STATE OF NEW MEXICO
REVISED PROPOSED REGIONAL HAZE STATE IMPLEMENTATION PLAN REVISION
SECOND PLANNING PERIOD (2019-2028)

Prepared by staff of the
New Mexico Environment Department
Air Quality Bureau

September 11, 2024

(Revisions dated February 24, 2025)

TABLE OF CONTENTS

TABLE OF CONTENTS ..... **ii**
List of Figures ..... **iv**
List of Tables ..... **vii**
List of Appendices ..... **ix**
List of Abbreviations ..... **x**
Executive Summary ..... **xii**
Chapter 1: Introduction **1**
1.1 Definitions of Visibility-Related Concepts 1
1.2 A Brief History of the Regional Haze Rule 6
1.3 Overview of Regulatory Provisions in the Regional Haze Rule 8
1.4 Overview of How this SIPr Document is Organized 9
1.5 Technical Assistance from the Western Regional Air Partnership 10
1.6 Supplementary Data from non-WRAP Sources 12
1.7 Joint Regional Haze Planning by NMED and EHD 12
1.8 Role of NMED 12
1.9 Role of the New Mexico Environmental Improvement Board 12
1.10 Role of the U.S. EPA 13
Chapter 2: New Mexico Class I Areas and IMPROVE Monitor Sites **15**
2.1 IMPROVE Monitoring Network 15
2.2 New Mexico Class I Areas and IMPROVE Monitor Sites 17
Chapter 3: Ambient Monitor Data Analysis **38**
3.1 Regulatory Requirements 38
3.2 Trends in Visibility Conditions 39
3.3 New Mexico IMPROVE Network Light Extinction Trends Analysis 43
3.4 Monitoring Data Summary 53
3.5 Tracking Visibility Progress Regulatory Requirements 53
3.6 Uniform Rate of Progress for New Mexico Class I Areas 54
Chapter 4: Determination of Affected Class I Areas in Other States **63**
4.1 Regulatory Requirements 63
4.2 New Mexico Approach 63
4.3 Additional Evidence 63
4.4 Communications with Neighboring States 65
Chapter 5: Embedded Progress Report **66**
5.1 Regulatory Requirements 66
5.2 Background on Section 309 of the Regional Haze Rule 67
5.3 Implementation Status of All Control Measures in First Period SIP 69
5.4 Summary of Emission Reductions Achieved by Control Measure Implementation 77
5.5 Assessment of Visibility Conditions 80
5.6 Analysis Tracking the Change in Emissions Contributing to Visibility Impairment from all Sources and Activities within the State over Time 81
5.7 Assessment of Significant Changes in Anthropogenic Emissions from Within or Outside the State 89
Chapter 6: Selection of Sources for Control Measures Analysis **91**
6.1 Regulatory Requirements 91
6.2 Tier One Q/d Assessment for Selecting New Mexico Facilities for Control Measures Analysis 91
6.3 Tier One Q/d Assessment Results – Selected Sources 93
6.4 Tier Two PTE Screen for Selecting Individual Source Equipment Requiring a Four-Factor Analysis 100

Chapter 7: Four-Factor Analyses and Reasonable Progress Control Measures Determinations 102
7.1 Regulatory Requirements....102
7.2 Controls Evaluated....102
7.3 Cost of Compliance....103
7.4 Selection of Controls....105
7.5 Four-Factor Analyses and Reasonable Progress Control Measures Determinations....107
7.6 Estimated Emissions Reductions....135
Chapter 8: Long-term Strategy for Second Planning Period....137
8.1 Regulatory Requirements....137
8.2 Measures Necessary to Make Reasonable Progress....137
8.3 Consideration of Additional Factors for Long-term Strategy....145
Chapter 9: Regional Scale Modeling to Set Reasonable Progress Goals for 2028....153
9.1 Regulatory Requirements....153
9.2 Modeled Future Year Most Impaired Days for New Mexico Class I Areas....153
9.3 Modeled Future Year Clearest Days for New Mexico Class I Areas....162
Chapter 10: Glidepath Checks for New Mexico Class I Areas and Robust Demonstration....170
10.1 Regulatory Requirements....170
10.2 Uniform Rate of Progress Glidepath Check for Most Impaired Days at each Class I Area in New Mexico....170
10.3 Robust Demonstration for Salt Creek Wilderness Area....170
10.4 No Degradation Check for New Mexico Class I Areas....177
Chapter 11: Coordination and Discussions with Other Parties....178
11.1 Coordination with Local Jurisdictions and Other States....179
11.2 Consultation, Notification and Information Sharing between New Mexico and Federal Land Managers....180
11.3 Discussions with Environmental Protection Agency....181
11.4 Coordination with Tribes, Nations, and Pueblos....181
11.5 Industry Specific Engagement on Sources Selected for Four-Factor Analysis....182
11.6 General Outreach, Education, and Stakeholder Engagement....182
11.7 Overarching Responses to Comments Received.....183
Chapter 12: Monitoring Strategy and Other Elements....185
12.1 Regulatory Requirements....185
12.2 Assessment of Current Monitoring Strategy....185
12.3 Statewide Inventory of Emissions....188

WRAP TSS	Western Regional Air Partnership Technical Support System (Version 2)

Executive Summary

In the 1977 Clean Air Act amendments, Congress declared as a national goal "the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from man-made air pollution." The amendments also required the EPA to issue regulations to assure "reasonable progress" toward meeting this national goal. The Regional Haze Rule, promulgated in 1999 and amended in 2017, calls for state and federal agencies to work together to improve visibility in the 156 national parks and wilderness areas designated as federal Class I Areas. New Mexico is home to nine Class I Areas: Bandelier Wilderness Area, Bosque del Apache Wilderness Area, Carlsbad Caverns National Park, Gila Wilderness Area, Pecos Wilderness Area, Salt Creek Wilderness Area, San Pedro Parks Wilderness Area, Wheeler Peak Wilderness Area, and White Mountain Wilderness Area.

Regional haze is visibility impairment from pollutants that absorb and scatter light, reducing overall visibility. These pollutants are emitted by many anthropogenic sources located across a broad geographic area. Under the Regional Haze Rule, states must develop periodic state implementation plan (SIP) revisions that include long-term strategies addressing regional haze visibility impairment for Class I Areas within their borders and Class I Areas in other states that may be affected by emissions from sources within their borders. In establishing their long-term strategies, states must evaluate and determine the emission reduction measures necessary to make reasonable progress toward the goal of no "impairment . . . from man-made air pollution" in Class I Areas by 2064. The rule also requires states to establish goals for each affected Class I Area that provide for improved visibility on the most impaired days and ensure no degradation in visibility on the clearest days.

This document, consisting of 12 chapters, represents the latest comprehensive revision to the State of New Mexico's Regional Haze SIP and covers the second planning period (2019 to 2028). It describes visibility conditions in New Mexico's Class I Areas; the methodology used by NMED to select sources for an analysis of emission control measures; the control measures NMED determined are necessary to make reasonable progress and corresponding emissions limitations and compliance schedules; NMED's "robust demonstration" for Salt Creek Wilderness Area, which is the sole Class I Area in New Mexico currently not on track to achieve natural visibility conditions by 2064; and coordination and consultation with Federal Land Managers, EPA, states, Tribes, and other interested parties. It also includes a periodic progress report describing the status of implementation of the control measures in New Mexico's Regional Haze SIP for the first planning period as required by the Regional Haze Rule. An overview of the structure of this Regional Haze SIP revision and the contents of the individual chapters is provided below.

Chapter 1 provides definitions of important visibility-related terms, a summary of the Regional Haze Rule's history and regulatory requirements, and an overview of the regional haze planning process and the roles of the various entities involved.

Chapter 2 provides a brief introduction to each of New Mexico's nine Class I Areas and to the Interagency Monitoring of Protected Visual Environments (IMPROVE) network monitor sites that provide data on visibility conditions in each area.

Chapter 3 provides detailed IMPROVE monitoring data for New Mexico's Class I Areas. For each Class I Area, changes in visibility conditions on the most impaired and clearest days over time are assessed, as are the contributions to visibility interference of each of the major haze-forming aerosol species.

NMED's analysis of monitoring trends shows that ammonium nitrate (NH_4NO_3) and ammonium sulfate ($(NH_4)_2SO_4$) are important contributors to visibility impairment at all Class I Areas on both the most impaired days and clearest days. It also shows improving visibility at all areas since the baseline period (2000-2004) on both the most impaired days and clearest days. Chapter 3 also provides the Uniform Rate of Progress (URP) for each New Mexico Class I Area. The URP represents the uniform rate of visibility improvement that would need to be maintained during each planning period to attain natural visibility conditions by 2064.

Chapter 4 describes New Mexico's analysis of the potential impact of emissions from sources within New Mexico on visibility in out-of-state Class I Areas. The analysis suggests possible impacts on Class I Areas in Colorado and Texas from sources in the San Juan Basin in the Four Corners region in northwestern New Mexico, and in the Permian Basin in southeastern New Mexico. New Mexico addresses these potential out-of-state impacts in this SIP revision through a robust source selection process and control measures determinations that will provide for significant reductions in nitrogen oxides (NO_X) and sulfur dioxide (SO_2) emissions in these areas, which can be reasonably expected to improve visibility at both in-state and out-of-state Class I Areas.

Chapter 5 contains an embedded progress report describing the status of implementation of the control measures included in New Mexico's Regional Haze SIP for the first planning period during the five years following the required submittal of a mid-period progress report in 2013. All first period measures were fully implemented during this time, resulting in thousands of tons of NO_X and SO_2 emissions reductions. These reductions are responsible, in part, for improving visibility conditions at New Mexico's Class I Areas since the baseline period.

Chapter 6 describes NMED's source selection process for the second planning period. NMED worked closely with the City of Albuquerque Environmental Health Department (EHD) and consulted with Federal Land Managers on the methodology used to select sources for an analysis of emission control measures. Based on recommendations from the Western Regional Air Partnership (WRAP), NMED and EHD collectively used the Q/d method, which involved calculating Q/d scores for all New Mexico Title V facilities (excluding those on Tribal lands) and comparing them to a threshold necessary to capture 80% of the total NO_X and SO_2 emissions from all Title V facilities combined. This resulted in the selection of 24 facilities statewide for analysis, including 23 in NMED's jurisdiction, which encompasses all areas of New Mexico, except Bernalillo County and Tribal lands. NMED then applied a secondary (tier two) screen based on allowable emissions to select 133 individual emissions units at the 23 facilities within its jurisdiction for an analysis of emission control measures for NO_X and/or SO_2, which are precursors to the primary haze-forming aerosol species impacting visibility in New Mexico's Class I Areas.

Chapter 7 describes NMED's analyses of emission control measures for individual emissions units, which took into consideration four statutory factors (costs of compliance, time necessary for compliance, energy and non-air quality environmental impacts of compliance, and the remaining useful life of the source), and its subsequent reasonable progress control measures determinations. Cost effectiveness was the predominant factor in NMED's decision-making, with controls below $10,000/ton cost generally deemed cost effective and necessary for reasonable progress. Based on this threshold and other decision-making criteria, NMED determined that reasonable progress requires new controls on 50 of the emissions units evaluated. Emissions reductions from these controls, coupled with emission reductions due to recent retirements and previously installed controls, are estimated to result in approximately 17,964 tons/yr of NO_X reductions and 5,348 tons/yr of SO_2 reductions during the second planning period.

Chapter 8 provides New Mexico's long-term strategy for the second planning period, which is the core of this SIP revision. The long-term strategy includes all measures NMED determined are necessary to make reasonable progress. These include new emissions limitations and compliance schedules for the 50 emissions units NMED determined require new controls; the permanent retirement of 34 emissions units at facilities that have shut down or made significant operational changes since the start of the second planning period; new emissions limitations to ensure the continued use of in-place controls on eight (8) emissions units; and the incorporation into the SIP of certain NSR permit conditions to ensure the continued use of in-place controls on the amine treatment systems at four (4) facilities. Chapter 8 also examines the anticipated net effect on visibility due to projected changes in emissions during the second planning period. These changes are projected to result in decreased anthropogenic contributions to aerosol light extinction at all New Mexico Class I Areas at the end of the period.

Chapter 9 and Chapter 10 provide reasonable progress goals and URP glidepath checks for New Mexico's nine Class I Areas. Reasonable progress goals reflect the visibility conditions that are projected to be achieved by the end of the second planning period as a result of the long-term strategy and must provide for improvement in visibility on the most impaired days and no degradation in visibility on the clearest days. URP glidepath checks involve comparing reasonable progress goals to the URP glidepath to ensure they provide for a rate of visibility improvement that equals or exceeds the URP. NMED's glidepath checks show that eight of New Mexico's nine Class I Areas are projected to fall below the URP glidepath in 2028, which is indicative of a faster rate of improvement than the URP. Only Salt Creek Wilderness Area in Chaves County is projected to be above the glidepath, indicating a slower rate of improvement than the URP. As such, Chapter 10 also includes a "robust demonstration" for Salt Creek Wilderness Area showing that that all reasonable measures to improve visibility have been included in the long-term strategy, as required by the Regional Haze Rule.

Chapter 11 gives an overview of how NMED has made efforts to keep open paths of communication and coordination with outside entities throughout the process and development of this SIP Revision and to fulfill specific regulatory requirements on consultations with states and FLMs. Monthly meetings with WRAP and EPA, along with weekly check-ins with EHD, helped answer any questions that arose during the source selection and SIPr development processes. NMED's dedicated Regional Haze website at https://www.env.nm.gov/air-quality/reg-haze/ has allowed NMED to engage with members of the public and stakeholders throughout the planning process, along with providing a platform to post relevant updates and background information on the Regional Haze Rule.

Finally, Chapter 12 covers additional requirements pertaining to Regional Haze SIPs, including an assessment of NMED's current monitoring strategy for measuring, characterizing and reporting visibility impairment in New Mexico's Class I Areas, and various emission inventory-related provisions.

In addition to the main SIP narrative provided in Chapters 1-12, this SIP revision includes a number of appendices providing reference materials, technical support, and other documentation. These include WRAP's emission inventory and modeling references (Appendices A and B), NMED's four-factor analyses and control measures determinations technical support document (Appendix C), four-factor analyses supporting documentation (Appendix D), coordination and outreach supporting documentation (Appendix E), federal land manager formal consultation supporting documentation (Appendix F), and proposed rule 20.2.68 NMAC – Regional Haze Requirements (Appendix G).

Chapter 1: Introduction

The New Mexico Environment Department (NMED) Air Quality Bureau (AQB) prepared this Regional Haze State Implementation Plan Revision (SIPr) element in accordance with U.S. Environmental Protection Agency (EPA) regulations for consideration by the New Mexico Environmental Improvement Board (EIB). The plan element describes how New Mexico meets the requirements of the federal regulation known as the Regional Haze Rule, which appears in Title 40 of the Code of Federal Regulations, Part 51, Subpart P, Sections 308 and 309 (40 CFR §§ 51.308 and 309). The purpose of the Regional Haze Rule is to reduce visibility impairment in 156 national parks and wilderness areas across the country due to haze caused by emissions of manmade air pollutants known to result in such impairment. Further details about the Regional Haze Rule appear in this chapter and throughout this Regional Haze SIPr element for New Mexico.

NMED refers to this document as a plan "element" for the state because it functions in tandem with a similar plan element, to be proposed separately by the City of Albuquerque Environmental Health Department (EHD) for consideration by the Albuquerque - Bernalillo County Air Quality Control Board (AQCB) for application to the City of Albuquerque and Bernalillo County, which are a separate air quality jurisdiction from the rest of New Mexico. The two plan elements together will function as a single plan for the entire state of New Mexico, excluding Tribal lands. As discussed below, EPA has requested this cooperative approach because the Regional Haze Rule applies to entire states, not to political subdivisions of states.

This introductory chapter provides an overview of the Regional Haze Rule and its requirements, how this SIPr satisfies those requirements, and the organizations involved in preparing and approving this SIPr at the local, state, regional, and federal level. For simplicity, this New Mexico Regional Haze State Implementation Plan Revision element for the second planning period (2019-2028) for the entire state, excluding the City of Albuquerque/Bernalillo County and Tribal lands, will be referred to as the “Regional Haze SIPr Rd 2 (2019-2028)” throughout the remainder of this document.

1.1 Definitions of Visibility-Related Concepts

Implementation of the Regional Haze Rule depends on sound technical methods to characterize visibility in protected areas, which are known as mandatory Federal Class I areas (Class I Area). A list of selected definitions from 40 CFR § 51.301,[1] which apply to 40 CFR § 51.308 that covers EPA’s Regional Haze Rule requirements, is provided in Section 1.1.1: 40 CFR § 51.301 Definitions. These definitions will help to serve as a reference for some of the technical terms that will be used throughout this Regional Haze SIPr Rd 2 (2019-2028). Other relevant definitions and explanations of visibility-related terms are provided in Section 1.1.2: Other definitions.

1.1.1 40 CFR § 51.301 definitions

- **Baseline visibility condition** means the average of the five annual averages of the individual values of daily visibility for the period 2000–2004 unique to each Class I Area for either the most impaired days or the clearest days.

[1] https://www.ecfr.gov/current/title-40/chapter-I/subchapter-C/part-51/subpart-P/section-51.301.

- **Best Available Retrofit Technology (BART)** means an emission limitation based on the degree of reduction achievable through the application of the best system of continuous emission reduction for each pollutant which is emitted by an existing stationary facility. The emission limitation must be established, on a case-by-case basis, taking into consideration the technology available, the costs of compliance, the energy and non-air quality environmental impacts of compliance, any pollution control equipment in use or in existence at the source, the remaining useful life of the source, and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.

- **Clearest days** means the twenty percent of monitored days in a calendar year with the lowest values of the deciview index.

- **Current visibility condition** means the average of the five annual averages of individual values of daily visibility for the most recent period for which data are available unique to each Class I Area for either the most impaired days or the clearest days.

- **Deciview (dv)** is the unit of measurement on the deciview index scale for quantifying in a standard manner human perceptions of visibility.

- **Deciview index** means a value for a day that is derived from calculated or measured light extinction, such that uniform increments of the index correspond to uniform incremental changes in perception across the entire range of conditions, from pristine to very obscured. The deciview index is calculated based on the following equation (for the purposes of calculating deciview using IMPROVE data, the atmospheric light extinction coefficient must be calculated from aerosol measurements and an estimate of Rayleigh scattering):

$$10 \ln (b_{ext}/10\ Mm{-}1)$$

  where, b_{ext} = atmospheric light extinction coefficient, expressed in inverse megameters (Mm−1).

- **Federal Land Manager (FLM)** means the Secretary of the department with authority over the Federal Class I Area (or the Secretary's designee) or, with respect to Roosevelt-Campobello International Park, the Chairman of the Roosevelt-Campobello International Park Commission.

- **Federally enforceable** means all limitations and conditions which are enforceable by the Administrator under the Clean Air Act including those requirements developed pursuant to parts 60 and 61 of [Title 40], requirements within any applicable State Implementation Plan, and any permit requirements established pursuant to § 52.21 of [Chapter I] or under regulations approved pursuant to part 51, 52, or 60 of [Title 40].

- **Fixed capital cost** means the capital needed to provide all of the depreciable components.

- **Fugitive emissions** means those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening.

- **Implementation plan** means, for the purposes of [Part 51], any State Implementation Plan, Federal Implementation Plan, or Tribal Implementation Plan.

- **Native American tribe or tribe** means any Native American tribe, band, nation, or other organized group or community, including any Alaska Native village, which is federally recognized as eligible for the special programs and services provided by the United States to Native Americans because of their status as Native Americans.

- **In existence** means that the owner or operator has obtained all necessary preconstruction approvals or permits required by Federal, State, or local air pollution emissions and air quality laws or regulations and either has (1) begun, or caused to begin, a continuous program of physical on-site construction of the facility or (2) entered into binding agreements or contractual obligations, which cannot be cancelled or modified without substantial loss to the owner or operator, to undertake a program of construction of the facility to be completed in a reasonable time.

- **Installation** means an identifiable piece of process equipment.

- **Integral vista** means a view perceived from within the mandatory Class I Federal area of a specific landmark or panorama located outside the boundary of the mandatory Class I Federal area.

- **Least impaired days** means the twenty percent of monitored days in a calendar year with the lowest amounts of visibility impairment.

- **Major stationary source** and major modification mean major stationary source and major modification, respectively, as defined in [40 CFR § 51.166].

- **Mandatory Class I Federal Area or Mandatory Federal Class I Area** means any area identified in part 81, subpart D of [Title 40].

- **Most impaired days** means the twenty percent of monitored days in a calendar year with the highest amounts of anthropogenic visibility impairment.

- **Natural conditions** reflect naturally occurring phenomena that reduce visibility as measured in terms of light extinction, visual range, contrast, or coloration, and may refer to the conditions on a single day or a set of days. These phenomena include, but are not limited to, humidity, fire events, dust storms, volcanic activity, and biogenic emissions from soils and trees. These phenomena may be near or far from a Class I Area and may be outside the United States.

- **Natural visibility** means visibility (contrast, coloration, and texture) on a day or days that would have existed under natural conditions. Natural visibility varies with time and location, is estimated or inferred rather than directly measured, and may have long-term trends due to long-term trends in natural conditions.

- **Natural visibility condition** means the average of individual values of daily natural visibility unique to each Class I Area for either the most impaired days or the clearest days.

- **Potential to emit** means the maximum capacity of a stationary source to emit a pollutant under its physical and operational design. Any physical or operational limitation on the capacity of the source to emit a pollutant including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its

design if the limitation or the effect it would have on emissions is federally enforceable. Secondary emissions do not count in determining the potential to emit of a stationary source.

- **Prescribed fire** means any fire intentionally ignited by management actions in accordance with applicable laws, policies, and regulations to meet specific land or resource management objectives.

- **Regional haze** means visibility impairment that is caused by the emission of air pollutants from numerous anthropogenic sources located over a wide geographic area. Such sources include, but are not limited to, major and minor stationary sources, mobile sources, and area sources.

- **Secondary emissions** means emissions which occur as a result of the construction or operation of an existing stationary facility but do not come from the existing stationary facility. Secondary emissions may include, but are not limited to, emissions from ships or trains coming to or from the existing stationary facility.

- **Stationary Source** means any building, structure, facility, or installation which emits or may emit any air pollutant.

- **Visibility** means the degree of perceived clarity when viewing objects at a distance. Visibility includes perceived changes in contrast, coloration, and texture elements in a scene.

- **Visibility impairment or anthropogenic visibility impairment** means any humanly perceptible difference due to air pollution from anthropogenic sources between actual visibility and natural visibility on one or more days. Because natural visibility can only be estimated or inferred, visibility impairment also is estimated or inferred rather than directly measured.

- **Visibility in any mandatory Class I Federal area** includes any integral vista associated with that area.

1.1.2 Other definitions

These additional definitions are from the Western Regional Air Partnership Technical Support System glossary,[2] unless otherwise noted.

- **Aerosol** means suspensions of tiny liquid and/or solid particles in the air.

- **Anthropogenic** means produced by human activities.

- **Class I Area** as defined by the Clean Air Act, include national parks greater than 6,000 acres, wilderness areas and national memorial parks greater than 5,000 acres, and international parks that existed as of August 1977.[3]

- **Extinction Budget** means apportioning the extinction coefficient to atmospheric constituents to analysis estimate the change in visibility caused by a change in constituent concentrations.

[2] https://views.cira.colostate.edu/tssv2/Pub/Glossary.aspx.

[3] Equivalent to Section 1.1.1 - Mandatory Class I Federal Area or Mandatory Federal Class I Area

- **Extinction coefficient** means a measure of the ability of particles or gases to absorb and scatter photons from a beam of light; a number that is proportional to the number of photons removed from the sight path per unit length.

- **Haze** means an atmospheric aerosol of sufficient concentration to be visible. The particles are so small that they cannot be seen individually, but are still effective in scene distortion and visual range restriction.

- **Light Extinction** means the attenuation of light due to scattering and absorption as it passes through a medium.

- **Particulate matter** means particles found in the air, including dust, dirt, soot, smoke, and liquid droplets. Some particles are large or dark enough to be seen as soot or smoke. Others are so small that individually they can only be detected with an electron microscope.[4]

- **$PM_{2.5}$** means particulate matter smaller than 2.5 microns in diameter.[5]

- **PM_{10}** means particulate matter less than 10 microns in diameter.[6]

- **Rayleigh Scattering** means the scattering of light by particles much smaller than the wavelength of the light, e.g., molecular scattering in the natural atmosphere.[7]

- **Secondary aerosols** means aerosols formed by the interaction of two or more gas molecules and/or primary aerosols.

- **URP framework** means the interrelated Regional Haze Rule requirements regarding the quantification of historical and projected visibility conditions using specific metrics, the quantification of natural conditions, the quantification of the uniform rate of progress (URP) that would achieve natural visibility conditions for the 20 percent most anthropogenically impaired days in 2064, the URP glidepath, the setting of reasonable progress goals (RPG) for the end of the implementation period, and the comparison of the RPG for the 20 percent most anthropogenically impaired days to the URP glidepath.[8]

- **URP glidepath** means the hypothetical straight-line path on the deciview scale between the baseline period visibility condition in 2000-2004 (associated with December 31, 2004) and the sum of the natural visibility condition and optional adjustments for international anthropogenic impacts and impacts from certain wildland prescribed fires (associated with December 31, 2064), for the 20 percent most anthropogenically impaired days for a particular Class I Area.[9]

- **Visual Range** means the distance at which a large black object just disappears from view.

- **Western Regional Air Partnership (WRAP)** is one of five Regional Planning Organizations. It includes the states and Tribal areas encompassed by Arizona, California, Colorado, Idaho, Montana, New Mexico, North Dakota, Oregon, South Dakota, Utah, Washington, and Wyoming and is affiliated with the Western States Air Resources Council.

1.2 A Brief History of the Regional Haze Rule

In 1977, Congress adopted amendments to the federal Clean Air Act (CAA or Act) protecting visibility in Class I Areas.[10] This early provision of the CAA focused on emissions from major sources of human-caused (i.e. anthropogenic) air pollutants that "may reasonably be anticipated to cause or contribute" to visibility impairment at Class I Areas located close to the contributing major sources. Over time, EPA and other stakeholders realized that further action was necessary to address more numerous, widely scattered sources that may not be located close to a Class I Area. In light of this need, Congress amended the visibility protection provisions of the CAA in 1990.[11] In accordance with these CAA provisions, as amended, EPA adopted the Regional Haze Rule in 1999.[12] The rule addressed the more numerous, widely scattered sources responsible for Class I Area visibility issues. It required states to take gradual steps over time to improve visibility at Class I Areas, returning visibility to "natural conditions," free of anthropogenic interference, by the year 2064. To that end, the rule required states to submit Regional Haze State Implementation Plans (SIPs) beginning in 2003 and at ten-year intervals thereafter, corresponding with ten-year planning periods. However, litigation substantially delayed the SIP submittal process and required EPA to amend the Regional Haze Rule.[13] The initial Regional Haze SIPs were ultimately due to EPA by December 17, 2007.[14]

On December 1, 2003 (received by EPA December 22, 2003) and June 24, 2011 (received by EPA July 5, 2011), the State of New Mexico submitted Regional Haze SIPs to meet the requirements of 40 CFR § 51.309 (the Section 309 SIP) and 51.309(g) (the Section 309(g) SIP), respectively. The Section 309 SIP addressed the first phase of Regional Haze Rule requirements, with an emphasis on stationary source sulfur dioxide (SO_2) emission reductions and a focus on improving visibility in the 16 Class I Areas on the Colorado Plateau (including San Pedro Parks Wilderness Area in New Mexico). Under 40 CFR § 51.309(g)(2)(i), states that prepare Section 309 SIPs can take credit for improved visibility in Class I Areas not on the Colorado Plateau. The Section 309(g) SIP extended the scope of the Section 309 SIP to all Class I Areas within the state, addressing the visibility requirements and improvements in New Mexico's remaining eight Class I Areas, including Bandelier Wilderness Area, Bosque del Apache Wilderness Area, Carlsbad Caverns National Park, Gila Wilderness Area, Pecos Wilderness Area, Salt Creek Wilderness Area, Wheeler Peak Wilderness Area, and White Mountain Wilderness Area.

On November 27, 2012, EPA published final approval of New Mexico's 2003 and 2011 SIP submittals with the exception of the Best Available Retrofit Technology (BART) determination for nitrogen oxides (NO_X) for San Juan Generating Station (SJGS).[15] EPA had previously issued a federal implementation plan

[10] 42 U.S.C. § 7491.
[11] 42 U.S.C. § 7492.
[12] 64 Fed. Reg. 35714 (July 1, 1999) (Regional Haze Regulations).
[13] 71 Fed. Reg. 60612 (October 13, 2006) (Regional Haze Regulations; Revisions to Provisions Governing Alternative to Source-Specific Best Available Retrofit Technology (BART) Determinations).
[14] 40 CFR § 51.308(b).
[15] 77 Fed. Reg. 70693 (November 27, 2012) (Approval and Promulgation of State Implementation Plans; State of New Mexico; Regional Haze Rule Requirements for Mandatory Class I Areas).

(FIP) containing a different NO_X BART determination for SJGS.[16] New Mexico challenged EPA's NO_X BART FIP for SJGS, and the case was filed in the U.S. Court of Appeals for the Tenth Circuit.[17] To resolve litigation arising from New Mexico's and EPA's incompatible SJGS NO_X BART determinations, New Mexico, EPA, and the Public Service Company of New Mexico (PNM, operator of the SJGS) reached a tentative agreement (contained in a Term Sheet) on February 15, 2013, on an alternative plan to address pollution control requirements for SJGS under the CAA's requirements for regional haze and interstate transport for visibility. The agreement called for a new BART determination based on the retirement of Units 2 and 3 at the facility by December 31, 2017; the installation of Selective Non-Catalytic Reduction technology on the remaining Units 1 and 4, with a NO_X emission rate of no greater than 0.23 lbs/MMBtu; and further reductions in SO_2 emissions. On September 5, 2013, the EIB unanimously approved a SIP revision incorporating the terms of the tentative agreement as a revised BART determination. The revised SIP was submitted to EPA on October 8, 2013, and on December 17, 2013, EPA determined that the revised SIP submission was administratively complete.

On October 9, 2014, EPA approved a revision to the New Mexico Regional Haze SIP that addressed BART for SJGS, making the emission limitations federally enforceable, satisfying CAA 110(a)(2)(D)(i)(II) with respect to interstate transport of air pollution and visibility protection for the 8-hour ozone National Ambient Air Quality Standard (NAAQS) and the $PM_{2.5}$ NAAQS.[18] EPA simultaneously withdrew its FIP for New Mexico that applied to SJGS.[19] Therefore, the requirement for New Mexico under Section 110(a)(2)(D)(i)(II) is satisfied by the SIP revisions approved on November 27, 2012.

Originally, Regional Haze SIPs for the second planning period (2019 to 2028) were to be submitted to EPA in 2018. However, on January 10, 2017, EPA revised the Regional Haze Rule so that the SIPs for the second planning period would instead be due July 31, 2021.[20] However, the years for the second planning period remain 2019 to 2028 despite the revised SIP submittal deadline.

Future Regional Haze SIP submittals are due by July 31, 2028, and at ten-year intervals thereafter, unless EPA revises the Regional Haze Rule again.[21]

[16] 76 Fed. Reg. 52388 (August 22, 2011) (Approval and Promulgation of Implementation Plans; New Mexico; Federal Implementation Plan for Interstate Transport of Pollution Affecting Visibility and Best Available Retrofit Technology Determination).

[17] NMED filed a "Petition for Reconsideration and Stay of Final Rule" on or about October 21, 2011. The Navajo Nation joined in the PNM and NMED petitions for reconsideration and for administrative stay. The petitions for reconsideration and administrative requests for stay of the Final Rule are still pending." (Page 22 / Page 28 Bate Stamp, Appellate Case: 11-9552, 1/13/12). On April 27, 2012, New Mexico's Governor Susana Martinez sent a letter to EPA Administrator Lisa Jackson urging EPA to work with PNM and the NMED to find an alternative to the federal and state plans. Both the Governor and PNM asked for a stay of the federal rule to delay the implementation since significant dollars were at stake. On July 16, 2012, EPA issued an administrative 90-day stay. PNM agreed to work with the parties to find an alternative. [21] 40 CFR § 51.308(f). On December 23, 2024, EPA proposed revising the due date for the next required regional haze SIP revision from the current due date of July 31, 2028, to a revised due date of July 31, 2031. 89 Fed. Reg.

