treated ground water from a remediation system into four injection wells. Potential contaminants associated with this type of discharge include organic compounds. The facility is located at 844 East Highway 66, Zuzax, in Section 7, T10N, R06E, Bernalillo County. Ground water beneath the site is at a depth of approximately 50 feet and has a total dissolved solids concentration of approximately 870 milligrams per liter.	Steven Pedro
1195	Elmira Dairy Earl Heilbult, Owner 5560 Jacqueline Dr. Albuquerque, NM 8712	Albuquerque	Bernalillo	Elmira Dairy, Earl Heibult, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 9,999 gallons per day of agricultural wastewater. Dairy wastewater is discharged from the milking parlor to a concrete holding tank and is then pumped to a solids settling separator followed by a synthetically lined lagoon for disposal by evaporation. Potential contaminants associated with this type of discharge include nitrogen	Bill Pearson

				compounds. The facility is located at 5560 Jacqueline Dr. SW, in Section 33, T09N, R02E, Bernalillo County. Ground water beneath the site is at a depth of approximately 108-127 feet and has a total dissolved solids concentration of approximately 844 milligrams per liter.	
646	Rio Vista Dairy Raymond Vaz, Owner 3909 Woodbine Way Roswell, NM 88203	Roswell	Chaves	Rio Vista Dairy, Raymond Vaz, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 60,000 gallons per day of agricultural wastewater. Up to 60,000 gallons per day of dairy wastewater is discharged from the milking parlor to a sand separator followed by a concrete sump and is pumped through a screen solids separator to a synthetically lined lagoon for storage. Wastewater from the lagoon is land applied to 161 acres of center pivot and flood irrigated cropland under cultivation. The modification consists of increasing the wastewater discharge from 48,000 to 60,000 gallons per day and increasing the land application area from 100 acres of flood irrigated cropland to 161 acres of center pivot and flood irrigated cropland under cultivation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 3909 Woodbine Way, approximately 3 miles southeast of Roswell in Section 16, T11S, R25E, Chaves County. Ground water beneath the site is at a depth of approximately 20 feet and has a total dissolved solids concentration of approximately 2,300 milligrams per liter.	Bill Pearson
1030	Mighty Vac Rocky Horton, Owner Mighty Vac 1319 N. Main Clovis, NM 88101	Clovis	Curry	Mighty Vac, Rocky Horton, Owner, proposes to renew the Discharge Permit for the discharge of up to 6,000 gallons per day of restaurant grease interceptor waste and car wash sand trap waste to two concrete decanting beds for dewatering. Wastewater from the beds is discharged to a concrete lined evaporative lagoon. Grease is decanted and mixed with dirt in a concrete drying/mixing bed. The dewatered grease mixture and sand trap solids are disposed of at the City of Clovis Landfill. Potential contaminants associated with this type of discharge include nitrogen compounds, metals, and organic compounds. The facility is located at 601 CR L, approximately 1 mile southwest of Clovis, in Section 23, T02N, R35E, Curry County. Ground water beneath the site is at a depth of	Kathie Deal

				approximately 290 feet and has a total dissolved solids concentration of approximately 450 milligrams per liter.	
1199	Palla Dairy Eric Palla, Manager 902 Colonial Parkway Clovis, NM 88101	Clovis	Curry	Palla Dairy, Eric Palla, Manager, proposes to renew and modify the Discharge Permit for the discharge of up to 160,000 gallons per day of agricultural wastewater. Wastewater is discharged from the milking parlor to a concrete settling basin from which it is pumped through a solids separator to a synthetically lined lagoon for storage. Wastewater from the lagoon is land applied by center pivot/sprinkler irrigation to 400 acres of irrigated cropland under cultivation. The modification consists of increasing the discharge from 80,000 to 160,000 gallons per day and increasing the land application area from 220 to 400 acres. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 11 miles north of Clovis on State Highway 288, in Sections 7 and 18, T04N, R36E, Curry County. Ground water beneath the site is at a depth of approximately 410 feet and has a total dissolved solids concentration of approximately 373 milligrams per liter.	Steven Pedro
74	Buena Vista Dairy 2 Mike Weatherly Buena Vista Dairy 2 PO Box 346 Mesquite, NM 88880	Vado	Doña Ana	Buena Vista Dairy 2, Mike Weatherly, Owner, proposes to renew and modify the Discharge Permit for up to 55,000 gallons per day of agricultural wastewater. Wastewater is discharged from the milking parlor through a solids separator system to two synthetically lined combination wastewater/stormwater lagoons (Cell A & B) and an additional synthetically lined wastewater lagoon for storage. Wastewater from the lagoons is land applied by flood irrigation to 156 acres of irrigated cropland under cultivation. The modification consists of increasing the wastewater discharge from 26,000 to 55,000 gallons per day and increasing the land application area from 115 to 156 acres of flood irrigated cropland under cultivation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 1 mile east of Vado in Sections 21, T25S, R03E, Dona Ana County. Ground water beneath the site is at a depth of approximately 13-32 feet and has a total dissolved solids concentration of approximately 1,500 milligrams per liter.	Bill Pearson

126	Daybreak Dairy Jon Gorzeman PO Box 170 Mesquite, NM 88048	Mesquite	Doña Ana	Daybreak Dairy, Jon Gorzeman, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 24,000 gallons per day of agricultural wastewater. Up to 24,000 gallons per day of dairy wastewater is discharged to a concrete sump and pumped through a screen solids separator to a synthetically lined lagoon for storage. Wastewater is discharged to 119 acres of irrigated cropland under cultivation. The modification consists of decreasing the wastewater discharge from 40,500 to 24,000 gallons per day. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 1.5 miles east of Mesquite in Sections 5 & 6, T25S, R03E, Dona Ana County. Ground water beneath the site is at a depth of approximately 10 feet and has a total dissolved solids concentration of approximately 3,000 milligrams per liter.	Bill Pearson
167	River Valley Dairy Bruce Bonestroo, Owner River Valley Dairy P.O. Box 1929 Anthony, NM 88021	Vado	Doña Ana	River Valley Dairy, Bruce Bonestroo, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 35,000 gallons per day (gpd) of agricultural wastewater. Wastewater discharged from the milking parlor flows to a concrete-lined sump, is pumped over a screen solids separator and collects in a synthetically lined lagoon for storage. Wastewater is then land applied by flood irrigation to 129 acres of irrigated cropland. The modification consists of increasing the discharge volume from 27,000 to 35,000 gpd and the land application area from 98 to 129 acres of irrigated cropland. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 1.5 miles southeast of Vado, in Sections 28 and 33, T25S, R3E, Doña Ana County. Ground water beneath the site is at a depth of approximately 11 feet and has a total dissolved solids concentration of approximately 1800 milligrams per liter.	Kimberly Kirby
692	Del Oro Dairy Jerry Settles P.O. Box 1846 Anthony, NM 88021	Anthony	Doña Ana	Del Oro Dairy, Jerry Settles, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 60,000 gallons per day of agricultural wastewater. Wastewater is discharged from the milking parlor through a screen solids separator to a concrete sump and pumped to	Bill Pearson

				a synthetically lined lagoon followed by a second synthetically lined lagoon for disposal by evaporation. Wastewater, when needed, is authorized to be discharged to two synthetically lined stormwater impoundments (Pond C & D) as long as these impoundments are maintained, at a minimum, to contain run-off from a 25-year, 24-hour rainfall event at all times. The modification consists of discontinuing wastewater applications to the 7 acre land application area. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 2 miles north of Anthony in Section 23, T26S, R03E, Dona Ana County. Ground water beneath the site is at a depth of approximately 55 feet and has a total dissolved solids concentration of approximately 1,500 milligrams per liter.	
833	Big Sky Dairy Ed DeRuyter, Owner Big Sky Dairy PO Box 10 Mesquite, NM 88048	Mesquite	Doña Ana	Big Sky Dairy, Ed DeRuyter, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 80,000 gallons per day (gpd) of agricultural wastewater from two milking parlors. Wastewater from the Big Sky Dairy milking parlor is pumped through a screen solids separator and a solids settling separator to two synthetically lined lagoons for storage. Wastewater from the former Desertland Dairy milking parlor is pumped through a screen solids separator to a holding tank. Wastewater from this holding tank is pumped to the Big Sky Dairy synthetically lined lagoons for storage. Wastewater from the Big Sky Dairy storage lagoon is land applied by center pivot and sprinkler irrigation to 151 acres of irrigated cropland under cultivation. The modifications consist of combining the wastewater discharge from the former Desertland Dairy, DP-260, into the Big Sky Dairy Discharge Permit, DP-833. This modification will increase the discharge volume from 36,000 to 80,000 gpd and increase the land application area from 101.2 to 151 acres. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 17900 S. Stern Drive, Mesquite, in Section 27, T25S, R3E, Doña Ana County. Ground water beneath the site is at a depth of approximately 40 feet and has a total dissolved solids concentration of approximately 2,000 - 4,000 milligrams per liter.	Bill Pearson

831	U.S. Department of Energy, Waste Isolation Pilot Plant David C. Moody, Manager U.S. Dept. of Energy Carlsbad Field Office P.O. Box 3090 Carlsbad, NM 88221	Carlsbad	Eddy	U.S. Department of Energy, Waste Isolation Pilot Plant, Dave Moody, Manager, proposes to modify the Discharge Permit, which presently allows for the discharge of up to 23,000 gallons per day (gpd) of sewage effluent, up to 2,000 gpd of non-hazardous high-TDS and brine water, up to 8,000 gpd of non-hazardous miscellaneous water, up to 100 gpd of neutralized acid waste, and a designed flow of 3,231,260 gpd of storm water runoff based on a 24-hour, 25-year storm event. The permit modification includes an increase of the designed storm water discharge to 4,224,835 gpd, the inclusion of the Site Preliminary Design Validation (SPDV) material pile, and the inclusion of a comprehensive closure plan. The facility is located approximately 26 miles east of Carlsbad, New Mexico, in Sections 20, 28 and 29, T22S, R31E, Eddy County. Depth to ground water in the area of the permitted discharge is approximately 225 feet and has a total dissolved solids concentration of approximately 3,920 milligrams per liter.	Clint Marshall
363	Phelps Dodge Tyrone, Inc. Rick Moore, General Manager Phelps Dodge Tyrone, Inc. P.O. Drawer 571 Tyrone, NM 88065	Silver City	Grant	Phelps Dodge Tyrone, Inc., Rick Moore, General Manager, proposes to renew the Discharge Permit, which presently allows for the discharge of up to 10,000 gallons per minute of an acidic leach solution with a pH of 2 to the No. 1A Leach Stockpile. Leach solution is applied to the top of the stockpile to remove copper. The leach solution is collected at the base of the stockpile and transferred to a solvent extraction/electrowinning plant for processing. The facility is located approximately 12 miles southwest of Silver City, New Mexico, in parts of Sections 24 and 25, T19S, R15W, Grant County. Depth to ground water in the area of the permitted discharge ranges from approximately 300 to 650 feet and has a total dissolved solids concentration of approximately 280 milligrams per liter.	Clint Marshall
435	Phelps Dodge Tyrone, Inc., Rick Moore, General Manager Phelps Dodge Tyrone, Inc.	Silver City	Grant	Phelps Dodge Tyrone, Inc., Rick Moore, General Manager, proposes to renew and modify the Discharge Permit, which presently allows for the discharge of up to 12,000 gallons per minute of an acidic leach solution with a pH of 2 to the No. 2A Leach Stockpile. Leach solution is applied to the top of the stockpile to remove copper. The leach solution is	Keith Ehlert

	P.O. Drawer 571 Tyrone, NM 88065			collected at the base of the stockpile and transferred to a solvent extraction/electrowinning plant for processing. The proposed modification to this permit renewal includes increasing the discharge rate of leach solution to the No. 2A Leach Stockpile to 15,000 gallons per minute, bringing into operation an existing synthetically lined mine dewatering surge pond, and creating a new stockpile (9A Stockpile) consisting of waste rock from the Little Rock Mine. The 9A Stockpile will be located immediately northwest of the 2A Leach Stockpile and will not be leached. The facilities are located approximately 12 miles southwest of Silver City, New Mexico, in parts of Section 15, 16, 21, and 22, T19S, R15W, Grant County. Depth to ground water in the area of the permitted discharge ranges from approximately 180 to 210 feet and has a total dissolved solids concentration of approximately 250 to 880 mg/l.	
526	Phelps Dodge-Chino Mine Timothy Eastep, Manager Chino Mines Company 210 Cortez St. Hurley, NM 88043	Bayard/ Hurley	Grant	Phelps Dodge-Chino Mine, Timothy Eastep, Manager, proposes to renew and modify the discharge permit for the discharge of up to 24,500,000 gallons per day of mining process water from a Copper Mine. Potential contaminants from this type of discharge include metals and non-metals. The Whitewater Leach System includes the South Stockpile, Upper South Waste Rock Pile and West Stockpile. Acidic leach solution (raffinate) may be discharged up to 20,180,000 gallons per day (gpd) on the South Stockpile and up to 4,320,000 gpd on the eastern portion of the West Stockpile. The raffinate infiltrates through the stockpiles, dissolving copper minerals and the resultant pregnant leachate solution (PLS) is collected and processed at the SX/EW Plant that has a separate discharge permit, DP-591. The South Stockpile and eastern portion of the West Stockpile may receive ore from the open pit and ore blended with Lake One material for leaching. The Upper South Waste Rock Pile is for storage of waste rock only and is not permitted to be leached. The western portion of the West Stockpile includes a ground water interceptor system that collects contaminated ground water. Modifications to DP-526 include the addition of Reservoir 9, which has a capacity of approximately 15 million gallons to receive storm water from the Upper South Waste Rock Pile as well as the surrounding area south of	Tom Dewers

				the reservoir. Also, wastewater discharges up to 60,000 gallons per day from Mine Maintenance and General Offices, located at the southwestern toe of the West Stockpile, will be included in this renewal. The Whitewater Leach System is located approximately 2 miles northeast of Bayard and includes the reach of Whitewater Creek from Hanover Creek to the northern end of Hurley at the northern boundary of the former Lake One in Sections 28, 29, 32, 33 and 34, T17S, R12W; Sections 3, 4, 5, 6, 7, 18, 19, 30 and 31, T18S, R12W; and Sections 12 and 13, T18S, R13W; in Grant County. Ground water most likely to be affected is at a depth of approximately 0 to over 300 feet below ground surface and has a total dissolved solids concentration of approximately 1,000 milligrams per liter.	
1237	Village of Mosquero Wastewater Treatment Plant Pablo Trujillo, Mayor 38 Main St. PO Box 116 Mosquero, NM 87733	Mosquero	Harding	Village of Mosquero Wastewater Treatment Plant, Pablo Trujillo, Mayor, proposes to renew and modify the Discharge Permit for the discharge of up to 9,000 gallons per day of domestic wastewater through two synthetically lined lagoons. After disinfection, treated wastewater is land applied via spray irrigation to 3 acres of native vegetation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 0.5 miles southeast of Mosquero in Section 22, T18N, R28E, Harding County. Ground water beneath the site is at a depth of approximately 45 - 80 feet and has a total dissolved solids concentration of approximately 280 milligrams per liter.	Rebecca Cook
1311	Village of Roy-Wastewater Treatment Plant Edward Fluhman, Mayor PO Box 8 Roy, NM 87743	Roy	Harding	Village of Roy-Wastewater Treatment Plant, Edward Fluhman, Mayor, proposes to renew the Discharge Permit for the discharge of up to 40,000 gallons per day of domestic wastewater through one clay-lined and one synthetically-lined lagoon to 1.5 acres of flood irrigated native vegetation. Excess wastewater collects in a synthetically-lined overflow lagoon at the down slope end of the land application area. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 0.5 miles north east of Roy in Section 21, T20N, R26E, Harding County. Ground water beneath the site is at a depth of approximately 70-90 feet and has a total dissolved solids	Rebecca Cook

				concentration of approximately 660 milligrams per liter.	
950	Santa Fe Ingredients Company Mr. Dean Rodriguez Santa Fe Ingredients Co. 1448 Hwy 338 Animas, NM 88020	Animas	Hidalgo	Santa Fe Ingredients Company, Henry Rodriguez, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 150,000 gallons per day of agricultural wastewater. Process wastewater from a vegetable processing plant is discharged to a concrete sump, pumped through a screen solids separator to a 5,000 gallon storage tank and land applied by flood irrigation to 50 acres of irrigated cropland under cultivation. If wastewater cannot be applied to the irrigated cropland, it shall be applied by flood irrigation to 70 acres for surface disposal. The modification consists of decreasing the wastewater discharge from 750,000 to 150,000 gallons per day and changing the land application area from 120 acres for surface disposal to 50 acres of flood irrigated cropland under cultivation and 70 acres of flood irrigated land for surface disposal. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located approximately 15 miles north of Animas in Section 3, T26S, R20W, Hidalgo County. Ground water beneath the site is at a depth of approximately 150 feet and has a total dissolved solids concentration of approximately 500 milligrams per liter.	Bill Pearson
120	Columbus-Industrial Park Martha Skinner, Mayor Village of Columbus PO Box 350 Columbus, NM 88029	Columbus	Luna	Columbus-Industrial Park, Martha Skinner, Mayor, proposes to renew and modify the Discharge Permit to treat up to 6,300 gallons per day of domestic wastewater that includes 1,200 gallons per day of domestic septage and chemical toilet waste in a lined facultative lagoon before it is discharged to a clay-lined evaporative lagoon for disposal. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 26162 East Oro Ave, approximately 2 miles south of Columbus in Section 14, T29S, R08W, Luna County. Ground water beneath the site is at a depth of approximately 60 feet and has a total dissolved solids concentration of approximately 750 milligrams per liter.	Kathie Deal
209	City of Deming-Wastewater Treatment Plant	Deming	Luna	City of Deming-Wastewater Treatment Plant, Louis Jenkins, Director, proposes to renew and modify the Discharge Permit to treat up to 3.0 million gallons per day of domestic	Kathie Deal

	Louis Jenkins, Director City of Deming PO Box 706 Deming, NM 88031			wastewater in a combined lagoon and trickling filter system. Reclaimed wastewater is distributed to two storage ponds and disinfected for municipal reuse on 122 acres of the Rio Mimbres Golf Course, the Mountain View Cemetery and recreational fields. Reclaimed wastewater is also land applied to 265 acres of cropland under cultivation and distributed to Border Foods Inc., for land application practices regulated under DP-1058. The majority of the treated wastewater from the settling ponds undergoes additional treatment in a series of sand filters before it is distributed to Luna Energy Facility (DP-1305) for reuse as cooling water. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 4370 J Street, approximately 3 miles southeast of Deming, in Section 6, T24S, R08W, Luna County. Discharges from the facility also occur in Sections 7 and 18, T24S, R08W, Section 36, T23S, R09W, and Section 01, T24S, R09W. Ground water beneath the site is at a depth of approximately 125 feet and has a total dissolved solids concentration of approximately 300 milligrams per liter.	
1526	Naturally NM Food Products Donald Martinez, Owner PO Box 52 El Rito, NM 87530	El Rito	Rio Arriba	Naturally NM Food Products, Donald Martinez, Owner, proposes to discharge up to 750 gallons per day of combined agricultural and domestic wastewater to a septic tank/leachfield system for disposal. Wastewater generated from the washdown of slaughterhouse operations is discharged through a grease trap to the septic tank/leachfield system. Blood and offal are collected in plastic drums and removed for offsite disposal. Domestic wastewater from one restroom at the facility is also discharged to the septic tank/leachfield system. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 1138 Highway 554 in El Rito, in Section 3, T24N, R07E, Rio Arriba County. Ground water beneath the site is at a depth of approximately 26 feet and has a total dissolved solids concentration of approximately 366 milligrams per liter.	Sarah McGrath
880	W-Diamond Dairy Robert Rogers, Owner P.O. Box 206	Portales	Roosevelt	W-Diamond Dairy, Robert Rogers, Owner, proposes to renew and modify the discharge permit for the discharge of 49,999 gallons per day of agricultural wastewater. Up to 49,999 gallons per day of dairy wastewater is discharged	Bill Pearson

	Portales, NM 88130			from two milking parlors to a synthetically lined combination wastewater/stormwater lagoon, through a solids separator, followed by two additional synthetically lined combination wastewater/stormwater lagoons for disposal by evaporation. The modification consists of increasing the discharge volume from 12,000 to 49,999 gallons per day, discontinuing wastewater applications to the land application area, and disposing of wastewater by evaporation in a synthetically lined lagoon system. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located 9 miles southwest from Portales in Section 7, T02S, R33E, Roosevelt County. Ground water most likely to be affected is at a depth of approximately 75 feet and has a total dissolved solids concentration of approximately 640 milligrams per liter.	
1001	James Idsinga, Sr. & Son Dairy James Idsinga 2116 East Third St. Portales, NM 88130	Portales	Roosevelt	James Idsinga, Sr. & Son Dairy, James Idsinga, Sr., Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 32,000 gallons per day of agricultural wastewater. Up to 32,000 gallons per day of dairy wastewater will be discharged from the milking parlor to a clay-lined lagoon and then land applied to 150 acres of center-pivot sprinkler irrigated cropland under cultivation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 43321 US Hwy 70 approximately 9 miles northeast of Portales in Sections 29 & 30, T01N, R36E, Roosevelt County. Ground water beneath the site is at a depth of approximately 150 feet and has a total dissolved solids concentration of approximately 360 milligrams per liter.	Bill Pearson
1250	Sky Country Farms Al Fiske, Owner 1392 Baseline Rd. Portales, NM 88130	Portales	Roosevelt	Sky Country Farms, Al Fiske, Owner, proposes to renew the Discharge Permit for the discharge of up to 90,000 gallons per day of dairy wastewater from the milking parlor through a solids separator to a synthetically lined lagoon for storage. Wastewater is land applied by center pivot irrigation to 601 acres of cropland under cultivation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 1392 Baseline Rd, Portales in Section 33, T01N,	Christopher Vick

				R35E, Roosevelt County. Ground water beneath the site is at a depth of approximately 133 feet and has a total dissolved solids concentration of approximately 350 milligrams per liter.	
1139	Village of Corrales-Recreation Center Nora Scherzinger, Administrator Village of Corrales 4324 Corrales Rd. Corrales, NM 87048	Corrales	Sandoval	Village of Corrales-Recreation Center, Nora Scherzinger, Administrator, proposes to renew the Discharge Permit for the discharge of up to 1,200 gallons per day of domestic wastewater to four 5,200 gallon underground holding tanks. Wastewater from the holding tanks is periodically pumped and disposed of off-site. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 500 Jones Road, in Corrales, in Sections 33 and 34, T12N, R03E, Sandoval County. Ground water beneath the site is at a depth of approximately 5 feet and has a total dissolved solids concentration of approximately 288 milligrams per liter.	Melanie Sanchez
1295	City of Farmington-Family Sports Complex Mr. Jeff Bowman, Director Parks & Recreation Dept. 901 Fairgrounds Rd. Farmington, NM 87401	Farmington	San Juan	City of Farmington-Family Sports Complex, Jeff Bowman, Director, proposes to renew the Discharge Permit for the discharge of up to 9,600 gallons per day of domestic wastewater from the Family Sports Complex to three septic tank/leachfield systems. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 2301 Pinon Hills Boulevard, approximately 1 mile west of Farmington, in Section 5, T29N, R13W, San Juan County. Ground water beneath the site is at a depth of approximately 30 feet and has a total dissolved solids concentration of approximately 3,721 milligrams per liter.	Melanie Sanchez
234	New Mexico (State of) Correctional Facility-State Penitentiary Stephen Wust, Director Santa Fe County Water Resources Dept. 205 Montezuma Ave. Santa Fe, NM 87501	Santa Fe	Santa Fe	New Mexico (State of) Correctional Facility-State Penitentiary, Stephen Wust of Santa Fe County Utilities Department, proposes to renew and modify the Discharge Permit for the discharge of up to 280,000 gallons per day of domestic wastewater from the New Mexico State Penitentiary Complex, the New Mexico National Guard Complex, the Santa Fe County Detention Center, and the proposed Santa Fe County Business Park Development. The wastewater is treated in two synthetically-lined stabilization ponds. Effluent from the stabilization ponds is disinfected in a chlorine contact chamber and then held in a	Steve Pedro

				clay lined storage pond prior to use for irrigation of 95 acres of fescue and/or alfalfa. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 4311 Highway 14 approximately 12 miles south of Santa Fe in Section 35, T16N, R08E, Santa Fe County. Ground water beneath the site is at a depth of approximately 85-100 feet and has a total dissolved solids concentration of approximately 170 milligrams per liter.	
1037	The Agora Shopping Center Gary Grable, Manager MA Agora WW LLC C/O Security Bank of Kansas City 1000 Minnesota Ave. Kansas City, KS 66101	Santa Fe	Santa Fe	The Agora Shopping Center, Gary Grable, Manager, proposes to renew the Discharge Permit for the discharge of up to 5,802 gallons per day of treated wastewater from a mechanical treatment system to a 4,200 square foot leachfield. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 7 Avenida Vista Grande, approximately 13 miles east of Santa Fe in Section 9, T15N, R10E, Santa Fe County. Ground water beneath the site is at a depth of approximately 100 feet and has a total dissolved solids concentration of approximately 500 milligrams per liter.	Christopher Vick
563	A and M Dairy Pedram Ghoreishi, Owner PO Box 591 Veguita, NM 87062	Veguita	Socorro	A and M Dairy, Pedram Ghoreishi, Owner, proposes to renew the Discharge Permit for the discharge of up to 4,200 gallons per day of agricultural wastewater. Dairy wastewater from the milking parlor is discharged through a concrete holding tank for solids settling to a clay-lined lagoon for disposal by evaporation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 125 Carlos Martinez Road, approximately 1.5 miles south of Veguita, in Section 16, T03N, R02E, Socorro County. Ground water beneath the site is at a depth of approximately 65 feet and has a total dissolved solids concentration of approximately 250 milligrams per liter.	Melanie Sanchez
731	Peñasco Schools Dorothy Sanchez, Superintendent PO Box 520 Peñasco, NM 87553	Peñasco	Taos	Peñasco Schools, Dorothy Sanchez, Superintendent, proposes to renew the Discharge Permit for the discharge of up to 10,000 gallons per day of treated domestic wastewater from a package treatment plant to a leachfield for disposal. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located in Peñasco, in Section 5, T22N, R12E, Taos	Christopher Vick

				County. Ground water beneath the site is at a depth of approximately 16 feet and has a total dissolved solids concentration of approximately 250 milligrams per liter.	
1063	Sanchez Mobile Home Park Joe Sanchez, Owner Sanchez MHP 3803 Alta Monte, NE Albuquerque, NM 87110	El Prado	Taos	Sanchez Mobile Home Park, Joe Sanchez, Owner, proposes to renew the Discharge Permit for the discharge of up to 5,000 gallons per day of domestic wastewater to two septic tank/leachfield systems. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 194 Valencia Rd, approximately 2 miles north of Taos, El Prado, within the Antonio Martinez de Godoi Land Grant, Section 24 (projected), T26N, R12E, Taos County. Ground water beneath the site is at a depth of approximately 115 feet and has a total dissolved solids concentration of approximately 135 milligrams per liter.	Kathie Deal
1004	Zens Dairy Galen (Butch) Zens, Owner Zens Dairy PO Box 200 Willard, NM 87063	Willard	Torrance	Zens Dairy, Galen (Butch) Zens, Owner, proposes to renew the Discharge Permit for the discharge of up to 80,000 gallons per day of dairy wastewater from the milking parlor to a concrete sump before it is pumped through a solids separator to a synthetically lined lagoon for storage. Wastewater is mixed with irrigation water in a holding tank prior to land application by sprinkler irrigation to 440 acres of irrigated cropland under cultivation. Potential contaminants associated with this type of discharge include nitrogen compounds. The facility is located at 190 Dairy Rd, approximately 1 mile southwest of Willard, in Sections 18 and 19, T04N, R09E, Torrance County. Ground water beneath the site is at a depth of approximately 95 feet and has a total dissolved solids concentration of approximately 528 milligrams per liter.	Kathie Deal
1176	Jarratt Dairy Raymond Jarratt, Owner 2104 Los Lentes Rd., SE Los Lunas, NM 87031	Los Lunas	Valencia	Jarratt Dairy, Raymond Jarratt, Owner, proposes to renew and modify the Discharge Permit for the discharge of up to 27,000 gallons per day of dairy wastewater from the milking parlor through a solids separator to a synthetically lined lagoon for storage. Wastewater is land applied with a vacuum truck to 335 acres of irrigated cropland under cultivation. The modification consists of increasing the discharge volume from 2,000 gallons per day to 27,000 gallons per day. Potential contaminants associated with	Christopher Vick

				this type of discharge include nitrogen compounds. The facility is located at 2520 Los Lentes Rd SE, Los Lunas, in Section 4, T06N, R02E, Valencia County. Ground water beneath the site is at a depth of approximately 5 feet and has a total dissolved solids concentration of approximately 240 milligrams per liter.	

Prior to ruling on any proposed Discharge Permit or its modification, the New Mexico Environment Department (NMED) will allow thirty days after the date of publication of this notice to receive written comments and during which a public hearing may be requested by any interested person, including the applicant. Requests for public hearing shall be in writing and shall set forth the reasons why the hearing should be held. A hearing will be held if NMED determines that there is substantial public interest. Comments or requests for hearing should be submitted to the Ground Water Quality Bureau at PO Box 26110, Santa Fe, NM 87502.

To view this and other public notices issued by the Ground Water Quality Bureau on-line, go to: www.nmenv.state.nm.us/Common/public_notice.htm and select Ground Water Quality Bureau

Subject: Completion of Public Notice Requirements for the March 4, 2005 Discharge Plan Modification

Reference: Administrative Completeness Determination and Applicant's Public Notice Requirements, DP-831, Waste Isolation Pilot Plant, dated May 23, 2006

Dear Mr. Olson:

The purpose of this letter is to provide proof of the completion of the public notice requirements (Option #2) for the March 4, 2005, Discharge Plan (DP-831) modification in accordance with your letter dated May 23, 2006, and the public notice requirements of 20.6.2.3108 NMAC. Public Notice Option #2 requires that within 15 days of the completion of the public notice requirements, the Permittee must submit proof of notice to NMED containing:

1. A signed affidavit that the public notice sign was posted at the facility.
2. A copy of the published display notice indicating the newspaper and date of publication.
3. The list of discharge site owners' names and addresses and copies of certified mail return receipts for owners, if different from the applicant.

Enclosed is a copy of the public notice that was published in the *Carlsbad Current Argus* newspaper on June 20, 2006. Also enclosed is the signed affidavit, payment fee (check #012717) and photograph of the public notice that was posted in a prominent location in front of the facility where it would be visible to the public passing by the site. Pertaining to the requirements for item 3, the discharge site owner is the same as the applicant, the U.S. Department of Energy, Manager, Dr. David C. Moody; therefore, no change is necessary.

If you have any questions or need additional information regarding this information, please contact Mr. H. L. Plum of my staff at (505) 234-7462.

Sincerely,

David C. Moody

PUBLIC NOTICE 1

DP-831

Public Notice Correction

DP-831, U.S. Department of Energy's Waste Isolation Pilot Plant, Dave Moody, Manager, proposes to modify the Discharge Permit for the discharge and treatment of up to 33,000 gallons per day of domestic and industrial wastewater and up to 4,224,835 gallons per day of storm water runoff from synthetically lined and/or capped salt storage piles. This permit modification addresses additional potential contamination sources at the WIPP facility and incorporates all potential sources into a comprehensive closure plan. The sources addressed in the closure plan include three salt storage piles that are the result of constructing underground access drifts and rooms for the disposal of transuranic radioactive waste and transuranic radioactive mixed waste. Potential contaminants from these types of discharges include total dissolved solids, chloride and nitrogen compounds.

The previous public notice for this discharge permit incorrectly stated the storm water runoff volume as 3,231,360 gallons per day and originating from facility grounds and parking lots as well as the salt storage piles. The storm water volumes covered under this permit originate only from the salt storage piles and are based on the maximum runoff that could occur form a 24-hour/25-year storm event.

The facility is located 26 miles southeast of Carlsbad, in Sections 20, 21, 28, and 29, T22S, R31E, Eddy County, New Mexico. Ground water that could potentially be affected by the discharges ranges from the Culebra Member of the Rustler Formation at a depth of approximately 608 feet with a total dissolved solids concentration of approximately 234,000 mg/l to water in the Dewey Lake Formation south of the site at a depth of 225 feet with a total dissolved solids concentration of approximately 3,920 mg/l.

Information in this public notice was provided by the applicant and will be verified by the New Mexico Environment Department during the permit application process. NMED will accept comments and statements of interest regarding the application and will create a facility specific mailing list for persons who wish to receive future notices. Comments and statements of interest should be sent to Clint Marshall, DP-831, Ground Water Quality Bureau, PO Box 26110, Santa Fe, NM 87502. For additional information please call (505) 827-2900.

AFFIDAVIT OF SIGN POSTING, DP- *831*

I certify, under penalty of law, that I fulfilled the ground water Discharge Permit public notice requirements of Section 20.6.2.3108.A.1 NMAC. I prominently posted a synopsis of the public notice (prepared by NMED), in English and in Spanish, at a conspicuous public location, approved by NMED, at or near the proposed facility for 30 days. I am aware that there are significant penalties for false certification including the possibility of fines. I have included a payment of $15.00 for the poster (If public notice option 1 or 2 was selected).

RE: Administrative Completeness Determination and Applicant's Public Notice Requirements, DP-831, Waste Isolation Pilot Plant

Dear Discharge Permit Applicant:

The New Mexico Environment Department (NMED) received a Ground Water Discharge Permit Application from you on March 8, 2005. Pursuant to Section 20.6.2.3106 NMAC of the New Mexico Water Quality Control Commission Regulations (20.6.2 NMAC), NMED determined on March 10, 2005 that your application is administratively complete.

Within 30 days of the submission of an administratively complete Discharge Permit Application, you must provide public notice using one of the 3 options listed in Section 20.6.2.3108 NMAC. You selected public notice option # 2. The instructions and materials needed to complete this option are enclosed.

A technical reviewer will contact you within the next few months if additional information is needed to process your application. If you have a deadline of concern in the interim or any questions, please call the Ground Water Quality Bureau at (505) 827-2900.

Sincerely,

Naomi Davidson

Subject: Infiltration Controls, As-Built Run-Off Volumes, and Pond Design Capacities Associated With the Draft DP-831 Permit

Dear Mr. Marshall:

The purpose of this letter is to provide you with the run-off volumes for each of the stormwater Infiltration Control Ponds noted in the draft DP-831 permit in accordance with your verbal request on May 2, 2006. This information was requested by you due to our comment regarding the draft permit's condition that states:

The permitted discharge consists of up to 23,000 gallons per day (gpd) of sewage effluent, up to 2,000 gpd of non-hazardous brine water, up to 8,000 gpd of non-hazardous miscellaneous water, up to 100 gpd of neutralized acid wste, and up to 3,231,260 gpd of stormwater runoff.

In lieu of the permit establishing a maximum allowable discharge, the Permittees suggest the following language:

The permitted activities consist of:

- The discharge of up to 23,000 gallons per day of wastewater to the sewage lagoons and up to 2,000 gallons per day to Evaporation Pond B.
- The discharge of up to 8,000 gallons per day of non-hazardous wastewater into the H-19 Evaporation Pond.
- The collection and evaporation of stormwater run-off in evaporation ponds as follows:

Evaporation Pond	Drainage Area	Run-off volumes (3.90 inch rainfall event)[1]	Pond Capacity[2]
Salt Pile Evaporation Pond	690,100 square feet	1,677,633 gallons	5,506,989 gallons
Salt Storage Extension Basin w/ Cell A and Cell B	1,047,800[3] square feet	2,547,202 gallons	4,170,732 gallons

[1] Run-off volumes assume 100 percent run-off since infiltration coefficients are unknown and can only be estimated. This also includes the volume that falls onto the surface area of the pond.
[2] Capacity is the maximum capacity without any freeboard.
[3] Current configuration with only Cell A has a drainage area of 538,000 square feet, run-off volumes for the 3.90 inch rainfall event is 1,307,878 gallons.

CBFO:AMO:HLP:KJB:06-0554:UFC 5486.00

With respect to the stormwater infiltration controls, the suggested permit language quantifies the volume of run-off from the drainage areas reporting to each evaporation pond in the event of the 25-year, 24-hour storm event of 3.90 inches. As noted in our September 12, 2005 letter outlining our maintenance plan for erosion control and drainage enhancements for the Salt Pile cover, a berm has been constructed on the north side of the covered salt pile that will divert run-off during significant storm events to a [still to be constructed] armored discharge chute in the north east corner of the pile. The volume of diverted water will be dependent upon the intensity and duration of the precipitation event; however the Salt Pile Evaporation Pond has sufficient available capacity to contain the additional diverted water.

If you have any questions or require additional information, please contact me at (505) 234-7462.

Sincerely,

H. L. Plum

Subject: Sewage Lagoon Leak Testing Results and Liner Integrity Evaluations, Corrective Action Plan, Conditional Approval, December 22, 2005

We received your letter granting conditional approval of our proposed corrective action plan December 28, 2005. You requested that we provide you additional information regarding plans to address protection of synthetic lining materials at the edges of the sewage lagoons, control of surface water drainage away from pond perimeters, correction of erosion problems, and placement of permanent or sacrificial material to allow removal of solids from a facility. In our telephone conversation on Friday, January 20, 2006, we discussed these issues. By this letter, I am providing written confirmation of the actions discussed that will address your concerns.

- What measures will be taken to protect the edges of Ponds 1A, 1B, 2A, 2B, A, B, C, from stone damage and traffic damage?

We are implementing administrative controls to limit the amount of foot and vehicle traffic to these areas. This will lessen the possibility of such traffic on the liners at the edges of these facilities. Vehicle traffic will be limited to required maintenance and construction activities. Sign(s) will be posted to assure that personnel are aware of the need to avoid walking on the liner and to take care not to damage the liner when it is absolutely necessary to walk on the liner.

- How will we control surface water drainage to direct rainfall runoff away from the pond perimeters?

We have planned maintenance for these facilities that includes a repair or replacement schedule for the synthetic liners used. Due to the nature of the materials of construction of these facilities (turf re-enforcement mats filled with soil and covered to stabilize the banks) and the fact that these would be damaged should grading be done at prior to planned work occurring, we are planning to address the drainage issues at the time repair or when liner replacement of liners occurs. This work will begin with the replacement of the liners for Ponds 2A and 2B. This is anticipated to begin by July 2006. Due to the location of these facilities many of the drainage issues that exist at the east end of the sewage lagoon facility are expected to be addressed with the completion of this work.

CBFO:AMO:HJP:KJB:06-0506:UFC5486

- How will we correct erosion control problem and redirect drainage away from the edges of H-19 Evaporation Pond?

Appropriate grading will occur where needed at this facility. The silt fence will continue to be maintained and soil will be graded on the outside of this facility as needed.

- Will you be installing a layer of sacrificial material or concrete ramp to allow access into the facility to prevent damage during the movement or removal of materials?

Installation of either a sacrificial layer of synthetic liner or placement of a mat of cement to provide access to this facility will be made to allow access and lessen the possibility of damage to the integrity of the facility liner.

It is my understanding that you concur with the proposed actions discussed above and that they address the concerns expressed in your conditional approval of our Corrective Action Plan on December 22, 2005. All other work will be performed as described in the Corrective Action Plan submitted to your office on November 3, 2005.

Sincerely,

R. C. Plum, Manager

RE: Conditional Approval of the Corrective Action Plan based on the Sewage Lagoon Leak Testing Results and Liner Integrity Evaluations, DP-831, Waste Isolation Pilot Plant

Dear Mr. Piper:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received the November 3, 2005 letter titled, *Sewage Lagoon Electrical Leak Testing Results, Liner Integrity Evaluations and Corrective Action Plan*, from the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP). The liner inspections and evaluations were conducted by Leak Location Services, Inc. (LLSI), which also provided recommendations for liner repairs. The leak testing and evaluations were conducted based on a request from NMED personnel during a site inspection conducted on August 11, 2004. The inspection plan for the sewage lagoon system was proposed in a letter from WIPP dated March 10, 2005, and approved in a letter from NMED dated April 7, 2005. NMED approves the Corrective Action Plan (CAP) with conditions described below.

The proposed CAP described in the November 3, 2005 letter is summarized as follows.

1. The Pond 2A and Pond 2B liners will be replaced in FY2006.
2. The Pond 1A and Pond 1B liners will be replaced in FY2007.
3. The Pond A liner will be inspected and repaired in FY2008.
4. The Pond B liner will be inspected and repaired in FY 2009.
5. The Pond C liner will be inspected and repaired in FY2010.