1.3 Overview of Regulatory Provisions in the Regional Haze Rule

This Section summarizes the major requirements of the Regional Haze Rule.[22] More detailed discussion of specific requirements will be presented in individual chapters of this Regional Haze SIPr Rd 2 (2019-2028), as warranted. The following discussion refers to regional haze requirements for a state. As a practical matter, a separate air quality jurisdiction within a state, such as Albuquerque – Bernalillo County, typically works in conjunction with state agencies to achieve a Regional Haze planning approach that works in an integrated fashion for the entire state.

1.3.1 Clean Air Act distinction between protection of visibility versus protection of health

The Regional Haze Rule, and the Clean Air Act visibility protection provisions upon which it is based, are not health-based air quality standards. They protect visibility in Class I Areas by gradually reducing visibility-impairing anthropogenic air pollutants over time.[23] Such pollutants are also known to have effects on human health, but the federal regulatory scheme addresses health effects by a different mechanism: the National Ambient Air Quality Standards.[24] The NAAQS define the maximum amount of six common air pollutants that can be present in outdoor air without harming public health.[25]

1.3.2 Specific regulatory provisions

The Regional Haze Rule establishes a multi-step process to improve visibility at Class I Areas. The Regional Haze Rule divides the process into ten-year planning periods. During each period, states undertake a series of steps to achieve gradual improvement in visibility, which must be documented in a Regional Haze SIP revision. The current planning period covers the years from 2019 to 2028. However, Regional Haze SIP revisions for this period were not due until July 31, 2021. EPA designed the Regional Haze Rule to achieve the Clean Air Act goal for visibility to be restored to natural conditions for each Class I Area.

The Regional Haze Rule requires a Regional Haze SIP revision that estimates emissions from natural sources (such as sea salt, dust, and wildfire smoke), emissions from anthropogenic sources, and amounts of pollution which are beyond the control of states (such as international emissions and some transportation-related emissions). Before submitting their Regional Haze SIP revisions for a ten-year planning period, states must complete a series of steps, described below. Further details about each step will appear throughout this Regional Haze SIPr Rd 2 (2019-2028).

104471 (December 23, 2024) (Regional Haze Third Implementation Period; Extension of the State Implementation Plan Due Date). At the time of preparation of this Regional Haze SIPr Rd2 (2019-2018), EPA had not taken final action on this proposal.

[22] This subsection is substantially based on an overview of the Regional Haze Rule prepared by the Western Regional Air Partnership. See WRAP, Overview of Regional Haze Planning, Regional Haze Planning Work Group Consensus, May 7, 2019, available at https://westar.org/wp-content/uploads/2022/09/Overview-of-RH-Planning-RHPWG-consensus-May7_2019.pdf.

[23] 42 U.S.C. §§ 7491 and 7492; 40 CFR §§ 51.300 to 51.309.

[24] 42 U.S.C. §§ 7408 and 7409; 40 CFR §§ 50.1 to 50.19.

[25] The six pollutants for which EPA must set National Ambient Air Quality Standards are carbon monoxide, lead, nitrogen dioxide, ozone, particulate matter, and sulfur dioxide.

1) States review the data from the Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring network, [26] which measures the visibility-impairing pollutant concentrations at Class I Areas throughout the U.S.
2) States calculate the amount of air pollutants known to contribute to poor visibility that is emitted within their boundaries from a variety of different sources.
3) States analyze this data on visibility and pollutants to identify pollution sources likely contributing to visibility problems at particular areas, both inside their own borders and in other states.
4) Each state identifies "reasonable" pollution control methods that will reduce emissions from human-caused sources and thus improve visibility at Class I Areas.
5) Technical experts at Regional Planning Organizations (RPO), which assist states in preparing Regional Haze SIPs, use computer modeling or other technical approaches to understand how pollution control measures at particular anthropogenic pollutant sources can reasonably be expected to improve visibility at each Class I Area over a ten-year Regional Haze planning period.
6) Throughout Regional Haze SIP development, states consult informally with the Federal Land Managers (FLMs) of the Class I Areas within their jurisdiction to communicate the intended benefits of proposed regulatory actions, and then ask the FLMs for a formal review of the plan before a formal public hearing on the plan is held. The Regional Haze Rule requires states to consult with other states that have emissions reasonably anticipated to contribute to visibility impairment in the same Class I Area or areas. EPA and RPOs also encourage states to consult informally with Tribes, local authorities, and any stakeholder that may desire to comment on a state's proposed approach to protecting visibility at Class I Areas.
7) EPA encourages states to consult with their respective EPA regional offices throughout the SIP planning process. This may help identify and resolve potential technical, policy, and legal issues before plan finalization and adoption by the state. This also improves the likelihood that the state will submit an approvable SIP revision. EPA recommends submission of a draft plan for review and feedback in advance of formal plan submission to EPA.
8) After public review, states hold public hearings of their air quality boards or commissions to adopt plans to implement the identified pollution control methods, make them legally binding, and thus strive to achieve visibility improvement at each Class I Area over the course of the planning period.
9) A Regional Haze SIP revision must include a progress report on past visibility trends and the implementation status of previously adopted pollution control measures to improve Class I Area visibility.

A Regional Haze SIP revision does not go into effect until EPA completes its review and approves the SIP following the state adoption process.

1.4 Overview of How this SIPr Document is Organized

This Regional Haze SIPr Rd 2 (2019-2028) is organized into twelve chapters. Each chapter presents information on a specific aspect of Regional Haze planning. Considered as a whole, the twelve chapters collectively meet Regional Haze Rule requirements for the State of New Mexico. Requirements for

[26] http://vista.cira.colostate.edu/Improve.

Albuquerque – Bernalillo County are addressed in a separate Regional Haze SIPr element, prepared by EHD and proposed to the Albuquerque-Bernalillo County AQCB.

The twelve chapters of this SIPr for the State of New Mexico cover the following topics:

- Chapter 1. Introductory material presenting an overview of the Regional Haze planning process.
- Chapter 2. An overview of the nine Class I Areas located in New Mexico, as well as the IMPROVE monitors providing data about the visibility conditions at these areas and visibility-impairing pollutants present at each area.
- Chapter 3. Detailed IMPROVE monitor data for each New Mexico Class I Area, monitoring trends analyses, and tracking visibility progress.
- Chapter 4. Provides approach of considering potentially affected Class I Areas in other states.
- Chapter 5. Progress report on implementation of the State of New Mexico Regional Haze SIP for the second half of the first Regional Haze planning period (i.e., 2014 – 2018).
- Chapter 6. A description of the process by which NMED cooperated with EHD on a common, statewide screening process to select facilities throughout New Mexico that are major sources of visibility-impairing pollutants, with a potential impact on Class I Area visibility, that would be subject to an analysis identifying potential new pollutant control measures at each facility. This process identified 24 sources total, including one source in Albuquerque – Bernalillo County.
- Chapter 7. A description of the technical analysis of potential new pollutant control measures for the 23 screened facilities outside of Albuquerque – Bernalillo County.
- Chapter 8. A description of the long-term strategy for control of visibility-impairing pollutants in the State of New Mexico during the second planning period. In the Regional Haze Rule, a long-term strategy is a set of legally enforceable control measures upon which an air quality jurisdiction (typically a state) will rely to improve visibility at Class I Areas within its borders and in other states during a Regional Haze planning period.
- Chapter 9. A description of 2028 visibility goals, which the Regional Haze Rule calls reasonable progress goals, for the nine Class I Areas in New Mexico and the relation of those goals to the long-term strategy.
- Chapter 10. Uniform rate of progress glidepath checks for the most impaired and clearest days for the nine Class I Areas in New Mexico, and additional information needed for a robust demonstration for areas that are not on the glidepath to natural visibility conditions by 2064.
- Chapter 11. A description of how NMED conducted outreach to stakeholders during preparation of this Regional Haze SIPr Rd 2 (2019-2028). This chapter also details how NMED met Regional Haze Rule requirements for consultation with FLMs who supervise the Class I Areas in New Mexico.
- Chapter 12 A final chapter addressing certain other aspects of the Regional Haze Rule, including provisions for future monitoring of visibility-impairing pollutants and future progress reports on implementation of this Regional Haze SIPr Rd 2 (2019 – 2028).

1.5 Technical Assistance from the Western Regional Air Partnership

The Western Regional Air Partnership (WRAP) is a voluntary partnership of government agencies from 15 western states involved in air quality regulation and planning. [27] WRAP members include state and

[27] WRAP membership is open to agencies located in the geographical area encompassed by the States of Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, North Dakota, Oregon, South Dakota, Utah, Washington, and Wyoming.

local air quality regulatory agencies, Native American Tribes, EPA, and the federal land management agencies, which are the National Park Service, U.S. Forest Service, U.S. Fish and Wildlife Service, and the Bureau of Land Management. [28] As an RPO, WRAP pools and coordinates the efforts of its member agencies to provide the technical assistance necessary for them to pursue air quality regulatory initiatives, including those related to Regional Haze.

1.5.1 WRAP Role in SIP Preparation

For the current Regional Haze planning period, WRAP has provided substantial resources for use by state, local, and Tribal air quality agencies in preparing Regional Haze SIPs. These resources include quantitative data in the form of air quality monitoring results, emissions inventory estimates, and computer modeling outputs. They also include two types of written documentation: 1) technical support documents describing how the quantitative data was assembled; and 2) written guidance on approaches states may wish to take (but are not required to take) in researching and writing their Regional Haze SIPs.

WRAP is not a regulatory body, but it does play an important role in the Regional Haze process. It has no legal authority to make decisions for its members. Rather, it provides technical resources and advice to those members, based on consensus decisions among them. States may then use the resulting technical resources based on their best judgment about their own circumstances and the applicable regulatory requirements. In meeting those requirements, the Regional Haze Rule allows states to rely on the technical data and advice of WRAP and other RPOs in deciding on control measures for a Regional Haze SIP. [29] This is the key role played by WRAP. It provides data and advice that the individual air agency members would otherwise lack the staff and resources to provide for themselves.

1.5.2 WRAP Technical Support System

For the second Regional Haze planning period, WRAP prepared an online resource and data portal called the Technical Support System (TSS). [30] The TSS provides data that state, local, and Tribal air agencies may use in preparing their Regional Haze SIPs. The TSS includes air monitor data, emissions inventory data, and modeling data. Explanations and documentation of the data and the methods by which it was obtained are provided on the TSS and on the WRAP website. [31] The TSS hosts the visibility monitoring, emissions, and air quality modeling analyses that support the 15 western states in developing Regional Haze SIPs. The Emissions Methods, Results, and References document, and the Modeling Methods, Results, and References document describe the WRAP emissions and modeling analyses and illustrate how the TSS products can be applied and interpreted to support the 2028 visibility progress demonstrations for western U.S. Class I Areas. These reports are included as Appendices A and B to this Regional Haze SIPr Rd 2 (2019 – 2028).

---

[28] The full list of WRAP member agencies is available at https://westar.org/wrap-council-members/.

[29] 40 CFR § 51.308(f)(2)(iii). WRAP is one of five U.S. regional planning organizations that assist states in preparing Regional Haze SIPs. See https://www.epa.gov/visibility/visibility-regional-planning-organizations.

[30] The TSS is available online at https://views.cira.colostate.edu/tssv2/default.aspx. The TSS for the current planning period is the second version (v2) of the TSS.

[31] The WRAP Regional Haze Planning Work Group web page provides thorough documentation of the process by which WRAP collated and generated data for air quality monitoring, emissions, and modeling. See the links and documents available at https://westar.org/regional-haze-planning-work-group/. Important technical documentation of WRAP Regional Haze planning also appears on the organization's Regional Tech Operations Work Group web page, available at https://westar.org/regional-tech-operations-work-group/.

1.6 Supplementary Data from non-WRAP Sources

This Regional Haze SIPr Rd 2 (2019-2028) also relies on data from sources other than WRAP. These will be noted in specific chapters/appendices, as appropriate.

1.7 Joint Regional Haze Planning by NMED and EHD

Because of the scope and design of the Regional Haze Rule, NMED prepared this Regional Haze SIPr Rd 2 (2019-2028) in close cooperation with EHD. Under state and local law, EHD prepares SIPs applicable to the City of Albuquerque and Bernalillo County, proposing these for consideration by the Albuquerque - Bernalillo County AQCB. [32] Separately, NMED prepares SIPs for the rest of the state and proposes these plans for consideration by the EIB. [33]

Subsequent chapters of this SIPr element will describe in detail the statewide Regional Haze analytical framework. This SIPr element should be read in conjunction with the SIPr element prepared by EHD for the City of Albuquerque and Bernalillo County.

1.8 Role of NMED

State law requires NMED to develop SIPs and SIP revisions for proposal to the EIB. [34] In accordance with that requirement, NMED staff developed and wrote this Regional Haze SIPr Rd 2 (2019-2028) and proposed it for consideration by the EIB in the form of a request for a formal, public hearing to consider the plan. [35] If the EIB adopts this Regional Haze SIPr Rd 2 (2019-2028), the Board will authorize NMED to submit the plan to EPA in accordance with EPA regulations.

This Regional Haze SIPr Rd 2 (2019-2028), developed and proposed by NMED, is a narrative document describing how the state will meet federal regulatory requirements in the Regional Haze Rule at 40 CFR §§ 51.308 and 51.309. This SIPr is not in itself an enforceable regulation, but it is legally mandatory for the state to submit it to EPA in order to meet the federal regulatory requirements.

1.9 Role of the New Mexico Environmental Improvement Board

The New Mexico Air Quality Control Act requires the EIB to promulgate air quality regulations [36] and adopt a plan for the "regulation, control, prevention, or abatement of air pollution." [37] The Board may also adopt regulations "to protect visibility in mandatory class I areas." [38] These regulatory provisions provide authority for the Board to consider the Regional Haze SIPr Rd 2 (2019 – 2028) proposed by NMED, including any new or amended legally enforceable regulations necessary to implement the SIP, in order to meet federal Regional Haze Rule requirements.

---

[32] NMSA 1978 §§ 74-2-5 and 74-2-5.1; ROA 1994 §§ 9-5-4 and 9-5-1-5; Bernalillo County Code §§ 30-33 and 30-34.
[33] NMSA 1978 §§ 74-2-5 and 74-2-5.1.
[34] NMSA 1978 § 74-2-5. The language in this section requires NMED to develop an air quality "plan" but, in practice, NMED develops many different plans that collectively satisfy the requirement of the federal Clean Air Act for a single SIP. *See* 42 U.S.C. § 7410.
[35] State law governing the conduct of an air quality rulemaking hearing is at NMSA 1978 § 74-2-6. The regulation governing NMED's request for a rulemaking hearing by the Environmental Improvement Board is 20.1.1 NMAC, *Rulemaking Procedures -- Environmental Improvement Board*.
[36] NMSA 1978 § 74-2-5(B)(1).
[37] NMSA 1978 § 74-2-5(B)(2).
[38] NMSA 1978 § 74-2-5(D)(1).

In considering a proposed SIP or SIPr and any accompanying proposed regulations, the EIB must "give weight it deems appropriate to all facts and circumstances," including facts and circumstances specified in the state Air Quality Control Act, related to the following:

1) "character and degree of injury to or interference with . . . visibility;" [39]
2) "social and economic value of the sources and subjects of air contaminants;" [40] and
3) "technical practicability and economic reasonableness" of emission reduction measures, with consideration of previous experience and available methods. [41]

Under state law, any emission control requirement, such as those contained in this Regional Haze SIPr Rd 2 (2019 – 2028), may be adopted by the EIB only after a duly noticed public hearing. [42] Regulations or emission control requirements adopted based on a rulemaking hearing cannot become effective until 30 days after filing with the State Records Center and Archives in accordance with the State Rules Act. [43] A rulemaking hearing must be held in accordance with procedural requirements in the state Air Quality Control Act [44] and the Board's regulation governing such hearings. [45]

1.10 Role of the U.S. EPA

This Regional Haze SIPr Rd 2 (2019-2028) is subject to several federal regulatory requirements implemented and enforced by EPA.

1) The Regional Haze Rule requires submittal of this SIPr to EPA, [46] with content in the SIPr that addresses specific requirements. [47]
2) The public rulemaking hearing held by the EIB to consider this SIPr must be held only after reasonable notice provided at least 30 days prior to the date of the hearing. [48]
3) The State of New Mexico must submit this SIPr to EPA with appropriate documentation, including documentation of the public hearing in accordance with federal, state, and local law. [49]

After a state submits a SIP to EPA, EPA has six months to certify that a state has made a complete submittal. [50]

Failure to submit an approvable Regional Haze SIPr Rd 2 (2019-2028) to EPA may result in federal action against the State of New Mexico. If a state fails to submit a SIP, EPA has until six months after the

[39] NMSA 1978 § 74-2-5(F)(1).
[40] NMSA 1978 § 74-2-5(F)(2).
[41] NMSA 1978 § 74-2-5(F)(3).
[42] NMSA 1978 § 74-2-6(B) and (C).
[43] NMSA 1978 § 74-2-6(F).
[44] NMSA 1978 § 74-2-6(A), (D), and (E).
[45] 20.1.1 NMAC, Rulemaking Procedures -- Environmental Improvement Board.
[46] 40 CFR § 51.308(f).
[47] 40 CFR §§ 51.308(f)(1) to (f)(6), 51.308(g), and 51.309.
[48] 40 CFR § 51.102(d). Note that the Board's regulation governing rulemaking hearings requires that notice be given at least 60 days prior to the date of the hearing. *See* Subsection A of 20.1.1.301 NMAC.
[49] 40 CFR § 51.103 and 40 CFR Part 51, Appendix V.
[50] 42 U.S.C. § 7410(k)(1)(B).

deadline for submittal to make a finding of failure to submit.[51] EPA must, within two years of such a finding, approve a SIP or issue a Federal Implementation Plan (FIP) that accomplishes the purposes for which the SIP should have been submitted.[52] In the case of the Regional Haze Rule, EPA may issue a FIP that unilaterally imposes Regional Haze control measures on facilities in the State of New Mexico in order to protect visibility at Class I Areas.

[51] 42 U.S.C. § 7410(k)(1)(B). EPA has already issued a finding of failure to submit second period Regional Haze SIPs for 15 states, including New Mexico. 87 Fed. Reg. 52856 (Aug. 30, 2022) (Finding of Failure to Submit Regional Haze State Implementation Plans for the Second Planning Period).

[52] 42 U.S.C. § 7410(c)(1). The current deadline for EPA to approve a Regional Haze SIP or issue a FIP for New Mexico is September 29, 2024.

Chapter 2: New Mexico Class I Areas and IMPROVE Monitor Sites

This chapter provides a brief description of the Interagency Monitoring of Protected Visual Environments ("IMPROVE") monitoring network, followed by an overview of New Mexico's nine Class I Areas and the eight IMPROVE monitor sites that provide visibility-related data for those areas.

2.1 IMPROVE Monitoring Network

The IMPROVE program is a cooperative measurement effort governed by a steering committee from federal, regional, and state organizations. The program was established in 1985 to aid the creation of Federal and State Implementation Plans for the protection of visibility in Class I Areas, as stipulated in the 1977 amendments to the Clean Air Act and expanded upon in the 1990 amendments. As required by the Act, as amended, the U.S. Environmental Protection Agency (EPA) promulgated regulations designating 156 national parks and wilderness areas as Class I Areas. The IMPROVE monitoring network began operating in 1988 with 20 monitor sites in Class I Areas and has subsequently grown to 110 monitor sites sponsored by the Federal Land Managers (FLMs) plus an additional 48 "protocol sites" sponsored by state, regional, Tribal, and national organizations that provide expanded spatial coverage for the network. [53]

The IMPROVE monitoring network consists of individual monitor sites across the United States containing aerosol speciation samplers, which measure the types, i.e., "species," and amounts of visibility-impairing pollutants present in the air in or around Class I Areas. A small number of IMPROVE monitor sites, in addition to measuring the type and amount of pollutants, also perform direct optical measurements of visibility impairment.

The regulatory objectives of the IMPROVE monitoring network are: [54]

- to establish current visibility and aerosol conditions in Class I Areas;
- to identify chemical species responsible for existing man-made visibility impairment, thereby allowing inference of emission sources for those species;
- to document long-term trends for assessing progress towards the Clean Air Act's national visibility goal, which is returning Class I Areas to natural visibility conditions; and,
- beginning with the EPA's enactment of the Regional Haze Rule in 1999, to provide regional haze monitoring representing all visibility-protected Class I Areas, using specific metrics and approaches defined in the Rule.

It is important to note that not every Class I Area has its own monitor. Sometimes, practicality requires that a single monitor provide representative data for more than one Class I Area. As discussed later in this chapter, IMPROVE monitor site WHPE1 provides data for two New Mexico Class I Areas, Pecos Wilderness Area and Wheeler Peak Wilderness Area. All other Class I Areas in New Mexico currently have their own monitors.

[53] *See* http://vista.cira.colostate.edu/Improve/improve-program/. *See also* http://vista.cira.colostate.edu/improve/wp-content/uploads/2022/09/IMPROVE_Sites_Active_Updated_September_2022.xlsx (current site list spreadsheet).
[54] https://vista.cira.colostate.edu/improve/wp-content/uploads/2023/01/IMPROVE-Charter.pdf.

In addition to the above regulatory functions, the IMPROVE program has also been a key participant in visibility-related research, including the advancement of monitoring instrumentation, analysis techniques, visibility modeling, policy formulation, and source attribution field studies.

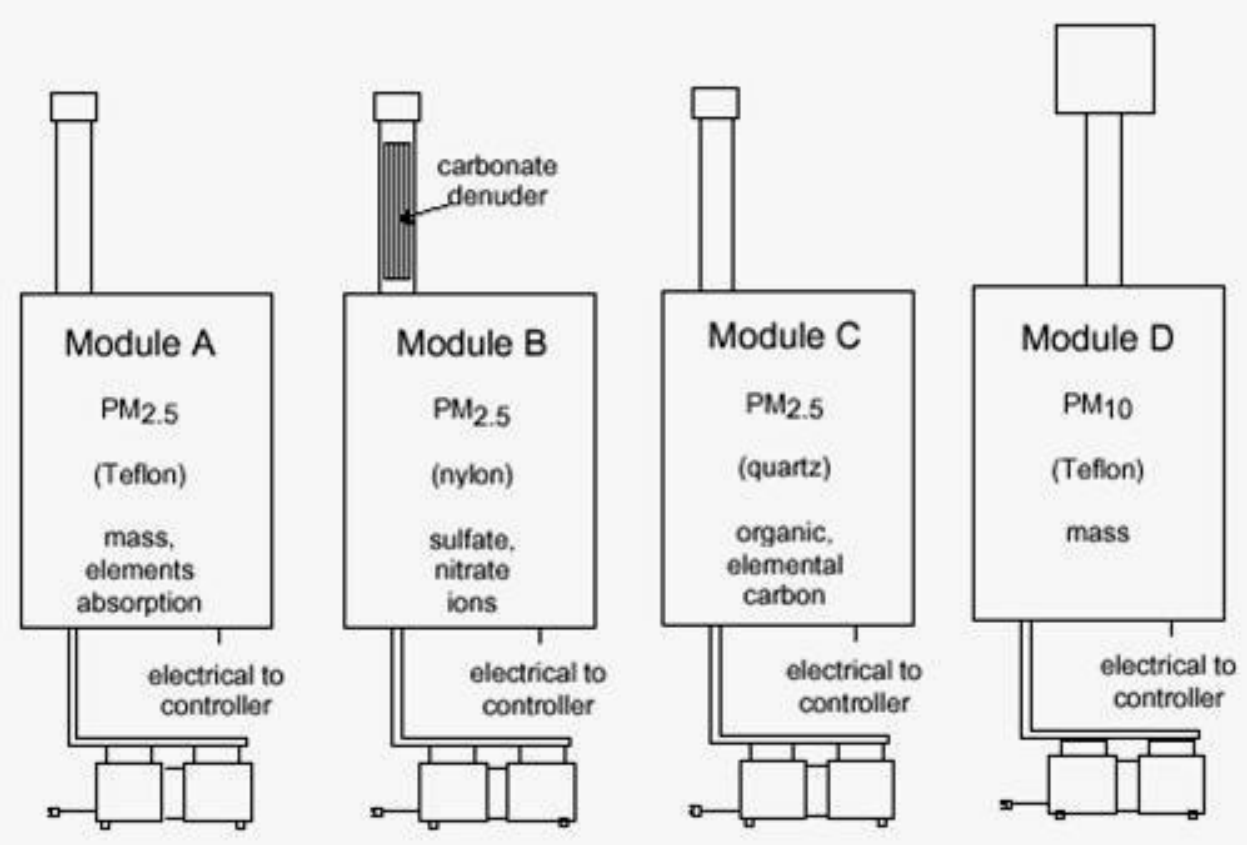

Figure 2-1 shows a typical IMPROVE monitor site, in this case located at Bosque del Apache Wilderness Area, which is one of the nine Class I Areas in New Mexico. Like the other IMPROVE monitor sites, the one at Bosque del Apache contains four separate modules used for sampling the particulate species responsible for visibility impairment, as diagrammed in Figure 2-2. Each module consists of a size-cut filter cassette with appropriate filter material for species of interest, flow control, and a sample pump. IMPROVE samplers collect 24-hour samples, every three days. The collected filter samples are subsequently analyzed at the UC-Davis Crocker Nuclear Laboratory and other analytical laboratories for the indicated particulate species.

Figure 2-1: IMPROVE Monitor Site at Bosque del Apache Wilderness Area.

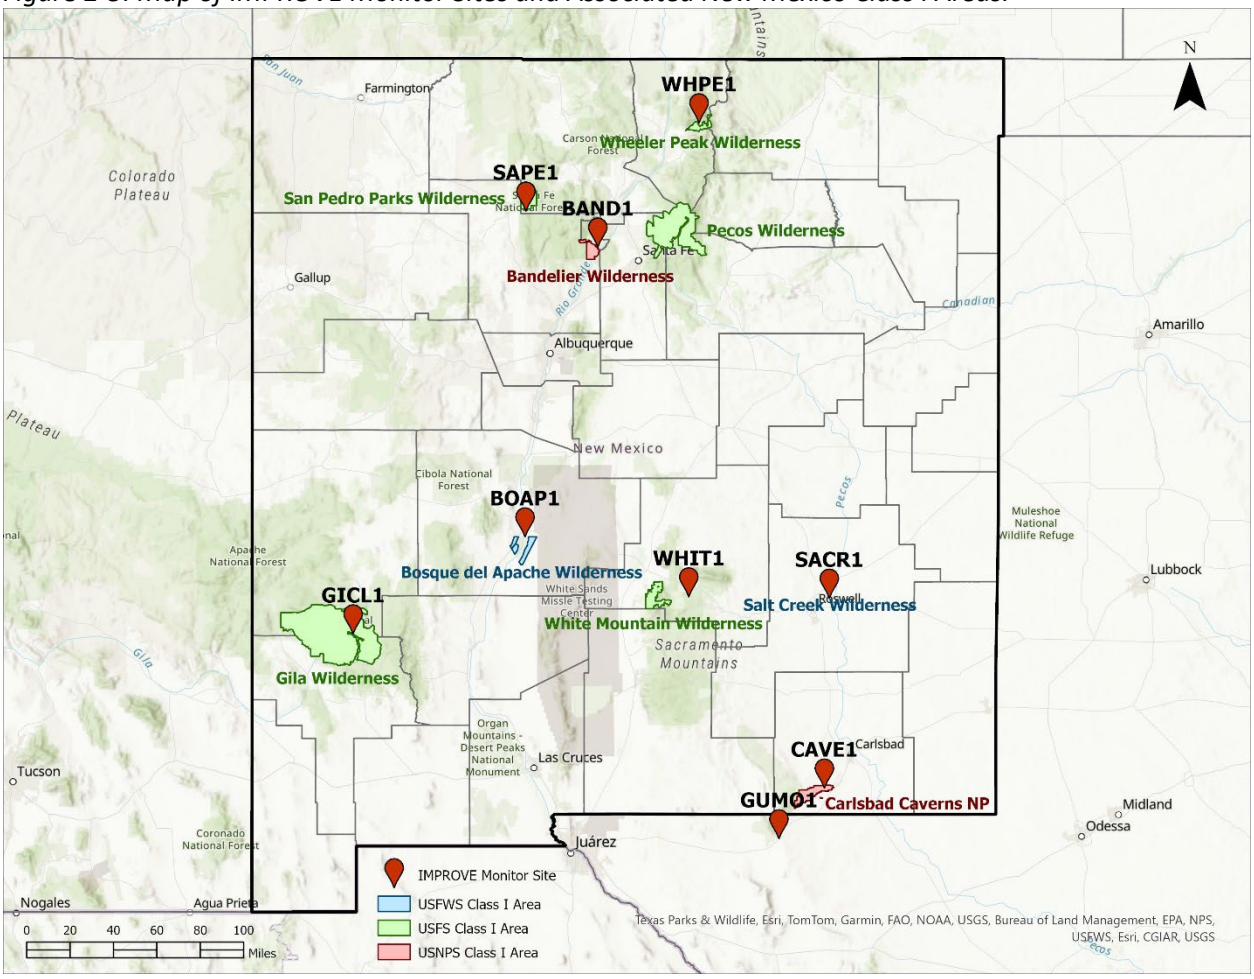
Photo credit: Kip Carrico

Figure 2-2: Four Aerosol Modules Used for Regional Haze Monitoring at IMPROVE Monitor Sites.

For purposes of this Regional Haze SIPr Rd 2 (2019 – 2028), the primary point of note here is that IMPROVE monitor sites provide technically reliable information about visibility conditions and causes of visibility interference for each Class I Area, by methods that meet all applicable federal regulatory requirements. Chapter 3 of this SIPr provides additional technical details on how the IMPROVE network carries out this function.

2.2 New Mexico Class I Areas and IMPROVE Monitor Sites

Table 2-1 lists the eight IMPROVE monitor sites that collect regional haze monitoring data for New Mexico's nine Class I Areas.[55] Note that the IMPROVE monitor for Wheeler Peak Wilderness Area is also used to represent visibility conditions at nearby Pecos Wilderness Area. Note too that the IMPROVE monitor for Carlsbad Caverns National Park is located in Texas at Guadalupe Mountains National Park. Figure 2-3 shows the locations of the eight IMPROVE monitors listed in Table 2-1 (and new monitor site CAVE1) relative to their associated Class I Areas. Each individual Class I Area in New Mexico is discussed further below.



[55] A new monitor site (CAVE1) was recently established closer to Carlsbad Caverns National Park but is not considered here because data collection only began in 2017. Likewise, one past New Mexico monitoring site (SAAN1) only operated from 1997-1999 and is not considered here because that data predates the time period covered by the Regional Haze Rule (2000-2064).

Table 2-1: IMPROVE Monitoring Network and Associated Class I Areas in New Mexico.

Site Name	Site Code and Geographic Coordinates	Location (County)	Associated Class I Area	Federal Land Manager	Elevation (feet) [1]	Start Date
Bandelier	BAND1 35.7797° N 106.2664° W	Los Alamos	Bandelier Wilderness Area	U.S. National Park Service (USNPS)	6,523	March 1988
Bosque del Apache	BOAP1 33.8695° N 106.852° W	Socorro	Bosque del Apache Wilderness Area	U.S. Fish and Wildlife Service (USFWS)	4,560	April 2000
Gila	GICL1 33.2204° N 108.2351° W	Catron	Gila Wilderness Area	U.S. Forest Service (USFS)	5,825	April 1994
Guadalupe Mountains (TX)	GUMO1 31.833° N 104.8094° W	Culberson (TX)	Carlsbad Caverns National Park	USNPS	5,486	March 1988

[1] Datum = mean sea level.

Figure 2-3: Map of IMPROVE Monitor Sites and Associated New Mexico Class I Areas.

The earliest New Mexico IMPROVE monitor sites, Bandelier and Guadalupe Mountains, have been active since the start of the IMPROVE program in 1988. Several New Mexico monitor sites became operational after January 1, 2000 (start dates are provided in Table 2-1); all, however, are considered by EPA to have complete data records as discussed in Chapter 3. The data from these sites provides a comprehensive record of visibility conditions in the Class I Areas of New Mexico.

2.2.1 Bandelier Wilderness Area

The Bandelier Wilderness Area encompasses approximately 90 percent of Bandelier National Monument, which sits at the southern end of the Pajarito Plateau. The plateau was formed by two eruptions 1.6 and 1.4 million years ago. Elevations at Bandelier range from 5,340 feet at the Rio Grande River to the south to 10,199 feet at the summit of Cerro Grande to the north, which is almost a mile of elevation change in just under 12 miles. This large elevation gradient creates a unique diversity of habitats specific to northern New Mexico. The diversity of habitats and quick access to water supported a relatively large population of ancestral Pueblo peoples. Currently, piñon-juniper woodlands dominate in the southern parts of the monument, transitioning through ponderosa pine savannahs and forests, finally reaching mixed conifer forests at the highest elevations. Scattered throughout the monument are desert grasslands, montane meadows, and riparian areas in the canyon bottoms. Bandelier is home

to a wide variety of wildlife. The backcountry trails at Bandelier climb in and out of deep canyons and cross large flat mesas, showcasing the entire spectrum of volcanic geology.

Additional information about Bandelier is available from the National Park Service at https://www.nps.gov/band/index.htm.

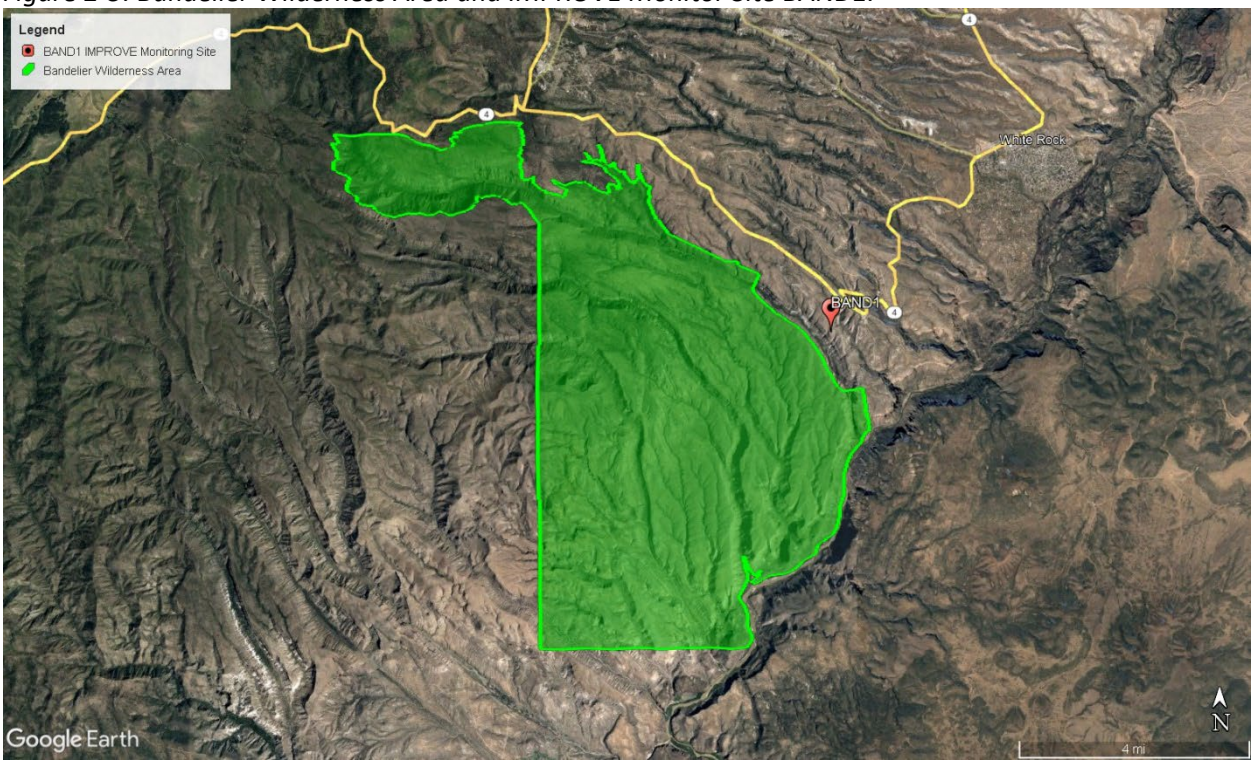

Figure 2-4: Bandelier Wilderness Area in Sandoval, Los Alamos, and Santa Fe Counties, NM.

Photo credit: Kip Carrico.

The IMPROVE monitor site for Bandelier Wilderness Area is BAND1, located near a fire tower on a ridge crest just outside of the eastern Wilderness boundary at an elevation of 6,523 feet. The BAND1 IMPROVE monitor site is in an exposed location at an elevation near the middle of the range of Wilderness elevations and about 1,000 feet above the Rio Grande River at the bottom of the canyon. The highest Bandelier Wilderness Area elevations are typically about 1,000 feet above the monitor site. As a result, BAND1 is considered representative of visibility conditions within Bandelier Wilderness Area.

Figure 2-5: Bandelier Wilderness Area and IMPROVE Monitor Site BAND1.

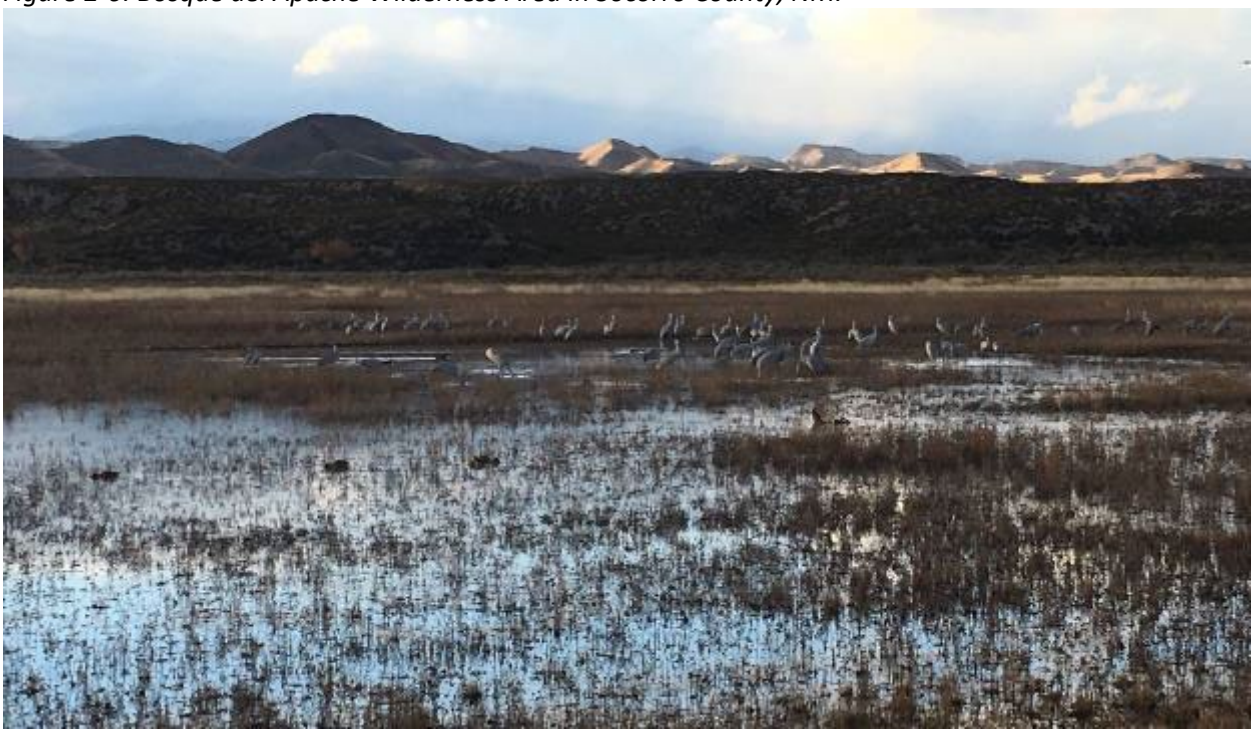
2.2.2 Bosque del Apache Wilderness Area

The Bosque del Apache Wilderness Area consists of three separate units within the larger Bosque del Apache National Wildlife Refuge (NWR), which is located along the Rio Grande River south of Socorro, New Mexico. The refuge is located at the northern edge of the Chihuahuan Desert and straddles the river. The heart of the refuge is about 12,900 acres of moist bottomlands – 3,800 acres are active floodplain, and 9,100 acres are areas where water is diverted to create extensive wetlands, farmlands, and riparian forests. The rest of Bosque del Apache NWR is made up of arid foothills and mesas, which rise to the Chupadera Mountains to the west and the San Pascual Mountains to the east. Most of these desert lands are preserved as wilderness areas.

Managed by the U.S. Fish and Wildlife Service, Bosque del Apache NWR is an important link in the more than 500 federal wildlife refuges in North America. The goal of refuge management is to provide habitat and protection for migratory birds and endangered species and provide the public with a high-quality wildlife and educational experience.

Additional information about Bosque del Apache is available from the U.S. Fish and Wildlife Service at https://www.fws.gov/refuge/bosque_del_apache/.

Figure 2-6: Bosque del Apache Wilderness Area in Socorro County, NM.



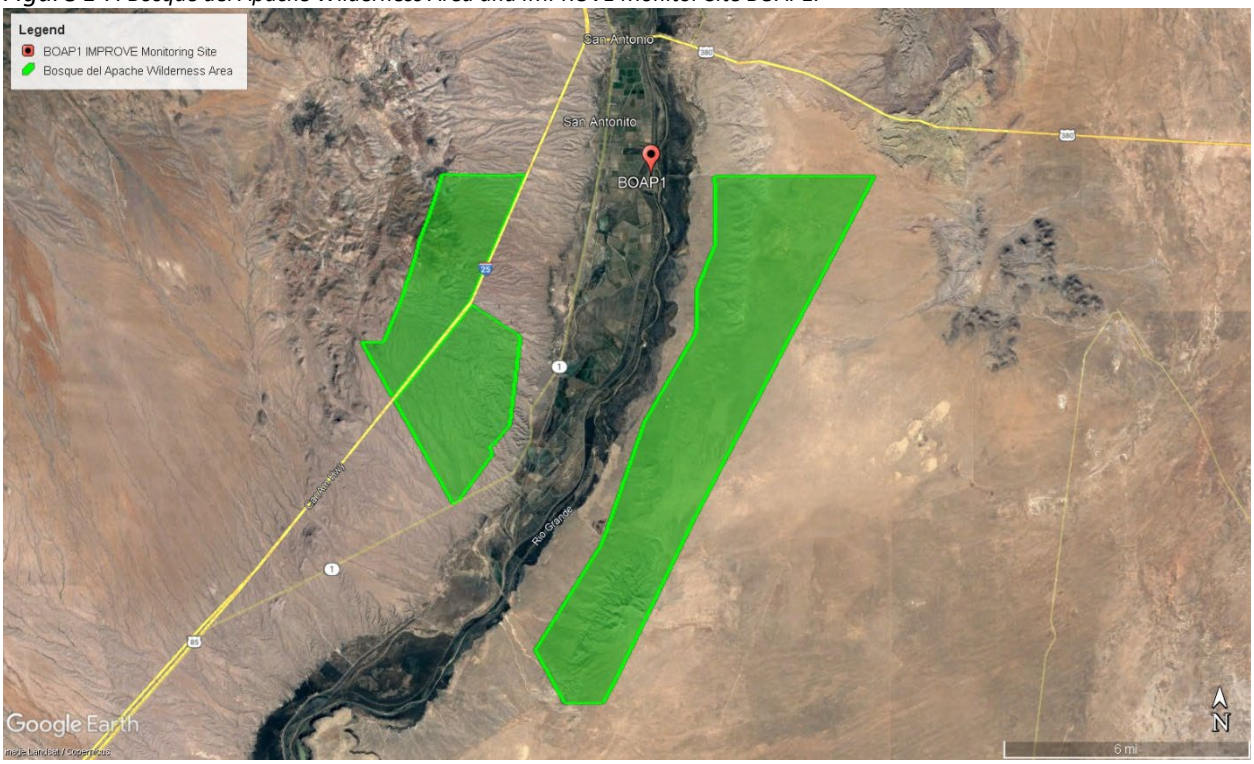


Photo credit: Kip Carrico

The IMPROVE monitor site for Bosque del Apache Wilderness Area is BOAP1, located at the northern boundary near the Rio Grande River at an elevation of 4,560 feet. Given the narrow range of elevations at Bosque del Apache, BOAP1 is considered representative of visibility conditions there.

Figure 2-7: Bosque del Apache Wilderness Area and IMPROVE Monitor Site BOAP1.

2.2.3 Carlsbad Caverns National Park

Carlsbad Caverns National Park is located in the Guadalupe Mountains, a mountain range that runs from west Texas into southeastern New Mexico. The most famous of all the geologic features in the park are the more than 110 limestone caves, the most well-known of which is Carlsbad Caverns. Carlsbad Caverns receives more than 300,000 visitors each year and offers a rare glimpse of the underground worlds preserved under the desert above.

Elevations within the park rise from 3,595 feet in the lowlands to 6,520 feet atop the escarpment. Though there are scattered woodlands in the higher elevations, the park is primarily a variety of grassland and desert shrub land habitats. The park supports a diverse ecosystem, including habitat for many plants and animals that are at the geographic limits of their ranges. For example, the ponderosa pine reaches its extreme eastern limit here and several species of reptiles are at the edges of their distributions.

Additional information about Carlsbad Caverns is available from the National Park Service at https://www.nps.gov/cave/index.htm.

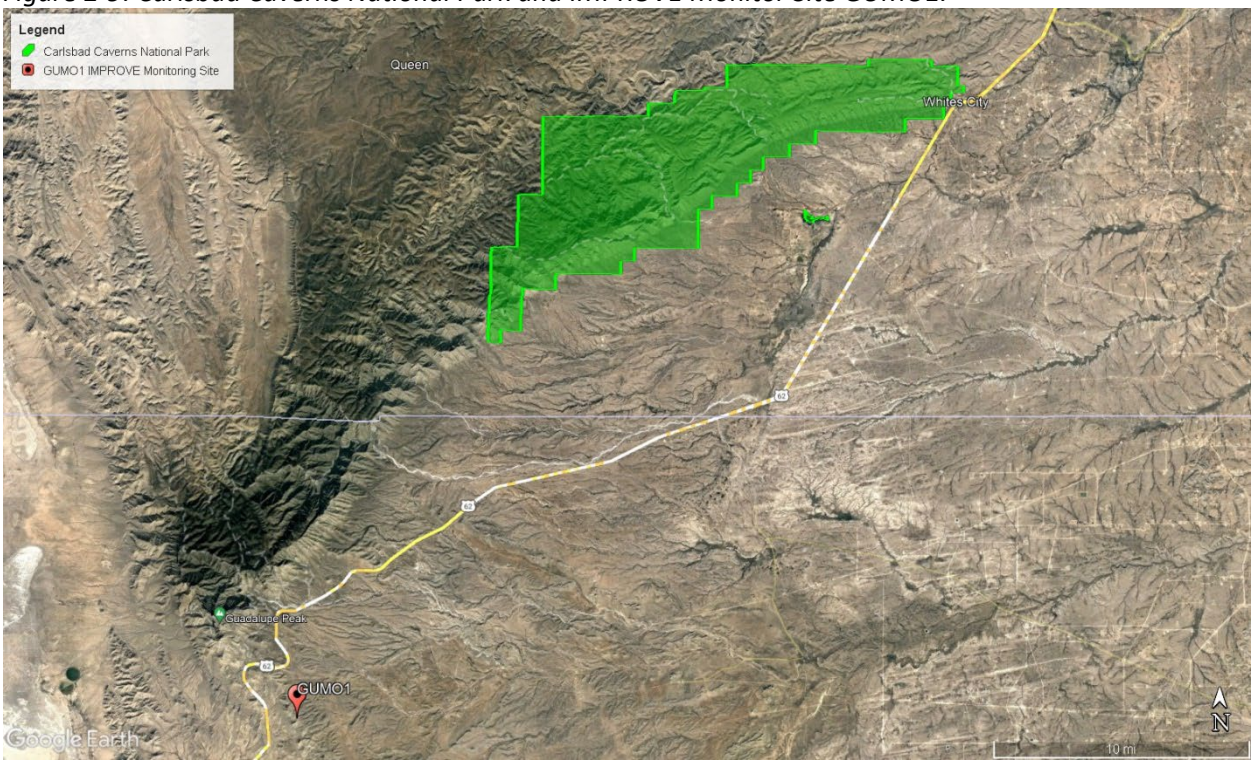

Figure 2-8: Carlsbad Caverns National Park in Eddy County, NM.

Photo credit: National Park Service (https://www.nps.gov/im/chdn/cave.htm).

The IMPROVE monitor site for Carlsbad Caverns National Park is GUMO1, located about 15 miles southwest in mountainous terrain near the crest of the Delaware Mountain Range at an elevation of 5,486 feet. It has good exposure to regional-scale winds and may be influenced by wind-blown dust from the salt flats in western Texas, as well as from the Mexican dry/barren region to the southwest. The ground cover near the monitor site is desert vegetation (e.g., shrubland and grassland). As a result, GUMO1 is considered representative of visibility conditions within Carlsbad Caverns National Park, especially at higher elevations.

Figure 2-9: Carlsbad Caverns National Park and IMPROVE Monitor Site GUMO1.

2.2.4 Gila Wilderness Area

The Gila Wilderness Area in southwestern New Mexico incorporates varied terrain. The northeastern and far eastern sections of the wilderness consist of high mesas and rolling hills, ranging in elevation from approximately 5,000 to 8,000 feet and cut by the deep canyons of the Gila River. The vegetation consists primarily of mixed junipers and piñon pines, grasses, and at the higher elevations and on northern slopes, ponderosa pines, vast stands of which cover the central part of the Gila. The river canyons offer spectacular cliffs, with mixed hardwoods and ponderosa pine growing along the riparian bottoms. The far western and southwestern sections of the Gila consist of high mountains, with the highest elevation reaching 10,895 feet in the Mogollon Range. Steep side canyons are common, and vegetation includes Douglas fir, ponderosa pine, aspen, and a variety of ferns. The area includes the drainage basins of both Mogollon Creek and Turkey Creek.

Additional information about the Gila is available from the U.S. Forest Service at https://www.fs.usda.gov/gila/.

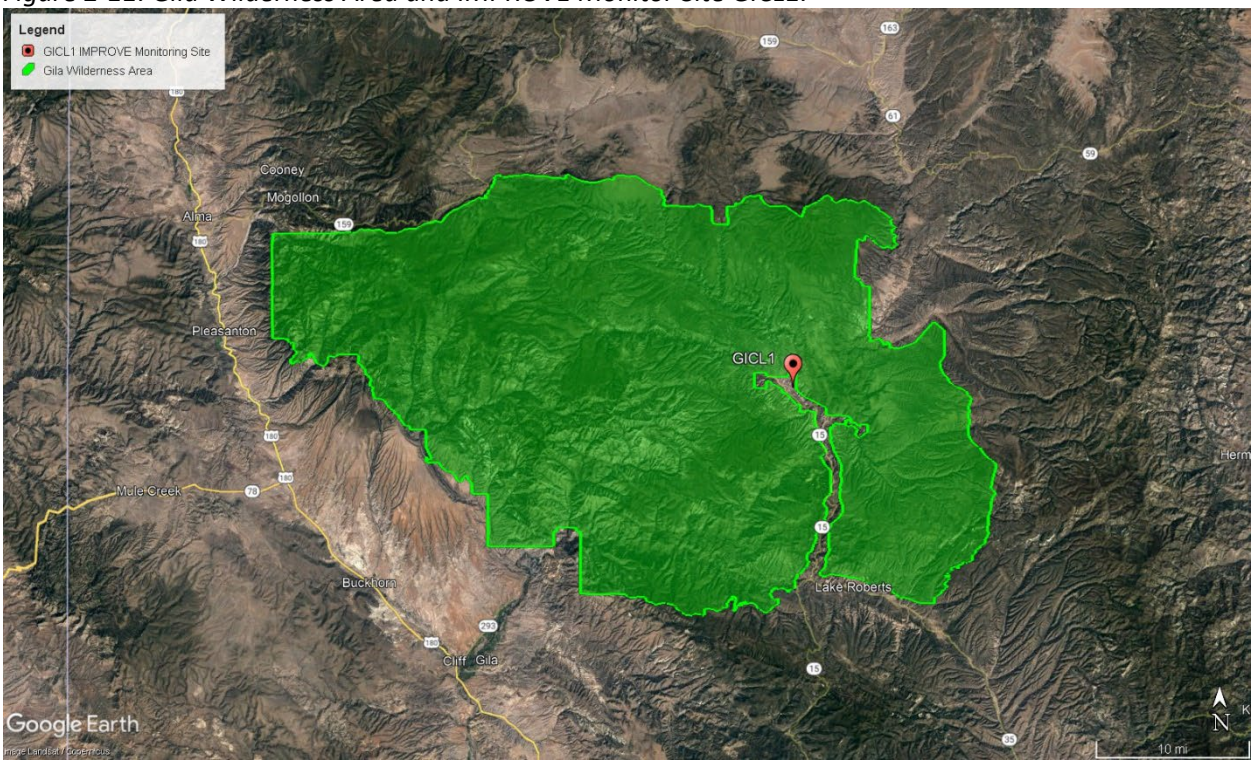

Figure 2-10: Gila Wilderness Area in Grant and Catron Counties, NM.

Photo credit: Elizabeth Sorells.

The IMPROVE site for the Gila Wilderness Area is GICL1, located on a bank overlooking the Gila River in the east-central part of the Wilderness at an elevation of 5,825 feet. As a result of its location near the center of the Wilderness, GICL1 is considered representative of visibility conditions within the area.

Figure 2-11: Gila Wilderness Area and IMPROVE Monitor Site GICL1.

2.2.5 Pecos Wilderness Area

The Pecos Wilderness Area extends through two Ranger Districts in the Santa Fe National Forest and into the Carson National Forest to the north. Within the boundaries of this expansive area are several landmarks including Truchas Peak, which tops out at 13,103 feet, and the southern stretch of the Rocky Mountains. The terrain varies from open meadows in the Pecos River Valley to the steep canyons of the Sangre de Cristo Mountain Range. Wildlife ranges from deer and elk to bighorn sheep, turkeys, and grouse. There are 15 lakes and eight major streams that sustain both plant and animal habitats, including for the native Rio Grande Cutthroat Trout.

Additional information about the Pecos is available from the U.S. Forest Service at https://www.fs.usda.gov/detail/santafe/ and https://www.fs.usda.gov/detail/carson/.

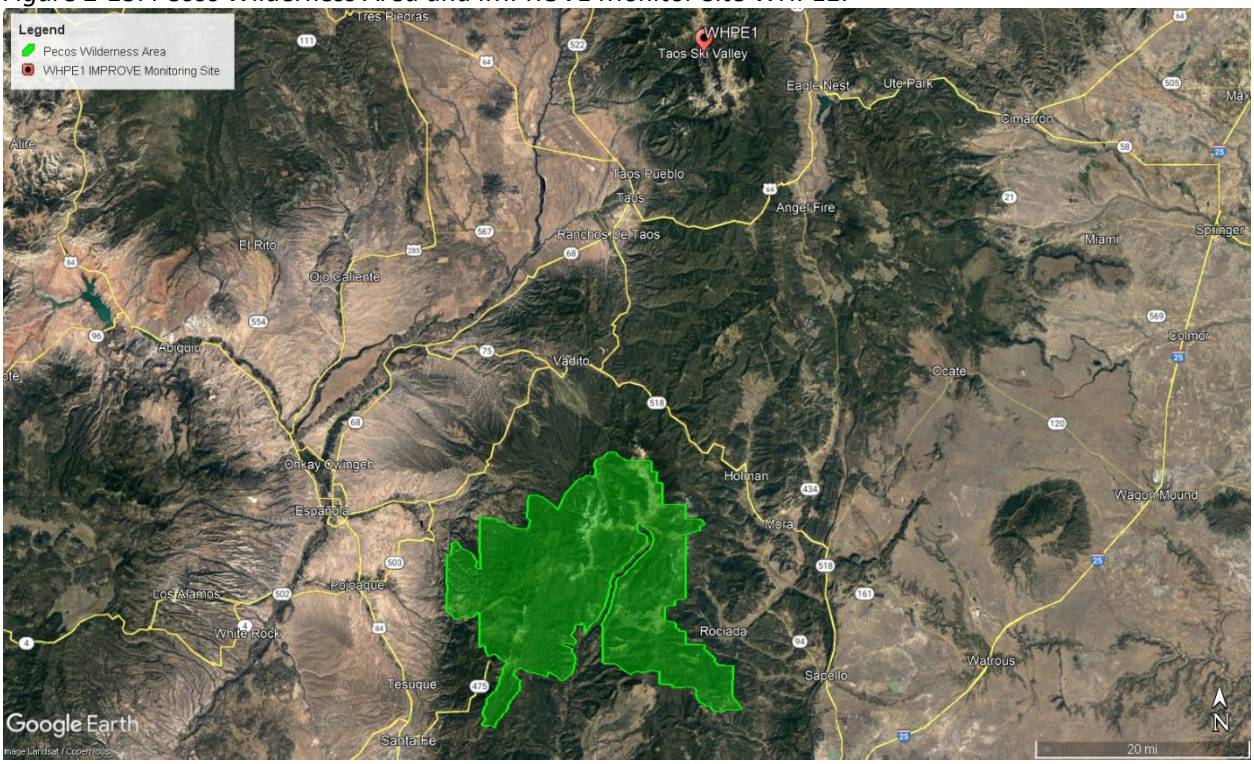

Figure 2-12: Pecos Wilderness Area in Mora, Rio Arriba, San Miguel, Santa Fe, and Taos Counties, NM.

Photo credit: Santa Fe National Forest.

The IMPROVE monitor site for Pecos Wilderness Area is WHPE1, located about 40 miles to the north near Wheeler Peak Wilderness Area at an elevation of 11,043 feet. Because it is at a high elevation, WHPE is considered representative of visibility conditions at high elevations of the Sangre de Cristo Mountains, including the Pecos Wilderness Area.

Figure 2-13: Pecos Wilderness Area and IMPROVE Monitor Site WHPE1.

2.2.6 Salt Creek Wilderness Area

The Salt Creek Wilderness Area is part of the Bitter Lake National Wildlife Refuge. Salt Creek Wilderness Area consists of river bottomlands, grasslands, sand dunes, and mixed shrub communities and comprises the watershed of Salt Creek, which empties into the Pecos River in southeastern New Mexico. The refuge, Bitter Lake, is located near Roswell, New Mexico, immediately west of the Pecos River. Virtually no waterfowl or water birds use the wilderness portion of the refuge because it is devoid of wetlands other than the river and a dozen sinkholes. Two or three of the sinkholes contain rare fish: the Pecos gambusia, which is endangered, and the Pecos pupfish, a species of concern. Part of the reason Salt Creek was established as wilderness was to protect the scenic red bluffs on the north side of Salt Creek.

Further information about Salt Creek is available from the U.S. Fish and Wildlife Service at https://www.fws.gov/refuge/bitter_lake/.

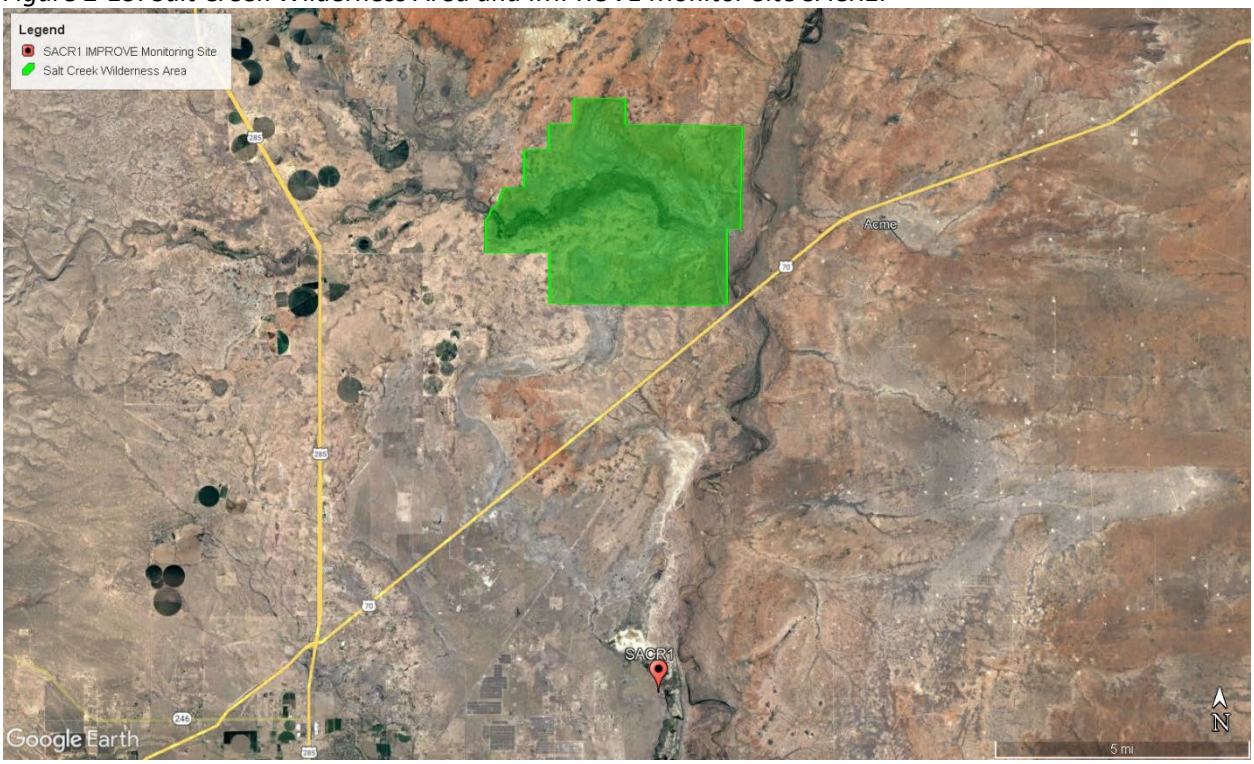

Figure 2-14: Salt Creek Wilderness Area in Chaves County, NM.

Photo credit: Jeff Howland (https://wilderness.net/).

The IMPROVE monitor site for Salt Creek Wilderness Area is SACR1, located about 6 miles south of the Wilderness at an elevation of 3,518 feet. SACR1 is considered representative of visibility conditions in the Salt Creek Wilderness Area since it is at the same elevation with no intervening terrain.

Figure 2-15: Salt Creek Wilderness Area and IMPROVE Monitor Site SACR1.

2.2.7 San Pedro Parks Wilderness Area

The San Pedro Parks Wilderness Area is on the western edge of the Santa Fe National Forest and part of the Colorado Plateau. It occupies 41,132 acres in Southern Rio Arriba County, New Mexico. It is an alpine site with stands of Engelmann spruce, mixed conifers, and aspen punctuated by grassy meadows. Due to its elevation, approximately 10,000 feet on average, it experiences significant rainfall, particularly in the monsoon season of July - August. It has streams that are abundant with trout and standing bodies of water including the San Gregorio Reservoir. The Wilderness is crossed by the Continental Divide National Scenic Trail.

Additional information about San Pedro Parks is available from the U.S. Forest Service at https://www.fs.usda.gov/detail/santafe/about-forest/districts/?cid=fsbdev7_021062".

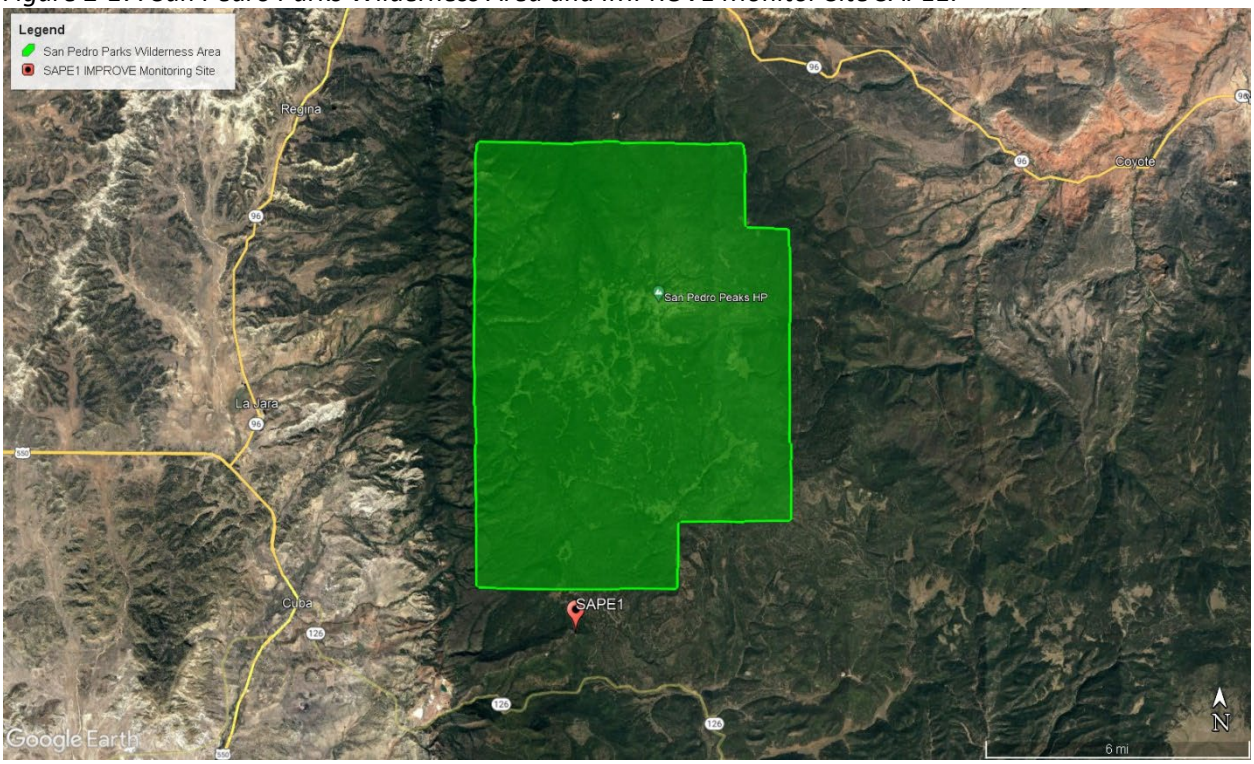

Figure 2-16: San Pedro Parks Wilderness Area in Southern Rio Arriba County, NM.