6. A single leak detected in the H-19 Pond will be repaired in FY2006.

While the proposed CAP goes beyond some of the repair recommendations of the contractor, LLSI, there are additional actions recommended by the contractor in Appendix 1B that are not included in the proposed CAP. NMED requires that the following corrective actions be included in the CAP for the sewage lagoon system and H-19 Evaporation Pond.

1. WIPP shall protect the edges of Ponds 1A, 1B, 2A, 2B, A, B and C from stone and stone/traffic damage. All surface water drainage shall be redirected away from pond perimeters. These actions shall be completed according to the recommendations in Appendix 1B of the July 8, 2005 report titled, *Sewage Lagoon Electrical Leak Testing Results, Liner Integrity Evaluations* by June 30, 2006. A report documenting the completion of these actions shall be submitted to NMED by July 31, 2006.

2. WIPP shall correct all erosion problems and redirect the drainage away from the edges of the H-19 Evaporation Pond. Eroded areas around the anchor berm and anchor trench areas shall be refilled and compacted. A sacrificial layer of Hypalon or similar material, or a concrete ramp shall be installed in one corner of the pond to prevent damage during movement of materials within the pond. These actions shall be completed according to the recommendations in Appendix 1B of the July 8, 2005 report titled, *Sewage Lagoon Electrical Leak Testing Results, Liner Integrity Evaluations* by June 30, 2006. A report documenting the completion of these actions shall be submitted to NMED by July 31, 2006.

Please respond to this letter within 30 days of receipt. If you have any questions, please contact me at 505-827-0027.

Sincerely,

Clint Marshall

Re: Inspection of Public Records Act Request

Dear Mr. Olson:

I have been referred to Mr. Clint Marshall for access to the bureau's public records concerning Discharge Permit DP831. Mr. Marshall has been very cooperative in making this information available. He requested that I send you this letter formalizing my request under the New Mexico Inspection of Public Records Act and under NMED Policy and Procedure 25-09.

Please call me if you have any questions.

Sincerely,

Gregory D. Huffaker, Jr.

Subject: Sewage Lagoon Electrical Leak Testing Results, Liner Integrity Evaluations and Corrective Action Plan

Dear Mr. Marshall:

We are writing to follow-up to our August 3, 2005, letter to you notifying the Ground Water Quality Bureau that the evaluation of the sewage lagoon and H-19 Evaporation Pond liners using an electrical leak detection methodology has been completed. In that letter, we committed to provide you with the results of the sewage lagoon electrical leak test results, the laboratory liner integrity results, and a corrective action plan within 90 days of our receipt of the liner laboratory results. We received those results on August 22, 2005.

LEAK TEST RESULTS AND EVALUATION

Attachment 1 contains three reports regarding the sewage lagoon liner inspections and evaluations conducted by Leak Location Services, Inc. (LLSI) and an independent specialist in geomembrane liners. The reports include:

- *Geomembrane Leak Location Surveys of Seven Sewage Lagoons and One Evaporation Pond Located at the WIPP Facility Near Carlsbad, New Mexico* dated July 8, 2005 (Attachment 1-A):
    - Results of Electrical leak testing of the liners for the sewage lagoons and the H-19 Evaporation Pond

- *Sewage Lagoons and Evaporation Pond Lining Inspection Site Visitation Summary Report* prepared by Ronald K. Frobel, dated June 24, 2005 (Attachment 1-B):
    - An expert geotechnical specialist's evaluation of the sewage lagoons and the H-19 Evaporation Pond.

*ED denotes electronic distribution

CBFO:AMO:DM:LR:05-1545:UFC:5486

- *Sewage Lagoons Pond Lining Evaluation Summary Laboratory Testing* dated August 22, 2005 (Attachment 1-C):
  - o The results of laboratory tests conducted on samples of the liner materials used in the construction of the sewage lagoons;
  - o Expert advice concerning the expected life of the liners in the lagoons;
  - o Recommendations related to the repair or replacement of the existing sewage and evaporation facilities.

In summary, a total of 46 leak signals were noted, with at least one leak signal recorded in each of the eight facilities inspected.

Fourteen leak signals are known to be the result of metal pipe penetrations through the liner to convey wastewater from one pond to another. Electrical conduction paths such as steel piping or fasteners that make continuity with ground establish a circuit and result in false leak signals. Therefore, only 32 of the 46 leak signals can be attributed to other causes and may be actual leaks in the liner material.

It is generally accepted that geomembrane liners installed with even the most rigorous construction quality assurance/quality control (CQA/QC) techniques have some leakage based on: (1) the permeability of the geomembrane material and (2) errors undetected by the CQA/QC techniques.

We have reviewed reports that investigated the potential presence of leaks occurring in impermeable liners. We believe that the number of leaks detected in the WIPP Sewage Lagoon synthetic liners is typical of the number of leaks that occur in newly installed single lined ponds using conventional methods following rigorous CQA/QC techniques and standards. In spite of the rigorous application of CQA/QC standards and protocols for installing synthetic liners, some incidental damage may occur during installation, inadequate field seaming or failures in factory seams that go undetected at installation.

The attached report by Southwest Research Institute (SwRI) (Attachment 2) discusses the development of the electrical leak detection method for the Environmental Protection Agency in the early 1980s. SwRI surveyed 61 sites (new and active waste storage sites). The 61 sites comprised 4,368,785 square feet of geomembrane. SwRI found an average of 3.23 leaks per 10,000 square feet of liner material surveyed with a range of 0.3 to 5 leaks per 10,000 square feet.

The results of the survey of the WIPP Sewage Lagoon System and H-19 Evaporation Pond performed by LLSI equates to 2.56 leaks per 10,000 square feet. The table below provides a comparison of the survey results for the WIPP Sewage Lagoon System and the H-19 Evaporation Pond to four different electrical leak detection surveys.

WIPP total	132,800	46	3.46	34.00	2.56
WIPP total minus H-19	118,400	45	3.80	2.61	2.79

* See the following notes:

Referenced leak detection studies correspond to the following references included in Attachment 2.

SwRI: Detection and Location of Leaks in Geomembrane Liners Using an Electrical Method: Case Histories, Daren L. Laine and Michael P. Miklas, Jr. Southwest Research Institute, San Antonio Texas

Study 1: Leakage through Liner Systems, George Yazdani, MSc., P.E., Polyfex Inc. Geomembrane Lining Systems, Issue No. 7- March 1997

Study 2: Cost and Benefits of Geomembrane Liner Installation CQA, Geo Synthetics Conference 2001

Study 3: Lessons Learned from Electrical Surveys: Improvement of Leachate Collection Ponds Design, A.L. Rollin and T. Jacquelin, Somers International, Quebec, Canada

Analysis of the WIPP Sewage Lagoons and H-19 Evaporation Pond data and the referenced studies show that the sewage lagoons and evaporation ponds are in generally good condition and the number of leaks is comparable to the number of leaks found in newly installed single lined facilities.

In addition to the synthetic liners installed in each of the subject ponds, the ponds are lined with compacted caliche to at least 90 percent standard proctor density in

*ED denotes electronic distribution

CBFO:AMO:DM:LR:05-1545:UFC:5486

accordance with ASTM D 698. The secondary liners meet the recommendations for sewage facilities with only soil or clay liners outlined in the New Mexico Environment

Department's publication titled *Recommended Standards for Wastewater Facilities, Policies for the design, review and approval of Plans and Specifications for Wastewater Collection and Treatment Facilities* (2003 Edition). Attachment 3 contains the specifications for the secondary liner for the sewage lagoons constructed in the mid-1980s (02203-009/010 *Stripping and Grading*) and the specifications for secondary liner for Evaporation Pond A and the addition of Ponds B and C in the mid-1990s (E-Z-261, *Specification for Earthwork*).

The only domestic water wells near the WIPP site are in groundwater from the upper portion of the Dewey Lake Formation. These are on the J. C. Mills Ranch located approximately three miles south-southwest of the WIPP surface facilities. These wells are the Barn Well and Ranch Well used for livestock watering and the commercial sale of water for construction and oil field use.

The WIPP sewage facilities perform an essential function by treating wastewater from the plant in an environmentally sound manner. Despite the age of the current system, it was well installed using rigorous CQA/QC techniques and has held up well. The leak detection and inspection results confirm that the liners are in generally good condition.

RECOMMENDATIONS OF LINER CONSULTING SERVICE

Below are the recommendations made by liner specialists in the attached report on the WIPP sewage lagoons and an evaporation pond (Attachment 1-C):

- Replace all temporary patches, repair visible damage and repair all leaks found by leak testing. (The temporary patches are used on small holes and tears above the water line until a qualified liner repair contractor can be brought in for permanent repair.)
- Remove all effluents and sediment.
- Perform a visual inspection of the liner below water line.
- Protect edges from stone and traffic damage.
- Provide positive drainage away from the pond edges.
- Replace the liner of Settling Pond 2A due to de-lamination of the top Hypalon® surface at the water line.
- Repair the liners in the remaining seven ponds.

*ED denotes electronic distribution

CBFO:AMO:DM:LR:05-1545:UFC:5486

PROPOSED CORRECTIVE ACTION PLAN

The leak detection procedure indicated one leak in the H-19 Evaporation Pond which is located in an easily accessible area that will be repaired in FY2006. Rather than attempting to repair the aged liners in the 2A/2B and 1A/1B pond systems, DOE has decided to replace both liners in the next two years. DOE has also determined, based on information provided in the consultant's report (Attachment 1-C) that we should expect another 10+ years of service life for Evaporation Pond A, B, and C liners. We have decided that we will perform an inspection of these liners by removing the sediment in the area indicated to have a leak and make needed repairs. If a liner's condition is found upon inspection to be in a much worse condition than expected, it will be scheduled for replacement. The following schedule is proposed for the liners in each pond, weather permitting and subject to contractor availability.

Replace Pond 2A and 2B liner	FY2006
Replace Pond 1A and 1B liner	FY2007
Inspect/Repair Evaporation Pond A liner	FY2008
Inspect/Repair Evaporation Pond B liner	FY2009
Inspect/Repair Evaporation Pond C liner	FY2010

The DOE will notify the NMED of the status of liner activities semi-annually at the time the discharge monitoring report is submitted. The schedule allows sufficient time to rotate ponds in and out of service and dry them to allow construction activities to take place. We believe that the proposed corrective actions outlined above are protective of human health and the environment and represent a reasonable time frame to complete the work.

Please contact me at (505) 234-7462, if you have any questions or concerns regarding the planned liner replacement activities or require additional information.

Sincerely,

H. L. Plum
RCRA Program Manager

RE: Approval of Extension Request for Construction of Cell B of the Salt Storage Area Extension, DP-831, Waste Isolation Pilot Plant

Dear Dr. Triay:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received a letter dated September 12, 2005 from the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) requesting an extension of time to construct Cell B of the Salt Storage Area Extension. Condition 2 of the Discharge Permit Modification, DP-831, dated December 22, 2003 requires construction activities for Cell B to be completed by October 2006 in accordance with the schedule provided by WIPP dated July 24, 2003.

The reason stated for the extension is that based on current mining rates, the storage capacity provided by Cell B will not be needed until late 2007. Due to variability in excavation rates, WIPP requests that the October 2006 completion date be replaced with 60-day notification prior to beginning construction of Cell B.

NMED hereby approves the extension request as provided for in Condition 2 of the Discharge Permit Modification dated December 22, 2003.

If you have any questions regarding this action, please contact me at 505-827-0027, or by e-mail at clint.marshall@state.nm.us.

Sincerely,

Clint Marshall

Subject: Waste Isolation Pilot Plant HWFP No. NM 4890139088 Exhaust Shaft Catch Basin

Dear Mr. Zappe:

The purpose of this letter is to provide follow-up information regarding the release of water from the Exhaust Shaft Catch Basin (Catch Basin) on August 18, 2005. You were initially provided information in a verbal notification of this occurrence on August 19, 2005, followed by a letter dated September 1, 2005.

The release was caused by damage to the sidewalls and the bottom of the basin due to material and debris falling down the shaft. The specific debris that caused the damage has not yet been identified. A video inspection of the Exhaust Shaft was performed on August 19, 2005. This inspection found damage to an electrical cable and a loose piece of salt evaporite buildup. Inspection of the Catch Basin from a safe distance showed an apparent increase in the amount of fallen salt debris and instrumentation cable in the basin. It should be noted that access to the Exhaust Shaft is not possible due to safety concerns caused by falling material and debris.

The use and operation of the Catch Basin were discussed in NMED's letter to the Permittees dated July 7, 2000 (enclosed). As indicated in that letter, the use of "This catch basin is an integral part of the mine dewatering process.... It is a collection device necessary to control the accumulation of mine water." NMED's determination in this letter indicated the management practice(i.e, the use of the Catch Basin) met the intent of EPA's discussion of alternative controls in its November 30, 1989 letter referenced in NMED's response. We have now determined that continued use of the Catch Basin in the confined work space at the base of the Exhaust Shaft is unacceptable. This area has significant worker safety issues due to falling debris barring safe entry to perform maintenance. The continued operation of the Catch Basin in this location is considered unsafe. To address worker safety concerns, an alternative approach for collection of water at the exhaust shaft follows.

During our conversation on August 19, 2005, an alternative means of collecting water in the Exhaust Shaft was proposed. As we discussed, a new system will be put in place to collect the water from the Exhaust Shaft that fully replaces the Catch Basin.

CBFO:AMO:HLP:GS:05-1527:UFC 5480.00

The new system will consist of a series of boreholes drilled in the South 400 drift at selected locations in the area between the East 140 drift and the East 300 drift, which will intercept the open fracture water flow in Marker Bed 139. This location was selected because the system can be installed, operated, and maintained without entering the exhaust air flow of the waste disposal circuit. The final number, locations, and size of boreholes will be determined as installation progresses. Dissolution is not expected to be a problem since flow in the open fractures in Marker Bed 139 will be fast, much of the flow path is in anhydrite, and the boreholes will be pumped as quickly as water is produced. Past experience indicates that vertical boreholes are quite stable and require little, if any, maintenance compared to excavations of other shapes.

Fractional horsepower submersible pumps capable of operating in either automatic or manual mode will be placed near the bottom of each borehole. The pumps will feed into a hose that will carry the water from the borehole location to a collection point located in the east S550 alcove off of the E140 drift. The collection point will include closed and appropriately labeled containers (typically of 55 or 500 gallon capacity). These containers will be transported to the surface where the water will be surveyed, analyzed, and dispositioned in accordance with applicable permit conditions and regulations.

This method of collecting Exhaust Shaft water is expected to be as effective as the former configuration utilizing the Catch Basin, and eliminates potential hazards to workers from material that may fall from within the Exhaust Shaft. The existing Catch Basin will be removed from under the shaft, cleaned, and disposed of appropriately.

If you have any questions or require additional information, please contact Mr. H. L. Plum at 505-234-7462.

Sincerely,

Lloyd L. Piper, Acting Manager
DOE Carlsbad Field Office

Subject: Maintenance Plan for Erosion Control and Drainage Enhancements for the Salt Pile Cover

Dear Mr. Marshall:

The purpose of this letter is to advise you of our maintenance plans for the repair of erosion on the salt pile soil cover and installation of certain erosion control and drainage enhancements.

As you are aware, intense precipitation events received in September and November of 2004 resulted in significant erosion on the side slopes of the salt pile soil cover. The erosion was repaired in March 2005 and the hydromulch/seed mix was applied in April 2005. Heavy rains received in May and June of 2005 resulted in new erosion primarily on the south and east sides of the salt pile soil cover before vegetation could be established. This has resulted in more extensive initial maintenance action than had been anticipated for the soil cover.

An engineering evaluation has been conducted to develop a plan for repairing the soil cover erosion that includes features that minimize recurrence of the need for such extensive maintenance. The phased implementation and description of the planned enhancements is outlined below and depicted on the enclosed draft drawing:

- First, as part of Phase 1, we plan to construct a new haul road routed to the east of the salt pile to Cell A of the Salt Storage Extension. The construction of the new haul road facilitates the construction of the erosion controls and drainage enhancements discussed below in Phase 2. Additionally, relocation of the haul road will eliminate interruptions to salt handling operations should significant precipitation cause additional erosion to occur and will guard against potential damage to the underlying liner on the salt pile. The haul road will not alter the infiltration controls.
- Also included in Phase 1, a berm is planned to be constructed on the salt pile cap at the top of the north 3:1 slope that will divert water from the north east quarter of the salt pile down a lined discharge channel to the salt pile run-off ditch. The run-off ditch will convey the water to the salt pile evaporation pond. Existing accumulation of sediments in the lined ditches will also be removed.
- In Phase 2, the plan is to repair the erosion to the salt pile soil cover when the weather will be more suitable to promote the germination and establishment of native vegetation.

CBFO:AMO:HJP:KJB:05-1520:UFC5486

Additional erosion control and drainage enhancements to the salt pile cover under consideration for Phase 2 include berms to direct run-off to a discharge chute near the center of the south side of the salt pile and the use of turf reinforcement mats. Such features are enhancements to the original design and the decision to implement these will be based on actual or anticipated performance of the cover system in resisting erosion. Conducting the repairs to erosion of the salt pile soil cover as Phase 2 of the effort will not impact the ability of the infiltration controls to collect, transport and store rainwater run-off for evaporation. The main function of the soil is to act as a ballast to prevent wind damage to the liner.

Please contact me at (505) 234-7462, if you have any questions or concerns regarding the planned maintenance and erosion control enhancements or require additional information.

Sincerely,

H. L. Plum, Manager
RCRA Program

Responses to NMED Letter Dated August 5, 2005
RE: Request for Additional Information, D-831, Waste Isolation Pilot Plant
September 7, 2005

<u>NMED Item 1</u>. In Section 6.b, Monitoring Plan, WIPP refers to Tab 1 of the Application titled, "Additional Potential Contamination Sources" for the required information. Information for monitoring is not located in Tab 1. The application should make reference to the approved Discharge Permits dated April 29, 2003, and December 22, 2003 for this information.

<u>Response to Item 1</u>: We concur with your conclusion. Section 6.b. of the application should read "Not the subject of this DP Modification. See approved Discharge Permits Dated April 29, 2003 and December 23, 2003."

<u>NMED Item 2</u>. On Page 3 under Tab 1, Item 5 of the reclamation activities states that the Site Preliminary Design Validation (SPDV) pile was seeded with shallow rooted plants. Please provide the seed mix used in the revegetation activities.

<u>Response to Item 2</u>: The seed mix used for the SPDV re-vegetation activity included seeds for cool and warm seasons. Cool season (over-winter) planting included Millet and Winter Wheat. Warm season native grasses planted the following spring included: (Hachita) Blue Gramma, Buffalo Grass, Firewheel/Indian Blanket, Little Bluestem, Sand Dropseed and Plains Bristlegrass.

<u>NMED Item 3</u>. On Page 3 under Tab 1, Item 6 of the reclamation activities states that the SPDV pile is regularly inspected, monitored and maintained. Please provide more details on the frequency and type of inspections, monitoring and maintenance conducted at the SPDV pile.

<u>Response to Item 3</u>: Between 1994 and May of 2001, documented inspections of the SPDV pile were conducted by the Environmental Compliance Department. Following the second quarter of 2001, the WIPP Environmental Monitoring personnel have conducted inspections approximately every other month and following severe rain events. Repairs have been conducted on minor surface erosion channels and subsidence holes as necessary. These inspections and repairs were not conducted in accordance with a formal inspection procedure and were not documented.

Beginning in October 2005 SPDV Pile inspections will be incorporated into the WIPP procedure *Site Discharge Area Inspections*, WP 02-EM1022. This procedure contains the inspection protocols for the Salt Storage Areas and other infiltration controls currently conducted by Environmental Monitoring Personnel. The inspections will be conducted monthly and the observations and corrective measures will be documented and maintained a minimum of five years.

<u>NMED Item 4</u>. On Page 4 under Tab I, three piezometers are proposed, one each on the east, west and south sides of the SPDV pile. Please provide a map showing the locations of the proposed piezometers.

<u>Response to Item 4</u>: Three piezometers are proposed for installation around the Site Preliminary Design Validation (SPDV) pile to evaluate if shallow subsurface water (SSW) was generated beneath the SPDV pile prior to lining. Figure 1 (enclosed) is a map of the WIPP site identifying the location of the SPDV pile approximately 2000 feet east of the WIPP waste-handling shaft. Locations for the piezometers were determined by evaluating the contact between the Santa Rosa (SR) Formation and Dewey Lake (DL) Formation. An isopach map of the contact was developed using well log descriptions from shallow wells and borings. From this isopach map the dip of the contact was estimated to trend west-southwest from the SPDV pile.

All piezometers will be located beyond the liner cover anchor trench as presented in Figure 2 (enclosed). It is assumed that if infiltration into the pile had occurred prior to liner installation and a SSW zone had developed

01248

at the DL/SR contact, a mounded w... able would have occurred creating a rad... gradient predominantly in the direction of the contact slope. Piezometers PZ-13 and PZ-14 are located to the west-southwest of the SPDV pile to determine what down-gradient impact there might have been. PZ-15 is located up the presumed gradient of the SR/DL contact. This well will serve to assess any up-gradient impacts. The total depth of each of the three proposed wells will be determined in the field based upon examination of core and drill cuttings. Expected depths are not expected to exceed 100 feet for any of the proposed wells.

NMED Item 5. On Page 5 under Tab 2, Section A, the Application refers to language in the December 16, 1996, DP-831 Permit Renewal Application stating, "Closure plans for the sewage facility and evaporation ponds will specifically require that all lagoons and ponds will be pumped or evaporated and that all sludges be sampled to determine if hazardous constituents exist as defined by the Resource Conservation and Recovery Act (RCRA - 40 CFR 261). If hazardous constituents are detected, the sludges will be managed accordingly." DP-831 regulates discharges that are not necessarily defined as hazardous by RCRA. Please provide more details on how liquids and sludges will be disposed of upon closure of the facultative lagoon system and evaporation ponds regardless of whether they are classified as hazardous.

Response to Item 5: In accordance with the Discharge Permit Issued on April 29, 2003, any sludge from the sewage lagoons will be disposed in accordance with 40 CFR Part 503, Standards for the Use or Disposal of Sewage Sludge.

Sludge from storm water or brine evaporation ponds will be managed in the following manner. Upon closure, any liquids that have not evaporated will be collected in an acceptable container and characterized to determine that it meets the waste acceptance criteria for disposal at a permitted off-site disposal facility.

Any solids that remain in the lagoons will be removed, containerized and characterized as necessary to determine that they meet the waste acceptance criteria for a permitted off-site disposal facility. A flow diagram of the characterization and disposal process is included as Figure 3 (enclosed). Liquids and solids removed from any ponds will be disposed in accordance with applicable federal, state and local regulations.

NMED Item 6. On Pages 5-6 under Tab 2, Section B, the Application states that the active salt piles will be closed in accordance with the requirements of the Land Withdrawal Act (LWA), Section 4(b)(4). The LWA makes further reference to Sections 2 and 3 of the Act of July 31, 1947 (30 D.S.C. 602, 603) commonly referred to as the "Materials Act of 1947." NMED recognizes that WIPP is required to dispose of the salt tailings according to federal law, however more specificity is needed regarding the final disposition of the salt piles whether onsite or off site. Options for onsite disposal should include conceptual descriptions regarding technical components such as covers and storm water diversion structures. Plans for off site disposal should discuss possible entities to receive the salt product as well as expected uses. WIPP may amend closure plans at a future date to adjust for unforeseen circumstances and federal requirements.

Response to Item 6

As stated on pages 5, 6 under Tab 2, Section B, the salt tailings may be used on-site for backfilling the repository or as a construction for the perimeter berm that is proposed as part of the passive institutional controls. Under the WIPP Land Withdrawal Act, P.L. 102-579, as amended, salt tailings that are not needed for berm construction or facility backfill are to be sold under the Materials Act of 1947, 30 USC 602, 603. DOE is in the process of identifying possible uses for the tailings, potential buyers, and on-site and off-site disposal alternatives if needed. It is anticipated that the purchase and removal of salt by interested entities would occur during current facility operations.

NMED Item 7. On Pages 6-7 under Tab 2, Section C, the Application states that an investigation of the SPDV pile determined that no remedial measures were required according to NMED guidelines. Please specify the guidelines to which the Application is referring.

Response to Item 7: The investigation of the SPDV Pile identified total petroleum hydrocarbons (TPH) concentrations for samples analyzed in the laboratory that ranged from less than 10 mg/kg to 43 mg/kg. Specific guidelines for TPH concentrations in soils are found in 20.9.1.708.E. NMAC which states, "remediation shall be deemed adequate when the following conditions are met in a soil sample of what appears to be the most heavily contaminated soil:

1. the sum of benzene, toluene, ethyl benzene and xylene isomer concentrations is less than 500 mg/kg, with benzene individually less than 10 mg/kg; and

2. the TPH concentration is less than 1,000 mg/kg"

Any metals, VOCs and SVOCs detected were at very low levels that would not be considered significant and are orders of magnitude below current levels outlined in the New Mexico Environment Department guidance, NMED Technical Background Document for Development of Soil Screening Levels, Rev. 2.0 (February 2004; updated August 2004). A copy of the report entitled Characterization of the Site Preliminary Design Validation Salt Pile dated January 5, 1996, is enclosed. Not in file – separate bound document.

NMED Item 8. Please provide as-built plans and specifications for the grading and cover of the SPDV pile.

Response to Item 8: Plans and specifications that were included in the Request for Proposals are included as Attachment 1 to this response. This information includes the SPDV Salt Pile Reclamation Scope of Work with section and plan views, a letter recommending Claymax 600CL, and properties and installation guidelines pertaining to the recommended geosynthetic clay liner. However, note that the side slopes and grades were modified in the field during construction. The SPDV Pile was constructed with the following slopes:

West Slope	12:1 H/V
East Slope	16:1 H/V
North Slope	6:1 H/V
South Slope	6:1 H/V

The SPDV Pile was surveyed on August 30, 2005 to produce an As-Built drawing of the current topographic expression which is included in Attachment 1.

NMED Item 9. On Page 8 of Table 2 under Tab 4, Evaporation Pond 007b is described as once containing soap, cleaning fluids, oil and brine. Please provide additional information on the current status of this facility, the pond dimensions, descriptions of any liners, and a map showing its location.

Response to Item 9: Solid Waste Management Unit (SWMU 007b) was an unlined evaporation pond that was approximately 145 feet long by 145 feet wide. SWMU 007b was used between late 1983 and early 1984 to receive grey water from temporary showers that were used during the construction phase of the facility.

A sketch illustrating the former approximate location of Solid Waste Management Unit (SWMU) 007b is included in Attachment 2 in this response as Figure 16.1 – Sample Location Sketch – taken from the WIPP No Further Action (NFA) Petition for Solid Waste Management Units and Areas of Concern, DOE/WIPP 02-3221, Rev. 0. The evaporation pond SWMU 007b was located approximately 770 feet due west of the Waste Handling Shaft. NMED documented in The Assessment of Solid Waste Management Units at the Waste Isolation Pilot Plant (NMED/DOE/AIP-94/1) that based on process knowledge SWMU 007b received grey water from the showers and the waste contained soap, cleaning solutions and trace amounts of oil. Samples collected in October 1992 found that iron, barium, and aluminum were above background control sample results; however, the concentrations are well below RCRA Action Levels. No semi-volatile compounds or hydrocarbons were detected.

The current status of SWMU 007b evaporation pond is that the area was graded and seeded in the mid 1980's and is currently within the footprint of Storm Water Infiltration Control Pond A which is lined with a high density polyethylene liner. A No Further Action Petition has been filed with the NMED Hazardous Waste Bureau based on the rationale that concentrations of hazardous constituents are at acceptably low levels. A letter dated December 4, 2000 to Dr. Ines Triay and Mr. Joe Epstein from Mr. Steve Zappe, Subject: Review and Comments on the Facility Work Plan, Sampling and Analysis Plan is included in Attachment 2 and contains the Hazardous Waste Bureau's comments on WIPP Sampling and Analyses Plan for Solid Waste Management Units and Areas of Concern dated May 2000. Item 31 notes NMED's comments relative to the sampling plan for SWMU 007b stating:

- "Based on historical informa... provided for this site, NMED does not se... need to perform additional sampling at the subject SWMU."

NMED made this determination based on the fact that 1) the pond presumably only received grey water from personnel showers and currently receives storm water and domestic water resulting form fire flow performance testing, and 2) detected concentration of lead and nickel are only slightly above background concentrations. NMED believes that enough information is available from this site to warrant NFA."

SPDV Salt Pile Reclamation Scope of Work and SPDV Pile Cross Section and Plan Views

October 11, 1999 Letter from Mr. David Pope, Ag Services Re: GCL Commitment and Submittals, WIPP SPDV Salt Pile Reclamation Project

Topographic Map of SPDV Salt Pile 8/30/05

SPDV SALT PILE
RECLAMATION
Scope of Work

Purchase Requisition Number: 2735
Date: 14 July 1999
Requestor: D.C. Lynn, WIPP Land Use Coordinator

I. Scope of Work:

Phase 1: Re-Contour the existing salt pile of an estimated average height of 15 feet above near ground surface elevation while maintaining the initial basal footprint of the pile (see attachment).

Phase 2: Establish a 4:1 horizontal to vertical slope ratio along the sides to deter veneer failure. The bulk of the pile should slope at (approximately) a three per cent grade toward the center crown to prevent ponding (see attachment).

Phase 3: Once contouring is complete, the pile will be capped with a geosynthetic liner that will encompass approximately 319,000 square feet. The liner will be rolled out over a subbase of approximately six inches of native material that contains no particles larger than ¾ inch in diameter (see attachment).

Phase 4: After the liner has been deployed, (a minimum of) three feet of soil rooting medium consisting of 15% (by weight) ½ inch crushed rock (to minimize wind erosion) will be established (see attachment). [Note: The majority of topsoil, excluding the crushed rock, is located near the existing pile, therefore, transportation of this material will be unnecessary. Mixing of the rock with the topsoil will be the responsibility of the contractor.] After establishing the rooting medium, the area will be seeded by WIPP Land Management personnel.

Phase 5: Hydromulch the surface after planting.

II. Period of Performance:
1. Work commencement within one month of notification from WIPP Land Use Coordinator that site conditions are ready for reclamation (e.g., archaeological clearance is complete)
2. Project completion should not exceed 90 days.

III. Contingencies:
1. Each phase of reclamation will be followed by an inspection. These will be conducted by Environmental Monitoring/Land Management personnel and are required before contractor can proceed to the next phase.
2. WIPP (Land Management) will provide:
   - technical expertise
   - appropriate seed mix
   - equipment for planting
   - manpower to seed the area
   - requisite authorization (e.g., Land Use Request)

IV. Contractor Shall:
1. Submit a complete job hazard analysis in accordance with WIPP safety requirements
2. Adhere to all WIPP safety requirements
3. Respond immediately to any stop work order

Subject: GCL Commitment and Submittals, WIPP SPDV Salt Pile Reclamation Project

Dear Mr. Pope:

This letter is to explain CETCO's position in the matter regarding the recommended GCL to be used at the above-mentioned project. CETCO outlined these concerns to you before the bid and would like to highlight these issues once again with the submittals.

CETCO recommends that you utilize the unreinforced Claymax 600CL instead of the Claymax 200R because it contains a polyethylene laminate that should provide a barrier to minimize the upward migration of the salts into the GCL bentonite. This Claymax 600CL can only be placed on slopes gentler than 10:1. The needlepunched reinfomced Bentomat ST can be placed on slopes steeper than 10:1, however, the Bentomat ST does not have the polyethylene laminate moisture barrier. CETCO, therefore, recommends that the owner consider regrading all of the slopes on the salt pile to gentler than 10:1, so that Claymax 600CL can be utilized everywhere.

The price quoted for Bentomat ST and Claymax 600CL are the same. Please note, however, that CETCO pricing increased effective September 15, 1999, and that the prices quoted to you are good only until November 1st, 1999 and shipped to the jobsite by December 31, 1999. Please forward a purchase order to CETCO by November 1, 1999 in order to keep your preferred pricing for the Claymax 600CL.

I have also included five (5) copies of product submittals for the Claymax 600CL and Bentomat ST.

- Certified properties sheet and roll specification for Bentomat ST & Claymax 600CL.
- Installation Guidelines.
- Samples of Bentomat ST and Claymax 600CL.
- General product brochure.

A Wholly Owned Subsidiary of AMCOL International

Printed on recycled paper.

Bentomat® ST Certified Properties

Bentomat "ST" is a reinforced GCL consisting of a layer of sodium bentonite between woven and non-woven geotextiles, which are needlepunched together.

MATERIAL PROPERTY	TEST METHOD	TEST FREQUENCY, ft^2 (m^2)	CERTIFIED VALUES
Bentonite Swell Index[1]	ASTM D 5890	1 per 50 tons	24 mL/2g min.
Bentonite Fluid Loss[1]	ASTM D 5891	1 per 50 tons	18 mL max.
Bentonite Mass/Area[2]	ASTM D 5993	40,000 ft^2 (4,000 m^2)	0.75 lb/ft^2 (3.6 kg/m^2)
GCL Grab Strength[3]	ASTM D 4632	200,000 ft^2 (20,000 m^2)	90 lbs (400 N)
GCL Peel Strength[3]	ASTM D 4632	40,000 ft^2 (4,000 m^2)	15 lbs (65 N)
GCL Index Flux[4]	ASTM D 5887	Weekly	1×10^{-8} $m^3/m^2/sec$
GCL Permeability[4]	ASTM D 5084	Weekly	5×10^{-9} cm/sec
GCL Hydrated Internal Shear Strength[5]	ASTM D 5321	Periodic	500 psf (24 kPa) typical

Notes:

1 Bentonite property tests performed at CETCO's bentonite processing facility before shipment to CETCO's GCL production facilities.

2 Bentonite mass/area reported at 0 percent moisture content.

3 All tensile testing is performed in the machine direction, with results as minimum average roll values unless otherwise indicated.

4 Index flux and permeability testing with deaired distilled/deionized water at 80 psi (551 kPa) cell pressure, 77 psi (531 kPa) headwater pressure and 75 psi (517 kPa) tailwater pressure. Reported value is equivalent to 925 gal/acre/day. This flux value is equivalent to a permeability of 5×10^{-9}cm/sec for typical GCL thickness. This flux value should not be used for equivalency calculations unless the gradients used represent field conditions. A flux test using gradients that represent field conditions must be performed to determine equivalency. The last 20 weekly values prior the end of the production date of the supplied GCL may be provided.

5 Peak value measured at 200 psf (10 kPa) normal stress. Site-specific materials, GCL products, and test conditions must be used to verify internal and interface strength of the proposed design.

Bentomat® ST Panel and Roll Specifications

STANDARD PANEL SPECIFICATIONS

Panel Dimensions*........................15 ft. (4.6 m) wide; 150 ft. (45.7 m) long
Total Panel Area...........................2,250 sq. ft. (209 sq. m)
Effective Area..............................2,145 sq. ft. (200 sq. m)
{Assumes 6-in. (150 mm) edge overlap and 2-ft. (600 mm) end overlap}

STANDARD ROLL SPECIFICATIONS

Dimensions.................................16 ft. (4.88 m) wide w/ core; 24 in. (610 mm) diameter
Nominal Weight...........................2,700 lbs. (1,225 kg)
Core Size (I.D.)............................4 in. (100 mm) I.D. Inner core plug measures 2.5 in. (63 mm)
Packaging..................................8-mil (0.2 mm) U.V.-resistant polyethylene sleeve

STANDARD SHIPPING SPECIFICATIONS

Shipment Size..............................15 rolls per truckload or container load
Granular Bentonite.......................50-lb. (23 kg) bags

UNLOADING AND HANDLING EQUIPMENT

Core Pipe and Spreader Bar.............18 ft. (5.5 m) long, 2.5 in. (63 mm) Nominal Pipe Size, XXH
OR: Solid steel pipe
OR: Stinger attachment for forklift
Chains or Straps...........................2 required; each approximately 12 ft. (3.7 m) long
Equipment..................................Front end loader or forklift (typical)

* Custom lengths/widths available

Lining Technologies www.cetco.com

Claymax® 600CL Certified Properties

Claymax "600CL" is an unreinforced GCL consisting of a layer of sodium bentonite between a geotextile and a laminate comprised of a geotextile and a polyethylene membrane, which are continuously adhered together.

MATERIAL PROPERTY	TEST METHOD	TEST FREQUENCY, ft^2 (m^2)	CERTIFIED VALUES
Bentonite Swell Index[1]	ASTM D 5890	1 per 50 tons	24 mL/2g min.
Bentonite Fluid Loss[1]	ASTM D 5891	1 per 50 tons	18 mL max.
Bentonite Mass/Area[2]	ASTM D 5993	40,000 ft^2 (4,000 m^2)	0.75 lb/ft^2 (3.6 kg/m^2)
GCL Grab Strength[3]	ASTM D 4632	200,000 ft^2 (20,000 m^2)	75 lbs (330 N)
GCL Peel Strength	ASTM D 4632	N/A	N/A
GCL Index Flux[4]	ASTM D 5887 or E96	Weekly	1×10^{-9} $m^3/m^2/sec$
GCL Permeability[4]	ASTM D 5084 or E96	Weekly	5×10^{-10} cm/s
GCL Hydrated Internal Shear Strength[5]	ASTM D 5321	Periodic	50 psf (2.4 kPa) typical

Notes:

1 Bentonite property tests performed at CETCO's bentonite processing facility before shipment to CETCO's GCL production facilities.

2 Bentonite mass/area reported at 0 percent moisture content, the GCL industry standard.

3 All tensile testing is performed in the machine direction, with results as minimum average roll values unless otherwise indicated.

4 Index flux and permeability testing with deaired distilled/deionized water at 80 psi (551 kPa) cell pressure, 77 psi (531 kPa) headwater pressure and 75 psi (517 kPa) tailwater pressure. Reported value is equivalent to 95 gal/acre/day. This flux value is equivalent to a permeability of 5×10^{-10} cm/sec for typical GCL thickness. Alternatively, hydraulic conductivity can be determined by performing water vapor transmissivity testing (ASTM E96) on the membrane side of the GCL and use conversion outlined by Koerner (1994). This flux value should not be used for equivalency calculations unless the gradients used represent field conditions. A flux test using gradients that represent field conditions must be performed to determine equivalency. The last 20 weekly values prior to the end of the production date of the supplied GCL may be provided.

5 Peak value measured at 200 psf (10 kPa) normal stress. Site-specific materials, GCL products, and test conditions must be used to verify internal and interface strength of the proposed design.

1500 West Shure Drive Arlington Heights, Illinois 60004 [800] 527.9948 tel [847] 392.5800 fax [847] 577.5571

Claymax® 600CL Panel and Roll Specifications

STANDARD PANEL SPECIFICATIONS

Panel Dimensions*........................13.8 ft. (4.2 m) wide; 150 ft. (45.7 m) long

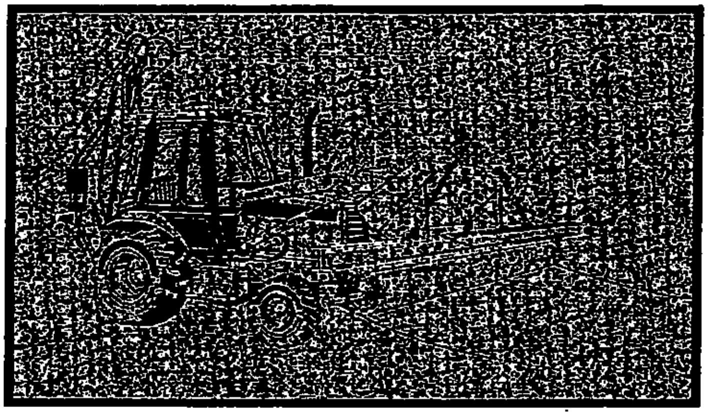
Installation Guidelines



BENTOMAT® CLAYMAX®

Geosynthetic Clay Liner

CETCO
COLLOID ENVIRONMENTAL TECHNOLOGIES COMPANY
LINING TECHNOLOGIES GROUP www.cetco.com

1 Introduction

1.1 This document provides procedures for the installation of CETCO's GCLs in a manner that maximizes safety, efficiency, and the physical integrity of the GCL.

1.2 These guidelines are based upon several years of experience at a variety of sites and should be generally applicable to any type of lining project using CETCO's GCLs. The user should contact CETCO if it is believed that conditions at a particular site warrant modifications to these guidelines.

1.3 The performance of the GCL is wholly dependent on the quality of its installation. It is the installer's responsibility to adhere to these guidelines, and to the project specifications and drawings, as closely as possible. It is the engineer's and owner's responsibility to provide construction quality assurance (CQA) for the installation, to ensure that the installation has been executed properly. This document covers only installation procedures.