Photo Credit: Kerry Jones, USFS.

The IMPROVE monitor site for San Pedro Parks Wilderness Area is SAPE1, located on a peak approximately 6 miles due east of Cuba, New Mexico at an elevation of 9,629 feet. It is in the middle of the altitude range of the Wilderness and thus is considered representative of Wilderness visibility conditions.

Figure 2-17: San Pedro Parks Wilderness Area and IMPROVE Monitor Site SAPE1.

2.2.8 Wheeler Peak Wilderness Area

Lying along the top of the Sangre De Cristo Mountain Range, Wheeler Peak Wilderness Area is characterized by high rugged terrain. Elevations range from a low of 7,650 feet to a high of 13,161 feet at Wheeler Peak, the highest point in the State of New Mexico. Marmots, pikas, elk, mule deer, and golden eagles are found in the Wheeler Peak Wilderness. Above Taos Ski Valley, the Rio Hondo has a natural population of cutthroat trout as does Sawmill Creek. From the cottonwoods along the Rio Hondo to the Bristlecone pines guarding the peaks, Wheeler Peak Wilderness has almost all of the trees native to Northern New Mexico. Engelmann spruce and sub-alpine fir are the predominant tree species. Because Wheeler Peak is so high, it is one of the only places in the state to see a true alpine "mat" as opposed to grasses that grow in other high alpine locales. The "mat" produces beautiful brilliantly colored flowers. The average annual precipitation is 34-40 inches, with about half from summer rains and half from winter snows. Average annual temperatures range between 80° Fahrenheit in the summer to -20° Fahrenheit in the winter.

Additional information about the Wheeler Peak Wilderness is available from the U.S. Forest Service at https://www.fs.usda.gov/detail/carson/.

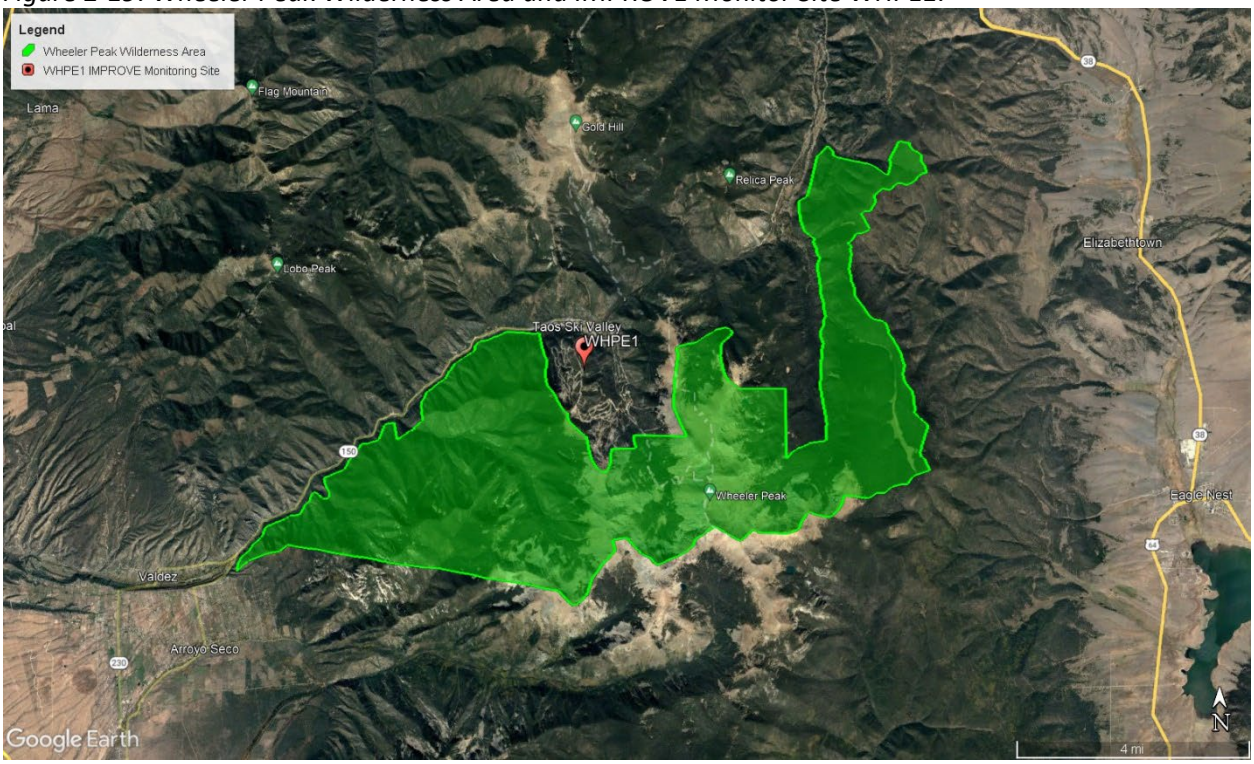

Figure 2-18: Wheeler Peak Wilderness Area in Taos County, NM.

The IMPROVE monitor site for Wheeler Peak Wilderness Area is WHPE1, located at a high point just outside the northern Wilderness boundary at an elevation of 11,043 feet. Because it is at a high elevation, WHPE is considered representative of visibility conditions at high elevations of the Sangre de Cristo Mountains, including the Wheeler Peak Wilderness Area.

Figure 2-19: Wheeler Peak Wilderness Area and IMPROVE Monitor Site WHPE1.

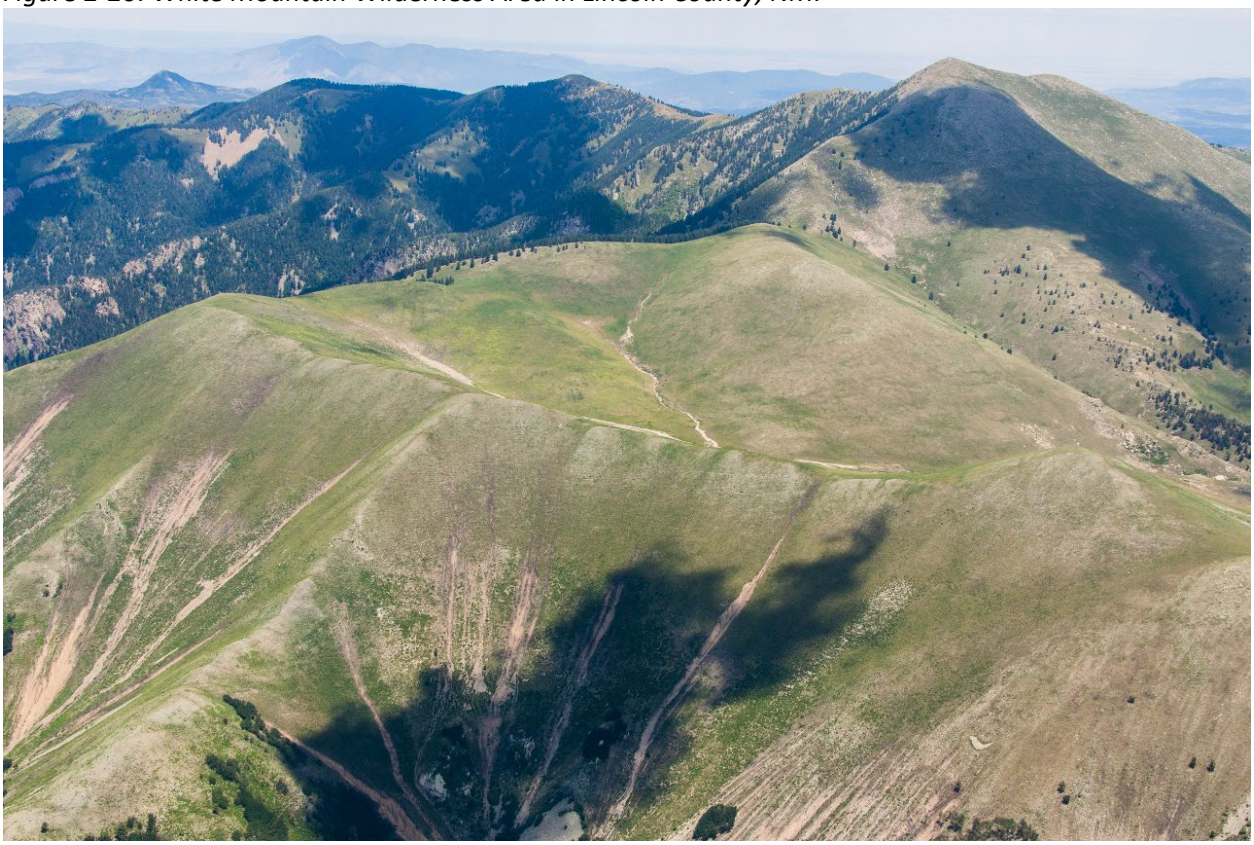
2.2.9 White Mountain Wilderness Area

The White Mountain Wilderness Area lies entirely within the Smokey Bear Ranger District of the Lincoln National Forest. The Wilderness is 12.5 miles long and ranges from 4 to 12 miles wide. The Wilderness consists mainly of a long, northerly running ridge and its branches. The west side of the ridge is steep and extremely rugged with many extensive rock outcroppings. The east side is gentler with broader, forested canyons and a few small streams. Elevations range from a low of 6,400 feet at Three Rivers Campground on the west side to a high of 11,580 feet near Lookout Mountain on the south. From Three Rivers to the crest there are four different life zones: piñon-juniper, ponderosa pine, mixed conifer, and sub-alpine forest. Abrupt changes in elevation, escarpments, rock outcrops, and avalanche chutes make for striking contrast and scenery. Interspersed along the crest are several meadows as well as some grass-oak savannahs, which are the result of fires.

Springtime is usually dry and windy throughout the Wilderness. July and August are the rainy months with frequent afternoon showers. In summer, while the desert is sweltering, the high country will likely be cool. Oak, maple and aspen on hillsides feature striking color changes in the autumn when days are usually cool and sunny with little wind. Winter snowfall usually begins in mid- to late November and can continue through June. During the winter months, the higher elevations may be under six or more feet of snow while it is above freezing at lower elevations.

Additional information about White Mountain Wilderness is available from the U.S. Forest Service at https://www.fs.usda.gov/main/lincoln/home.

Figure 2-20: White Mountain Wilderness Area in Lincoln County, NM.



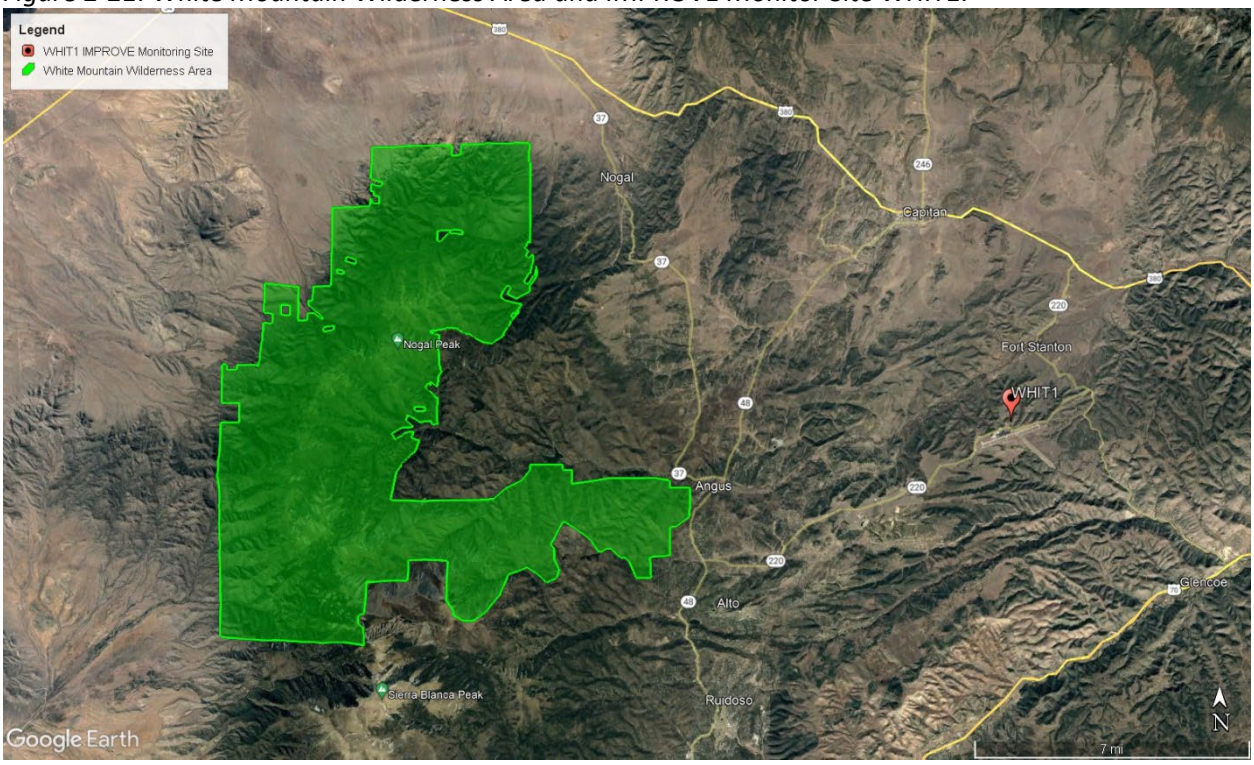


Photo credit: Dan Ryerson, USFS.

The IMPROVE monitor site for White Mountain Wilderness Area is WHIT1, located on a low ridge between the Rio Bonito and Little Creek, near the Sierra Blanca regional airport about nine miles east of the Wilderness, at an elevation of 6,770 feet. WHIT1 is on a well-exposed low ridge at an elevation near lower Wilderness elevations, where downslope flow conditions bring Wilderness air towards the monitor via the Rio Bonito and Little Creek drainages. As a result, WHIT1 is considered representative of visibility conditions in Wilderness locations.

Figure 2-21: White Mountain Wilderness Area and IMPROVE Monitor Site WHIT1.

Chapter 3: Ambient Monitor Data Analysis

This chapter provides an introduction to visibility-related concepts and a detailed look at the data, trends and contributors to light extinction at all New Mexico Class I Areas. Baseline, first period midpoint, first period end point, and current visibility conditions for the most impaired and clearest days are quantified to track visibility improvements over time and show progress to date and progress during the period covered by the embedded progress report in Chapter 5 of this Regional Haze SIPr Rd 2 (2019-2028). Natural visibility conditions for the most impaired and clearest days are also quantified to show the amount by which current visibility conditions exceed natural conditions.

This chapter also provides Regional Haze Rule requirements for ambient monitor data. Unless otherwise noted, all monitor data presented in this chapter comes from the Western Regional Air Partnership (WRAP) Technical Support System (TSS) website. Important definitions and concepts related to visibility can be found in this Regional Haze SIPr Rd 2 (2019 – 2028) (see Section 1.1: Definitions of Visibility-Related Concepts) and on the WRAP TSS website. [56]

3.1 Regulatory Requirements

The Regional Haze Rule requires that this Regional Haze SIPr Rd 2 (2019-2028) contain the following information about each New Mexico Class I Area:

1) The baseline visibility conditions at the site. [57] Baseline visibility conditions are the average of the five annual values for the 20% most impaired days of the year and 20% clearest days of the year during the period from 2000 to 2004. [58,]
2) The natural visibility conditions at the site. Natural visibility conditions are visibility that would exist at a Class I Area when only natural causes of visibility impairment, not anthropogenic causes, are present, on either the 20% most impaired days of the year or 20% clearest days of the year, as estimated by appropriate data analysis techniques. [59]
3) The current visibility conditions at the site. Current visibility conditions are the average of the five annual values for the 20% most impaired days of the year and 20% clearest days of the year during the most recent five-year period for which data are available. [60]
4) Progress to date for most impaired and clearest days. This information consists of the progress made toward natural visibility conditions since the baseline period, including during the

[56] https://views.cira.colostate.edu/tssv2/Pub/Glossary.aspx.

[57] The deciview (dv) or "haze index" is the unit of measurement of haze. It is a measure of visibility derived from light extinction that is designed so that incremental changes in the index correspond to uniform incremental changes in visual perception, across the entire range of conditions from pristine to highly impaired. The index (in units of dv) is calculated directly from the total light extinction (b_{ext} expressed in inverse megameters (Mm^{-1})) as follows: deciviews = 10 ln (b_{ext}/10). The index will be less than 0 for b_{ext} values below 10. All visibility conditions discussed here and elsewhere in this Regional Haze SIPr Rd 2 (2019 – 2028) are expressed in deciviews unless otherwise noted.

[58] 40 CFR §§ 51.301, 51.308(f)(1)(i).

[59] 40 CFR §§ 51.301, 51.308(f)(1)(ii). The provisions of the Regional Haze Rule cited do not specify a time period over which individual daily values must be averaged. The provisions also allow a choice of whether such averaging will occur on the Most Impaired Days "or" the Clearest Days. Based on EPA guidance, WRAP has developed an approach to this feature of the rule, which is discussed in the course of this chapter.

[60] 40 CFR §§ 51.301, 51.308(f)(1)(iii).

previous planning period, for the 20% most impaired days of the year and 20% clearest days of the year. [61]

5) The difference between current visibility conditions and natural visibility conditions for the most impaired days and clearest days. [62]

In addition to the above requirements, the U.S. Environmental Protection Agency's (EPA) August 2019 Guidance on Regional Haze State Implementation Plans for the Second Implementation Period indicates that a Regional Haze State Implementation Plan (SIP) may, but is not required to, include an extinction budget for each Class I Area. [63] An extinction budget shows the measured or estimated light extinction contribution from each ambient particulate matter (PM) species at a Class I Area and the extent to which each is responsible for that visibility interference.

This chapter presents the above-described regulatory information for each of New Mexico's Class I Areas. This information includes the mandatory information regarding visibility conditions described in items 1) through 5), above, as well as optional information related to extinction budgets. Additional information regarding visibility conditions and changes for the embedded progress report in Chapter 5 of this Regional Haze SIPr Rd 2 (2019-2028) is also presented in this chapter and discussed in Section 5.5.

3.2 Trends in Visibility Conditions

This section presents information to satisfy the requirements of 40 CFR § 51.308(f)(1)(i) through (v) and 40 CFR § 51.308(g)(3). These provisions require this Regional Haze SIPr Rd 2 (2019-2028) to present monitor data on visibility conditions for each New Mexico Class I Area to demonstrate progress toward natural visibility conditions. The information presented is as follows.

- Baseline, first period midpoint, first period end point, current, and natural visibility conditions on the 20% most impaired days and 20% clearest days. [64]
- Progress to date for the most impaired and clearest days, represented by the change from baseline to current visibility conditions.
- The difference between current and natural visibility conditions for the most impaired and clearest days.
- The difference between baseline and first period end point visibility conditions for the most impaired and clearest days.
- Progress during the period covered by the embedded progress report in Chapter 5 of this Regional Haze SIPr Rd 2 (2019-2028) for the most impaired and clearest days, represented by the change from first period midpoint to first period end point visibility conditions.

Table 3-1 lists the types of aerosol species measured by the Interagency Monitoring of Protected Visual Environments (IMPROVE) monitor sites in New Mexico and elsewhere. The table also presents the mechanism by which they form in the atmosphere and provides examples of the key sources of each aerosol species. Some of these sources are the result of human activities like industry or transportation,

[61] 40 CFR § 51.308(f)(1)(iv).
[62] 40 CFR § 51.308(f)(1)(v).
[63] EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, August 20, 2019 ("EPA Regional Haze SIP Guidance"), p. D-2.
[64] NM used the period from 2008 to 2012 to represent first period midpoint conditions, the period from 2014 to 2018 to represent first period end point conditions, and the period from 2019 to 2023 (the most recent five-year period for which data are available) to represent current conditions.

while others occur naturally. Each species listed in the table is part of a broader class of pollutant tracked by EPA for multiple regulatory purposes: particulate matter less than or equal to 2.5 microns in diameter ($PM_{2.5}$). For comparison, a human hair is about 50 to 70 microns in diameter. EPA provides additional background information about particulate matter at https://www.epa.gov/pm-pollution/particulate-matter-pm-basics.

Table 3-1: Aerosol Species Measured by IMPROVE Monitors.

Aerosol species	Alternate names for aerosol	Formation mechanism	Examples of key sources
Fine soil	Soil dust, fine mode mineral dust, windblown dust	Wind effects on earth's surface (global scale)	Long-range transport from global desert areas; dust from construction sites or unpaved road traffic; land areas disturbed from human or natural events
Coarse mass	Coarse particulate matter, mineral dust, CM	Wind effects on earth's surface (local to regional)	Windblown dust from arid regions; dust from construction sites or unpaved road traffic; land areas disturbed from human or natural events
Elemental carbon	Light absorbing carbon, EC	Combustion of carbon containing fuels	Fossil fuel combustion sources; on and off-road mobile engine sources, e.g. cars, trucks, construction equipment; biofuel and biomass (wildfires) burning
Organic mass	Organic carbon, particulate organic mass, particulate organic matter, OC, POM	Combustion of carbon containing fuels, biological processes	Fossil fuel-fired electrical generators; internal combustion engines; biogenic sources (forested areas); biofuel and biomass (wildfires) burning
Ammonium nitrate	NH_4NO_3	Conversion of nitrogen oxide emissions from combustion processes	Coal and natural gas-fired electric power plants; large industrial facilities like Portland cement plants; on and off-road mobile sources, e.g. cars, trucks, construction equipment; small industrial equipment like engines used for oil and gas production
Ammonium sulfate	$(NH_4)_2SO_4$	Conversion of sulfur dioxide emissions from combustion processes	Coal-fired electric power plants; other fuel combustion sources; large industrial facilities such as pulp and papermills, smelters, refineries and Portland cement plants; on and off-road mobile sources, e.g. cars, trucks, construction equipment.
Sea salt		Wind effects on earth's surface (local to global)	Wind over ocean surface, dry lake beds or playas; generally negligible at New Mexico Class I Areas.

Additional information on the above species and related scientific and technical information may be found at https://www.epa.gov/visibility.

Table 3-2 and Table 3-3 present the monitor data on visibility conditions discussed above. As these tables show, current visibility conditions are better than baseline conditions at all New Mexico Class I Areas on both the most impaired and clearest days, demonstrating progress toward natural visibility conditions since the baseline period in all areas. They also show that visibility conditions were better at the end point of the first period than at the midpoint on both the most impaired and clearest days, demonstrating progress toward natural visibility conditions during the period covered by the embedded progress report in Chapter 5 of this Regional Haze SIPr Rd 2 (2019-2028).

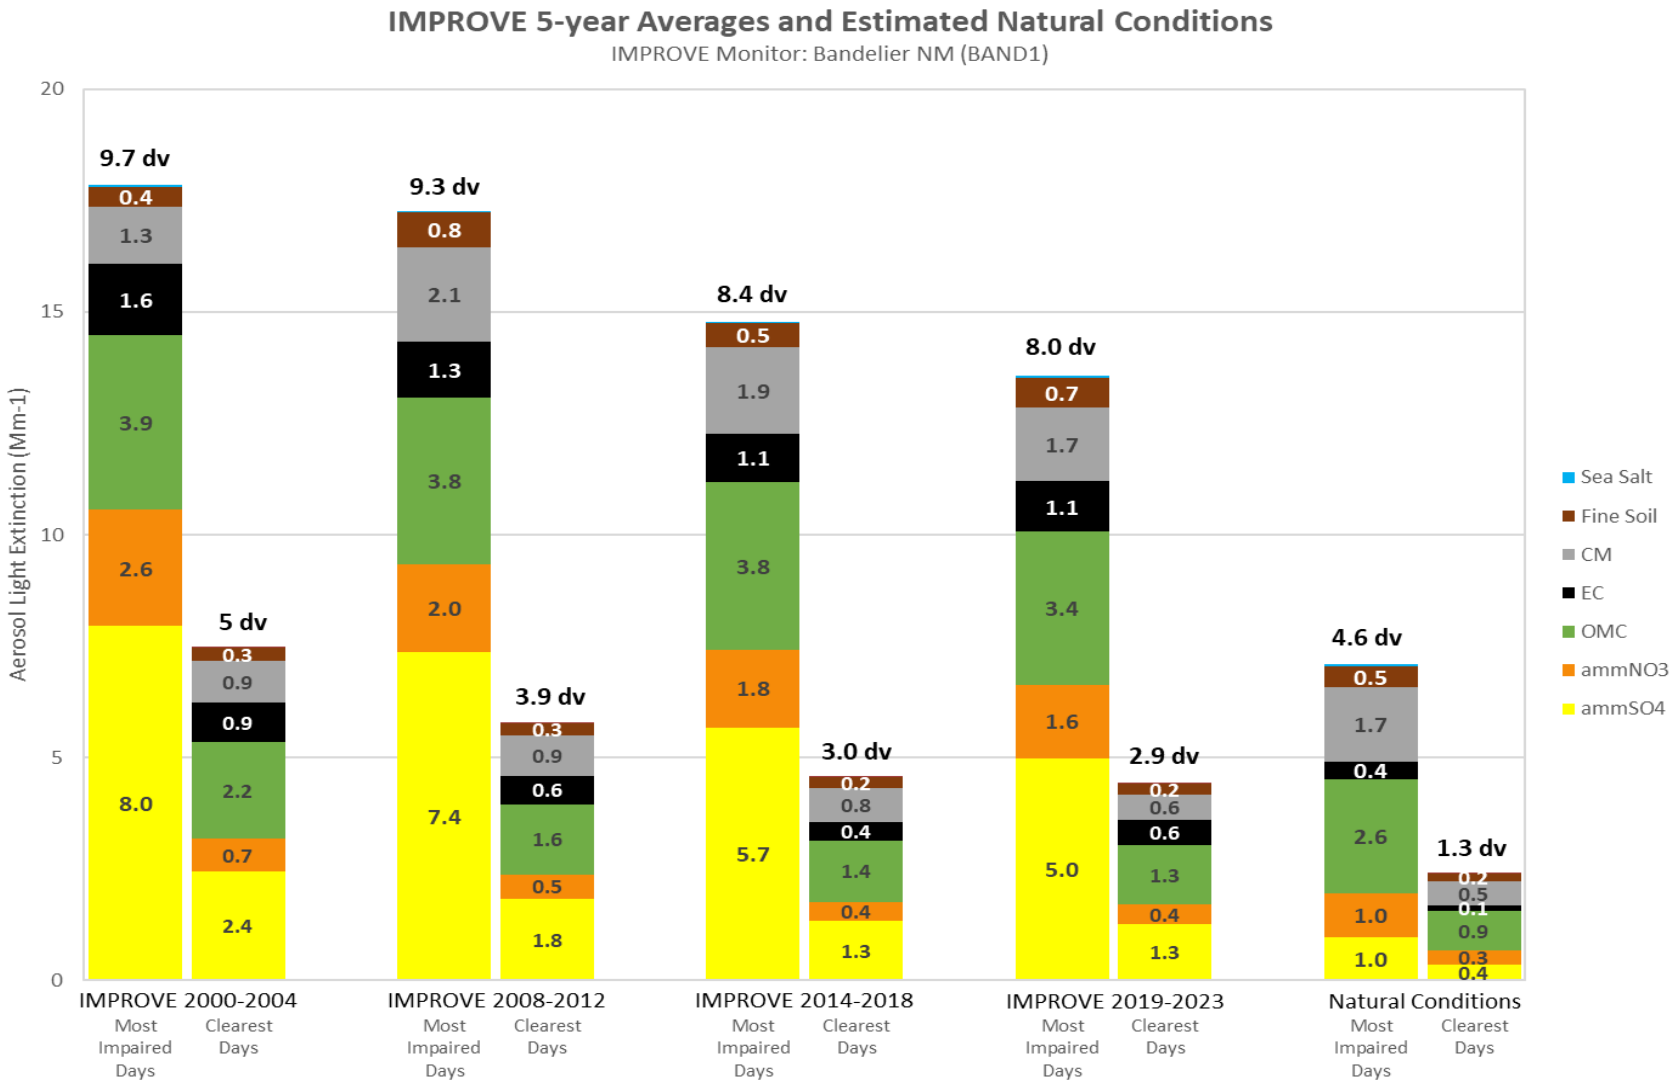
3.3 New Mexico IMPROVE Network Light Extinction Trends Analysis

Figure 3-1 provides an overview of the annual changes in the extinction magnitude and aerosol species contributors on the most impaired days at all New Mexico IMPROVE monitor sites over the 2000-2023 monitoring period. All sites have shown visibility improvement over the monitoring period, as indicated by the downward slope of the uppermost boundary of the bars. The graphs super-imposed over the map are meant to provide only a quick visual reference, not a full-sized rendition of each graph with complete notation. Full versions of the bar graphs in this map, and other detailed visualizations of monitor trends, are available on the WRAP TSS.

Figure 3-2 through Figure 3-9 show deciview trends and the aerosol species contributing to light extinction at each New Mexico IMPROVE monitor site during the five-year periods representing baseline, first period midpoint, first period end point, and current visibility conditions on the most impaired days and the clearest days, as well as the contributing species under natural conditions. The stacked bar charts give speciated contributions, which sum to the total particle light extinction coefficient. Note that the contributions to light extinction by each species are measured in inverse megameters. The total visibility conditions in deciviews appear above each bar for each five-year period represented. Contributions to light extinction from individual species are color-coded and presented in the following order: sea salt (light blue), fine soil (maroon), coarse mass (gray), organic mass from carbon (green), elemental carbon (black), ammonium nitrate (orange), and ammonium sulfate (yellow). Note that the dv value includes the Rayleigh Scattering contribution at each site. [65]



[65] Rayleigh Scattering is defined in 1.1.2: Other Definitions.

Figure 3-1: Map Overview of New Mexico and Adjacent Class I Areas and Progression of Speciated Visibility Impairment on the Most Impaired Days over the 2000-2023 Monitoring Period. Wheeler Peak Wilderness and Pecos Wilderness share a single monitor (WHPE1) as do Carlsbad Caverns NP and Guadalupe Mountains NP (GUMO1).

3.3.8 White Mountain Wilderness Area

Figure 3-9: Contributors to Light Extinction, Most Impaired and Clearest Days, White Mountain Wilderness Area.

3.4 Monitoring Data Summary

Figure 3-2 through Figure 3-9 show deciview trends and the aerosol species contributing to light extinction during the five-year periods representing baseline, first period midpoint, first period end point, and current visibility conditions, as well as the contributing species under natural conditions, at New Mexico Class I Areas. All network sites show improving visibility and progress toward the Regional Haze Rule goals of reducing impacts on the most impaired days while not backtracking during the clearest days.