2 Equipment Requirements

2.1 CETCO GCLs are delivered in rolls weighing 2,500-2,700 lbs. (1,2251 - 1,140 kg). It is necessary to support this weight using an appropriate core pipe as indicated in Table 1. For any installation, the core pipe must not deflect more than 3 inches (75 mm) as measured from end to midpoint when a full GCL roll is lifted.

Table 1. Core Pipe Requirements

Product	Nominal GCL Roll Size, W x L Ft. (m)	Typical GCL Roll Wt., lbs. (kg)	Interior Core Size, in. (mm)	Core Pipe Length x Diameter, ft. x in. (m x mm)	Minimum Core Pipe Strength
Bentomat CL, ST, DN	15 x 150 (4.6 x 45)	2,700 (1,225)	4 (100)	18 x 3 (5.5 x 75)	XXH
Claymax 200R, 600CL	13.8 x 125 (4.2 x 38)	2,500 (1,140)	4 (100)	16 x 3 (4.9 x75)	XXH

2.2 Lifting chains or straps appropriately rated, should be used in combination with a spreader bar made from an I-beam as shown in the cover illustration. The spreader bar ensures that the lifting chains or straps do not chafe against the ends of the GCL roll, allowing it to rotate freely during installation.

2.3 A front end-loader, backhoe, dozer, or other equipment can be utilized with the spreader bar and core bar. Alternatively, a forklift with a "stinger" attachment may be used for on-site handling and, in certain cases, installation. A forklift without a stinger attachment should not be used to lift or handle the GCL rolls. Stinger attachments specially fabricated to fit various forklift makes and models are available through CETCO.

2.4 When installing over certain geosynthetic materials, a 4-wheel, all-terrain vehicle (ATV) can be used to deploy the GCL from behind. An ATV can be driven directly on the GCL provided that no sudden stops, starts, or turns are made.

2.5 Additional equipment needed for installation of CETCO's GCLs includes:

- Utility knife and spare blades (for cutting the GCL).
- Granular bentonite or bentonite mastic (for overlapped seams of GCLs with needle-punched, non-woven geotextiles and for sealing around structures and details). Both are available from CETCO.
- Waterproof tarpaulins (for temporary cover on installed material as well as for stock-piled rolls).
- Optional chalk line marker to simplify bentonite placement at seams (when installing a GCL with needlepunched, non-woven geotextile components).
- Optional flat-bladed vise grips (for positioning the GCL panel by hand).

3 Subgrade Preparation

3.1 Subgrade surfaces consisting of granular soils or gravel may not be acceptable due to their large void fraction and puncture potential. In high head (greater than one foot) applications subgrade soils should possess a particle size distribution such that at least 80 percent of the soil is finer than a #60 sieve (0.250 mm).

3.2 When the GCL is placed over an earthen subgrade, the subgrade surface must be in accordance with the project specifications. Engineer's approval of the subgrade must be obtained prior to installation. The finished surface should be firm and unyielding, without abrupt elevation changes, voids, cracks, ice, or standing water.

3.3 The subgrade surface must be smooth and free of vegetation, sharp-edged rocks, stones, sticks, construction debris, and other foreign matter that could contact the GCL. The subgrade should be rolled with a smooth-drum compactor to remove any wheel ruts, footprints, or other abrupt grade changes. Furthermore, all protrusions extending more than 0.5 inch (12 mm) from the subgrade surface shall either be removed, crushed, or pushed into the surface with a smooth-drum compactor. The GCL may be installed on a frozen subgrade, but the subgrade soil in the unfrozen state should meet the above requirements.

4 Unloading

4.1 In most cases, CETCO GCLs are delivered on flatbed trucks. To unload the rolls from the flatbed, insert the core pipe through the roll. This may require removal of the core plug, which should be replaced after the roll is unloaded. Secure the lifting straps or chains to each end of the core pipe, and to the spreader bar mounted on the lifting equipment. Hoist the roll straight up; make sure its weight is evenly distributed so that it does not tilt or sway when lifted.

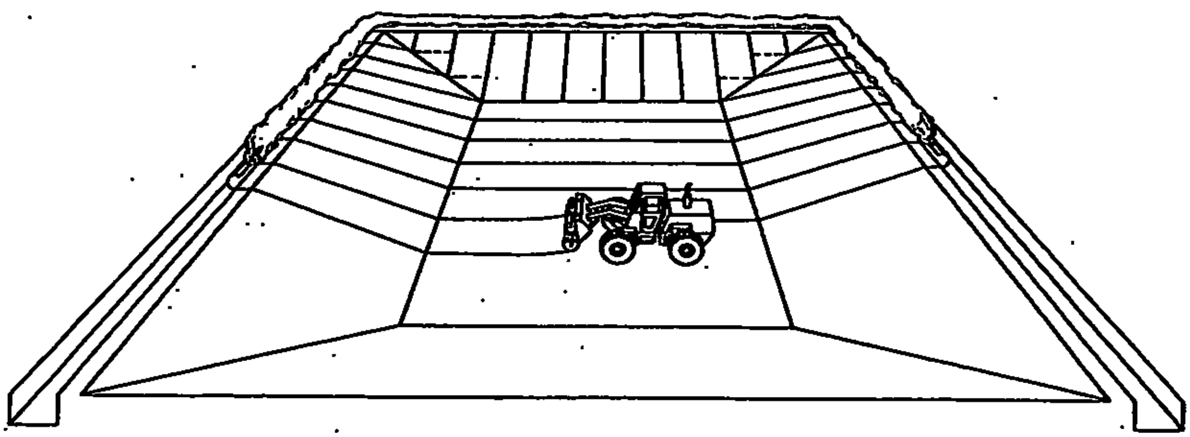
4.2 CETCO GCLs are also delivered in closed shipping containers. To remove the roll from the container, it is best to utilize a forklift mounted with a "stinger" attachment. Guide the stinger as far as possible through the core and lift the roll up and out of the container.

5 Installation

5.1 GCL rolls should be taken to the working area of the site in their original packaging. Prior to deployment, the packaging should be carefully removed without damaging the GCL. The orientation of the GCL (i.e., which side faces up) may be important if the GCL has two different geotextiles. Unless otherwise specified, however, the GCL should be installed such that the product name printed on one side of the GCL faces up.

5.2 Equipment which could damage the GCL should not be allowed to travel directly on it. Acceptable installation, therefore, may be accomplished such that the GCL is unrolled in front of the backwards-moving equipment (Figure 1). If the installation equipment causes rutting of the subgrade, the subgrade must be restored to its originally accepted condition before placement continues.

Figure 1. Typical Bentomat®/Claymax® installation strategy



5.3 GCL rolls should not be released on the slope and allowed to unroll freely by gravity.

5.4 Care must be taken to minimize the extent to which the GCL is dragged across the subgrade in order to avoid damage to the bottom surface of the GCL. A temporary geosynthetic subgrade covering commonly known as a slip sheet or rub sheet may be used to reduce friction damage during placement.

5.5 The GCL should be placed so that seams are parallel to the direction of the slope. End-of-roll seams should also be located at least 3 ft. (1 m) from the toe and crest of slopes steeper than 4H:1V.

5.6 All GCL panels should lie flat on the underlying surface, with no wrinkles or folds, especially at the exposed edges of the panels.

5.7 The GCL should not be installed in standing water or during rainy weather. Only as much GCL shall be deployed as can be covered at the end of the working day with soil, a geomembrane, or a temporary waterproof tarpaulin. The GCL shall not be left uncovered overnight. If the GCL is hydrated when no confining stress is present, it may be necessary to remove and replace the hydrated material. The project engineer and CQA inspector should be consulted for specific guidance if premature hydration occurs.

5.8 In hot weather conditions, Claymax must be covered with a soil layer within eight hours of deployment.

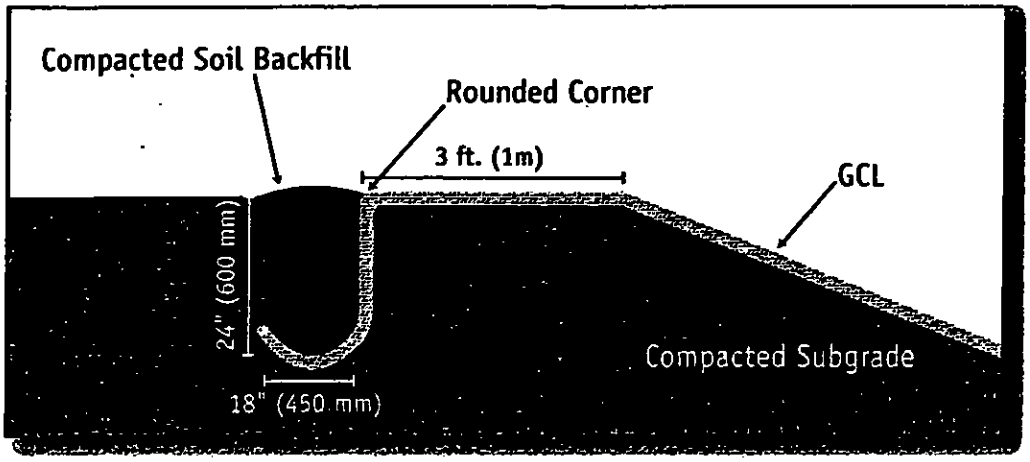
6 Anchorage

6.1 If required by the project drawings, the end of the GCL roll should be placed in an anchor trench at the top of a slope. The front edge of the trench should be rounded to eliminate any sharp corners that could cause excessive stress on the GCL. Loose soil should be removed or compacted into the floor of the trench.

6.2 Sufficient anchorage may alternately be obtained by extending the end of the GCL roll back from the crest of the slope. The length of this "runout" anchor is project-specific.

6.3 If a trench is used for anchoring the end of the GCL, soil backfill should be placed in the trench to provide resistance against pullout. The size and shape of the trench, as well as the appropriate backfill procedures, should be in accordance with the project drawings and specifications. Typical dimensions are shown in Figure 2.

Figure 2. Typical anchor trench design



6.4 The GCL should be placed in the anchor trench such that it covers the entire trench floor but does not extend up the rear trench wall.

7 Seaming

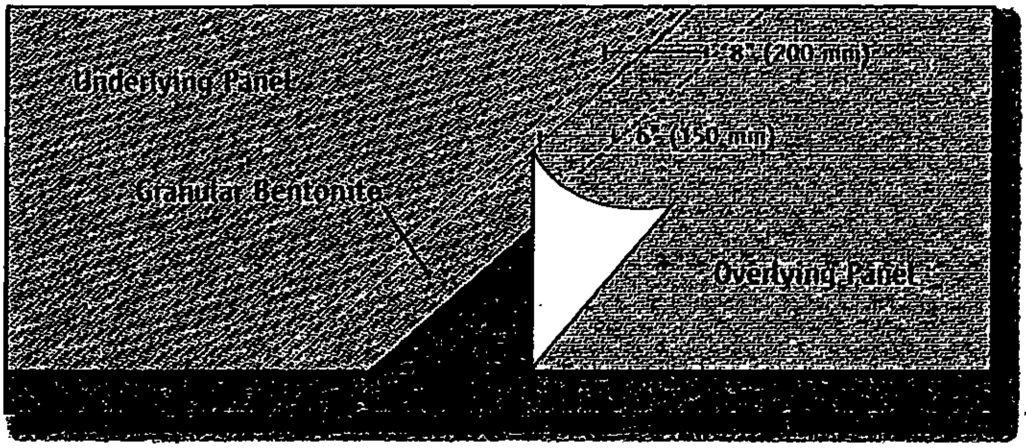
7.1 GCL seams are constructed by overlapping their adjacent edges. Care should be taken to ensure that the overlap zone is not contaminated with loose soil or other debris. Supplemental bentonite is required for CETCO Bentomat GCLs but not Claymax 200R or 600CL.

7.2 Unless otherwise specified, the minimum dimension of the longitudinal overlap should be 6 inches (150 mm). End-of-roll overlapped seams should be similarly constructed, but the minimum overlap should measure 24 inches (600 mm).

7.3 Seams at the ends of the panels should be constructed such that they are shingled in the direction of the grade to prevent the potential for runoff flow to enter the overlap zone. End panel overlap seams on slopes are permissible, provided adequate slope stability analysis has been conducted (i.e. the GCL is not expected to be in tension).

7.4 Bentonite-enhanced seams are constructed first by overlapping the adjacent panels as instructed above, exposing the underlying edge, and then applying a continuous bead or fillet of granular sodium bentonite (supplied with the GCL) along a zone defined by the edge of the underlying panel and the 6-inch (150 mm) line (Figure 3). The minimum application rate at which the bentonite is applied is one quarter pound per lineal foot (0.4 kg/m).

Figure 3. Bentonite-enhanced overlapped seam

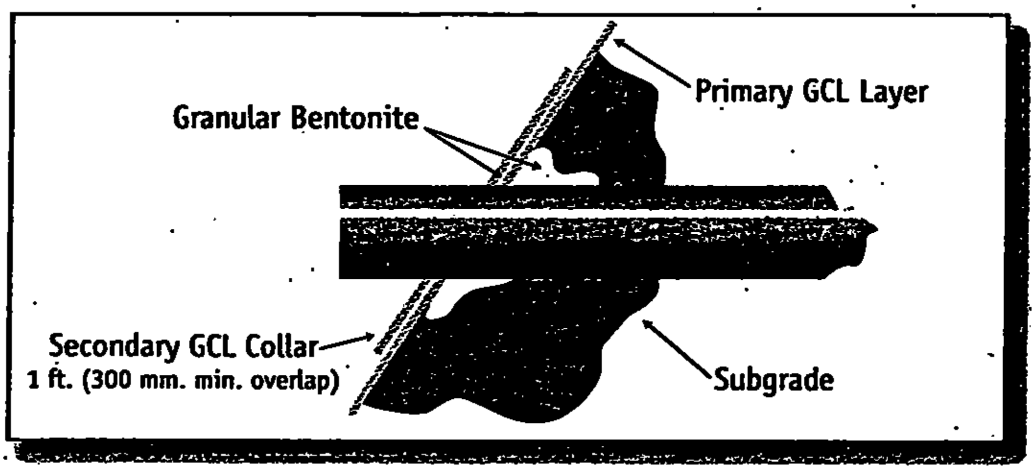


8 Sealing Around Penetrations and Structures

8.1 Cutting the GCL should be performed using a sharp utility knife. Frequent blade changes are recommended to avoid irregular tearing of the geotextile components of the GCL during the cutting process.

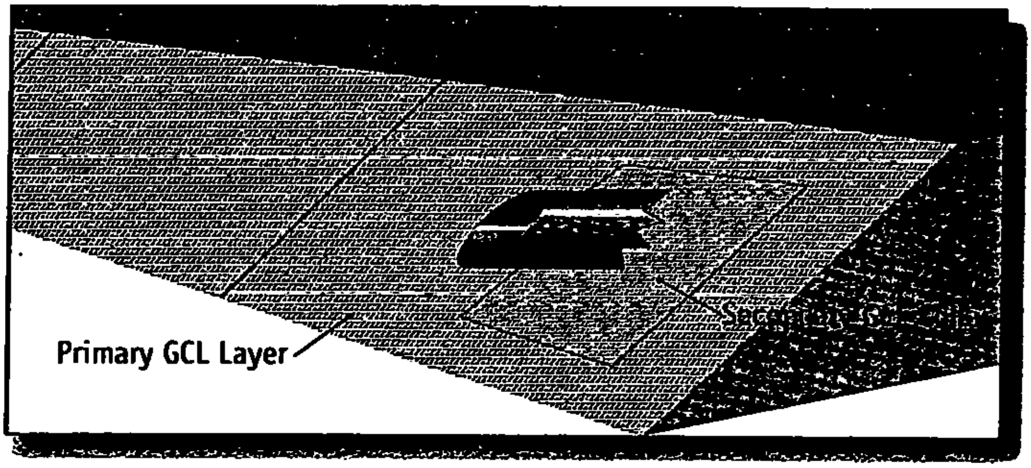
8.2 The GCL should be sealed around penetrations and structures embedded in the subgrade in accordance with Figures 4 through 6. Granular bentonite or a bentonite mastic shall be used liberally (approx. 2 lbs./ln ft. or 3 kg/m) to seal the GCL to these structures.

Figure 4a. Cross-section of a horizontal pipe penetration



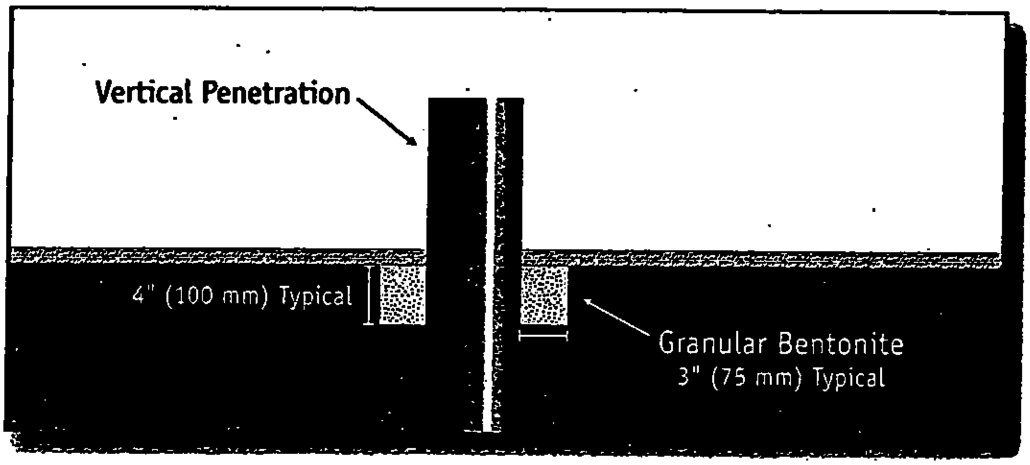
8.3 When the GCL is placed over an earthen subgrade, a "notch" should be excavated into the subgrade around the penetration (Figure 4a). The notch should then be backfilled with granular bentonite or bentonite mastic.

Figure 4b. Isometric view of a completed horizontal pipe penetration



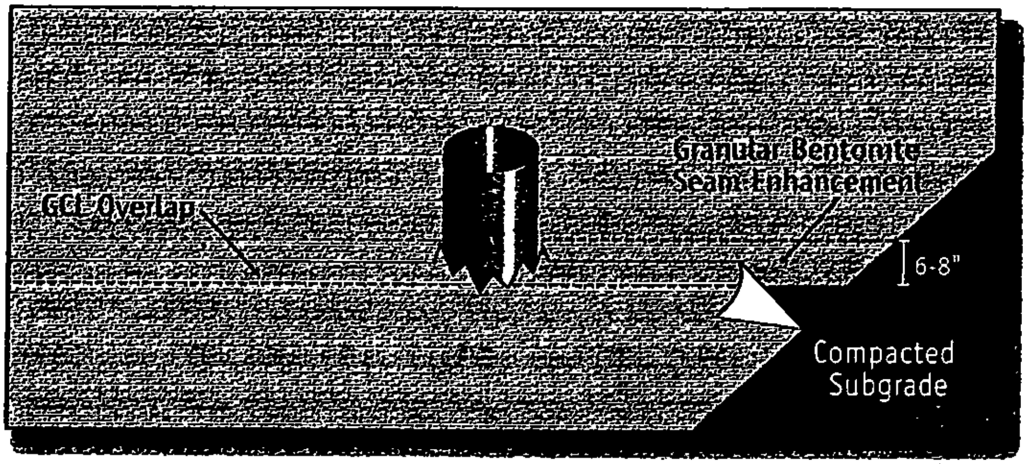
8.4 A secondary collar of GCL should be placed around the penetration as shown in Figure 4b. It is helpful to first trace an outline of the penetration on the GCL and then cut a "star" pattern in the collar to enhance the collar's fit to the penetration.

Figure 5a. Cross-section of a vertical penetration



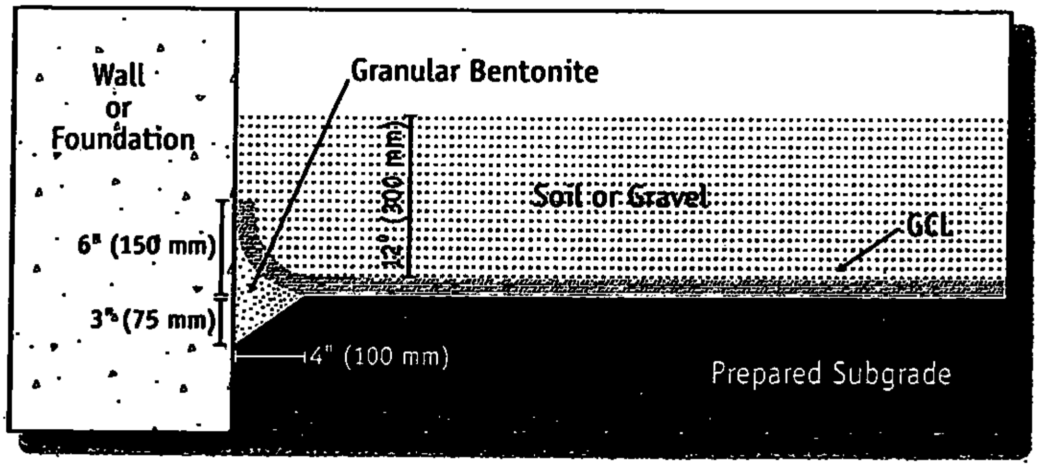
8.5 Vertical penetrations are prepared by notching into the subgrade as shown in Figure 5a. The penetration is completed with two separate pieces of GCL as shown in Figure 5b. A secondary collar is optional in this case.

Figure 5b. Isometric view of the completed vertical penetration



8.6 When the GCL is terminated at a structure or wall that is embedded into the subgrade, the subgrade should be notched as described in sections 8.3 and 8.5. The notch is filled with granular bentonite, and the GCL should be placed over the notch and up against the structure (Figure 6). The connection to the structure can be accomplished by placement of soil or stone backfill in this area.

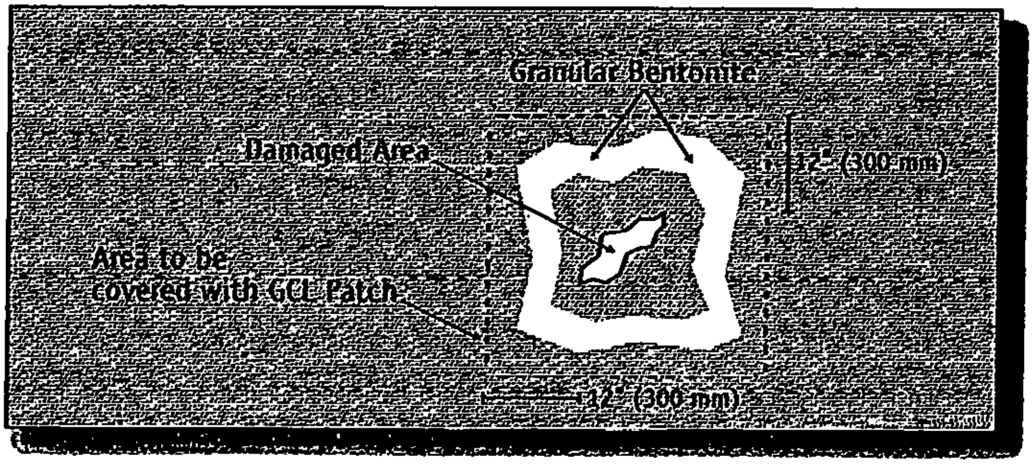
Figure 6. Cross-section of GCL seal against an embedded structure or wall



9 Damage Repair

9.1 If the GCL is damaged (torn, punctured, perforated, etc.) during installation, it may be possible to repair it by cutting a patch to fit over the damaged area (Figure 7). The patch should be obtained from a new GCL roll and should be cut to size such that a minimum overlap of 12 inches (300 mm) is achieved around all parts of the damaged area. Granular bentonite or bentonite mastic should be applied around the damaged area prior to placement of the patch. It may be necessary to use an adhesive such as wood glue to affix the patch in place so that it is not displaced during cover placement. Smaller patches also may be tucked under the damaged area to prevent patch movement.

Figure 7. Damage repair by patching



10 Cover Placement

10.1 Cover soils should be free of angular stones or other foreign matter that could damage the GCL. Cover soils should be approved by the Engineer with respect to particle size, uniformity, and chemical compatibility. Consult your CETCO representative if cover soils with high concentrations of calcium (e.g., limestone, dolomite) are present.

10.2 Recommended cover soils typically have a particle size distribution ranging between fines and 1 inch (25 mm).

10.3 Soil cover shall be placed over the GCL using construction equipment that minimizes stresses on the GCL. A minimum thickness of 1 foot (300 mm) of cover should be maintained between the equipment tires/tracks and the GCL at all times during the covering process. In frequently trafficked areas or roadways, a minimum thickness of 2 feet (600 mm) is required.

10.4 The final thickness of soil cover on the GCL varies with the application. A minimum cover layer must be at least 1 foot (300 mm) thick to provide confining stress to the GCL and prevent damage by equipment, erosion, etc.

10.5 Soil cover should be placed in a manner that prevents the soil from entering the GCL overlap zones. Soil cover should be pushed up slopes, not down slopes, to minimize tensile forces on the GCL.

10.6 When a textured geomembrane is installed over the GCL, a temporary geosynthetic covering known as a slip sheet or rub sheet should be used to minimize friction during placement and to allow the textured geomembrane to be more easily moved into its final position.

11 Hydration

11.1 In cases where the containment of non-aqueous liquids is required, it may be necessary to hydrate the covered GCL with water prior to use. Hydration is usually accomplished by natural rainfall and/or absorption of moisture from soil.

11.2 If manual hydration is necessary, water can be introduced by flooding the lined area or using a sprinkler system. Contact CETCO for specific procedures in these cases.

12 Shipping, Handling and Storage

12.1 All lot and roll numbers should be recorded and compared to the packing list. Each roll of GCL should also be visually inspected during unloading to determine if any packaging has been damaged. Damage, whether obvious or suspected, should be recorded and marked.

12.2 Major damage suspected to have occurred during transit should be reported immediately to the carrier and to CETCO. The nature of the damage should also be indicated on the bill of lading with the specific lot and roll numbers.

12.3 The party directly responsible for unloading the GCL should refer to this manual prior to shipment to ascertain the appropriateness of their unloading equipment and procedures. Unloading and on-site handling of the GCL should be supervised to ensure these goals are achieved. Roll dimensions and weights will vary with the dimensions of the product ordered.

12.4 Rolls should be stacked in a manner that prevents them from sliding or rolling from the stacks. This can be accomplished by frequent chocking of the bottom layer of rolls. Rolls should be stacked no higher than the height at which the spreader bar assembly can be safely handled by laborers (typically no higher than four). Rolls should never be stacked on end.

12.5 Rolls should be stored at the job site away from high-traffic areas but sufficiently close to the active work area to minimize handling. The designated storage area should be flat, dry and stable. Moisture protection of the GCL is provided by its packaging; however, an additional tarpaulin or plastic sheet is recommended.

RE: REVIEW AND COMMENTS ON FACILITY WORK PLAN, SAMPLING AND ANALYSIS PLAN
WIPP HAZARDOUS WASTE FACILITY PERMIT
EPA I.D. NUMBER NM4890139088

Dear Dr. Triay and Mr. Epstein:

The New Mexico Environmental Department (NMED) Hazardous Waste Bureau has completed the review of two corrective action documents submitted for the Waste Isolation Pilot Plant (WIPP). The Department of Energy/Carlsbad Field Office and Westinghouse Waste Isolation Division (Permittees) prepared both reports as required by Module VII (Corrective Action for Solid Waste Management, Sections VII.M.1 and .2) of the WIPP Hazardous Waste Facility Permit. The two reports are "WIPP Facility Work Plan for Solid Waste Management Units and Areas of Concern" (Work Plan), received by NMED on February 24, 2000 (report dated February 2000) and "WIPP Sampling and Analysis Plan for Solid Waste Management Units and Areas of Concern" (Sampling and Analysis Plan), received by NMED on May 24, 2000 (report dated May 2000). The scope of both reports is limited to those Solid Waste Management Units (SWMUs) and Areas of Concern (AOCs) identified in the permit.

The Work Plan describes the facility-wide approach to future investigations at the SWMUs and AOCs. The Sampling and Analysis Plan describes in greater detail the approach of investigations (past and proposed) at each of the SWMUs and AOCs. In general, NMED has found both documents are sufficiently complete to proceed with the proposed investigations; however, in order for these documents to meet NMED standards for technical adequacy, the following comments need to be addressed. While some of the comments are for informational purposes that may not require a response, others are of a more technical nature and require a response from the Permittees.

Please respond to the attached comments to NMED within thirty (30) calendar days from the date this letter is received. Should you have any questions or require additional explanation on any of the items discussed in this letter, please contact Will Fetner at 505-827-1558, extension 1038.

Sincerely,

Steve Zappe
Project Leader
Hazardous Waste Bureau

NMED comments on the Work Plan

1. General comment:- Based on current NMED policy, chemicals of concern detected in soil samples must be compared against the more stringent residential risk-based screening levels established by NMED (Soil Screening Levels, attached) or, for chemicals with no NMED values, EPA Region 6 (Human Health Medium-Specific Screening Levels) and not with industrial criteria as referenced in the Work Plan. This policy is based on the fact that, at the present time, NMED has no mechanism or authority to impose or enforce land-use restrictions at any facility in the State. NMED is unable to accept guarantees that the current land use of an individual site or facility will not change over time, even if such guarantees are a matter of federal law. As a result, NMED requires the Permittees to evaluate the more conservative assumption (i.e., residential) for soil screening values. NMED notes that soil analytical data available thus far from all the SWMUs and AOCs do not exceed the residential risk-based soil screening levels and, therefore, this requirement should not affect the general approach of investigations as proposed by the Permittees and those recommended in these comments.

2. Section 2.2, first sentence, page 6 - Section 2.1.4 should be referenced instead of 2.1.3.

3. Section 3.0, second bullet under DCQAP objectives, page 7 - Please provide more details or be more specific about the meaning of this particular item.

4. Section 3.1.2, first sentence of the second paragraph under the title "Completeness", page 9 - Please justify how the 85 percent completeness goal was derived.

5. Section 3.2.9, first sentence, page 14 - Note that laboratory bottleware typically consist of glass containers for the analysis of organic and inorganic soil samples; polyethylene containers are used for the analysis of inorganic water samples.

6. Section 3.2.12, page 15 - Clarification: since a number of soil samples have shown concentrations of contaminants above background levels (i.e., barium, chromium, lead, nickel and methanol), the possibility of generating contaminated materials does exist. At a minimum, field personnel should use Level D personal protection equipment and all waste generated from the investigations should be temporarily stored on-site pending analysis of samples.

7. Section 3.3, first paragraph, page 15 - It is the Permittees' responsibility to make sure that the selected analytical laboratory meets the minimum requirements set forth by EPA's Contract Laboratory Program (CLP).

NMED comments on the Sampling and Analysis Plan

1. Table of Contents, page i - "Acronyms and Abbreviations" are located in page xi and "Definitions" are located in page xiii.

2. Section 1.1, second sentence, page 1 - In addition to total metals, the objective of the SAP should include defining the extent of specific organic compounds, such as methanol detected in SWMU 004a (Portacamp Storage Yard, West Side).

3. Section 1.3.1.1, fifth bullet, page 3 - Remove the asterisks "**" for SWMU 001L (WIPP-12/P-5) since additional soil sampling to determine the extent of barium is proposed for this site.

4. Section 1.3.2, third paragraph, page 4 - The Permittees will need to provide additional documentation to justify "closure" and, therefore, No Further Action (NFA) for the relevant sites. Provide hard copy documentation from "another regulatory authority" that state that the specific sites were properly closed under their authority and why they are exempt from RCRA. If possible, also include more detailed information on the procedures used to "close" these sites (provide guideline(s)/rule(s), etc). This information should be included in the NFA request report for these sites.

5. Section 1.3.2.2, third sentence, page 5 - Note that there was a minor detection of thallium [0.13 parts per million (ppm)] in SWMU 001s (ERDA-9). The Permittees need to reference this exception in the text of this section.

6. Section 1.4.2, page 6 - See above NMED's Comment #1 on the Work Plan. Residential (not industrial) risk-based soil screening levels established by NMED (or EPA Region 6, as applicable) will be used as action levels.

7. Section 1.4.4, page 6 - NMED agrees with the Permittees' definition of "study boundary" (physical boundary) as contained in this section. However, horizontal and vertical boundaries should also be based on the extent of contaminant migration, if any. Therefore, should contamination (chemicals of concern showing concentrations above background levels) be found beyond the initial horizontal and vertical boundaries, these boundaries should be expanded accordingly to accommodate the extent of the contaminant plume.

8. Section 1.4.5, last two sentences, pages 6 and 7 - As previously stated, residential (not industrial) risk-based soil screening levels established by NMED (or EPA Region 6, as applicable) will be used as action levels. For those sites with constituent concentrations exceeding screening criteria, ecological risks must be evaluated in addition to human

health risk evaluations (in order to protect both human health and the environment) before NFA can be requested.

9. Section 1.4.6, next to last sentence, page 7 - See above NMED's Comment #1 on the Work Plan [residential (not industrial) risk-based soil screening levels established by NMED (or EPA Region 6, as applicable) will be used as action levels].

10. Section 1.4.7, third sentence, page 7 - Random sampling design does not seem appropriate. Sampling locations should target areas of concern (where soil impacts would most likely be found) and other areas that would fully delineate the extent of the contaminant plume, if one exists.

11. General comment - The SAP should include map(s) showing the location of all the SWMUs and AOCs in respect to each other and to other relevant WIPP surface features (buildings and other structures, access roads, drainage features, etc.).

12. Section 1.5, last sentence, page 7 - Table 27.1 should be introduced in the text of this section so it can be used as reference to subsequent sections (Sections 2.0 through 24.0).

13. Sections 2.0, 3.0, 6.0, 11.0, and 14.0 through 16.0, "Sampling" sections - The number of samples that are reported to have been collected under the "Sampling" section versus those shown on the respective figure and table need to be consistent. All samples locations (at minimum the 1996 sampling events for sites 001g, 001h, 001L, 001x and 004a) need to be shown on the respective table and figure including a summary of analytical results.

14. Figure 2.1, page 11 - Note that the industrial criteria for lead is 1,000 ppm according to the NMED Soil Screening Levels table (vs. 780 ppm shown on the figure). The residential criteria for lead is 400 ppm. The figure should list the residential criteria.

15. General comment - In reference to those sites that have been closed under another authority, under the "Nature and Extent of Contamination" section, the SAP should mention results of analyses that were below method detection limits (or below background levels) and, therefore, further support a NFA request (i.e., thallium and mercury results).

16. Section 6.1.2, page 24 - It is not clear in this section if WIPP-12 borehole was a continuation of the P-5 borehole (the location of P-5 needs to be shown on Figure 6.1). Are there any details on the total depth of P-5? How does the closure of the P-5 site by USGS in 1976 relate to subsequent drilling of WIPP-12 on the same pad from 1978 through 1982?

17. Figure 6.1 and Section 6.2.3.1, pages 26 and 28, respectively - NMED recommends the following:

- Advance at least one borehole and collect two samples (shallow and deep) from each of the two WIPP-12 mud pits that were not previously sampled (see attached NMED Figure 1 which is based on Figure 6.1 of the SAP for location). These samples should be analyzed for total barium and lead.

- Collect a "deeper" sample at the location of Hole 6 in order to delineate the vertical extent of total barium contamination [suggested depth - 8 to 9 feet below land surface (bls)].

- Collect sufficient samples "around" Hole 6 location so as to fully determine the horizontal extent of barium impacts (see attached NMED Figure 1 for suggested locations).

- The Permittees should keep in mind that any drainage feature or "low point" that may lead away from Hole 6 should also be evaluated and/or sampled in order to determine if any migration of contaminants has occurred due to surface runoff.

18. General comment - Under the "Nature and Extent of Contamination" section of those SWMUs that will be further investigated, the Permittees should specify the following in the text: 1) which borehole location exceeded background levels and 2) that the analytes that were detected above background levels were also significantly below the residential risk-based soil screening levels established by NMED (or EPA Region 6, as applicable).

19. Section 11.2.1.2, first paragraph, page 38 - In order to be consistent, please state in the text the number of samples (and QA/QC) collected from this SWMU. Please correct typographical error on second sentence: should be SWMU 001q instead of SWMU 001p. Also specify that the samples were collected only from the mud pit that was used (primary pit), if this is the case.

20. Figure 11.1 and Section 11.2.3.1, pages 40 and 42, respectively - NMED recommends the following:

- Collect a "deeper" sample at the previous sample location in order to delineate the vertical extent of total chromium, nickel and lead contamination (suggested depth - 4 to 5 feet bls).

- Collect enough samples "around" previous sample location so as to fully determine the horizontal extent of total chromium, nickel and lead impacts (for suggested locations, see attached NMED Figure 2 which is based on Figure11.1 of the SAP).

- The Permittees should keep in mind that any drainage feature or "low point" that may lead away from DOE-1 mud pit should also be evaluated and/or sampled in order to determine if any migration of contaminants has occurred due to surface runoff.

21. Table 11.1, pages 41 - The table should include nickel concentrations that also exceeded background concentrations. OK

22. Section 11.2.3.2, first sentence, page 43 - Samples should be analyzed for total chromium, nickel and lead, not barium. OK

23. Section 12.2.2.1, third sentence, page 45 - Emphasize that thallium was detected only slightly above the method detection limit. OK

24. Figure 14.1 and Section 14.2.3.1, pages 50 and 53, respectively - NMED recommends the following:

    - Collect a "deeper" sample at the location of Hole 4 in order to delineate the vertical extent of total barium, chromium and lead contamination (suggested depth - 8 to 9 feet bls).

    - Collect enough samples "around" Hole 4 location so as to fully determine the horizontal extent of total barium, chromium and lead impacts (for suggested locations, see attached NMED Figure 3 which is based on Figure14.1 of the SAP).

25. The Permittees should keep in mind that any drainage feature or "low point" that may lead away from Hole 4 should also be evaluated and/or sampled in order to determine if any migration of contaminants has occurred due to surface runoff.

26. Sections 15.2.1.2 and 15.2.2.1, pages 55 and 56, respectively - Numerous parameters (VOCs, metals and PCBs) were sampled at this SWMU; the text should specify the analyses performed on the samples. Regarding the last sentence of Section 15.2.1.2: Figure 15.1 does not show lead concentrations but does present nickel concentrations that are not mentioned in the text. Third sentence of Section 15.2.2.1: Table 15.1 does not (but should) include lead concentrations.

27. Table 15.1, Section 15.2.3.1 and Figure 15.1, pages 57, 58 and 59, respectively - NMED recommends the following:

   - To be consistent with other SWMUs (SWMU 001L and 001q), lead concentrations should be included in Table 15.1 and Figure 15.1 even if all concentrations of lead were below background.

   - On Figure 15.1, show NMED residential risk-based soil screening level for nickel and show background concentration for lead.

   - Collect "deeper" samples at the locations of Holes 1 through 4 in order to delineate the vertical extent of total chromium, nickel and methanol contamination (suggested depths - 8 to 9 feet bls).

   - Collect enough samples "around" previous sample locations exceeding background levels so as to fully determine the horizontal extent of total chromium, nickel and methanol impacts (for suggested locations, see attached NMED Figure 4 which is based on Figure 15.1 of the SAP).

   - The Permittees should keep in mind that any drainage feature or "low point" that may lead away from the SWMU 004a storage yard should also be evaluated and/or sampled in order to determine if any migration of contaminants has occurred due to surface runoff.

28. Section 15.2.3.1, third sentence, page 58 - To be consistent with previous sample intervals, the second set of subsurface samples should be collected 60 to 72 inches bls instead of the proposed 48 to 60 inches bls.

29. Table 16.1, page 61 - The table should include lead concentrations (<5 ppm) analyzed in the NMED sample collected from 12-24 inches bls.

30. Figure 16.1, page 63 - Please show the Permittees' and NMED's sample locations on this figure, if known.

31. Section 16.2.3, page 62 - Based on historical information provided for this site, NMED does not see the need to perform additional sampling at the subject SWMU. This suggestion is based on: 1) the evaporation pond presumably received only grey water from personnel showers and currently receives storm water and domestic water resulting from fire flow performance testing, and 2) detected concentrations of lead and nickel are only slightly above background concentrations. NMED believes that enough information is

available from this site to warrant NFA. However, the Permittees may proceed with the proposed scope of work if they believe that additional sampling is warranted for this SWMU.