Noteworthy trends across the network during the current period (2019-2023) include:

1) Ammonium sulfate was the primary driver of light extinction at all New Mexico Class I Areas on the most impaired days. On the clearest days, all sites were dominated by ammonium sulfate except for Gila Wilderness, Bosque del Apache Wilderness and Bandelier Wilderness, where organic mass made an equal or slightly larger contribution to light extinction, and Salt Creek Wilderness, where coarse mass made the largest contribution.
2) Though the order changed from site to site, the top three contributors to light extinction at New Mexico Class I Areas were ammonium sulfate, organic mass, and coarse mass on both the most impaired days and the clearest days. The only exceptions to this were Salt Creek Wilderness on the most impaired days and San Pedro Parks Wilderness on the clearest days, when ammonium nitrate was one of the top three contributors instead of either organic mass or coarse mass.
3) The combined ammonium sulfate and ammonium nitrate contribution to light extinction makes up approximately half of the total contribution at all sites through to the current period (2019-2023) on both the most impaired days and the clearest days. Sulfur dioxide (SO_2) and nitrogen oxides (NO_X), are precursors to ammonium sulfate and ammonium nitrate.
4) The largest haze reductions over time (i.e., the largest reduction in individual species' contributions to light extinction) are generally associated with ammonium sulfate and ammonium nitrate, which have likely occurred due to reduced SO_2 and NO_X emissions since EPA first promulgated the Regional Haze Rule in 1999.

3.5 Tracking Visibility Progress Regulatory Requirements

The Regional Haze Rule requires calculation of a Uniform Rate of Progress (URP) for each Class I Area in the state.[66] To calculate the URP, the state must compare baseline visibility conditions for the most impaired days to natural visibility conditions for the most impaired days in the Class I Area and determine the uniform rate of visibility improvement (measured in deciviews of improvement per year) that would need to be maintained during each planning period in order to attain natural visibility conditions by the end of 2064.

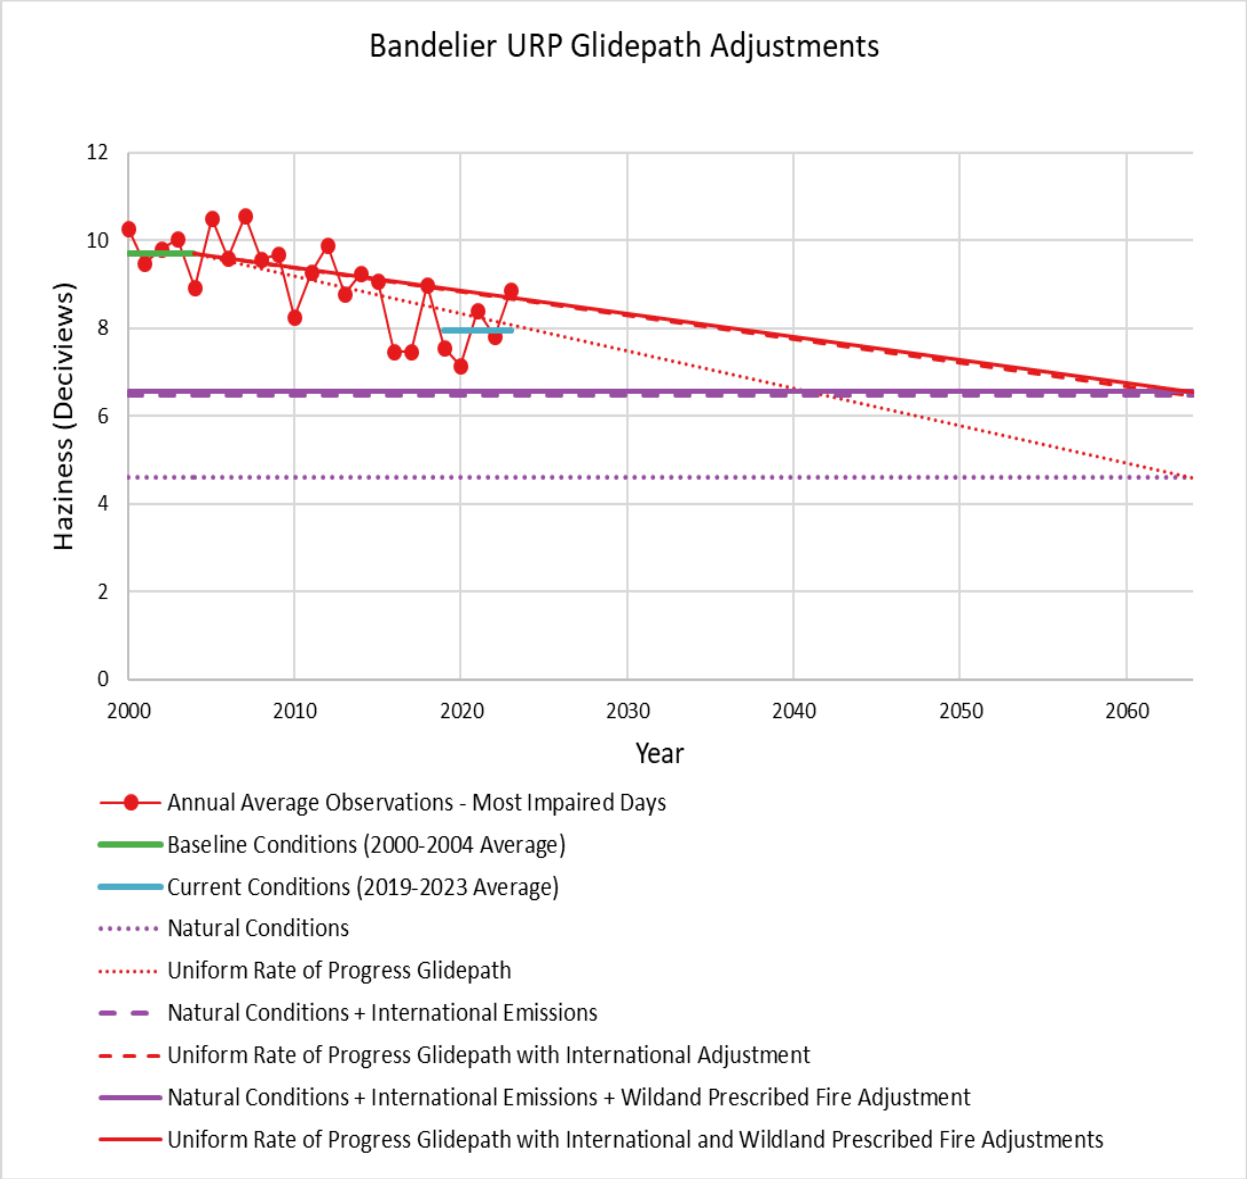
As part of its Regional Haze SIP submission, a state is allowed to propose:

1) an adjustment to the URP for a Class I Area to account for impacts from anthropogenic sources outside the United States;[67] and
2) an adjustment to the URP for a Class I Area to account for impacts from wildland prescribed fires that were conducted with the objective to establish, restore, and/or maintain sustainable and resilient wildland ecosystems, to reduce the risk of catastrophic wildfires, and/or to preserve

[66] 40 CFR § 51.308(f)(1)(vi)(A).
[67] 40 CFR § 51.308(f)(1)(vi)(B).

endangered or threatened species during which appropriate basic smoke management practices were applied. [68]

The WRAP contractor, Ramboll, developed URP adjustments to account for both types of impacts for all Class I Areas in WRAP states. The methods Ramboll used to calculate these adjustments are discussed in Appendix B. [69] NMED is using both of these adjustments for all of New Mexico's Class I Areas. [70]



3.6 Uniform Rate of Progress for New Mexico Class I Areas

Figure 3-10 through Figure 3-17 show the adjusted Uniform Rate of Progress (URP) accounting for impacts from anthropogenic sources outside the U.S. and wildland prescribed fires for all New Mexico Class I Areas.

[68] *Id*.
[69] *See* Section 9.0, Adjustments to the Uniform Rate of Progress Glidepath.
[70] URP glidepath adjustments for New Mexico Class I Areas are available on the Modeling Data Analysis page of the WRAP TSS (https://views.cira.colostate.edu/tssv2/Express/ModelingTools.aspx). *See* Product #5 under Visibility Progress and Projections.

Chapter 4: Determination of Affected Class I Areas in Other States

4.1 Regulatory Requirements

The Regional Haze Rule requires that this Regional Haze SIPr Rd 2 (2019-2028) contain a long-term strategy that addresses regional haze visibility impairment for each Class I Area within the state and for each Class I Area located outside the state that may be affected by emissions from the state. [71] According to the U.S. Environmental Protection Agency's (EPA) August 2019 Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, states have the flexibility to use any reasonable method for quantifying the impacts of their own emissions on out-of-state Class I Areas, and they may use any reasonable assessment for this determination. [72]

4.2 New Mexico Approach

The New Mexico Environment Department (NMED) integrated its assessment of the potential impacts of New Mexico's emissions on out-of-state Class I Areas into its source selection process. In coordination with other WRAP states and Federal Land Managers (FLMs) in 2019, NMED and the City of Albuquerque Environmental Health Department (EHD) chose to use the Q/d method to select a reasonable set of sources for an analysis of control measures necessary to make reasonable progress for the second planning period. As described in Chapter 6:, this method sums the quantity of aerosol precursor pollutants emitted by a facility (Q) and divides it by the distance from the facility to the nearest Class I Area (d). This provides a screening-level estimate of the potential for pollutants from the facility to impact the Class I Area.

In determining the distance to the nearest Class I Area for the 144 Title V facilities NMED calculated Q/d scores for, NMED considered all Class I Areas, not just those located in New Mexico. Of these, 57 were closest to Class I Areas in other states, i.e., Arizona, Colorado, and Texas. As such, the Q/d scores for more than a third of the facilities NMED screened reflect their potential to impact out-of-state Class I Areas, which was deemed greater than their potential to impact New Mexico Class I Areas due to their closer proximity to out-of-state areas. NMED ultimately selected a number of these facilities for an analysis of control measures, meaning they were evaluated based on their potential to impact out-of-state areas. Approximately half of the facilities selected for an analysis on this basis would not have been selected had NMED only considered Class I Areas in New Mexico when calculating Q/d scores. As a result, NMED's source selection process reasonably accounted for the impacts of New Mexico's emissions on out-of-state Class I Areas.

4.3 Additional Evidence

NMED participated in the Western Regional Air Partnership (WRAP) Regional Haze collaboration and planning process and made use of qualitative tools that were made available through the WRAP Technical Support System (TSS), as they were made available, to help provide context and weight of evidence regarding potential out-of-state emissions impacts. In September 2020, Weighted Emissions Potential and Area of Influence products were initially made available for Regional Haze planning in the western U.S. by WRAP. The analysis was performed for the most impaired days (MID) during each year of the 5-year period from 2014 through 2018 at 76 Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring sites representing 116 Class I Areas in the 13 contiguous WRAP

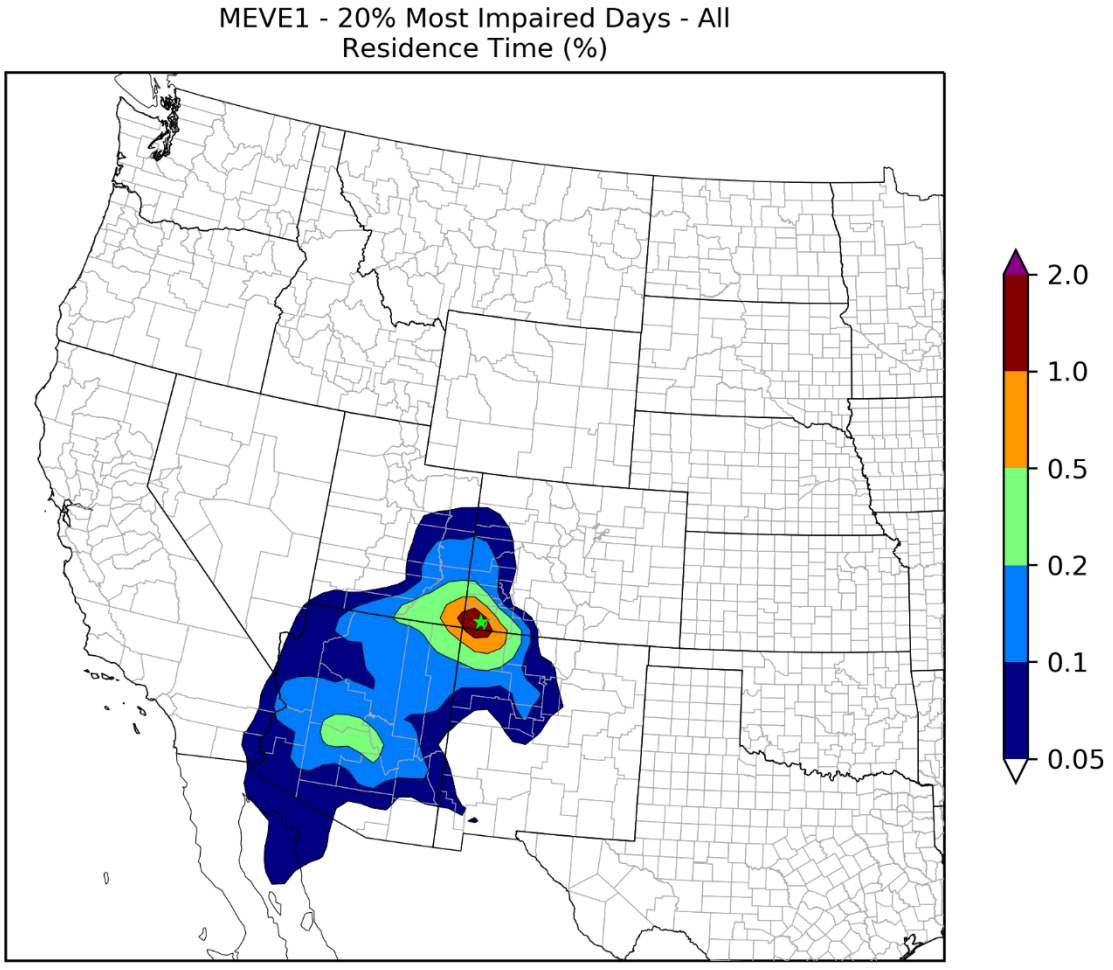
[71] 40 CFR § 51.308(f)(2).

[72] EPA Regional Haze SIP Guidance, p. 8.

states and neighboring states. Although not available when NMED completed its source selection process, these products support the conclusion that NMED's process adequately addresses the impacts of New Mexico's emissions on out-of-state Class I Areas.

As an example, Figure 4-1 and Figure 4-2 show calculated residence times from WRAP TSS data for Mesa Verde National Park in Colorado and Guadalupe Mountains National Park in Texas. The residence time is the percentage of air parcels that arrive at a Class I Area on the 2014-2018 most impaired days traveling from various locations. The parts of New Mexico that show some potential anthropogenic influence on Mesa Verde and Guadalupe Mountains based on residence time are the San Juan Basin in the Four Corners Region in northwest New Mexico, and the greater Permian Basin in the southeast part of the state. While it is a challenging exercise to estimate with any degree of certainty what the quantitative impacts of individual point sources are at Class I Areas, especially when projecting visibility into the future, reductions of visibility-impairing pollutant emissions from sources in these areas (as well as other parts of the state) can reasonably be expected to improve visibility at Mesa Verde and Guadalupe Mountains, as well as other out-of-state Class I Areas. NMED's robust source selection, control measures determinations, and long-term strategy (described in Chapters 6, 7, and 8, respectively) provide for significant reductions of sulfur dioxide (SO_2) and nitrogen oxides (NO_X) emissions from facilities in these areas of New Mexico.

Figure 4-1: Residence Time Plot for Mesa Verde National Park.



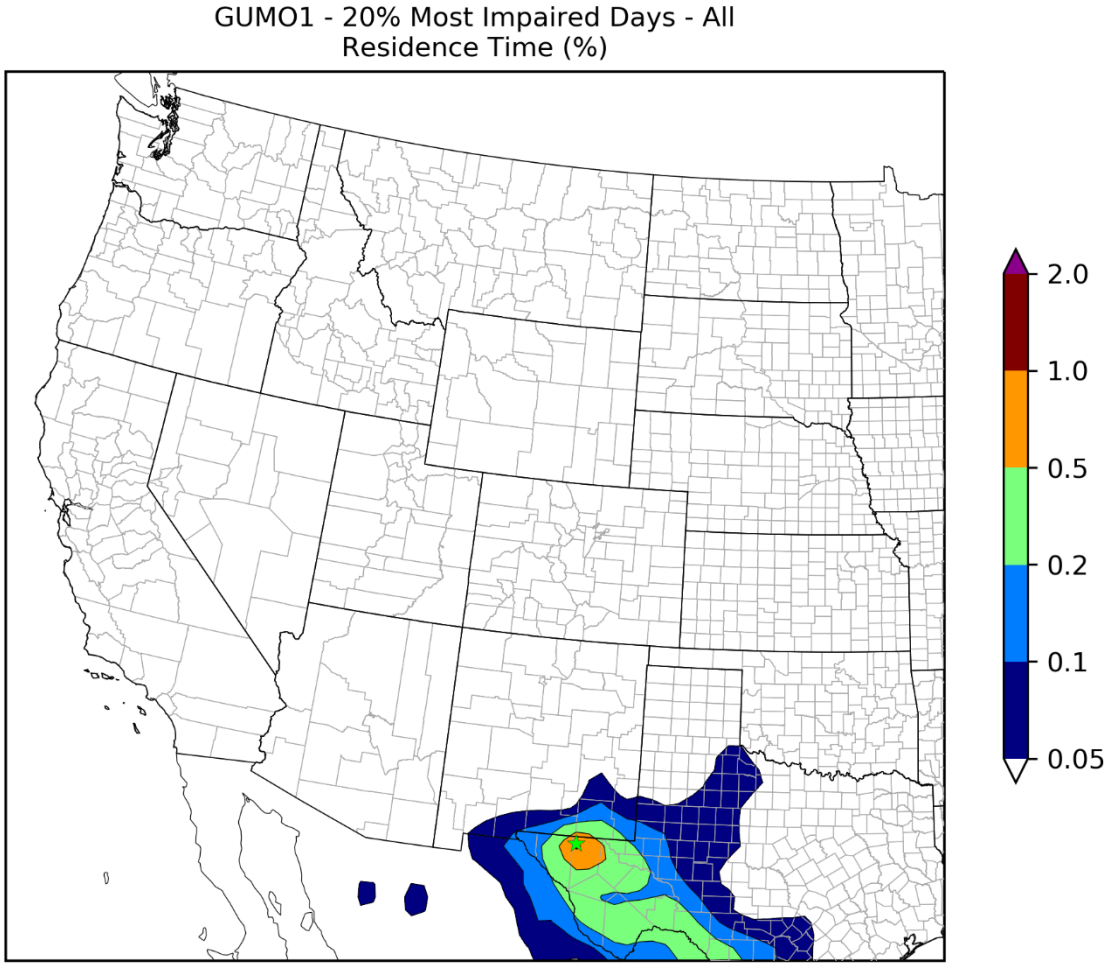


Figure 4-2: Residence Time Plot for Guadalupe Mountains National Park.

4.4 Communications with Neighboring States

NMED communicated with Arizona, Utah, and Colorado through the Western Regional Air Partnership collaborative process, and also met with Texas to discuss coordination as states were in various processes of developing their respective SIP revisions. This is discussed more in Chapter 11 - Coordination and Discussions with Other Parties. No neighboring state or other state requested that NMED select additional sources for an analysis of control measures or require the installation of controls at sources regulated by NMED to address impacts from New Mexico's emissions on any out-of-state Class I Area.

Chapter 5: Embedded Progress Report

The Regional Haze Rule requires that this Regional Haze SIPr Rd 2 (2019-2028) provide a progress report on implementation of the first planning period State Implementation Plan (SIP) during the five years following the required submittal of a mid-period progress report in 2013. [73] This Chapter provides the required progress report, covering the second half of the first planning period (i.e., 2014-2018).

The New Mexico Regional Haze SIP for the first planning period (2008-2018) was adopted under a different section of the Regional Haze Rule than this Regional Haze SIPr Rd 2 (2019-2028) is proposed under. The first planning period SIP was adopted in accordance with 40 CFR § 51.309, Requirements Related to The Grand Canyon Visibility Transport Commission ("Section 309"), whereas this second planning period SIP is proposed for adoption in accordance with 40 CFR § 51.308, Regional Haze Program Requirements ("Section 308"). Thus, the progress report in this Chapter, which satisfies Section 308 requirements, provides a progress report regarding implementation of Section 309 requirements for 2014-2018. For simplicity, this Chapter will refer to the first planning period SIP for New Mexico, adopted under Section 309, as the "First Period SIP," and will continue to refer to this SIP revision for the current (i.e., second) planning period, proposed for adoption under Section 308, as the Regional Haze SIPr Rd 2 (2019-2028). The first two Sections of this Chapter will cover, first, the Section 308 requirements that the progress report in this Chapter must satisfy and, second, the background of New Mexico's decision to adopt the First Period SIP under Section 309. That background will be useful in understanding the progress report, which is covered in the remaining 5 Sections of this Chapter.

5.1 Regulatory Requirements

The embedded progress report in this Regional Haze SIPr Rd 2 (2019-2028) must address the period since the most recent progress report, which was due in 2013 and addressed the period 2009-2013. [74] Therefore this progress report must address the period 2014-2018. As specified in 40 CFR § 51.308(f)(5), this progress report must provide the information specified in 40 CFR § 51.308(g)(1) to (7), which is described below.

1) A description of the status of implementation of all measures included in the implementation plan for achieving reasonable progress goals for mandatory Class I Federal areas both within and outside the state. [75]
2) A summary of the emissions reductions achieved throughout the state through implementation of the measures described in [40 CFR § 51.308(g)(1)]. [76]
3) For each mandatory Class I Federal area within the state, the state must assess the following visibility conditions and changes, with values for most impaired, least impaired and/or clearest days as applicable expressed in terms of 5-year averages of these annual values. The period for calculating current visibility conditions is the most recent 5-year period preceding the required date of the progress report for which data are available as of a date 6 months preceding the required date of the progress report.
    a. The current visibility conditions for the most impaired and least impaired days. [77]

[73] 40 CFR § 51.308(f)(5).
[74] 40 CFR § 51.308(f)(5); 40 CFR § 51.309(d)(10).
[75] 40 CFR § 51.308(g)(1).
[76] 40 CFR § 51.308(g)(2).
[77] 40 CFR § 51.308(g)(3)(i)(A).

b. The difference between current visibility conditions for the most impaired and least impaired days and baseline visibility conditions. [78]

c. The change in visibility impairment for the most impaired and least impaired days over the period since the period addressed in the most recent plan required under paragraph (f) of this section. [79]

4) An analysis tracking the change over the period since the period addressed in the most recent plan required under [40 CFR § 51.308(f)] in emissions of pollutants contributing to visibility impairment from all sources and activities within the state. [80]

5) An assessment of any significant changes in anthropogenic emissions within or outside the state that have occurred since the period addressed in the most recent plan required under [40 CFR § 51.308(f)] including whether or not these changes in anthropogenic emissions were anticipated in that most recent plan and whether they have limited or impeded progress in reducing pollutant emissions and improving visibility. [81]

6) An assessment of whether the current implementation plan elements and strategies are sufficient to enable the state, or other states with mandatory Class I Federal areas affected by emissions from the state, to meet all established reasonable progress goals for the period covered by the most recent plan required under [40 CFR § 51.308(f)]. [82]

7) For progress reports for the first implementation period only, a review of the state's visibility monitoring strategy and any modifications to the strategy as necessary. [83]

8) For a state with a long-term strategy that includes a smoke management program for prescribed fires on wildland that conducts a periodic program assessment, a summary of the most recent periodic assessment of the smoke management program including conclusions if any that were reached in the assessment as to whether the program is meeting its goals regarding improving ecosystem health and reducing the damaging effects of catastrophic wildfires. [84]

Following the 8-step framework outlined in the U.S. Environmental Protection Agency's (EPA) August 2019 Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, this Chapter covers the progress report elements described in 40 CFR § 51.308(g)(1) to (5). Chapter 12 of this Regional Haze SIPr Rd 2 (2019-2028) covers the progress report elements described in 40 CFR § 51.308(g)(6) and (7).

5.2 Background on Section 309 of the Regional Haze Rule

The federal Clean Air Act (CAA) provides the EPA Administrator with the authority to establish a visibility transport region for any area of at least two states where the Administrator has reason to believe that the current or projected interstate transport of air pollutants from one or more states contributes significantly to visibility impairment in Class I Areas located in the affected states. [85] The CAA directs the EPA Administrator to also establish a visibility transport commission whenever the Administrator

[78] 40 CFR § 51.308(g)(3)(ii)(A).
[79] 40 CFR § 51.308(g)(3)(iii)(A).
[80] 40 CFR § 51.308(g)(4).
[81] 40 CFR § 51.308(g)(5).
[82] 40 CFR § 51.308(g)(6).
[83] 40 CFR § 51.308(g)(7).
[84] 40 CFR § 51.308(g)(8).
[85] 42 U.S.C. § 7492(c)(1).

establishes a visibility transport region and provides specific direction on the composition of such a commission.[86] The CAA additionally specifies the duties of visibility transport commissions, which include: assessing scientific and technical data, studies, and other currently available information pertaining to adverse impacts on visibility from potential or projected growth in emissions from sources located in the visibility transport region; and, within four years of establishment, issuing a report to the EPA Administrator recommending what measures, if any, should be taken to remedy such adverse impacts.[87] Once such a report is issued, the CAA allows EPA 18 months to carry out its regulatory responsibility to promulgate a regional haze rule under 42 U.S.C. § 7491.[88] The CAA also expressly provides for the establishment of such a visibility transport commission - the Grand Canyon Visibility Transport Commission (GCVTC) - for the region affecting the visibility of Grand Canyon National Park.[89]

The EPA established the GCVTC in November 1991 for the Grand Canyon visibility transport region, which spans nine states (Arizona, California, Colorado, Idaho, Nevada, New Mexico, Oregon, Utah, and Wyoming) and 211 Tribal lands on the Colorado Plateau.[90] Members included the governors or their designees of each state in the region (with the exception of Idaho, which chose not to participate in the GCVTC); the leaders of the Navajo, Hopi, Hualapai, and Acoma Pueblo Tribes, or their designees; and ex officio members including EPA, federal land managers from the National Park Service, Bureau of Land Management, U.S. Fish and Wildlife Service, and U.S. Forest Service, and the Columbia River Inter-Tribal Fish Commission.[91] The GCVTC, following the instructions in 42 U.S.C. § 7492, issued a final report in June 1996 recommending long range strategies for addressing regional haze that impairs visibility in Class I Areas on the Colorado Plateau.[92] As required by the CAA, the EPA then promulgated the original Regional Haze Rule in July 1999. The Regional Haze Rule provided two paths for states to address regional haze. The first path, Section 308, required states to perform individual point source Best Available Retrofit Technology (BART) determinations and evaluate the need for other control strategies. The other path, Section 309, allowed the nine states in the Grand Canyon visibility transport region - and the 211 Tribes within those states - to implement the GCVTC's recommendations from its June 1996 report to address visibility impairment in the 16 Class I Areas on the Colorado Plateau. Five states - Arizona, New Mexico, Oregon, Utah, and Wyoming - as well as Albuquerque - Bernalillo County submitted their First Period SIPs under Section 309 by the December 31, 2003 deadline. Oregon ceased

participating in the program in 2006, followed by Arizona in 2010.[93, 94] While Tribes are not subject to the deadline and can still opt into the Section 309 program at any time, none have done so.

The EPA revised the Regional Haze Rule on July 6, 2005 and again on October 13, 2006 in response to two legal challenges.[95, 96] The October 13, 2006 revisions modified Section 309 to provide a methodology consistent with the Court's decision for evaluating the equivalence of alternatives to BART, such as the alternative Section 309 strategy based on the GCVTC recommendations. The Regional Haze Rule was revised again on January 10, 2017, requiring all states - including Section 309 states - to comply with Section 308 requirements in their periodic implementation plan revisions.[97] In the preamble to the January 10, 2017 final rule, EPA clarified that all measures and obligations contained in a state's First Period SIP submitted under Section 309 must continue to be implemented unless the SIP itself provides for that measure or obligation to sunset; that the revised provisions of Section 309 will apply to any SIP revision that would revise a First Period SIP provision that was part of the basis of EPA initially approving the First Period SIP as meeting the requirements of Section 309 of the original Regional Haze Rule; and that future periodic comprehensive SIP revisions and progress reports from the Section 309 states - including this Regional Haze SIPr Rd 2 (2019-2028) - will be subject to the requirements of Section 308.[98]

5.3 Implementation Status of All Control Measures in First Period SIP

The progress report must provide: "A description of the status of implementation of all measures included in the implementation plan for achieving reasonable progress goals for mandatory Class I Federal areas both within and outside the state."[99]

This Section describes control measures in New Mexico's First Period SIP that were adopted for the first Regional Haze planning period to regulate anthropogenic sources of haze-causing pollutants in New Mexico. For each control measure, this Section describes the pollutant being controlled, the method of control and how it affects visibility, the type of source affected, and the extent to which any applicable compliance date for sources has come into effect.

---

[93] "In 2003, Oregon did submit a Section 309 Regional Haze Plan, to primarily address the contribution of Oregon emissions to visibility impacts in the Colorado Plateau. This plan, along with 4 other state plans submitted under Section 309, were disapproved by EPA due to a lawsuit regarding the BART requirements in Section 309. [For more information see *Center for Energy and Economic Development v. EPA*, no. 03-1222, (D.C. Cir. Feb. 18, 2005)("CEED v. EPA")]. The four states chose to resubmit their 309 plans. The Department decided not to resubmit the plan, due to the optional nature of Section 309, the fact that Oregon is only a minor contributor to visibility impacts in the Colorado Plateau, and that a Section 308 plan is required in 2008 regardless under the Regional Haze Rule." Oregon Regional Haze Plan, December 2009, p. 9.

[94] "Originally, Arizona was to submit a SIP addressing both Section 309(d)(4) and Section 309(g); however, it was determined in 2010 that EPA did not approve of the revisions to the milestone program. To avoid a FIP, EPA requested that Arizona submit a plan under Section 308. Arizona agreed but with the understanding that all the work done on the previously submitted plans would be recognized and that the important long-term strategies would be incorporated into the 308 SIP as would have been the case under Section 309(g) except now for all 12 of Arizona's national parks and wilderness areas." Final Arizona Regional Haze SIP – 308, January 2011, p. 9.

5.3.1 SO_2 Milestone and Backstop Trading Program

The Regional Haze Rule requires Section 309 states to develop an emissions reduction program for stationary sources of sulfur dioxide (SO_2).[100] To meet this requirement, the First Period SIPs for New Mexico, Albuquerque – Bernalillo County, and the other Section 309 states (Utah and Wyoming) provided for an SO_2 Milestone and Backstop Trading program that:

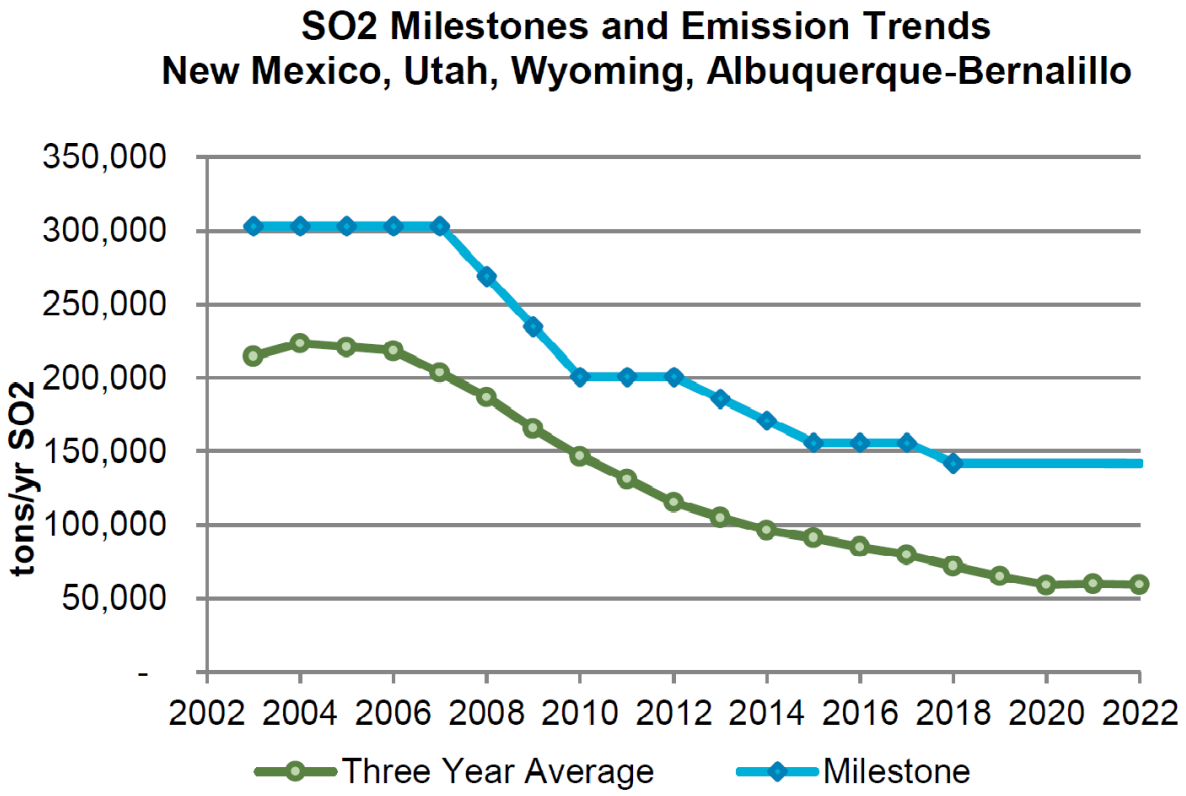
- tracks SO_2 emissions from major stationary sources reporting 100 tons per year or more of SO_2 emissions;
- requires that total emissions from the SO_2 sources tracked remain at or below specific annual milestones; and
- in the event an annual milestone is exceeded, requires implementation of a regional SO_2 emissions trading system among the three Section 309 states.