32. Section 25.1, last paragraph, second sentence, page 82 - in addition to metals, VOCs need to be included in the text (i.e., methanol at SWMU 004a).

33. Section 25.3.2, first paragraph, page 83 - See above NMED's Comment #7 on the Work Plan.

34. Section 26.1, third paragraph, page 85 - Please clarify the Permittees' reporting intentions. The Permittees are intending to submit to NMED a draft SAP that will summarize the results of investigations at each of the SWMUs; however, there is no mention how the final report will be structured.

   NMED would like to receive one RFI report for all of the SWMUs and AOCs. The report should be structure as described in Module VII.O and VII.U.5 of the WIPP Hazardous Waste Facility Permit. The report should contain detailed historical information, describe previous and recent sampling efforts and results, and contain recommendations. All recommendations (i.e., NFA, proposal for additional investigations, etc.) need to be fully supported in the report. For those SWMUs that exceed the NMED residential screening criteria for soils, human health and ecological risks will have to be evaluated and included in the final report.

35. Section 27.0, page 87 - For consistency, name the six AOCs (in the first paragraph, next to last sentence) and the four SWMUs (in the second paragraph, next to last sentence).

36. Appendix A, Section 2.2.2, first sentence, page 92 - Text should also include mercury in the evaluation of data distributions.

37. General comments on those SWMUs that will be further investigated (SWMUs 001L, 001q, 001x, 004a and, if applicable, 007b):

   - Permittees need prior NMED approval before any significant changes are made to the scope of work (i.e., reduction of sampling locations, modifying sample analyses, etc.).
   - Relevant surface features (i.e., borehole locations, mud pits, site boundaries, access roads, etc.) and sample locations (previous and proposed sample locations) need to be surveyed for each site by professional surveyors. This will assure that accurate scaled site maps are provided in the final report(s).

State of New Mexico Soil Screening Levels

Table A-1 provides State of New Mexico Soil Screening Levels (SSLs), as developed by the New Mexico Environment Department (NMED) Hazardous Waste Bureau (HWB) and the Ground Water Quality Bureau Voluntary Remediation Program for 133 chemicals most commonly associated with environmental releases within the state. These NMED SSLs are derived using default exposure parameter values (as presented in Table A-2) and chemical- and State of New Mexico-specific physical parameters (as presented in Table B-1 of Appendix B). These default values are assumed to be appropriately conservative in the face of uncertainty and are likely to be protective for the majority of site conditions relevant to soil exposures within New Mexico.

However, the NMED SSLs are not necessarily protective of all known human exposure pathways, reasonable land uses or ecological threats. Thus, before applying NMED SSLs at a site, it is extremely important to compare the conceptual site model (CSM) with the assumptions upon which the NMED SSLs are predicated to ensure that the site conditions and exposure pathways match those used to develop the NMED SSLs. If this comparison indicates that the site at issue is more complex than the corresponding SSL scenarios, or that there are significant exposure pathways not accounted for by the NMED SSLs, then the NMED SSLs are insufficient for use in a defensible assessment of the site. A more detailed site-specific approach will be necessary to evaluate the additional pathways or site conditions.

TABLE A-1

Column 1: The first column in Table A-1 presents the names of the 133 chemicals for which NMED has developed SSLs.

Column 2: The second column presents NMED SSLs predicated on residential soil exposures.

Column 3: The third column presents indicator categories for the NMED SSL residential basis, whether predicated on carcinogenic effects (ca), noncarcinogenic effects (nc), soil saturation limits (sat) or a non-risk based "max" determination. NMED SSLs predicated on a carcinogenic endpoint reflect age-adjusted child-to-adult exposures. NMED SSLs predicated on a noncarcinogenic endpoint reflect child-only exposures. Detected concentrations above the "sat" value may indicate the presence of nonaqueous phase liquid (NAPL). For certain inorganic and semivolatile organic compounds (SVOCs) that exhibit relatively low toxicity, a non risk-based maximum concentration of 10^5 mg/kg is given when the risk-based SSL exceeds that level. These are noted as "max" in the tables.

Columns 4 and 6: The fourth and sixth columns present NMED SSLs analogous to Column 1, with the exception that these values correspond to Industrial/Occupational and Construction worker (adult-only) exposures, respectively.

Columns 5 and 7: The fifth and seventh columns present endpoint bases analogous to Column 3

DRAFT

for the Industrial/Occupational and Construction worker receptor populations, respectively. Unlike the Residential population, noncarcinogenic endpoint notes for these receptor populations are predicated on adult-only exposures.

Column 8: The eighth column notes which chemicals are considered VOCs (for inhalation considerations). Those chemicals not considered VOCs are evaluated within the SSLs relative to inhalation of particulate emissions.

Columns 9 and 10: The ninth column presents NMED SSLs for the migration to groundwater pathway developed using a default dilution attenuation factor (DAF) of 1, which assumes no effective dilution or attenuation. These values can be considered at sites where little or no dilution or attenuation of soil leachate concentrations is expected (e.g., shallow water tables, karst topography). Column 10 presents NMED SSLs for the migration to groundwater pathway developed using a DAF of 20 to account for natural processes that reduce contaminant concentrations in the subsurface.

As noted above, separate NMED SSLs are presented for use in evaluating three discrete potential receptor populations: Residential, Industrial/Occupational, and Construction. Each NMED SSL considers incidental ingestion of soil, inhalation of volatiles (limited to those chemicals noted as volatile organic compounds [VOCs] within Table A-1) or particulate emissions from impacted soil, and dermal contact with soil.

Generally, if a contaminant is detected at a level in soil exceeding the most relevant NMED SSL, and the site-specific CSM is in general agreement with the underlying assumptions upon which the NMED SSLs are predicated, this result indicates the potential for adverse human health effects to occur. Conversely, if no contaminants are detected above the most relevant NMED SSL, this tends to indicate to the user that environmental conditions may not necessitate remedial action of the surface soil or the vadose zone.

A detection above an NMED SSL does not indicate that unacceptable exposures are, in fact, occurring. The NMED SSLs are predicated on relatively conservative exposure assumptions and an exceedance only tends to indicate the potential for adverse effects. The NMED SSLs do not account for additive exposures, whether for carcinogenic or noncarcinogenic endpoints. Section 5 of Part A addresses a methodology by which an environmental manager may determine whether further site-evaluation is warranted, however, this methodology does not replace the need for defensible risk assessment where indicated.

The NMED SSLs address a basic subset of exposures fundamental to the widest array of environmentally-impacted sites within the State of New Mexico. The NMED SSLs cannot address all relevant exposure pathways associated with all sites. The utility of the NMED SSLs depends heavily upon the understanding of site conditions as accurately reflected in the CSM and nature and extent of contamination determinations. Consideration of the NMED SSLs does not preclude the need for site-specific risk assessment in all instances.

RECEIVED
SEP 14 2005

Mr. Clint Marshall
Ground Water Quality Bureau
New Mexico Environment Department
P.O. Box 26110
Santa Fe, New Mexico 87502

Subject: Status of the Infiltration Controls Construction Project and Request for an Extension for the Construction of Cell B of the Salt Storage Area Extension

Dear Mr. Marshall:

The purpose of this letter is to:

1. Notify you of the status of the construction of the Infiltration Controls Project, and
2. Request a modification to the schedule referenced in the Discharge Permit issued on December 22, 2003 for the construction of Cell B of the Salt Storage Extension Area.

The infiltration controls proposed in the Design Basis Summary contained in Attachment A of the April 24, 2003 Discharge Plan Application have been completed, with the exception of Cell B of the Salt Storage Extension Area. Drawings depicting the as-built features of this project are currently being compiled and will be provided for your information when complete. The features constructed to date include:

- The Salt Storage Extension Cell A
- The Salt Storage Extension Evaporation Pond
- Capping the existing salt storage area with a High Density Polyethylene (HDPE) liner and cover
- The Salt Pile Evaporation Pond
- Storm water Infiltration Control Ponds 1, 2 and A

We are requesting a modification regarding the schedule for the construction of Cell B of the Salt Storage Extension Area. The December 23, 2003 Discharge Permit Modification states that the infiltration controls structures shall be constructed according to the schedule provided to NMED dated July 24, 2003. The scheduled dates are May 2006 to begin construction and October 2006 to complete Cell B of the Salt Storage Extension Area. The salt storage capacity for Cell B is not necessary until midway through the excavation of the underground Hazardous Waste Disposal Unit, Panel 6. Based on current mining rates, which are driven by waste shipment receipt rates, we anticipate that the excavation of Panel 6 will begin in late 2007. Because these rates

CBFO:AMO:HJP:KJB:05-1519:UFC5486

are subject to variation, we propose that Cell B be constructed and made available when additional salt storage capacity is necessary and that the schedule currently referenced in the Discharge Permit be modified such that notice to NMED would be given no later than 60 calendar days prior to the planned start of construction of Cell B.

Thank you for your consideration of our request to modify the plan for Cell B construction.

Please contact me at (505) 234-7462, if you have any questions or require additional information.

Sincerely,

H. L. Plum, Manager
RCRA Program

P.O. Box 26110
Santa Fe, NM 87502

Subject: Notice of Discharge, July 27, 2005, U.S. Department of Energy, Waste Isolation Pilot Plant Discharge Permit-831

Dear Mr. Olson:

The purpose of this letter is to verify the U.S. Department of Energy's (DOE) verbal report to you of potential discharge from the Sewage Lagoon System and Evaporation Pond H-19 that are in operation at the Waste Isolation Pilot Plant (WIPP). These facilities are subject to Discharge Plan-831 (DP-831) issued by the State of New Mexico, Environment Department (NMED) on December 23, 2003. The verbal report and this letter verifying the report are being made under the requirements of NMAC 20.6.2.1203, NOTIFICATION OF DISCHARGE-REMOVAL. Our Notification of Discharge in the format indicated by the above citation is attached for your review.

DOE's initial Notification of Discharge to NMED occurred at approximately 3:30 p.m., July 27, 2005 when H.L. Plum called the Ground Water Quality Bureau (GWQB). A message was left with your Administrative Assistant regarding the purpose of the call. When he was informed that you and staff were engaged in meetings, Mr. Plum agreed to call back and did provide a report of the occurrence to you at approximately 8:30 a.m., July 28, 2005.

In response to a request by the GWQB that we inspect the Sewage Lagoon System and Evaporation Pond H-19 geo-synthetic liners for potential leaks below the water line, DOE provided an inspection plan to the GWQB for review and approval in March 2005. The GWQB approved this plan on April 7, 2005. DOE implemented the approved plan utilizing an electronic leak detection methodology to inspect the referenced facilities for potential leaks. This work occurred June 7-11, 2005. GWQB staff was notified of the dates of the inspection, but were unable to be present due to other responsibilities. The NMED's Oversight Bureau staff at WIPP did, however, observe this work.

DOE has received a report from the consultant performing the stated work on July 26, 2005. A total of 46 leak signals were noted in the report received. At least one leak signal was recorded in each of the eight facilities inspected. DOE is currently reviewing

CBFO:AMO:HLP:LR:05-1507:UFC:5486

the information provided in the report. DOE believes that it is appropriate to notify the NMED of the information received and the potential that leaks have occurred due to the requirements of the NMAC 20.6.2.1203 Notice of Discharge Step and the WIPP DP-831 Permit conditions.

DOE believes that some percentage of the leak signals may actually be leaks. We do know that studies have confirmed that some leakage in geo-synthetic lined facilities is present in the form of small gaps in seams and where pipe penetrations are present. We are currently developing a plan to respond to the information provided in the report received. We have begun our discussion to determine what actions are appropriate to physically inspect the liners to confirm the accuracy of the leak signals, what corrective action may be appropriate, the extent of work required, the budgetary impacts, and the development of a schedule to implement the actions needed. Much of this information must be available to provide a final report, Corrective Action Plan that may be necessary to the GWQB within 90 days of our receiving our report.

In addition to the inspection of the geo-synthetic liner, the GWQB"s April 7, 2005 letter approving the inspection plan required "...liner material will be collected...above the waterline and subjected to laboratory testing to further determine the condition of the liners." The collection of liner samples for laboratory analysis was delayed until after the testing occurred. Sample coupons measuring approximately 2 feet square were collected from ponds 2A and Evaporation Pond A. The consultant performing the work believed it was appropriate to limit the number of penetrations of the liners to reduce the potential for introduction of leaks. Laboratory results on the potential serviceability and condition of the geo-synthetic liners are not yet available This information is needed prior to the development of any corrective action plan for these facilities. The final report regarding the inspection results and corrective action plan the DOE will submit to the GWQB will provide the results of this laboratory testing.

Should you have any additional questions, please call Mr. H.L. Plum at (505) 234-7462.

Sincerely,

Lloyd L. Piper
Acting Manager

NMAC 20.6.2.1203, NOTIFICATION OF DISCHARGE...July 27,2005, 3:30 p.m.

(1)(a) Name, address, and telephone number of the person...in charge of the facility:

Lloyd Piper, Acting Manager
U. S. Department of Energy
Carlsbad Field Office
P. O. Box 3090
4021 National Parks Highway
Carlsbad, NM 88221-3090

(b) The name and address of the facility:

Waste Isolation Pilot Plant (WIPP)
34 Louis Whitlock Road (formerly WIPP North Access Road)
26 miles E-SE of Carlsbad
Eddy County
New Mexico

(c) The date, time, location, and duration of the discharge:

July 26, 2005, 3:30 p.m., first knowledge of potential leaks from the WIPP Sewage Lagoon System and Evaporation Pond H-19 was provided to DOE by its management and operations contractor; the duration and potential impact of any leakage that may have occurred has not yet been defined, however, no obvious leakage outside of the lined facilities has been or is observed.

(d) The source and cause of discharge:

Potential leaks in the Sewage Lagoon System and Evaporation Pond H-19 geo-synthetic liner material, in the seams joining liner panels together, or locations where pipe penetrations occur.

(e) A description of the discharge, including its chemical composition:

Sewage effluent discharged to a series of seven synthetically lined ponds for treatment and evaporation (facultative lagoon system) and non-hazardous brine water discharged to a synthetically lined evaporation cell (H-19).

(f) The estimated volume of the discharge:

Unknown if any significant quantity has leaked from any geo-synthetically lined facility. Investigation is ongoing to determine the size and extent of any leakage that may have occurred

(g) Any actions taken to mitigate immediate damage from the discharge:

Coupon samples of the liner material have been submitted to a laboratory to determine material condition and to assist in determination of the options available for corrective action to be implemented if required. A final report on what the inspection found and a corrective action plan will be developed and submitted to NMED. These will be based on the laboratory analysis of the geo-synthetic liner materials in use and confirmation of conditions discussed in the contractor's report on the conditions present in the facilities inspected. Information on the condition of the liners will be used to determine the ability of the liners to be repaired or need for replacement.

RE: Response to Proposed Construction Design Changes to the SWIC Pond A, DP-831, Waste Isolation Pilot Plant

Dear Mr. Plum:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received a letter proposing construction design changes to the Storm Water Infiltration Control Pond A, submitted by the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) dated July 29, 2005. The letter confirms an approval given by NMED by telephone on July 21, 2005 to realign anchor trenches and seams for the synthetic liner from an east-west to north-south orientation. In addition, four overflow pipes as originally designed will be replaced with a spillway located on the west side of the pond. NMED approves of the design changes as stated in the letter and depicted on the attached drawing. As-built drawings must be submitted after project completion.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

Clint Marshall

Subject: Weekly Status Report on Construction Activities for Storm Water Infiltration Control Pond A, Week Ending August 5, 2005

Dear Mr. Marshall:

The purpose of this letter is to provide a weekly status report on activities related to the dewatering and construction of Storm Water Infiltration Control (SWIC) Pond A. On June 6, 2005, WIPP received a letter dated May 20, 2005, from William C. Olson, Chief of the Ground Water Quality Bureau. The letter authorizes pumping storm water from SWIC Pond A to SWIC Pond 1 and/or 2 as needed to facilitate construction of SWIC Pond A and states that WIPP shall submit weekly reports on: (1) the volume of storm water transferred to SWIC Ponds 1 and 2, (2) the remaining capacity in SWIC Ponds 1 and 2, and (3) the progress of construction activities on SWIC Pond A. The statuses of these three items are as follows:

1.) No storm water has been transferred to SWIC Pond 1 or 2 during this reporting period.

2.) The remaining capacity in SWIC Pond 1 is approximately 5.8 feet or 755,000 gallons. The remaining capacity in SWIC Pond 2 is approximately 2.0 feet or 660,000 gallons.

3.) The installation of the HDPE liner in SWIC Pond A was completed on Saturday July 30, 2005. The anchor trenches were backfilled and final grading around the pond was completed on August 2, 2005. The infiltration controls required to be constructed by the December 23, 2003 DP-831 Modification are substantially complete with the exception of final seeding in areas disturbed by construction activities. Accordingly, this will be the last weekly status report related to the construction of SWIC Pond A.

If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

Lloyd L. Piper
Acting Manager

Subject: Written Follow-Up Confirming a Verbal Discussion on July 21, 2005, Noting Construction Enhancements For The WIPP Salt Pile Infiltration Controls Project, Pond A

Dear Mr. Marshall:

The purpose of this letter is to confirm our discussion on July 21, 2005, regarding two design changes implemented in the construction of Storm Water Infiltration Control (SWIC) Pond A of the WIPP Salt Pile Infiltration Controls Project. These two changes involved relocating the anchor trenches to hold the high density polyethylene liner (HDPE) liner in place and a change in the location and design of the overflow for SWIC Pond A.

The original design drawing illustrated anchor trenches and seams for the liner oriented in the east and west direction of SWIC Pond A. Due to the unusual amount of rainfall received during construction, we have been delayed in continuing this project. This has been noted in several letters submitted to you between March and July 2005.

After considering several alternatives, we have determined that constructability will be improved and the completion of the project expedited by installing the liner with anchor trenches and seams oriented in the north/south direction. In addition, this change will provide greater stability for the liner and reduce uplift by wind.

The other change pertains to overflow options. The original design drawing notes that four overflow pipes exist through the earthen berm. These will be abandoned in place with the ends cut off and covered with soil. The construction change to be implemented is to install an emergency spillway in the berm with the down slope covered by liner and rip-rap or concrete slurry to prevent soil erosion. This spillway will discharge to the roadside drainage adjacent to the Louis Whitlock Road (formerly the WIPP North Access Road), which will divert emergency overflows west from SWIC Pond A along the highway should this be required in the future.

Enclosed is a drawing, for your information only, that depicts the construction plan as described in this letter.

RE: Request for Additional Information, DP-831, Waste Isolation Pilot Plant

Dear Dr. Triay:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received an application for discharge permit modification (Application) dated March 4, 2005, from the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP). NMED determined that the application was administratively complete on April 26, 2005. WIPP notified NMED on June 27, 2005 that the public notice requirements for the application have been completed. NMED has reviewed the application for discharge permit modification and requests additional information as follows.

1. In Section 6.b, Monitoring Plan, WIPP refers to Tab 1 of the Application titled, "Additional Potential Contamination Sources" for the required information. Information for monitoring is not located in Tab 1. The application should make reference to the approved Discharge Permits dated April 29, 2003, and December 22, 2003 for this information.

2. On Page 3 under Tab 1, Item 5 of the reclamation activities states that the Site Preliminary Design Validation (SPDV) pile was seeded with shallow rooted plants. Please provide the seed mix used in the revegetation activities.

3. On Page 3 under Tab 1, Item 6 of the reclamation activities states that the SPDV pile is regularly inspected, monitored and maintained. Please provide more details on the frequency and type of inspections, monitoring and maintenance conducted at the SPDV pile.

4. On Page 4 under Tab 1, three piezometers are proposed, one each on the east, west and south sides of the SPDV pile. Please provide a map showing the locations of the proposed piezometers.

5. On Page 5 under Tab 2, Section A, the Application refers to language in the December 16, 1996, DP-831 Permit Renewal Application stating, "Closure plans for the sewage facility and evaporation ponds will specifically require that all lagoons and ponds will be pumped or evaporated and that all sludges be sampled to determine if hazardous constituents exist as defined by the Resource Conservation and Recovery Act (RCRA – 40 CFR 261). If hazardous constituents are detected, the sludges will be managed accordingly." DP-831 regulates discharges that are not necessarily defined as hazardous by RCRA. Please provide more details on how liquids and sludges will be disposed of upon closure of the facultative lagoon system and evaporation ponds regardless of whether they are classified as hazardous.