Under its First Period SIP, New Mexico cooperates with its Western Regional Air Partnership (WRAP) partners (including Albuquerque - Bernalillo County) to maintain an inventory of regional SO_2 emissions across the Section 309 states. Annual regional emissions must not exceed specific milestones for each year, which have gradually decreased over time. If an annual regional milestone is exceeded, then a regional backstop trading program (Western Backstop SO_2 Trading Program) will be triggered to bring emissions below the milestone.

Once triggered, the trading program would require New Mexico to allocate "allowances" to each source for specific maximum permissible amounts of SO_2 emissions. Sources would be allowed to trade allowances in order to comply with source-specific emissions targets. A tracking system would be used to manage emissions monitoring, allowances allocation, and allowances trading. This backstop SO_2 trading program has been adopted in the currently effective rule, 20.2.81 NMAC, Western Backstop Sulfur Dioxide Trading Program. However, the program, by design, will not be implemented unless the annual regional SO_2 milestones are exceeded. Only at that time would applicable compliance dates for specific regulatory provisions under 20.2.81 NMAC become effective. New Mexico is prepared to implement the SO_2 backstop trading program if it becomes necessary in the future.

20.2.73 NMAC, Notice of Intent and Emissions Inventory Requirements, requires major industrial sources of SO_2 to submit an annual emissions inventory in the pre-trigger phase of the program to measure compliance with the regional SO_2 milestones. If the backstop program is triggered, then these requirements will eventually be replaced by more rigorous monitoring requirements in 20.2.81 NMAC.

Table 5-1 presents the adjusted actual regional SO_2 emissions for 2014 - 2022 in tabular form. Figure 5-1 presents the adjusted actual regional SO_2 emissions for 2003-2022 in graphical form. Each year, adjusted actual SO_2 emissions were well below the regional milestone. Consequently, the backstop trading program was not triggered.



[100] 40 CFR § 51.309(d)(4).

Table 5-1: 2014 - 2022 Regional SO2 Milestones and Emission Trends in Section 309 States. [101]

Year	SO_2 Milestone (tons)	Adjusted Actual SO_2 Emissions (tons) [102]	3-Yr Avg. Adjusted SO_2 Emissions (tons)	Difference between Milestone and 3-Yr Avg. Adjusted SO_2 Emissions [103]	3-Yr Avg. Adjusted SO_2 Emissions as a Percent of Milestone	Adjusted Actual SO_2 Emissions as a Percent of Milestone
2014	170,868	92,553	96,392	<74,476>	56%	NA
2015	155,940	81,454	91,310	<64,630>	59%	NA
2016	155,940	98,035	90,591	<65,349>	58%	NA
2017	155,940	76,504	79,709	<76,231>	51%	NA
2018	141,849	71,994	NA	<69,854>	NA	51%

2022	141,849	59,364	NA	<82,485>	NA	42%

[101] The full content of the SO_2 Emissions and Milestone Reports for the years 2015 to 2022 are available at https://westar.org/regional-haze/. Earlier reports are available at https://www.wrapair2.org/reghaze.aspx.
[102] The First Period SIPs require states to adjust reported emissions to account for changes in monitoring, calculation methods, and enforcement actions.
[103] From 2003 to 2017 states compared the milestone to a three-year average of adjusted region-wide SO_2 emissions as required by the First Period SIPs. The First Period SIPs require states to compare the final 2018 regional milestone to 2018 emissions rather than the three-year average. Negative Value = Emissions < Milestone

Figure 5-1: 2003 - 2022 SO2 Milestones and Emission Trends.

5.3.2 Best Available Retrofit Technology

The San Juan Generating Station (SJGS) is the only facility in New Mexico that was subject to a BART determination during the first Regional Haze planning period. At that time, SJGS consisted of four coal-fired boilers: Unit 1 (1976) at 370 megawatts (MW), Unit 2 (1973) at 350 MW, Unit 3 (1979) at 544 MW, and Unit 4 (1982) at 544 MW. On November 27, 2012, EPA published final approval of New Mexico's 2003 and 2011 SIP submittals but expressly declined to take action on the portion of the 2011 SIP making a nitrogen oxides (NO_X) BART determination for SJGS, which consisted of selective non-catalytic reduction (SNCR) with an emission rate of 0.23 lbs/MMBtu.[104] EPA had previously issued a Federal Implementation Plan (FIP) containing a different NO_X BART determination for SJGS.[105] In its final rule, EPA determined that a NO_X emission limit from the SJGS of no greater than 0.27 – 0.28 lbs./MMBtu was necessary to satisfy the requirements of Section 110(a)(2)(D)(i)(II) of the CAA (visibility prong), and that no other additional reductions in New Mexico were required under that section.[106] Although New Mexico's July 5, 2011 NO_X BART determination of 0.23 lbs/MMBtu represented a lower emission rate than EPA determined to be necessary to satisfy Section 110(a)(2)(D)(i)(II), EPA promulgated its own NO_X BART determination of 0.05 lbs/MMBtu based on selective catalytic reduction (SCR).

[104] 77 Fed. Reg. 70693 (November 27, 2012) (Approval and Promulgation of State Implementation Plans; State of New Mexico; Regional Haze Rule Requirements for Mandatory Class I Areas).
[105] 76 Fed. Reg. 52388 (August 22, 2011) (Approval and Promulgation of Implementation Plans; New Mexico; Federal Implementation Plan for Interstate Transport of Pollution Affecting Visibility and Best Available Retrofit Technology Determination).
[106] *Id*. at 52424.

New Mexico challenged EPA's NO_X BART FIP for SJGS, and the case was filed in the U.S. Court of Appeals for the Tenth Circuit. New Mexico, EPA, and the Public Service Company of New Mexico (PNM, operator of the SJGS) reached a tentative agreement (contained in a "Term Sheet") on February 15, 2013 on an alternative plan to address pollution control requirements for the SJGS under the Clean Air Act's requirements for regional haze and interstate transport for visibility. The agreement called for a new BART determination based on the retirement of Units 2 and 3 at the facility by December 31, 2017; the installation of SNCR technology on the remaining Units 1 and 4, with a NO_X emission rate of no greater than 0.23 lbs/MMBtu; and further reductions in SO_2 emissions. On September 5, 2013, the Environmental Improvement Board (EIB) unanimously approved a SIP revision incorporating the terms of the tentative agreement as a revised BART determination. The revised SIP was submitted to EPA on October 8, 2013, and on December 17, 2013, EPA determined that the revised SIP submission was administratively complete.

On October 9, 2014, EPA approved a revision to the New Mexico Regional Haze SIP that addressed BART for SJGS, making the emission limitations federally enforceable, and satisfying CAA 110(a)(2)(D)(i)(II) with respect to interstate transport of air pollution and visibility protection for the 8-hour ozone and fine particulate matter ($PM_{2.5}$) National Ambient Air Quality Standards (NAAQS). [107] At the same time, EPA withdrew its FIP for New Mexico that applied to SJGS. [108] Therefore, the requirement for New Mexico under Section 110(a)(2)(D)(i)(II) is satisfied by the SIP revisions approved on November 27, 2012.

Units 2 and 3 were shut down at the end of 2017 in accordance with the approved, revised BART determination for SJGS. Table 5-2 shows NO_X and SO_2 emission reductions resulting from the implementation of BART at SJGS through to the end of 2018.

Table 5-2: San Juan Generating Station Declining NOx and SO2 emissions resulting from the implementation of BART through to the end of the first planning period, Dec 31, 2018. [109]

5.3.3 New Source Review Program

The New Source Review (NSR) Program is a permit program for the construction of new stationary sources and modification of existing stationary sources established by 20.2.72 NMAC – Construction Permits; 20.2.74 NMAC – Permits – Prevention of Significant Deterioration; and 20.2.79 NMAC – Permits – Nonattainment Areas. The primary purposes of the NSR Program are to assure compliance with the NAAQS, which provide public health protection; assure that Best Available Control Technology is utilized for major facilities subject to 20.2.74 NMAC to prevent deterioration of air quality in areas that are attaining the NAAQS; and assure that the Lowest Achievable Emission Rate and emission offsets are required for major facilities subject to 20.2.79 NMAC to move areas that are not attaining the NAAQS towards attainment. New Mexico has been granted the authority by EPA to implement the state's NSR Program, and all state regulations are up to date with 40 CFR § 51.166. [110].

20.2.79 NMAC sets forth permitting requirements for new major stationary sources or major modifications of existing stationary sources if those sources will be: (1) located within a nonattainment area so designated pursuant to Section 107 of the CAA and will emit a regulated pollutant for which it is major and which the area is designated nonattainment for; or (2) located within an area designated as attainment or unclassifiable for any NAAQS pursuant to Section 107 of the CAA, when it would cause or contribute to a violation of any NAAQS. A major source or major modification will be considered to cause or contribute to a violation of a NAAQS when such source or modification would, at a minimum, exceed any of the significance levels in Subsection A of 20.2.79.119 NMAC at any location that does not or would not meet the applicable national standard. [111]

The EPA designated a portion of Doña Ana County near Sunland Park, New Mexico as a marginal nonattainment area for the 2015 Ozone NAAQS on August 3, 2018, requiring a determination of adequacy of 20.2.79 NMAC, and submittal to EPA by August 3, 2021.20.2.79 NMAC was subsequently analyzed to determine if it was adequate to implement and enforce the standard. The AQB compared 20.2.79 NMAC with 40 CFR § 51.165, Permit Requirements, and identified certain inconsistencies and errors. On June 25, 2021, at a hearing before the EIB, the AQB presented proposed amendments to make technical and administrative corrections to the rule which were adopted by the EIB. This proposed SIP revision was submitted to EPA on August 10, 2021, and approved on November 16, 2022, effective December 16, 2022. [112]

New Mexico's Prevention of Significant Deterioration (PSD) program is protective of visibility impairment from proposed major stationary sources or major modifications to existing facilities. New Mexico has a fully approved PSD program and has successfully implemented this program since 1984. [113]

[113] Progress Report for the SIP for Regional Haze, March 11, 2014, p. 8.

5.3.4 Mobile Sources

Section 309 of the Regional Haze Rule required the First Period SIP to perform projections demonstrating a continuous decline in mobile source emissions [114] from 2003 to 2018. [115] If projected emissions did not in fact demonstrate a continuous decline forecast to occur over that period, then the First Period SIP would have been required to consider other control measures for mobile sources. [116] Such consideration was not necessary because the First Period SIP did in fact demonstrate a projected continuous decline in mobile source emissions for the period 2003 to 2018. Section 309 also required an interim report to EPA and the public in the year 2018 on the status of regional and local control strategies for mobile sources. [117] The progress report in this Chapter addresses that requirement (see Section 5.4.5 – Mobile Sources).

5.3.5 Fire/Smoke Management

Section 309 of the Regional Haze Rule required the First Period SIP to include programs for managing visibility-impairing emissions caused by prescribed fire sources. [118] In 2003, the EIB adopted 20.2.65 NMAC - Smoke Management, effective December 31, 2003. The AQB subsequently developed the state Smoke Management Program (SMP) to protect the health and welfare of New Mexicans from the impacts of smoke from all sources of fire. This SMP meets the requirements of the CAA and the Regional Haze Rule.

The SMP is applicable in all of New Mexico, except for Tribal lands and Bernalillo County, which are separate air quality jurisdictions. Burners must also comply with all city and county ordinances relating to smoke management and vegetation burning. The New Mexico Smoke Management Program Guidance Document was revised May 25, 2005, to assist burners in understanding the requirements and aid in the implementation of 20.2.65 NMAC. [119] The First Period SIP contained all elements required by Section 309. It continues to provide fire and smoke management programs under 20.2.65 NMAC - Smoke Management, to help control prescribed fire-related emissions of volatile organic compounds (VOC), NO_X, elemental carbon, organic carbon, and $PM_{2.5}$. The regulation requires that most prescribed burning in New Mexico be conducted under a permit (registration) from the AQB subject to specific requirements, including: reporting of emissions for use in emissions inventories; consideration of alternatives to burning; use of enhanced smoke management techniques recommended by the WRAP; and use of specific emission reduction techniques. The AQB implemented this regulation throughout the period since the most recent progress report and continues to rely on this regulation to achieve its fire and smoke management goals. The AQB is not proposing amendments to this regulation at this time.

[114] For the Regional Haze Rule definition of the term "continuous decline in mobile source emissions," *see* 40 CFR § 309(b)(6). The "continuous decline" is a decline in "the projected level of emissions" from mobile sources, forecast to occur in the future, after submittal of the First Period SIP.
[115] 40 CFR § 51.309(d)(5)(i).
[116] 40 CFR § 51.309(d)(5)(i)(A).
[117] 40 CFR § 51.309(d)(5)(ii). This regulatory provision requires a report on implementation status of mobile source control strategies recommended by the predecessor organization to WRAP, the GCVTC. For purposes of the progress report presented in this Chapter, the relevant control strategy being discussed here is the projection made in the First Period SIP of a continuous decline in mobile source emissions for the years 2003 to 2018.
[118] 40 CFR § 309(d)(6).
[119] Progress Report for the SIP for Regional Haze, March 11, 2014, p. 9.

5.3.6 Fugitive and Unpaved Road Dust

Section 309 of the Regional Haze Rule required the First Period SIP to include an assessment of the impact on visibility conditions in the 16 Class I Areas on the Colorado Plateau of regional-scale dust emissions by WRAP states from paved and unpaved roads.[120] If such dust emissions are determined to be a significant contributor to visibility impairment in these Class I Areas, then a SIP must implement emissions management strategies to address the impact as necessary and appropriate. The First Period SIP conducted the required assessment and determined, based on WRAP data, that regional-scale dust emissions for the purpose of the Regional Haze Rule were not a significant contributor to visibility impairment within the 16 Colorado Plateau Class I Areas.

5.3.7 Pollution Prevention - Renewable Energy Goals

Section 309 of the Regional Haze Rule required that the First Period SIP describe programs that New Mexico and Albuquerque - Bernalillo County would rely upon for the state's contribution toward renewable energy goals set forth by the GCVTC for states in the Grand Canyon visibility transport region.[121] Those goals provided that ". . . [renewable energy] will comprise 10% of [the power needs in transport region states] by 2005 and 20% by 2015."[122] Consistent with the GCVTC goals and the intent of the programs described, available information on renewable energy's role in meeting New Mexico's power needs indicates increasing reliance on such energy over time. The U.S. Energy Information Administration estimates that in 2018 wind power accounted for almost 19% of New Mexico's electricity generation, utility scale solar photovoltaic accounted for 4%, and small scale, customer-sited solar photovoltaic accounted for about 1%.[123]

In addition, the New Mexico Renewable Energy Act, as amended, requires that the state's publicly owned electric utilities obtain 15% of their total retail sales from renewable energy by 2015 and 20% by 2020, with smaller, additional requirements for percentages of retail electricity sales applicable to rural electric cooperatives for these years.[124] New Mexico's governor signed amendments to this state law in

---

[120] 40 CFR § 309(d)(7).

[121] 40 CFR § 51.309(d)(8)(vi). Section 309 did not require numerical quantification (for example, as a percentage) of New Mexico's "contribution" toward the GCVTC regional renewable energy goals. Accordingly, the First Period SIPs for New Mexico and Albuquerque - Bernalillo County described the state's contribution in terms of numerous renewable energy programs whose implementation would be consistent with the regional renewable energy goals. Section 309 also required the First Period SIP to describe or provide for several other pollution prevention programs. 40 CFR § 51.309(d)(8)(i) to (v). EPA found that the First Period SIP met these requirements. 77 Fed. Reg. 70693 (November 27, 2012) (Approval and Promulgation of State Implementation Plans; State of New Mexico; Regional Haze Rule Requirements for Mandatory Class I Areas).

[122] GCVTC, Recommendations for Improving Western Vistas (June 1996), p. 35. Section 309 did not define "renewable energy". It did define "eligible renewable energy resource" as "electricity generated by non-nuclear and non-fossil low or no air emission technologies." 40 CFR § 51.309(b)(13). The latter term does not appear in the Regional Haze Rule.

[123] U.S. Energy Information Administration, New Mexico State Profile and Energy Estimates (last updated February 20, 2020), available at https://www.eia.gov/state/analysis.php?sid=NM, accessed August 14, 2020.

[124] These requirements are codified in NMSA 1978 § 62-15-34 (setting renewable energy portfolio requirements for rural electric cooperatives); NMSA 1978 § 62-16-4 (setting renewable energy portfolio requirements for publicly owned utilities). Although the state legislature has amended these statutes several times during the first and second Regional Haze planning periods, these amendments did not change the obligation of publicly owned electric utilities and rural electric cooperatives to meet the retail electricity sale requirements for 2015 and 2020 noted above.

2019 requiring publicly owned electric utilities to account for 40% of retail electricity sales from renewables by 2025, 50% by 2030, 80% by 2040, and 100% by 2045, with smaller, additional requirements for percentages of retail sales by rural electric cooperatives during the same time span. [125]

This control measure was limited to the period of time through 2018 and will not be further addressed in this Regional Haze SIPr Rd 2 (2019-2028) or in subsequent progress reports.

5.3.8 Implementation of Additional GCVTC Recommendations

Section 309 of the Regional Haze Rule required that the First Period SIP provide for implementation of all other recommendations in the GCVTC's report that can be practicably included as enforceable emission limits, schedules of compliance, or other enforceable measures (including economic incentives) to make reasonable progress toward remedying existing and preventing future regional haze in the 16 Class I Areas on the Colorado Plateau. [126] Section 309 states must provide a report to EPA and the public in 2018 on the progress toward developing and implementing policy or strategy options recommended in the GCVTC's report.

The First Period SIP evaluated the GCVTC's 1996 report, Recommendations for Improving Western Vistas, to first determine which recommendations were not already incorporated into 40 CFR § 51.309, and then to determine whether any of those additional recommendations could be practicably included in the First Period SIP. After this evaluation, none of the GCVTC's additional recommendations that were not already incorporated into 40 CFR § 51.309 were included in the First Period SIP, which noted a lack of supporting modeling or technical guidance from WRAP necessary to evaluate the additional recommendations. This situation has not changed as of the submittal of this Regional Haze SIPr Rd 2 (2019-2028). Further, New Mexico is proposing that this Regional Haze SIPr Rd 2 (2019-2028) be adopted under Section 308, with an accordingly different process for assessing potential new control measures necessary to make reasonable progress at Class I Areas potentially affected by New Mexico emissions. [127] Therefore, this Regional Haze SIPr Rd 2 (2019-2028) will not further evaluate the additional recommendations of the GCVTC.

This control measure was limited to the first planning period and will not be further addressed in this Regional Haze SIPr Rd 2 (2019-2028) or in subsequent progress reports.

5.4 Summary of Emission Reductions Achieved by Control Measure Implementation

The progress report must provide: "A summary of the emissions reductions achieved throughout the State through implementation of the measures described in [40 CFR § 51.308(g)(1)." [128]

[125] *Id*.
[126] 40 CFR § 51.309(d)(9).
[127] As noted earlier, in the preamble to the January 10, 2017 Regional Haze Rule, EPA clarified that future periodic comprehensive SIP revisions and progress reports from the Section 309 states will be subject to the requirements of Section 308.
[128] 40 CFR § 51.308(g)(2).

5.4.1 SO_2 Milestone and Backstop Trading Program

Emission reductions attributable to this control measure were addressed in Section 5.3.1 – SO2 Milestone and Backstop Trading Program.

5.4.2 Best Available Retrofit Technology

Emission reductions attributable to this control measure were addressed in Section 5.3.2 – Best Available Retrofit Technology.

5.4.3 New Source Review Program

Emission reductions attributable to this control measure were addressed in Section 5.3.3 – New Source Review Program.

5.4.4 Mobile Sources

As discussed in Section 5.3.5 – Mobile Sources, Section 309 required an interim report to EPA and the public in the year 2018 on the status of regional and local control strategies for mobile sources. This Section presents data from WRAP consistent with a decline in mobile source emissions over the period 2003 to 2018.

Table 5-3 presents data from WRAP on emissions of coarse mass (particulate matter), fine soil (particulate matter), primary organic aerosols, and elemental carbon over the period 2000 to 2013 for the combined source categories of on-road mobile and off-road mobile. Table 5-4 presents data from WRAP on emissions of PM_{10} and $PM_{2.5}$ over the period 2014 to 2018 for the combined source categories of on-road mobile and non-road mobile. The differences in WRAP's emission inventory methodology for these periods are explained in Section 5.5 – Assessment of Visibility Conditions.

Table 5-3: New Mexico Mobile Source Emissions (On-Road Mobile + Off-Road Mobile) Over the Period 2000 to 2013 (Selected information from New Mexico Progress Report, 3/11/2014, Tables 3.27, 3.28, 3.29, and 3.30, and WRAP TSS Archived, IWDW-2011).

Year	Coarse Mass (Particulate Matter) (TPY)	Fine Soil (Particulate Matter) (TPY)	Primary Organic Aerosols (TPY)	Elemental Carbon (TPY)
2002 (Plan02d)	403 + 0 = 403	429 + 0 = 429	653 + 563 = 1,216	756 + 1,526 = 2,282
2008 (WEstJump2008)	2,994 + 41 = 3,035	258 + 25 = 283	1,506 + 349 = 1,855	2,999 + 457 = 3,456
2011 (IWDW-2011)	588.73 + 38.47 = 627	206.34 + 0 = 206	798.24 + 596.31 = 1,395	1256.67 + 405.96 = 1,662

Table 5-4: New Mexico Mobile Source Emissions (On-Road Mobile and Non-Road Mobile) Over the Period 2014 to 2018 (WRAP TSS - Emissions Data Analysis - Express Tools).

Year	PM_{10} (TPY)	$PM_{2.5}$ (TPY)
2014v2 Actual	3,361 + 674 = 4,035	2,171 + 640 = 2,811
Representative Baseline 2	3,361 + 626 = 3,987	2,171 + 597 = 2,768

5.4.5 Fire/Smoke Management

Emission reductions attributable to this control measure were addressed in Section 5.3.6 – Fire/Smoke Management.

5.4.6 Fugitive and Unpaved Road Dust

As discussed in Section 5.3.7 – Fugitive and Unpaved Road Dust, regional-scale dust emissions for the purpose of the Regional Haze Rule were determined to not be a significant contributor to visibility impairment within the 16 Colorado Plateau Class I Areas. Emission tables that include fugitive dust and unpaved road dust include:

- Table 5-16: New Mexico Coarse Mass Emissions by Category 2000 - 2013 (From Table 3.30, NM Progress Report, 3/11/14, p. 43 and WRAP TSS Archived)
- Table 5-17: New Mexico PM10 Emissions 2014 - 2018 (WRAP Technical Support System - Emissions Data Analysis - Express Tools – New Mexico PM10 emissions summary)
- Table 5-18: 5-19 New Mexico Fine Soil Emissions by Category 2000 - 2013 (From Table 3.29, NM Progress Report, 3/11/14, p. 42 and WRAP TSS Archived, IWDW-2011)
- Table 5-19: 5-20 New Mexico PM2.5 Emissions 2014 - 2018 (WRAP Technical Support System - Emissions Data Analysis - Express Tools - PM2.5 emissions summary)

NMED doesn't have a way of precisely attributing emission reductions to its program for fugitive dust from unpaved roads or stationary sources but is presenting this information for context.

5.4.7 Pollution Prevention - Renewable Energy Goals

As discussed in Section 5.3.8 – Pollution Prevention - Renewable Energy Goals, the State of New Mexico and Albuquerque-Bernalillo County have dramatically expanded their use of renewable energy in recent years. This Section presents data from WRAP on New Mexico's emissions of sulfur dioxide and nitrogen oxides from point sources over the period 2000 to 2018 to provide context regarding the state's ongoing transition to renewable energy sources. Table 5-5 presents data from WRAP on emissions of sulfur dioxide and nitrogen oxides over the period 2000 to 2013 for the Point source category.
Table 5-6 presents data from WRAP on emissions of sulfur dioxide and nitrogen oxides over the period 2014 to 2018 for the EGU Point, Oil & Gas Point, and Remaining Non-EGU Point source categories.

Table 5-5: New Mexico Point Source Emissions Over the Period 2000 to 2013 (From NM Progress Report, 3/11/2014: Table 3.23, p. 36; Table 3.24, p. 37 and WRAP TSS Archived, IWDW 2011).

Year	SO_2 (TPY)	NO_X (TPY)
2002 (Plan02d)	37,436	100,387
2008 (WestJump2008)	24,681	62,502
2011 (IWDW 2011)	19,943	48,085

Table 5-6: New Mexico Point Source Emissions (EGU Point + Oil & Gas Point + Remaining Non-EGU Point) Over the Period of Years 2014 Through 2018 (WRAP Technical Support System - Emissions Data Analysis - Express Tools).

Year	SO_2 (TPY)	NO_X (TPY)
2014v2 Actual	11,911 + 8,642 + 303 = 20,856	43,071 + 31,437 +3,720 = 78,228
Representative Baseline 2	3,665 + 8,641 +627 = 12,933	15,964 + 31,244 + 4,036 = 51,244

In 2021 and 2022, the two remaining New Mexico coal-fired power plants on non-Tribal land (Prewitt Escalante Generating Station and San Juan Generating Station) were decommissioned. In 2022 wind energy accounted for 35% of New Mexico's total in-state electricity generation, surpassing coal for the first time. At the beginning of 2023, the state ranked ninth in the nation in wind capacity with approximately 4,400 megawatts installed. [129] In 2022, renewable resources accounted for the largest share – about 42% - of New Mexico's in-state electricity generation from utility-scale (1 megawatt or larger) and small-scale (less than 1 megawatt) facilities combined. [130]

5.5 Assessment of Visibility Conditions

The progress report requirement is as follows: "For each mandatory Class I Federal area within the State, the State must assess the following visibility conditions and changes, with values for most impaired, least impaired and/or clearest days as applicable expressed in terms of 5-year averages of these annual values. The period for calculating current visibility conditions is the most recent 5-year period preceding the required date of the progress report for which data are available as of a date 6 months preceding the required date of the progress report." [131] The visibility conditions and changes to be assessed depend on when the progress report is due; progress reports due before January 31, 2025 must assess: "The current visibility conditions for the most impaired and least impaired days," [132]; "[t]he difference between current visibility conditions for the most impaired and least impaired days and baseline visibility conditions," [133]; and "[t]he change in visibility impairment for the most impaired and least impaired days over the period since the period addressed in the most recent plan required under [40 CFR § 51.308(f)]." [134]

The material presented in Chapter 3 of this Regional Haze SIPr Rd 2 (2019-2028) addresses these progress report requirements. Table 5-7 provides a crosswalk comparison of these requirements and the tables in Chapter 3 where the information can be found.

[129] U.S. Energy Information Administration, New Mexico State Profile and Energy Estimates (last updated May 18, 2023), available at https://www.eia.gov/state/analysis.php?sid=NM, accessed September 28, 2023.
[130] *Id*.
[131] 40 CFR § 51.308(g)(3). Because the required date of this embedded progress report was July 31, 2021, the period for calculating current visibility conditions pursuant to 40 CFR § 51.308(g)(3) (2014-2018) is different than the period for calculating current visibility conditions pursuant to 40 CFR § 51.308(f)(1)(3) (2019-2023). Therefore, current visibility conditions for purposes of this embedded progress report are referred to as first period end point visibility conditions in Chapter 3 of this Regional Haze SIPr Rd 2 (2019-2028).
[132] 40 CFR § 51.308(g)(3)(i)(A).
[133] 40 CFR § 51.308(g)(3)(ii)(A).
[134] 40 CFR § 51.308(g)(3)(iii)(A).

Table 5-7: Embedded Progress Report Requirement to Chapter 3 Crosswalk.

Embedded Progress Report Requirement	Table No. – Column Heading
40 CFR § 51.308(g)(3)(i) The current visibility conditions for the most impaired and least impaired days.	Table 3-2: Visibility Conditions in New Mexico Class I Areas, 20% Most Impaired Days (in dv) and Table 3-3: Visibility Conditions in New Mexico Class I Areas, 20% Clearest Days (in dv) –First Period End Point Visibility Conditions (2014-2018 avg.)
40 CFR § 51.308(g)(3)(ii) The difference between current visibility conditions for the most impaired and least impaired days and baseline visibility conditions.	Table 3-2 and Table 3-3 –Difference Between First Period End Point and Baseline Visibility Conditions
40 CFR § 51.308(g)(3)(iii) The change in visibility impairment for the most impaired and least impaired days over the period since the period addressed in the most recent plan required under [40 CFR § 51.308(f)].	Table 3-2 and Table 3-3 –Change from First Period Midpoint to First Period End Point Conditions

5.6 Analysis Tracking the Change in Emissions Contributing to Visibility Impairment from all Sources and Activities within the State over Time

The progress report must provide: "An analysis tracking the change over the period since the period addressed in the most recent plan required under [40 CRF § 51.308(f)] in emissions of pollutants contributing to visibility impairment from all sources and activities within the State. Emissions changes should be identified by type of source or activity. With respect to all sources and activities, the analysis must extend at least through the most recent year for which the state has submitted emission inventory information to the Administrator in compliance with the triennial reporting requirements of Subpart A of [40 CFR Part 51] as of a date six months preceding the required date of the progress report. With respect to sources that report directly to a centralized emissions data system operated by the Administrator, the analysis must extend through the most recent year for which the Administrator has provided a State-level summary of such reported data or an internet-based tool by which the State may obtain such a summary as of a date six months preceding the required date of the progress report. The State is not required to backcast previously reported emissions to be consistent with more recent emissions estimation procedures, and may draw attention to actual or possible inconsistencies created by changes in estimation procedures." [135]

This Section presents an analysis of emissions of haze causing pollutants in New Mexico over time, by type of source or activity, using data provided by WRAP. EPA's April 2013 General Principles for the 5-Year Regional Haze Progress Reports for the Initial Regional Haze State Implementation Plans states that the reports should, ideally, present the most recent available data for emissions inventories performed five years apart, or as approximate as practicable given the methodology and availability of emissions

[135] 40 CFR § 51.308(g)(4).

inventories.[136] This Regional Haze SIPr Rd 2 (2019-2028) uses WRAP 2002 data to represent the 2000-2004 baseline period meteorological and emissions data, WRAP 2008 data to represent the 2005-2009 progress period meteorological and emissions data, WRAP 2011 data to represent the 2010-2013 progress period meteorological and emissions data, and WRAP 2014 data to represent the 2014-2018 progress period meteorological and emissions data.[137] Collectively, then, this Section will present WRAP data that is the most recent available and that covers the most recent period of approximately five years for which data is available in practical terms (2014 to 2018).

The WRAP data for 2002, 2008, and 2011 describe emissions inventories for the following pollutants: sulfur dioxide, nitrogen oxides, ammonia, volatile organic compounds, coarse particulate matter,[138] fine particulate matter,[139] primary organic aerosols,[140] and elemental carbon.[141] The WRAP data for 2014 describes emissions inventories for the following pollutants: sulfur dioxide, oxides of nitrogen, ammonia gas,[142] volatile organic compounds, PM_{10}, and $PM_{2.5}$. Changes in estimation procedures for the 2014 WRAP data mean that the pollutants coarse particulate matter, fine particulate matter, primary organic aerosols, and elemental carbon were not individually included. Instead, emissions inventories were included for PM_{10} and $PM_{2.5}$. Additionally, changes in estimation procedures for the 2014 WRAP data mean that the other pollutants - sulfur dioxide, nitrogen oxides, ammonia, and volatile organic compounds - are also not comparable to WRAP data for earlier periods. This Regional Haze SIPr Rd 2 (2019-2028) will not backcast previously reported emissions to be consistent with more recent emissions estimation procedures, nor will it speciate PM_{10}, and $PM_{2.5}$ into coarse particulate matter, fine particulate matter, primary organic aerosols, and elemental carbon.

---

[136] EPA, General Principles for the 5-Year Regional Haze Progress Reports for the Initial Regional Haze State Implementation Plans, April 2013 ("EPA 2013 Guidance"), pp. 11-12.

[137] On the methodology for WRAP emissions inventories, see, for example, Zac Adelman and B.H. Baek, Three-State Air Quality Modeling Study Emissions Modeling Report: Simulation Years 2008 and 2011 (University of North Carolina at Chapel Hill, Institute for the Environment and ENVIRON Corporation), available by contacting the WRAP, http://wrapair2.org/; Cyndi Loomis, Zac Adelman, and Ralph Morris, Technical Memorandum No. 1: Point Source Emissions (March 15, 2013) (addressing the subject of "Point Source Emissions, including Electricity Generating Units (EGUs) and non EGUs, for the WestJumpAQMS 2008 Photochemical Modeling"), available at http://www.wrapair2.org/pdf/Memo1_PointSources_Mar15_2013final.pdf; Mobile Source Emissions (June 2011) (addressing the mobile source inventory scope and methodology) available at http://vista.cira.colostate.edu/docs/wrap/emissions/TSS%20Mobile%20Emissions%20June%202011.doc; Run Specification Sheet: Representative Baseline and 2028 On-The-Books CAMx Simulations (February 27, 2020) (addressing the inputs for developing domains that are representative of the 2014-2018 period) available at https://views.cira.colostate.edu/docs/iwdw/platformdocs/WAQS_2014/Run_Spec_WRAP_2014_Task2.3-RepBase_Task%204.4-2028_CAMx_v3.pdf.

[138] Coarse mass is reported by the IMPROVE network as the difference between PM_{10} and $PM_{2.5}$ mass measurements. Coarse mass is not separated by species in the same way that $PM_{2.5}$ is speciated, but these measurements are generally associated with crustal components. Similar to crustal $PM_{2.5}$, natural windblown dust is often the largest contributor to coarse mass. WRAP 2013 Summary Report, p. 6-223.

[139] Fine soil is reported here as the crustal or soil components of $PM_{2.5}$. WRAP 2013 Summary Report, p. 6-223.

[140] Primary organic aerosols represent organic aerosols that are emitted directly as particles, as opposed to gases. Wildfires in the west generally dominate primary organic aerosol emissions, and large wildfire events are generally sporadic and highly variable from year-to-year. WRAP 2013 Summary Report, p. 6-223.

[141] Large elemental carbon events are often associated with large particulate organic matter events during wildfires. Other sources include both on- and off-road diesel engines. WRAP 2013 Summary Report, p. 6-223.

[142] Despite a change in nomenclature from "ammonia" in the 2002, 2008, and 2011 WRAP emissions inventories to "ammonia gas" in the 2014 WRAP emission inventory, all of the emissions inventories are reporting on the pollutant "ammonia gas", with a chemical composition of NH_3.

Table 5-8 through Table 5-21, below, present the 2002, 2008, 2011, and 2014 WRAP data for the pollutants sulfur dioxide, nitrogen oxides, ammonia gas, volatile organic compounds, coarse particulate matter, PM_{10}, fine particulate matter, primary organic aerosols, elemental carbon, and $PM_{2.5}$ for all anthropogenic source categories. Collectively, this data covers the years 2000 through 2018. All values in the below tables are rounded to the nearest whole number, meaning that some results may show an emissions amount of zero.

5.6.1 Sulfur Dioxide Emissions 2000 – 2018

Table 5-8: New Mexico Sulfur Dioxide Emissions by Category 2000 - 2013 (From Table 3.23, NM Progress Report 3/11/2014, p. 36 and WRAP TSS Archived, IWDW-2011).

Source Category	Sulfur Dioxide Emissions (tons/year)

5.7 Assessment of Significant Changes in Anthropogenic Emissions from Within or Outside the State

The progress report must provide: "An assessment of any significant changes in anthropogenic emissions within or outside the State that have occurred since the period addressed in the most recent plan required under [40 CFR § 51.308(f)] including whether or not these changes in anthropogenic emissions were anticipated in that most recent plan and whether they have limited or impeded progress in reducing pollutant emissions and improving visibility." [143]

5.7.1 Significant emissions reductions

5.7.1.1 SO_2 Milestone and Backstop Trading Program

Figure 5-1: 2003 - 2021 SO_2 Milestones and Emission Trends, shows that the regional SO_2 emissions have always met the milestone since the inception of the SO_2 Milestone and Backstop Trading Program. Table 5-1 further shows that participating states have held emissions below 60% of the milestone every year since 2014. Regional SO_2 emissions decreased from 92,553 tons in 2014 to 71,994 tons in 2018.

[143] 40 CFR § 51.308(g)(5).

5.7.1.2 Best Available Retrofit Technology

Emission reductions attributable to this control measure were discussed in Section 5.3.2: Best Available Retrofit Technology. A summary of first planning period estimated reductions is provided in Table 5-22. First planning period reductions were approximately 12,213 tons NO_X and 5,458 tons SO_2.

Table 5-22: Estimated reductions from BART at SJGS during first planning period.

Avg.	NO_X (tons)	SO_2 (tons)7
2008-2010	18,764	6,809
2018-2020	6,551	1,352
Total estimated reductions	12,213	5,458

5.7.1.3 Mobile Sources

Section 309 of the Regional Haze Rule required the First Period SIP to perform projections demonstrating a continuous decline in mobile source emissions [144] from 2003 to 2018. The data shown in Section 5.4.4 – Mobile Sources, confirmed this overall decline.

5.7.1.4 Pollution Prevention - Renewable Energy Goals

New Mexico Point Source emissions over the period of Years 2000-2013, and also from 2014-2018 have continued to decrease due, in part, to less reliance on fossil-fuel electricity generation over time.

5.7.2 Visibility trends from baseline period to 2018.

Chapter 3: Ambient Data Analysis, details all of the Regional Haze Rule requirements for visibility reporting at each of New Mexico's Class I Areas. From the 2000-2004 baseline period to the 2014-2018 current period addressed in this progress report, all network sites showed improving visibility and progress toward the Regional Haze Rule goals of reducing impacts on the most impaired days while not backtracking during the clearest days.

A progress report due before January 31, 2025, will further assess "[t]he current visibility conditions for the most impaired and least impaired days." [145]

[144] For the Regional Haze Rule definition of the term "continuous decline in mobile source emissions," *see* 40 CFR § 309(b)(6). The "continuous decline" is a decline in "the projected level of emissions" from mobile sources, forecast to occur in the future, after submittal of the First Period SIP.

[145] 40 CFR § 51.308(g)(3)(i)(A).

Chapter 6: Selection of Sources for Control Measures Analysis

The Regional Haze Rule requires that each state select emission sources for an analysis for potential new emission reduction measures that may be cost-effective to implement at the source.[146] The New Mexico Environment Department (NMED) conducted a two-tiered source selection process in coordination with the City of Albuquerque Environmental Health Department (EHD) on a statewide basis, excluding Tribal jurisdictions. The two-tiered source selection was based on guidance from the U.S. Environmental Protection Agency (EPA) and the Western Regional Air Partnership (WRAP). This chapter describes the methods and results which identified 24 facilities (tier one), and 133 individual pieces of equipment or treatment systems at the 23 facilities within NMED's jurisdiction with the potential to emit sulfur dioxide (SO_2) and/or nitrogen oxides (NO_X) in quantities above NMED's threshold for requiring an analysis of potential new emission reduction measures (tier two).

6.1 Regulatory Requirements

- A Regional Haze State Implementation Plan (SIP) revision must "evaluate and determine the emission reduction measures that are necessary to make reasonable progress" at Class I Areas.[147]
- The SIP revision's evaluation of emission reduction measures "should consider evaluating major and minor stationary sources or groups of sources, mobile sources, and area sources."[148]
- The SIP revision must include "a description of the criteria it used to determine which sources or groups of sources it evaluated" that would be subject to analysis for potential new control measures.[149]

6.2 Tier One Q/d Assessment for Selecting New Mexico Facilities for Control Measures Analysis

For tier one of the source selection process, NMED and EHD utilized the Q/d method, based on recommendations from WRAP. This method sums the quantity of aerosol precursor pollutants emitted by the facility (NO_X plus SO_2) and divides it by the distance from the facility to the nearest Class I Area. This provides a screening-level estimate of the potential for pollutants from the facility to impact the Class I Area. The WRAP recommendations (hereinafter, the "WRAP Source Selection Protocol") were completed in February 2019 and subsequently approved by consensus by WRAP's Regional Haze Planning Work Group.[150] A contractor, Ramboll, then developed a database application for facilitating regionally-consistent western U.S. Regional Haze source screening to assist in determining which emission sources might potentially require Reasonable Progress controls.

NMED and EHD agreed upon a single, statewide procedure for tier one of the source selection process, based on the WRAP Source Selection Protocol. The procedure involved calculating Q/d scores for all

[146] 40 CFR § 51.308(f)(2)(i).
[147] *Id*.
[148] *Id*.
[149] *Id*.
[150] WRAP Regional Haze Planning Workgroup - Control Measures Subcommittee, WRAP Reasonable Progress Source Identification and Analysis Protocol for Second 10-Year Regional Haze State Implementation Plans, February 27, 2019. WRAP Regional Haze Planning Work Group consensus is documented at https://www.wrapair2.org/TSC_Docket.aspx.

New Mexico Title V facilities [151] and comparing them to a threshold value to identify facilities requiring an analysis of potential new emission reduction measures. NMED and EHD followed these steps to complete the tier one screening:

1) NMED and EHD calculated "Q" in the Q/d equation as the sum of annual reported NO_X and SO_2 emissions by Title V facilities for 2016.
    a. NMED and EHD chose NO_X and SO_2 as the targeted pollutants because monitoring data indicates that aerosol species related to emissions of these two precursor pollutants (i.e., ammonium nitrate and ammonium sulfate) are the key drivers of anthropogenic visibility impairment at Class I Areas, as described in Chapter 3 of this Regional Haze SIPr Rd 2 (2019-2028). NMED and EHD chose not to include PM_{10} or other pollutants in the Q component of the Q/d calculation (which the WRAP Source Selection Protocol had identified as potential candidates for the calculation) because emissions of those pollutants from Title V facilities would have been a negligible contributor to the overall Q/d score, based on the information available to NMED.
    b. EHD and NMED chose the emissions reported by Title V facilities in 2016 as the basis for "Q" in the Q/d equation based in part on consultation with the Federal Land Managers, who used 2016 reported emissions as the basis for their own independent assessments of the potential visibility impacts of facilities. Additionally, EPA used reported 2016 emissions data as the basis for its own Regional Haze modeling of emissions and their potential visibility impacts. [152] Finally, NMED and EHD judged that 2016 reported emissions were sufficiently representative of recent emissions of NO_X and SO_2 for Title V facilities in New Mexico for purposes of assessing the potential visibility impacts of emissions from those facilities and selecting which would be subject to further analysis for potential control measures to reduce visibility impairing pollutants.
2) NMED and EHD calculated "d" in the Q/d equation as the distance in kilometers from the centroid of each facility to the boundary of the nearest Class I Area.
3) Using these "Q" and "d" values, NMED and EHD calculated Q/d scores for every Title V facility in the state, including in Albuquerque - Bernalillo County. NMED and EHD then identified a Q/d threshold necessary to capture 80% of the total NO_X and SO_2 emissions from all New Mexico Title V facilities combined. NMED and EHD chose this 80% threshold based on guidance in the WRAP Source Selection Protocol. The Protocol noted draft guidance from EPA [153] recommending an 80% threshold applied to emissions from all stationary sources. However, the Protocol recognized that emissions information for some types of stationary sources and area sources might be lacking in particular jurisdictions. In view of the lack of such information for minor stationary sources and area sources in NMED's and EHD's jurisdictions, [154] NMED and EHD decided to conduct a source selection process for major (i.e. Title V) sources only, applying an

[151] A Title V facility is a major source requiring a Title V operating permit pursuant to 20.2.70 NMAC.
[152] Technical documentation for EPA's modeling is available at https://www.epa.gov/visibility/technical-support-document-epas-updated-2028-regional-haze-modeling (last accessed September 29, 2023).
[153] EPA, Draft Guidance on Progress Tracking Metrics, Long-term Strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period, July 2016.
[154] NMED and EHD lack detailed emissions inventory data for minor stationary sources and area sources for the current Regional Haze planning period. Sufficient statewide data was not available to adequately assess the potential visibility impact of such sources at Class I Areas. Therefore, NMED and EHD chose not to evaluate minor stationary sources or area sources for potential new control measures in the current Regional Haze planning period. Minor stationary sources and area sources may be addressed in future planning periods or addressed through other rule makings.

80% threshold to the sum of emissions from these sources. EHD and NMED consulted with Federal Land Managers on this approach and received a favorable response.

6.3 Tier One Q/d Assessment Results – Selected Sources

NMED and EHD performed the state-level Q/d assessment in June 2019. As described above, the goal of the assessment was to identity the Title V facilities with the highest Q/d scores responsible for 80% of the total NO_X and SO_2 emissions from all New Mexico Title V facilities combined (i.e. adding the sum of those two pollutants together for all such facilities in the state), including facilities in Albuquerque - Bernalillo County. The assessment indicated that a Q/d threshold of 5.6 would achieve this goal. In all, 24 facilities had an individual Q/d score of 5.6 or greater. Therefore, NMED and EHD determined that those 24 facilities would each be required to perform a four-factor analysis (Chapter 7) to assess potential new emission reduction measures that may be cost-effective to implement. Several facilities selected to perform a four-factor analysis based on the Q/d assessment were nearest or in proximity to Class I Areas in neighboring states (Mesa Verde National Park, CO and Guadalupe Mountains National Park, TX).

Table 6-1 provides a list of all 134 Title V facilities included in NMED and EHD's tier one source screening and information related to the Q/d assessment for each facility, including: the name of the facility; the agency interest ("AI") number (for sources in NMED's jurisdiction); the Q/d score; the 2016 emissions information ("Q" term); the distance to the nearest Class I Area ("d" term); the name of the nearest Class I Area; and cumulative emissions, both in tons and as a percent of the total for all facilities combined, demonstrating that a Q/d threshold of 5.6 captures 80% of the total NO_X and SO_2 emissions from all New Mexico Title V facilities. Only one facility with a Q/d score above the threshold is located in Albuquerque - Bernalillo County under EHD's jurisdiction, the GCC Tijeras portland cement plant.

1

Figure 6-1 shows the locations of all 24 Title V facilities selected to perform a four-factor analysis in relationship to New Mexico's and neighboring states' Class I Areas.

Figure 6-1: Location of Facilities Selected to Perform a Four-Factor Analysis Based on NMED and EHD's Q/d Assessment.

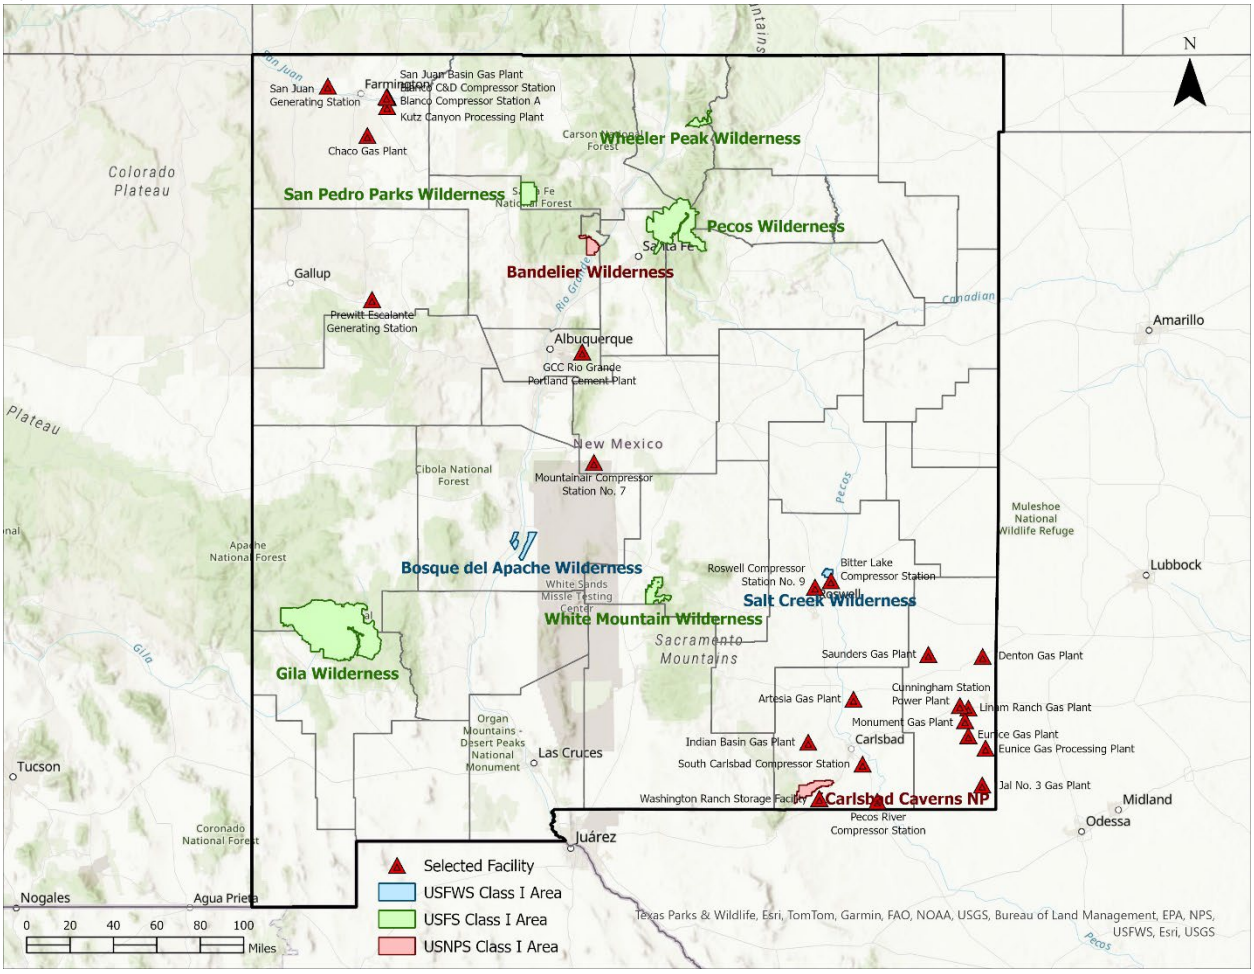

Table 6-2 shows the percentage of total statewide combined NO_X and SO_2 emissions from Title V facilities and the number of facilities responsible for that percentage of emissions at different Q/d thresholds. For example, a Q/d threshold of 10 or more would capture 13 Title V facilities responsible for 69.89% of the total NO_X and SO_2 emissions from all New Mexico Title V facilities combined. As noted above, NMED and EHD decided to use a Q/d threshold of 5.6, which captures 24 Title V facilities responsible for 80.69% of the total NO_X and SO_2 emissions from all New Mexico Title V facilities combined in 2016 .

Table 6-2: Statewide 2016 Title V Facility NOX and SO2 Emissions Captured by Various Q/d Thresholds.

Q/d Threshold	Number of Title V Sources Captured by Threshold	NO_X + SO_2 Emissions Captured by Threshold (tons per year)	% of Annual NO_X + SO_2 Emissions Captured by Threshold
10 or more	13	35,129	69.89%
9	14	35,415	70.46%
8	15	35,944	71.51%
7	20	39,246	78.08%
6	20	39,246	78.08%
5.7	23	40,201	79.98%
5.6	24	40,558	80.69%

6.4 Tier Two PTE Screen for Selecting Individual Source Equipment Requiring a Four-Factor Analysis

After selecting facilities to perform a four-factor analysis based on the Q/d assessment described above, NMED and EHD developed a secondary (tier two) screen to identify individual equipment for which an analysis of potential new control measures for NO_X and/or SO_2 would be required. Title V facilities are often complex and usually have numerous regulated sources of air pollutants. Each source typically has its own allowable emission limit, which is calculated using the maximum rated capacity of the source, accounting for any federally enforceable physical or operational limits (e.g., restricted operating hours) the source is subject to. Such limits are also known as potential to emit (PTE) and are listed in Title V operating permits and other types of air quality permits (e.g., construction permits).

In order to focus on the most significant sources of NO_X and SO_2 at the selected facilities and expend their limited resources where they would have the greatest impact in terms of reducing anthropogenic visibility impairment at Class I Areas, NMED and EHD determined that a four-factor analysis would only be required on individual equipment with a PTE greater than ten pounds per hour of NO_X or SO_2 pursuant to the facility's latest Title V operating permit. NMED further determined that equipment exempt under 20.2.72 NMAC – Construction Permits (e.g., emergency generators subject to stringent operating restrictions) or insignificant under 20.2.70 NMAC – Operating Permits, as well as equipment that emits less than five tons per year of NO_X or SO_2, did not need to undergo an analysis. At all but a few selected facilities within NMED's jurisdiction, equipment meeting these screening criteria accounts, in the aggregate, for over 90 percent – and in some cases 100 percent – of the facility's total allowable NO_X and/or SO_2 emissions.

NMED applied a tier two Potential to Emit (PTE) screen to the 23 facilities selected to perform a four-factor analysis in its jurisdiction after completing its Q/d assessment in June 2019. The screen identified 133 individual pieces of equipment or treatment systems with the potential to emit SO_2 and/or NO_X in quantities above NMED's 10 pounds per hour threshold and therefore requiring a four-factor analysis for NO_X, SO_2, or both. Table 6-3 summarizes all equipment requiring a four-factor analysis at the 23 facilities selected by NMED. Chapter 7 of this Regional Haze SIPr Rd 2 (2019-2028) describes these analyses for all screened equipment at the 23 facilities within NMED's jurisdiction.

Table 6-3: Tally of Individual Equipment Category Sources Selected in Tier-2 Screening.

Chapter 7: Four-Factor Analyses and Reasonable Progress Control Measures Determinations

This chapter provides the Regional Haze Rule requirements for determining what control measures are necessary to make reasonable progress and describes how NMED developed the cost/ton threshold used to identify cost-effective controls and how NMED determined which cost-effective controls are necessary to make reasonable progress. This chapter also summarizes the results of NMED's four-factor analyses and control measures determinations for selected sources.

7.1 Regulatory Requirements

The Regional Haze Rule requires that this Regional Haze SIPr Rd 2 (2019-2028) contain an evaluation of the emission reduction measures that are necessary to make reasonable progress toward natural visibility conditions in Class I Areas in New Mexico, as well as in Class I Areas outside New Mexico that may be affected by emissions from New Mexico.[157] In determining which measures are necessary to make reasonable progress, states are required to consider four statutory factors, including "the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment."[158] Hence, these evaluations are commonly referred to as four-factor analyses.

7.2 Controls Evaluated

NMED first identified all commercially available NO_X and/or SO_2 controls for the various types of units selected for analysis via the two-tiered screening process described in Chapter 6. These types of units include two-stroke lean burn engines (2SLB RICE), four-stroke lean burn engines (4SLB RICE), four-stroke rich burn engines (4SRB RICE), combustion turbines (CT), industrial and utility boilers, and amine treatment systems (ATS). NMED then determined which of the commercially available controls are technically feasible, as a four-factor analysis is only required for technically feasible controls. Based on the information available, NMED determined that the following controls are technically feasible for the units selected for analysis:[159]

- 2SLB RICE: Low-Emission Combustion (LEC), replacement and electrification.
- 4SLB RICE: LEC, Selective Catalytic Reduction (SCR), replacement, and electrification.
- 4SRB RICE: LEC, Non-Selective Catalytic Reduction (NSCR), replacement and electrification.
- CT: Dry Low NO_X Combustion (DLN), SCR, replacement, and electrification. For certain turbine models, water or steam injection (WSI) is also technically feasible.
- Boilers: Low NO_X Burners (LNB), Flue Gas Recirculation (FGR), SCR, and replacement.
- ATS: Flaring, sulfur recovery unit (SRU), thermal oxidizer (TO), and acid gas injection (AGI) well.

NMED received feedback from some of the facilities selected for analysis in the second planning period suggesting that replacement and electrification are outside the scope of the Regional Haze program and

[157] 40 CFR 305(f)(2)(i).

[158] *Id*.

[159] Good combustion practices (GCP) and retirement were also identified as technically feasible controls for all types of units selected for analysis. However, all screened facilities utilize GCP already based on their compliance with various provisions of their Title V permits, and with just a few exceptions, all facilities indicated that they do not plan to permanently retire any of the units selected for analysis. Therefore, NMED generally excluded these control options from its analyses.

that states are limited to considering new add-on controls (i.e., retrofits) and upgrades to existing controls under the program. NMED discussed this issue with EPA Region 6 staff, and they indicated that replacement and electrification are not outside the scope of the program given the prodigious flexibility afforded to states by the Regional Haze Rule. In addition, NMED's Office of General Counsel performed its own analysis and determined that NMED has the legal authority under the Regional Haze program to require replacement and electrification. Therefore, NMED evaluated the cost effectiveness of these options for those sources for which they are technically feasible, along with that of retrofits and upgrades to existing controls.

7.3 Cost of Compliance

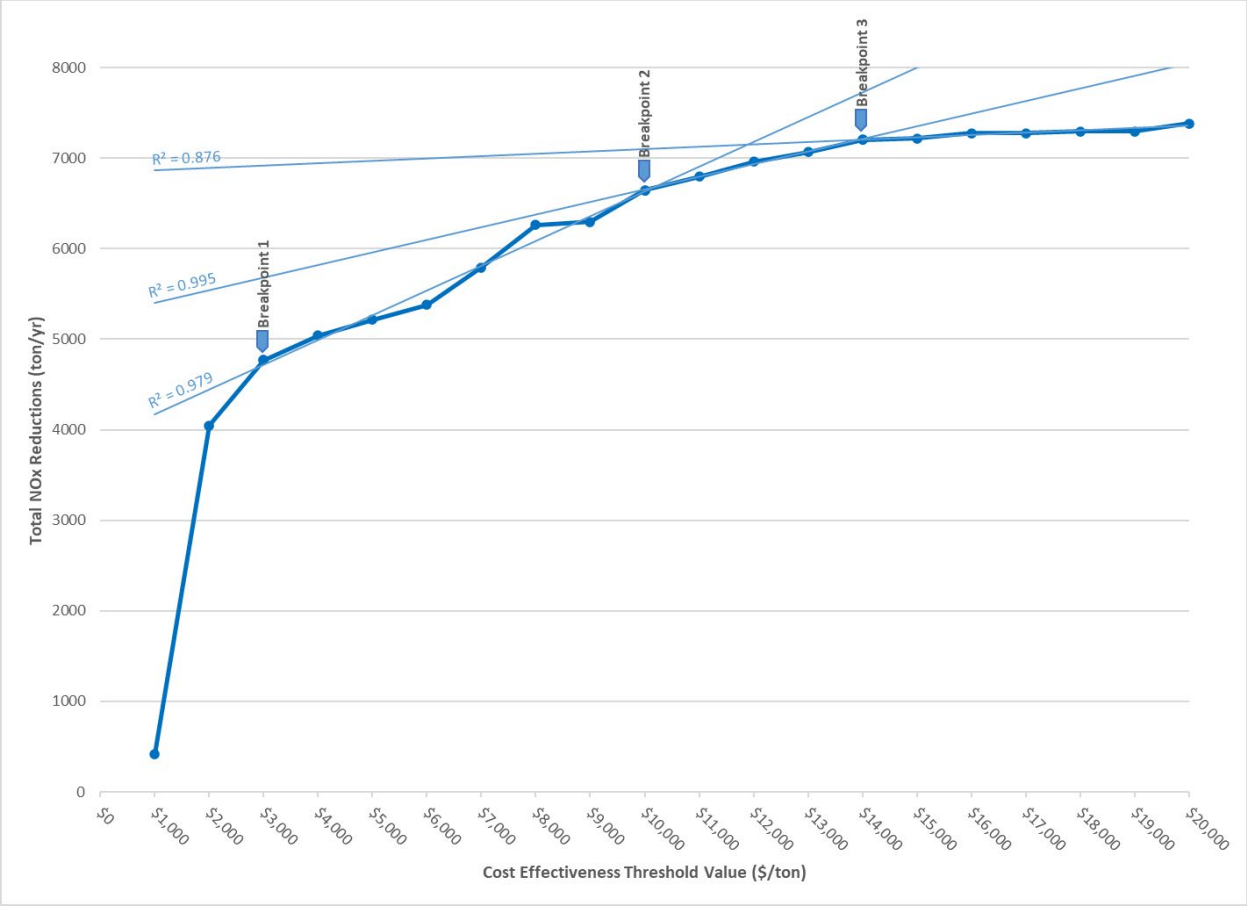
After determining which controls are technically feasible, NMED performed a four-factor analysis of all technically feasible controls for all units that met the tier two screening criteria described in Chapter 6. To characterize the cost of compliance, which was the predominant factor in NMED's decision-making regarding control measures, NMED calculated the cost effectiveness of each control, expressed in terms of cost per ton of emissions reduced. NMED utilized source-specific cost estimates provided by the facilities in its calculations whenever possible. In cases where facilities failed to provide source-specific cost estimates or NMED found estimates provided by facilities to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including -four-factor analyses developed for similar facilities in New Mexico and other states, to estimate costs.

Consistent with EPA guidance, [160] NMED chose to apply a cost effectiveness threshold value (CETV) to remove control measures deemed not cost-effective from further consideration. To determine its CETV, which represents the cost effectiveness value above which further incremental reductions in NO_X emissions are insufficient to justify more expensive controls, NMED catalogued the available controls, identified the most effective controls available at potential CETVs ranging from $1,000/ton to $20,000/ton, and then determined the estimated total and incremental NO_X reductions provided by the most effective controls at each potential CETV. NMED then binned the incremental NO_X reductions and performed a segmented linear regression on a plot of the estimated total NO_X reductions with breakpoints at the bin edges. The results are shown in Figure 7-1. The binning and associated regression analysis showed that incremental NO_X reductions were significant up to $10,000/ton and then decreased by approximately 50%, with an even larger decrease at $14,000/ton. This led NMED to identify $10,000/ton as its CETV.

After completing its initial analysis, NMED decided to categorically exclude electrification from further consideration, for reasons discussed in Section 7.4.2. NMED also revised some of its underlying cost estimates due to ongoing data quality assurance efforts and comments from stakeholders. Therefore, NMED removed electrification from its catalogue of available controls and updated its CETV analysis using the revised cost estimates. The results are shown in Figure 7-2. The binning and associated regression analysis for the updated analysis continue to show that incremental NO_X reductions are significant up to $10,000/ton then decrease by approximately 50%, with an even larger decrease at $13,000/ton (versus $14,000/ton in the original analysis).

[160] EPA Regional Haze SIP Guidance, p. 38.

Figure 7-1. Estimated total NOX reductions at increasing CETVs with segmented linear regression (initial analysis).