6. On Pages 5-6 under Tab 2, Section B, the Application states that the active salt piles will be closed in accordance with the requirements of the Land Withdrawal Act (LWA), Section 4(b)(4). The LWA makes further reference to Sections 2 and 3 of the Act of July 31, 1947 (30 U.S.C. 602, 603) commonly referred to as the "Materials Act of 1947." NMED recognizes that WIPP is required to dispose of the salt tailings according to federal law, however more specificity is needed regarding the final disposition of the salt piles whether onsite or offsite. Options for onsite disposal should include conceptual descriptions regarding technical components such as covers and storm water diversion structures. Plans for offsite disposal should discuss possible entities to receive the salt product as well as expected uses. WIPP may amend closure plans at a future date to adjust for unforeseen circumstances and federal requirements.

7. On Pages 6-7 under Tab 2, Section C, the Application states that an investigation of the SPDV pile determined that no remedial measures were required according to NMED guidelines. Please specify the guidelines to which the Application is referring.

8. Please provide as-built plans and specifications for the grading and cover of the SPDV pile.

9. On Page 8 of Table 2 under Tab 4, evaporation pond 007b is described as once containing soap, cleaning fluids, oil and brine. Please provide additional information on the current status of this facility, the pond dimensions, descriptions of any liners, and a map showing its location.

Please respond to this letter within 30 days of receipt. If you have any questions, please contact me at 505-827-0027.

Sincerely,

Clint Marshall

Subject: Weekly Status Report on Construction Activities for Storm Water Infiltration Control Pond A, Week Ending July 29, 2005

Dear Mr. Marshall:

The purpose of this letter is to provide a weekly status report on activities related to the dewatering and construction of Storm Water Infiltration Control (SWIC) Pond A. On June 6, 2005, WIPP received a letter dated May 20, 2005, from William C. Olson, Chief of the Ground Water Quality Bureau. The letter authorizes pumping storm water from SWIC Pond A to SWIC Pond 1 and/or 2 as needed to facilitate construction of SWIC Pond A and states that WIPP shall submit weekly reports on: (1) the volume of storm water transferred to SWIC Ponds 1 and 2, (2) the remaining capacity in SWIC Ponds 1 and 2, and (3) the progress of construction activities on SWIC Pond A. The statuses of these three items are as follows:

1.) No storm water has been transferred to SWIC Pond 1 or 2 during this reporting period.

2.) The remaining capacity in SWIC Pond 1 is approximately 5.5 feet or 726,000 gallons. The remaining capacity in SWIC Pond 2 is approximately 2.9 feet or 629,000 gallons.

3.) Liner installation on SWIC Pond A began on Tuesday July 26, 2005, and is approximately 20% complete.

If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

Lloyd L. Piper

Subject: Weekly Status Report on Construction Activities for Storm Water Infiltration Control Pond A, Week Ending July 22, 2005

Dear Mr. Marshall:

The purpose of this letter is to provide a weekly status report on activities related to the de-watering and construction of Storm Water Infiltration Control (SWIC) Pond A. On June 6, 2005, WIPP received a letter dated May 20, 2005, from William C. Olson, Chief of the Ground Water Quality Bureau. The letter authorizes pumping storm water from SWIC Pond A to SWIC Pond 1 and/or 2 as needed to facilitate construction of SWIC Pond A and states that WIPP shall submit weekly reports on: (1) the volume of storm water transferred to SWIC Ponds 1 and 2, (2) the remaining capacity in SWIC Ponds 1 and 2, and (3) the progress of construction activities on SWIC Pond A. The status of these three items is as follows:

1.) No storm water has been transferred to SWIC Pond 1 or 2 during this reporting period.

2.) The remaining capacity in SWIC Pond 1 is approximately 5.7 feet or 745,000 gallons. The remaining capacity in SWIC Pond 2 is approximately 1.8 feet or 598,000 gallons.

3.) Earthwork for SWIC Pond A resumed on July 19, 2005, preparing the subgrade of SWIC Pond A for installation of the synthetic liner.

If you have any questions or require additional information, please contact Mr. H. L. Plum at (505) 234-7462.

Subject: Weekly Status Report on Construction Activities For Storm Water Infiltration Control Pond A

Dear Mr. Marshall:

The purpose of this letter is to provide a weekly status report on activities related to the dewatering and construction of Storm Water Infiltration Control (SWIC) Pond A. On June 6, 2005, WIPP received a letter dated May 20, 2005, from William C. Olson, Chief of the Ground Water Quality Bureau. The letter authorizes pumping storm water from SWIC Pond A to SWIC Pond 1 and/or 2 as needed to facilitate construction of SWIC Pond A and states that WIPP shall submit weekly reports on: (1) the volume of storm water transferred to SWIC Ponds 1 and 2, (2) the remaining capacity in SWIC Ponds 1 and 2, and (3) the progress of construction activities on SWIC Pond A.

Following a 1.7 inch rain event on May 27 through May 28, 2005 approximately 1.7 million gallons of water had accumulated in SWIC Pond A. To date, we have taken no action regarding the removal of this water from the pond. A letter from the Ground Water Quality Bureau dated June 21, 2005, granted WIPP permission to breach the berm on SWIC Pond A permitting the water to be discharged to the environment. The berm of SWIC Pond A was breached on Saturday, June 25, 2005. Arrangements will then be made with the construction contractor to resume construction, once the pond has adequately dried.

If you have any questions or require additional information, please contact Jody Plum of my staff at (505) 234-7462.

Sincerely,

Ines R. Triay
Acting Manager

RE: Response to Notices of Intent and Continuance to Discharge Storm Water from SWIC Pond A to the Ground, DP-831, Waste Isolation Pilot Plant

Dear Dr. Triay:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received the Notice of Intent (NOI), submitted by the U.S. Department of Energy (DOE) Waste Isolation Pilot Plant (WIPP) dated June 21, 2005. The NOI request the discharge of 1.7 million gallons of storm water from the unlined Storm Water Infiltration Control (SWIC) Pond A to the ground. Excessive precipitation in the area in late May has caused further delay in lining SWIC Pond A and the discharge of storm water to the environment is necessary to complete construction.

Based on a telephone conversation with Jody Plum of the DOE on June 21, 2005, WIPP proposes to release the storm water by breaching a berm in the SWIC Pond A to empty the pond more rapidly.

Based on the presently available information in your letter and telephone discussion, a discharge permit is not being required for the discharge described above. A discharge permit is not being required because the discharge meets the New Mexico Water Quality Control Commision (WQCC) standards as listed in Section 20.6.2.3103 NMAC.

If at some time in the future WIPP intends to change the amount, the character, or location of the discharges so that they will not be as described, or if observation or monitoring shows that the discharges are threatening ground water quality, you must file a new NOI with the NMED.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

William C. Olson, Chief
Ground Water Quality Bureau

Subject: Completion of Public Notice Requirements for the March 4, 2005, Discharge Plan Modification

Dear Mr. Marshall:

The purpose of this letter is to provide proof of the completion of the public notice requirements Option #2 for the March 4, 2005, Discharge Plan (DP-831) modification in accordance with your letter dated April 26, 2005, and the public notice requirements of 20.6.2.3108 NMAC. Public Notice Option #2 requires that within 15 days of the completion of the public notice requirements, the Permitee must submit proof of notice to the New Mexico Environment Department containing:

1. A signed affidavit of sign posting a synopsis of the public notice
2. A copy of the published display ad indicating the newspaper and date of publication.
3. The list of discharge site owners' names and addresses and copies of certified mail return receipts for owners, if different from the applicant.

Enclosed are a copy of the public notice that was published in the Carlsbad Current Argus newspaper on May 5, 2005, a signed affidavit, check number 009681 and a photograph of the synopsis of the public notice that was posted in a prominent location in front of the facility where it would be visible to the public passing by the site. To address Item 3, the discharge site owner is the same as the applicant, the U.S. Department of Energy, Acting Manager, Dr. Inés R. Triay.

If you have any questions or need additional information regarding this information, please contact Mr. H. L. Plum of my staff at (505) 234-7462.

Sincerely,

for

Ines R. Triay
Acting Manager

Home projects sought

CARLSBAD — First United Methodist Church, Epworth Methodist Church, First Presbyterian Church, First Assembly of God, Carlsbad Family Fellowship and First Baptist Church are planning a home repair mission June 6-10. Eligible projects may include porch construction, exterior and interior painting, weatherization, step repair, wheelchair ramps, drywall repair, carpentry, mobile home underpinning and roof coating, and roll roofing. Labor and materials will be free to qualifying homes.

Applicants will be carefully reviewed to determine qualifications. Applications can be picked up at the Southeast New Mexico Community Action Corporation, 1915 San Jose Blvd. Applications must be submitted by 4 p.m. Friday. The project is funded by PNM Foundation and co-sponsored by SNMCAC. For more information, call Kitty Huber at 887-3939.

Scholarships available

CARLSBAD — Class Act and Washington TRU Solutions plans to award four $1,000 scholarships at the Class Act party May 23. Scholarship applications will be available for pickup by homeschool students at First United Methodist Church (ask for Judi Waters). Applications are due Friday. Carlsbad High School, Phoenix, Victory and Faith students will receive applications at their respective schools.

CAAA. Entry packets are available at The Artist Gallery, 120 S. Canyon St. For more information, call Josie Tabor at 885-3317 or Loretta Forbes at 885-3583.

Subject: Notice of Intent to Discharge

Dear Mr. Marshall:

The purpose of this letter is to provide you with the information you requested during phone conversations the week of May 30 through June 3, 2005, to accommodate our request to discharge approximately 1.7 million gallons of water from Storm Water Infiltration Control Pond A to the environment. Following a rainfall event of 1.7 inches May 27 through 28, 2005, this request is to facilitate drying the pond so that construction may resume.

The Department of Energy is providing the information below to the New Mexico Environment Department as required pursuant to 20.6.2.1201 NMAC.

(1) Name of the person making the discharge;
Dr. Inés Triay, Acting Manager

(2) The address of the person making the discharge;
U.S. Department of Energy
Carlsbad Field Office
P.O. Box 3090
4021 National Parks Highway
Carlsbad, NM 88221
(505) 234-7303

(3) The location of the discharge;

Name	County	Township	Range	Section	Latitude	Longitude
Pond A	Eddy	22S	31E	SE 1/4 of the SW 1/4 of the SE 1/4 of section 20	N32°, 22 Minutes, 19.9 Seconds	W103°, 47 Minutes, 51.9 Seconds

CBFO:AMO:HJP:KJB:05-0288:UC5486

(4) An estimate of the concentration of water contaminates in the discharge (based upon sample collected on June 6, 2005);

Parameter	Result	20.6.2.3103 NMAC Standard
Chloride (mg/l)	73.7	250
Nitrate (NO_3) (mg/l)	1.68	10
Nitrite (NO_2) (mg/l)	0.0146	NA
pH mg/l (s.u.)	8.41	6 - 9
Sulfate(mg/l)	12.8	600.0
Total dissolved solids (mg/l)	269	1,000.0
Total suspended solids (mg/l)	7.00	NA
Total silver (mg/l)	<0.003	0.05
Total arsenic (mg/l)	<0.010	0.1
Total barium (mg/l)	0.109	1.0
Total cadmium (mg/l)	<0.001	0.01
Total chromium (mg/l)	0.009	0.05
Total mercury (mg/l)	<0.0002	0.002
Total lead (mg/l)	<0.005	0.05
Total selenium (mg/l)	<0.010	0.05

(5) The quantity of the discharge;

Approximately 1.7 million gallons of storm water may be discharged from Storm Water Infiltration Control Pond A to the environment.

If you have any questions regarding this notification, please contact Mr. Jody Plum at (505) 234-7462.

Sincerely,

Dr. Ines R. Triay
Acting Manager

Subject: Transfer of Water from Pond A to Pond 1 And or 2 and Weekly Status Report for the WIPP Storm water Infiltration Controls Project Pond A

Dear Mr. Marshall:

The purpose of this letter is to confirm the telephone discussion between you, Jody Plum of the U.S. Department of Energy, and Dale Bignell of Washington TRU Solutions on Monday, May 16, 2005. During this phone conversation, it was requested and you authorized a continuance of the verbal authorization you provided on May 10, 2005, to pump an estimated 130,000 gallons of water from Storm Water Infiltration Control (SWIC) Pond A to SWIC Pond 1 and/or 2. A Notice of Intent (NOI) documenting your May 10, 2005, authorization was documented in a letter mailed on May 16, 2005.

Based on your May 10, 2005, verbal authorization for the NOI letter mailed on May 16, 2005, the estimated 130,000 gallons of water was transferred to SWIC Pond 1. Over the weekend, May 14 and 15, 2005, the Waste Isolation Pilot Plant (WIPP) site received an additional 0.48 inches of rain resulting in collection of an equal volume of water and continued need to pump from SWIC Pond A to SWIC Pond 1 and or 2.

The removal of this water from Pond A is necessary to facilitate resuming construction in SWIC Pond A. Pond A is estimated to contain less than 130,000 gallons of water. The construction contractor is scheduled to resume earthwork during the week of May 23, 2005, if the pond is adequately dried and no additional rainfall is received.

Due to continued precipitation events and submittal of several NOIs, DOE would like to request that it be allowed to submit a weekly status report of the pumping activities and associated construction progress on Pond A. In this manner, you will be informed of our progress and conditions at hand and have a subsequent reduction in administrative action. If you have no objections to this proposal, we will provide you the first report on the date you request by letter or e-mail as directed by your office.

Thank you for your assistance and if you have any questions or need additional information please contact Mr. H. L. Plum at (505) 234-7462.

Sincerely,

Ines Triay

Subject: Notification of the Freeboard Levels in the Sewage Lagoons and the H-19 Evaporation Pond and Monthly Construction/Dewatering Progress Report for Stormwater Infiltration Control Pond A

Dear Mr. Marshall:

The purpose of this letter is to report the Freeboard Levels remaining in the Waste Isolation Pilot Plant (WIPP) Sewage Lagoons and the H-19 Evaporation Pond.

Your letter dated December 28, 2004, approved the corrective actions proposed by Department of Energy (DOE) for required DOE provide notification to New Mexico Environment Department (NMED) by the last day of each month. As requested, the freeboard levels for May 2005 are listed below.

Location	**Remaining Freeboard on May 16, 2005**
Settling Pond 1A	33 inches
Polishing Pond 1B	30 inches
Settling Pond 2A	30 inches
Settling Pond 2B	32 inches
Evaporation Pond A	27 inches
Evaporation Pond B	26 inches
Evaporation Pond C	26 inches
H-19 Evaporation Pond	30 inches

A minimum of two feet of freeboard has been re-established in all seven ponds in the sewage lagoon system and the H-19 Evaporation Pond. For this reason, the corrective actions approved in your December 28, 2004, letter have been completed and this will be the last monthly status report on the freeboard levels in these ponds. The WIPP project will return to the normal inspection schedule and discontinue daily inspections of the sewage system ponds and the H-19 Evaporation Pond.

A Notice of Intent dated March 4, 2005, from DOE to you, references your request for WIPP to provide NMED with a monthly report of the status of activities for the construction of Storm Water Infiltration Control Pond A. Correspondence dated May 6,

CBFO:AMO:HLP:LR:05-0279:UFC:5486

May 16 and May 19, 2005, documents efforts taken to transfer water from Pond A to Ponds 1 and/or 2 to facilitate drying Pond A so that construction may be continued. All water has been removed from Pond A; however, the dirt is not dry enough to permit the use of heavy equipment at this time. We are currently attempting to schedule the liner and construction contractor to complete the earthwork and liner installation in Pond A in early June 2005.

If you have any questions or require additional information, please contact me at (505) 234-7462.

Sincerely,

Ines Triay

Subject: Sewage Lagoon Liner Integrity Inspection Plan

Dear Mr. Marshall:

The purpose of this letter is notify you that we anticipate having a subcontractor on site during the week of June 6, 2005, to conduct leak testing on the synthetic liners in each of the seven ponds that constitute the Waste Isolation Pilot Plant (WIPP) sewage treatment system.

During your last inspection of the WIPP Site on August 11, 2004, you requested that WIPP develop and submit to you an inspection plan for the liners of the sewage lagoon system. On March 10, 2005, we provided you with a letter notifying the Ground Water Quality Bureau of our intent to establish a contract with a company that provides professional services for locating leaks in geomembrane-lined facilities using electrical leak detection methods and laboratory testing to evaluate the condition of the liners.

You and other representatives of the New Mexico Environment Department are welcome, as always, to observe the testing procedures during the week of June 6, 2005. To coordinate the specific dates and times that the testing will be conducted or if you have any questions or need any additional information relative to this inspection plan, please contact me at (505) 234-7462.

Sincerely,

H. L. Plum

RE: Response to Notices of Intent and Continuance to Transfer Storm Water from SWIC Pond A to SWIC Ponds 1, 2, DP-831, Waste Isolation Pilot Plant

Dear Dr. Triay:

The Ground Water Quality Bureau of the New Mexico Environment Department (NMED) has received three Notices of Intent (NOI), submitted by the U.S. Department of Energy Waste Isolation Pilot Plant (WIPP) dated April 29, May 13, and May 19, 2005. The NOIs request the transfer of storm water from the unlined Storm Water Infiltration Control (SWIC) Pond A to the lined SWIC Ponds 1 and 2. Excessive precipitation in the area has caused further delay in lining SWIC Pond A and transfer of storm water to SWIC Ponds 1and 2 is necessary to complete construction.

Due to repeated storm events triggering several NOI requests, WIPP has also submitted a request, dated May 19, 2005, to continue to transfer storm water from SWIC Pond A to SWIC Ponds 1 and 2 as needed to facilitate construction activities. WIPP proposes to submit weekly status reports on storm water transfer activities and construction progress on Pond A.

Based on the presently available information in your letters, a discharge permit is not being required for the discharges described above. A discharge permit is not being required because the storm water discharges are to synthetically lined impoundments designed to contain storm water and therefore no releases to the ground are expected. NMED approves your request to continue the transfer of storm water on an as-needed basis until the construction of SWIC Pond A is complete. WIPP shall submit weekly reports on the volume of storm water transferred to Ponds 1 and 2, the remaining capacity in

Ponds 1and 2, and the progress of construction activities on SWIC Pond A.

If at some time in the future WIPP intends to change the amount, the character, or location of the discharges so that they will not be as described, or if observation or monitoring shows that the discharges are threatening ground water quality, you must file a new NOI with the NMED.

If you have any questions, please call Clint Marshall of the Mining Environmental Compliance Section at 505-827-0027.

Sincerely,

William C. Olson, Chief
Ground Water Quality Bureau

Subject: Notice of Intent to Discharge

Dear Mr. Marshall:

The purpose of this letter is to document your verbal authorization on May 10, 2005, to discharge approximately 130,000 gallons of water from Storm Water Infiltration Control (SWIC) Pond A to Storm Water Infiltration Control Ponds 1 and/or 2.

As the result of a storm event on May 6, 2005, additional water has accumulated in SWIC Pond A. In order to facilitate resuming earth work and the installation of the synthetic liner in SWIC Pond A as required by the Discharge Permit Modification issued on December 22, 2003, the DOE requests authorization to discharge the water from SWIC Pond A to SWIC Pond 1 and/or 2.

It is estimated that there is approximately 130,000 gallons in SWIC Pond A. The SWIC Ponds 1 and 2 are lined with a 60-mil high-density polyethylene liner so the discharge will not infiltrate to the subsurface or impact groundwater. The transfer of this water will present no threat to human health or the environment.

The DOE is providing the information below to the NMED as required pursuant to 20.6.2.1201 NMAC.

(1) Name of the person making the discharge;
Dr. Inés Triay, Acting Manager

(2) The address of the person making the discharge;
U.S. Department of Energy
Carlsbad Field Office
P.O. Box 3090
4021 National Parks Highway
Carlsbad, NM 88221
(505) 234-7303

CBFO:AMO:HLP:GS:05-0271:UFC 5487.00

MAY 19 2005

(3) The location of the discharge:

Name	County	Township	Range	Section	Latitude	Longitude
Pond 1	Eddy	22S	31E	SW ¼ of the SE 1/4 of the SE 1/4 of Section 20	N32°, 22 Minutes, 13.6 Seconds	W103°, 47 Minutes, 39.4 Seconds
Pond 2	Eddy	22S	31E	SE ¼ of the SE 1/4 of the SE 1/4 of section 20	N32°, 22 Minutes, 13.7 Seconds	W103°, 47 Minutes, 34.3 Seconds