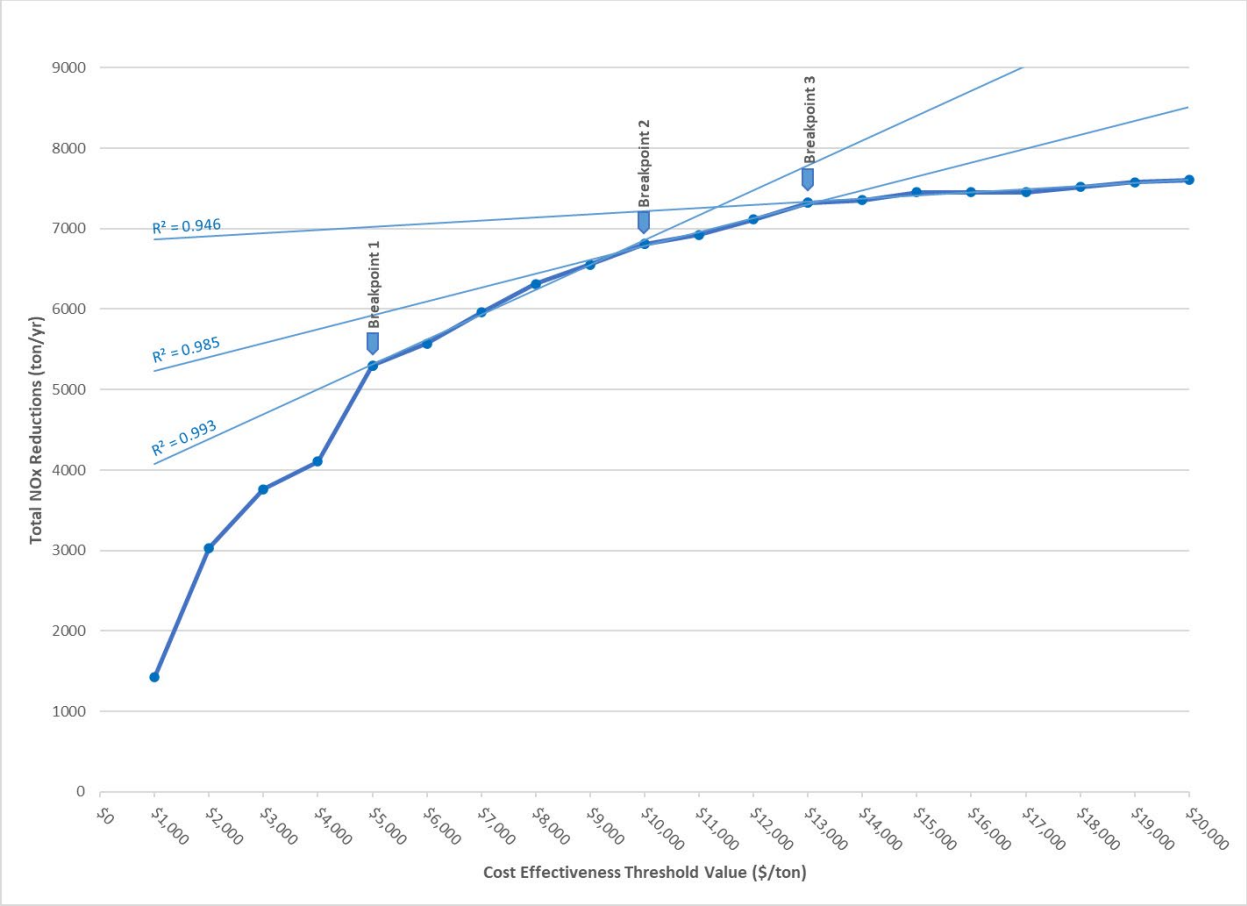


Figure 7-2. Estimated total NOX reductions at increasing CETVs with segmented linear regression (updated analysis).

Due to the similarity of the revised estimated total NO_X reductions plot to the original, and the fact that the breakpoints are nearly identical on both plots with the key breakpoint occurring at $10,000/ton, NMED decided to retain $10,000/ton as its CETV. NMED surveyed other states' second period SIPs, and $10,000/ton is within the range of CETVs proposed by other states. As such, NMED believes $10,000/ton strikes a reasonable balance, providing significant emissions reductions and, by extension, visibility benefits without subjecting New Mexico sources to more costly and burdensome requirements than sources in other states.

7.4 Selection of Controls

7.4.1 Baseline decision-making approach

Cost effectiveness was the predominant factor in NMED's decision-making regarding necessary control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance, whereas compliance time, which is more important at the next step, i.e., determining reasonable deadlines for installing selected controls, was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not directly consider the visibility benefits of potential control measures when making its control determinations. EPA has

consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making control determinations. [161] NMED's approach is based on the assumption that substantial reductions in emissions of NO_X and SO_2 will translate into visibility benefits.

As discussed in Section 7.3, NMED identified $10,000/ton as the threshold value above which further incremental reductions in NO_X emissions are insufficient to justify more expensive controls. With one notable exception, discussed in Section 7.4.2, for emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent control (i.e., the one providing the greatest estimated NO_X reductions) is necessary to make reasonable progress.

7.4.2 Exceptions

The sole exception to NMED's baseline decision-making approach involves electrification. Electrification entails replacing a natural gas-fired compressor driver (reciprocating engine or combustion turbine) with a zero-emitting electric motor drive (EMD), making it one of the most effective controls available. NMED developed numerous cost estimates for electrification, and with only a few exceptions, the cost effectiveness of electrification far exceeded NMED's CETV of $10,000/ton. For the few facilities for which the cost effectiveness was below the CETV, NMED had concerns about the reliability of the estimates. Electrification generally involves significant ancillary costs associated with upgrading electrical infrastructure to handle the increased load associated with EMDs. These upgrades can include upgrading or building new electrical substations and upgrading or installing new high voltage transmission lines to the facility. Detailed engineering studies, which are rarely available, are generally needed to accurately assess specific infrastructure needs and reliably estimate costs. Further complicating matters is uncertainty regarding the willingness and ability of local utility providers to service the increased load associated with EMDs, even assuming all of the infrastructure upgrades necessary to support electrification are completed, and how the costs for any new energy resources that must be acquired would be apportioned. Based on these and other uncertainties, NMED determined that electrification, despite its obvious benefits, should be categorically excluded from selection as the reasonable progress control as there are simply too many unknowns to reliably estimate the costs involved and/or determine whether it is truly feasible.

[161] EPA, Responses to Comments on Protection of Visibility: Amendments to Requirements for State Plans (December 2016) at 186 ("While the CAA lists the four reasonable progress factors, it is silent as to whether states or the EPA may consider other, additional factors. This final rule neither requires nor prohibits states from considering visibility when making reasonable progress determinations."). *See also* EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) at 28 ("Section 169A(g)(1) of the CAA lists four factors that must be taken into consideration in determining reasonable progress … The visibility benefit of an emission reduction measure is not listed as a required factor, but neither the CAA nor the Regional Haze Rule prohibits a state from considering visibility benefits when it determines what emission control measures are required for a source to make reasonable progress at a Class I area. Therefore, a state **may** consider the visibility benefits of potential control measures when determining what is necessary to make reasonable progress.")(emphasis added).

7.4.3 Implementation of controls

NMED's reasonable progress control measures determinations are not prescriptive. That is, a determination by NMED that a particular control is necessary for reasonable progress does not mean the source must install that control. Instead, NMED is imposing new emissions limitations in this Regional Haze SIPr Rd 2 (2019-2028) commensurate with controls deemed necessary for reasonable progress and leaving it up to facilities to determine how to comply. This means a facility could elect to install a different control than the one NMED determined is necessary for reasonable progress, as long as the alternative is capable of meeting the new limit. This approach is intended to give facilities the flexibility to consider factors beyond the four statutory factors considered by NMED when deciding how to comply with Regional Haze requirements. For example, if NMED determines that reasonable progress requires the installation of LEC on a 2SLB RICE, and the engine has already been in service for decades and is becoming more difficult and costly to maintain, the facility could opt to replace it with a new, lower-emitting engine instead of retrofitting it with LEC – even if NMED rejected replacement on cost effectiveness grounds – because the facility believes that the enhanced reliability and extended service life a new engine outweighs the additional upfront cost and thus represents a better business decision.

7.5 Four-Factor Analyses and Reasonable Progress Control Measures Determinations

NMED's four-factor analyses and reasonable progress control measures determinations for the 23 facilities selected for analysis in the second planning period are described in detail in Appendix C and summarized below. Supporting documentation for NMED's cost estimates and cost effectiveness determinations is provided in Appendix D.

7.5.1 Davis Gas Processing, Inc. – Denton Gas Plant

7.5.1.1 Facility Description

Denton Gas Plant (DGP) is a former natural gas processing facility previously located 11 miles east of Lovington in Lea County, New Mexico at latitude 33^{o} 2' 38", longitude -103^{o} 10' 15". It was owned and operated by Davis Gas Processing, Inc. (Davis), and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Chapter 6 in 2019. However, Davis subsequently shut down DGP on December 1, 2022, and submitted an administrative permit revision closing NSR Permit No. 0065-M8 and voluntarily discontinuing Title V Operating Permit No. P079-R3 on February 2, 2022. Davis demolished the facility shortly thereafter.

7.5.1.2 Summary of Four-Factor Analysis

NMED originally selected DGP's ATS for an analysis of potential control measures for SO_2 in the second planning period due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). However, because DGP has since been shut down and demolished, NMED did not perform a FFA of potential control measures for the ATS. There is no more effective control for an ATS than retirement, which reduces emissions by 100 percent. Therefore, NMED has determined that DGP's ATS is already effectively controlled by virtue of its retirement, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

7.5.1.3 Control Measures Determination

Because it is already effectively controlled, NMED determined that reasonable progress does not require new controls on the ATS at DGP.

7.5.2 DCP Operating Company, LP – Artesia Gas Plant

7.5.2.1 Facility Description

Artesia Gas Plant (AGP) is a natural gas processing facility located 13 miles east-southeast of Artesia in Eddy County, New Mexico at latitude 32° 45' 18", longitude -104° 12' 36". It is owned and operated by DCP Operating Company, LP (DCP), and currently operates under Title V Operating Permit No. P095-R4, which expires on March 8, 2028. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 39.8 miles.

The function of the facility is to process natural gas, including condensate removal, H2S and CO2 removal with an amine unit, separation of natural gas liquids through the cryogenic plant, and inlet and residue compression. The facility is authorized for continuous operation, and its total potential to emit is 476.0 tons per year of NO_X and 389.3 tons per year of SO_2.

7.5.2.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for the ATS at AGP due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED's analysis of the four statutory factors is discussed in detail in Section C.5.2.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
ATS	Redundant Compression	$16,000	2-3	20	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.2.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that there are no cost-effective controls for the ATS at AGP. Therefore, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.3 DCP Operating Company LP – Eunice Gas Plant

7.5.3.1 Facility Description

Eunice Gas Plant (EGP) is a former natural gas processing facility located 7 miles northwest of Eunice in Lea County, New Mexico at latitude 32° 30' 31", longitude -103° 17' 08". It was owned and operated by DCP and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Chapter 6 in 2019. However, DCP subsequently entered into a Settlement Agreement and Stipulated Compliance Order (SASFCO) with NMED on September 10, 2021, which required DCP to permanently cease operations at EGP within 60 days. As required by the SASFCO, DCP shut down EGP on June 6, 2021, and submitted an administrative permit revision closing NSR Permit No. 0044-M11R1 and voluntarily discontinuing Title V Operating Permit No. P086-R2 on November 3, 2021.

7.5.3.2 Summary of Four-Factor Analysis

NMED originally selected EGP's five combustion turbines for an analysis of potential control measures for NO_X in the second planning period. NMED also elected to evaluate the ATS at EGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). However, because EGP has since been shut down and decommissioned pursuant to the SASFCO, NMED did not perform a FFA of potential control measures for any of these units. There is no more effective control for a turbine or ATS than retirement, which reduces emissions by 100 percent. Therefore, NMED has determined that EGP's turbines and ATS are already effectively controlled by virtue of their retirement, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

7.5.3.3 Control Measures Determination

Because they are already effectively controlled, NMED determined that reasonable progress does not require new controls on the turbines or ATS at EGP.

7.5.4 DCP Operating Company, LP – Linam Ranch Gas Plant

7.5.4.1 Facility Description

Linam Ranch Gas Plant (LRGP) is a natural gas processing facility located 7 miles west of Hobbs in Lea County, New Mexico at latitude 32° 41' 43", longitude -103° 17' 07". It is owned and operated by DCP and currently operates under Title V Operating Permit No. P094-R3, which expires on December 18, 2025. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 72.7 miles.

The function of the facility is to remove hydrogen sulfide, water and carbon dioxide from field natural gas and separate natural gas liquids (NGL) from the field natural gas stream. The facility is authorized for continuous operation, and its total potential to emit is 973.5 tons per year of NO_X and 87.1 tons per year of SO_2.

7.5.4.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for NO_X for six (6) 2SLB RICE and four (4) combustion turbines at LRGP that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.4.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
6	LEC	$15,000	2-3	20	None
	Replacement	$22,000	3-4	30	None
	Electrification	$35,000	4-6	25	None
7	LEC	$13,000	2-3	20	None
	Replacement	$20,000	3-4	30	None
	Electrification	$31,000	4-6	25	None
8	LEC	$15,000	2-3	20	None
	Replacement	$15,000	3-4	30	None
	Electrification	$24,000	4-6	25	None
9	LEC	$5,000	2-3	20	None
	Replacement	$15,000	3-4	30	None
	Electrification	$24,000	4-6	25	None
10	LEC	$14,000	2-3	20	None
	Replacement	$14,000	3-4	30	None
	Electrification	$24,000	4-6	25	None
11	LEC	$24,000	2-3	20	None
	Replacement	$23,000	3-4	30	None
	Electrification	$36,000	4-6	25	None
29	SCR	$124,000	3-4	20	None
	Replacement	-$315,000 [(2)]	3-4	30	None
	Electrification	$1,106,000	4-6	25	None
30	SCR	$70,000	3-4	20	None
	Replacement	-$1,373,000 [(2)]	3-4	30	None
	Electrification	$604,000	4-6	25	None
31	SCR	$27,000	3-4	20	None
	Replacement	$501,000	3-4	30	None
	Electrification	$188,000	4-6	25	None
32B	SCR	$30,000	3-4	20	None
	Replacement	N/A [(3)]	3-4	30	None
	Electrification	$181,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.
[(2)] Negative cost effectiveness is an artifact of NMED's method for calculating this value and does not accurately represent the cost effectiveness of the control. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and were not considered further.
[(3)] Because estimated reductions are zero, and division by zero is undefined, cost effectiveness cannot be calculated for replacement of this unit.

NMED also evaluated the ATS at LRGP due to the potential for significant SO_2 emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED concluded that a FFA of potential control measures for SO_2 for the ATS was not required because the most effective ATS control available – an AGI well with redundant compression – is already being utilized at LRGP.

7.5.4.3 Control Measures Determination

NMED's FFA did not identify any cost-effective controls for LRGP Units 6, 7, 8, 9, 10, 11, 29, 30, 31, or 32B. Therefore, NMED determined that reasonable progress does not require new controls on any of these units. However, as discussed in Section 8.2.3, Units 29, 30, 31, and 32B are already equipped (or in the process of being equipped) with DLN, which was a major, if not the deciding factor in the outcome of NMED's analyses. As a result, NMED determined that continued use of the existing controls on these units is necessary for reasonable progress.

As noted above, NMED did not conduct a FFA of potential control measures for LRGP's ATS. Because the most effective control available – an AGI well with redundant compression – is already being utilized at LRGP, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.5 El Paso Natural Gas Company, LLC – Blanco Compressor Station A

7.5.5.1 Facility Description

Blanco Compressor Station A (BCSA) is a natural gas compressor station located 0.1 miles north of Bloomfield in San Juan County, New Mexico at latitude 36° 43' 42", longitude -107° 57' 21". It is owned and operated by El Paso Natural Gas Company, LLC (EPNG), a subsidiary of Kinder Morgan, and currently operates under Title V Operating Permit No. P048-R4, which expires on September 18, 2025. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 39.8 miles.

The function of the facility is to compress natural gas for the purpose of transportation to another facility or a major transportation pipeline. The facility is authorized for continuous operation, and its total potential to emit is 1344 tons per year of NO_X and 0.3 tons per year of SO_2.

7.5.5.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for NO_X for fourteen (14) 2SLB RICE at BCSA that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.5.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
A01	LEC1	$48,000	1-3	20	None
	LEC2	$42,000	1-3	20	None
	LEC3	$36,000	1-3	20	None
	Replacement	$23,000	3-4	30	None
A02	LEC1	$164,000	1-3	20	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
	LEC2	$122,000	1-3	20	None
	LEC3	$101,000	1-3	20	None
	Replacement	$65,000	3-4	30	None
A03	LEC1	$111,000	1-3	20	None
	LEC2	$60,000	1-3	20	None
	LEC3	$49,000	1-3	20	None
	Replacement	$31,000	3-4	30	None
A04	LEC1	-$103,000	1-3	20	None
	LEC2	$711,000	1-3	20	None
	LEC3	$286,000	1-3	20	None
	Replacement	$185,000	3-4	30	None
A05	LEC1	$2,975,000	1-3	20	None
	LEC2	$2,641,000	1-3	20	None
	LEC3	$2,245,000	1-3	20	None
	Replacement	$1,448,000	3-4	30	None
A06	LEC1	$114,000	1-3	20	None
	LEC2	$101,000	1-3	20	None
	LEC3	$86,000	1-3	20	None
	Replacement	$56,000	3-4	30	None
A07	LEC1	$40,000	1-3	20	None
	LEC2	$36,000	1-3	20	None
	LEC3	$30,000	1-3	20	None
	Replacement	$20,000	3-4	30	None
A08	LEC1	$177,879,000	1-3	20	None
	LEC2	$157,945,000	1-3	20	None
	LEC3	$134,231,000	1-3	20	None
	Replacement	$86,605,000	3-4	30	None
A09	LEC1	$58,000	1-3	20	None
	LEC2	$54,000	1-3	20	None
	LEC3	$46,000	1-3	20	None
	Replacement	$30,000	3-4	30	None
A10	LEC1	$80,854,000	1-3	20	None
	LEC2	$71,793,000	1-3	20	None
	LEC3	$61,014,000	1-3	20	None
	Replacement	$39,366,000	3-4	30	None
A11	LEC1	$11,000	1-3	20	None
	LEC2	$13,000	1-3	20	None
	LEC3	$11,000	1-3	20	None
	Replacement	$7,000	3-4	30	None
A12	LEC1	$235,000	1-3	20	None
	LEC2	$209,000	1-3	20	None
	LEC3	$177,000	1-3	20	None
	Replacement	$114,000	3-4	30	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
A13	LEC1	$14,000	1-3	20	None
	LEC2	$16,000	1-3	20	None
	LEC3	$14,000	1-3	20	None
	Replacement	$9,000	3-4	30	None
A14	LEC1	$84,000	1-3	20	None
	LEC2	$75,000	1-3	20	None
	LEC3	$63,000	1-3	20	None
	Replacement	$41,000	3-4	30	None
All Units	Electrification	$20,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.5.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
A11	Replacement	51.7
A13	Replacement	42.1

NMED did not identify any cost-effective controls for BCSA Units A01, A02, A03, A04, A05, A06, A07, A08, A09, A10, A12, or A14. Therefore, NMED determined that reasonable progress does not require new controls on any of these units.

7.5.6 El Paso Natural Gas Company, LLC – Pecos River Compressor Station

7.5.6.1 Facility Description

Pecos River Compressor Station (PRCS) is a natural gas compressor station located approximately 11.5 miles south-southeast of Malaga in Eddy County, New Mexico at latitude 32° 03' 49", longitude -104° 01' 06". It is owned and operated by EPNG and currently operates under Title V Operating Permit No. P129-R4, which expires on March 4, 2026. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 22.1 miles.

The function of the facility is to compress natural gas and deliver the compressed gas to a pipeline for mainline transportation. The facility is authorized for continuous operation, and its total potential to emit is 697.7 tons per year of NO_X and 5.6 tons per year of SO_2.

7.5.6.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for three (3) combustion turbines at PRCS that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.6.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
A-01	SCR	$13,000	3	20	None
	Replacement	$38,000	3-4	30	None
A-02	SCR	$8,000	3	20	None
	Replacement	$23,000	3-4	30	None
A-03	SCR	$9,000	3	20	None
	Replacement	$24,000	3-4	30	None
All Units	Electrification	$28,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.6.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
A-02	SCR	92.8
A-03	SCR	89.8

NMED's FFA did not identify any cost-effective controls for PRCS Unit A-01. Therefore, NMED determined that reasonable progress does not require new controls on this unit.

7.5.7 El Paso Natural Gas Company, LLC – Washington Ranch Storage Facility

7.5.7.1 Facility Description

Washington Ranch Storage Facility (WRSF) is a natural gas storage facility located 9.1 miles southwest of Whites City in Eddy County, New Mexico at latitude 32° 04' 54", longitude -104° 29' 04". It is owned and operated by EPNG and currently operates under Title V Operating Permit No. P064-R4M2, which expires on December 30, 2025. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 3.4 miles.

The function of the facility is to compress and inject natural gas into underground storage wells and to withdraw the gas for delivery into the pipeline. The facility is authorized for continuous operation, and its total potential to emit is 243.6 tons per year of NO_X and 4.8 tons per year of SO_2.

7.5.7.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for two (2) 2SLB RICE at WRSF that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.7.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
1	Replacement	$316,000	3-4	30	None
2	Replacement	$1,136,000	3-4	30	None
All Units	Electrification	$239,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.7.3 Control Measures Determination

NMED's FFA did not identify any cost-effective controls for WRSF Units 1 and 2. Therefore, NMED determined that reasonable progress does not require new controls on either of these units. However, as discussed in Section 8.2.3, both units are already equipped with LEC, which was a major, if not the deciding factor in the outcome of NMED's analyses. As a result, NMED determined that continued use of the existing controls on these units is necessary for reasonable progress.

7.5.8 Enterprise Field Services, LLC – Blanco C&D Compressor Station

7.5.8.1 Facility Description

Blanco C&D Compressor Station (BCDCS) is a natural gas compressor station located 2 miles northeast of Bloomfield in San Juan County, New Mexico at latitude 36° 43' 57", longitude -107° 57' 42". It is owned by Enterprise Field Services, LLC and operated by Enterprise Products Operating, LLC, and currently operates under Title V Operating Permit No. P218-R3, which expires on October 28, 2025. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 40 miles.

The function of the facility is to compress natural gas for the purpose of transportation to another facility or a major transportation pipeline. The facility is authorized for continuous operation, and its total potential to emit is 1332.6 tons per year of NO_X and 4.0 tons per year of SO_2.

7.5.8.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for three (3) combustion turbines at BCDCS that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.8.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
T-C01	WSI	$12,000	3-4	15	None
	SCR	$6,000	3-4	20	None
	Replacement	$34,000	3-4	30	None
	Electrification	$35,000	4-6	25	None
T-C02	WSI	$9,000	3-4	15	None
	SCR	$5,000	3-4	20	None
	Replacement	$32,000	3-4	30	None
	Electrification	$34,000	4-6	25	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
T-D01	DLN	$3,000	3-4	20	None
	WSI	$4,000	3-4	15	None
	SCR	$4,000	3-4	20	None
	Replacement	$26,000	3-4	30	None
	Electrification	$28,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.8.3 Control Measures Determination

NMED's FFA identified cost-effective controls for BCDCS Units T-C01, T-C02, and T-D01. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
T-C01	SCR	223.1
T-C02	SCR	230.4
T-D01	SCR	412.6

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
T-C02	WSI	Less stringent than SCR
T-D01	DLN	Less stringent than SCR
T-D01	WSI	Less stringent than SCR

7.5.9 Enterprise Field Services, LLC – Chaco Gas Plant

7.5.9.1 Facility Description

Chaco Gas Plant (CGP) is a natural gas processing facility located 14 miles southwest of Bloomfield in San Juan County, New Mexico at latitude 36° 29' 00", longitude -108° 07' 13". It is owned by Enterprise Field Services, LLC and operated by Enterprise Products Operating, LLC, and currently operates under Title V Operating Permit No. P116-R3, which expires on November 13, 2025. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 49.8 miles.

The function of the facility is to receive field natural gas, process the gas through removal of water, then extract/separate natural gas liquids (NGL) through a cryogenic process. Recovered NGL are then treated to remove carbon dioxide and hydrogen sulfide, and then delivered to a pipeline for transport to fractionation facilities downstream. The facility is authorized for continuous operation, and its total potential to emit is 2608.6 tons per year of NO_X and 91.8 tons per year of SO_2.

7.5.9.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for three (3) 2SLB RICE engines and five (5) combustion turbines at CGP that met the tier two screening criteria described in Chapter 6.

NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.9.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
12	LEC	$12,000	2-3	20	None
	Replacement	$20,000	3-4	30	None
	Electrification	$15,000	4-6	25	None
13	LEC	$30,000	2-3	20	None
	Replacement	$45,000	3-4	30	None
	Electrification	$30,000	4-6	25	None
14	LEC	$8,000	2-3	20	None
	Replacement	$13,000	3-4	30	None
	Electrification	$10,000	4-6	25	None
17	WSI	-$46,000	3-4	15	None
	SCR	$19,000	3-4	20	None
	Replacement	$131,000	3-4	30	None
	Electrification	$114,000	4-6	25	None
18	WSI	-$55,000	3-4	15	None
	SCR	$18,000	3-4	20	None
	Replacement	$119,000	3-4	30	None
	Electrification	$106,000	4-6	25	None
35	DLN	$11,000	3-4	20	None
	SCR	$11,000	3-4	20	None
	Replacement	$65,000	3-4	30	None
	Electrification	$63,000	4-6	25	None
36	DLN	$12,000	3-4	20	None
	SCR	$12,000	3-4	20	None
	Replacement	$67,000	3-4	30	None
	Electrification	$62,000	4-6	25	None
37	DLN	$13,000	3-4	20	None
	SCR	$13,000	3-4	20	None
	Replacement	$77,000	3-4	30	None
	Electrification	$67,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

NMED also elected to evaluate the ATS at CGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED concluded that a FFA of potential control measures for SO_2 for the ATS was not required because alternatives to the existing TO are either inferior, presumptively not cost effective, or both.

7.5.9.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
14	LEC	118.3

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
14	Electrification	Categorically excluded

NMED's FFA did not identify any cost-effective controls for CGP Units 12, 13, 17, 18, 35, 36, or 37. Therefore, NMED determined that reasonable progress does not require new controls on any of these units. As noted above, NMED did not conduct a FFA of potential control measures for CGP's ATS. Because the alternatives to the existing TO are either inferior, presumptively not cost effective, or both, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.10 Enterprise Field Services, LLC – South Carlsbad Compressor Station

7.5.10.1 Facility Description

South Carlsbad Compressor Station (SCCS) is a natural gas compressor station located 2.8 miles northwest of Loving in Eddy County, New Mexico at latitude 32° 18' 56", longitude -104° 08' 12". It is owned by Enterprise Field Services, LLC and operated by Enterprise Products Operating, LLC, and currently operates under Title V Operating Permit No. P130-R4, which expires on June 9, 2028. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 16.2 miles.

The function of the facility is to compress gas to direct to a pipeline for transport. The facility is authorized for continuous operation, and its total potential to emit is 211.3 tons per year of NO_X and 17.0 tons per year of SO_2.

7.5.10.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for two (2) combustion turbines at SCCS that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.10.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	DLN	$4,000	3-4	20	None
	SCR	$6,000	3-4	20	None
	Replacement	$23,000	3-4	30	None
	Electrification	$25,000	4-6	25	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
2	DLN	$4,000	3-4	20	None
	SCR	$7,000	3-4	20	None
	Replacement	$24,000	3-4	30	None
	Electrification	$25,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.10.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	DLN	68.0
2	DLN	67.7

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
1	SCR	Less stringent than DLN
2	SCR	Less stringent than DLN

7.5.11 ET Gathering & Processing LLC – Jal #3 Gas Plant

7.5.11.1 Facility Description

Jal #3 Gas Plant (JGP) is a natural gas processing facility located 4 miles north-northeast of Jal in Lea County, New Mexico at latitude 32° 10' 25", longitude -103° 10' 27". It is owned and operated by ET Gathering & Processing LLC – formerly ETC Texas Pipeline, LTD (ETC) – and currently operates under Title V Operating Permit No. P090-R3M1, which expired on March 27, 2024. [162] The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 70 miles.

7.5.11.2 Summary of Four-Factor Analysis

JGP was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Chapter 6 in 2019. NMED originally selected two (2) 2SLB RICE at JGP for an analysis of potential control measures for NO_X in the second planning period. NMED also elected to evaluate the ATS at JGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). However, due to subsequent changes at JGP, NMED did not perform a four-factor analysis for any of the emissions units at JGP.

[162] ETC submitted a timely application to renew Title V Operating Permit No. P090-R3M1 in March 2023. At the time of preparation of this Regional Haze SIPr Rd2 (2019-2028), NMED had not taken final action on the application. Pursuant to 20.2.70.201 NMAC, a Title V source may continue to operate after its operating permit expires if it has submitted a timely renewal application and meets other requirements.

As discussed in Section C.5.11 of Appendix C, ETC has retired the two 2SLB RICE originally selected for analysis and removed them from JGP's NSR permit. ETC has also reconfigured JGP's ATS, eliminating the SRU and adding redundant compression to the AGI well, which is now the primary control for the ATS. There is no more effective control for RICE than retirement, which reduces emissions by 100 percent, and an AGI well with redundant compression is the most effective control for ATS. Therefore, NMED has determined that these units are already effectively controlled, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

7.5.11.3 Control Measures Determination

Because they are already effectively- controlled, NMED determined that reasonable progress does not require new controls on the two retired 2SLB RICE originally selected for analysis or the ATS at JGP.

7.5.12 Transwestern Pipeline Company, LLC – Mountainair Compressor Station No. 7

7.5.12.1 Facility Description

Mountainair Compressor Station No. 7 (MCS) is a natural gas compressor station located 12 miles south-southwest of Mountainair in Torrance County, New Mexico at latitude 34^{o} 20' 29", longitude -106^{o} 17' 51". It is owned and operated by Transwestern Pipeline Company, LLC (TWP), and currently operates under Title V Operating Permit No. P153-R4, which expires on October 14, 2025. The shortest distance to the boundary of the nearest Class I Area, Bosque del Apache Wilderness Area, is approximately 50 miles.

The facility services a natural gas pipeline system, removing small amounts of entrained liquid from the gas stream before directing it back into the pipeline at a higher pressure. The facility is authorized for continuous operation, and its total potential to emit is 2263.5 tons per year of NO_X.

7.5.12.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for three (3) 4SLB RICE and two (2) 4SRB RICE at MCS that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.12.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
701	LEC	$3,000	2-5	20	None
	SCR	$1,000	2-5	20	None
702	LEC	$2,000	2-5	20	None
	SCR	$1,000	2-5	20	None
703	LEC	$2,000	2-5	20	None
	SCR	$1,000	2-5	20	None
721	LEC	$1,000	2-5	20	None
722	LEC	$6,000	2-5	20	None
All Units	Replacement	$3,000	3-4	30	None
	Electrification	$7,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.12.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
701	Replacement [(1)]	362.0
702	Replacement [(1)]	445.1
703	Replacement [(1)]	413.7
721	Replacement [(1)]	50.3
722	Replacement [(1)]	13.4

[(1)] The replacement scenario evaluated by NMED for MCS involves replacing Units 701, 702, and 703 two functionally equivalent CT and replacing Units 721 and 722 with microturbine generators.

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
701	LEC	Less stringent than replacement
701	SCR	Less stringent than replacement
701	Electrification	Categorically excluded
702	LEC	Less stringent than replacement
702	SCR	Less stringent than replacement
702	Electrification	Categorically excluded
703	LEC	Less stringent than replacement
703	SCR	Less stringent than replacement
703	Electrification	Categorically excluded
721	LEC	Less stringent than replacement
722	LEC	Less stringent than replacement

7.5.13 Transwestern Pipeline Company, LLC – Roswell Compressor Station No. 9

7.5.13.1 Facility Description

Roswell Compressor Station No. 9 (RCS) is a natural gas compressor station located 5 miles north of Roswell in Chaves County, New Mexico at latitude 33° 30' 37", longitude -104° 31' 08". It is owned and operated by TWP and currently operates under Title V Operating Permit No. P154-R4, which expired on September 28, 2023. [163] The shortest distance to the boundary of the nearest Class I Area, Salt Creek Wilderness Area, is approximately 5.6 miles.

[163] Transwestern Pipeline Company, LLC submitted a timely application to renew Title V Operating Permit No. P154-R4 in September 2022. At the time of preparation of this Regional Haze SIPr Rd2 (2019-2028), NMED had not taken final action on the application. Pursuant to 20.2.70.201 NMAC, a Title V source may continue to operate after its operating permit expires if it has submitted a timely renewal application and meets other requirements.

The facility services a natural gas pipeline system, removing small amounts of entrained liquid from the gas stream before directing it back into the pipeline at a higher pressure. The facility is authorized for continuous operation, and its total potential to emit is 1122.5 tons per year of NO_X and 0.8 tons per year of SO_2.

7.5.13.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for two (2) 4SLB RICE at RCS that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.13.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
903	LEC	$2,000	2-5	20	None
	SCR	$1,000	2-5	20	None
904	LEC	$6,000	2-5	20	None
	SCR	$2,000	2-5	20	None
All Units	Replacement	$3,000	3-4	30	None
	Electrification	$9,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.13.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
903	Replacement [(1)]	443.7
904	Replacement [(1)]	201.0

[(1)] The replacement scenario evaluated by NMED for RCS involves replacing Units 903 and 904 with one functionally equivalent CT.

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
903	LEC	Less stringent than replacement
903	SCR	Less stringent than replacement
903	Electrification	Categorically excluded
904	LEC	Less stringent than replacement
904	SCR	Less stringent than replacement
904	Electrification	Categorically excluded

7.5.14 Harvest Four Corners, LLC – Kutz Canyon Processing Plant

7.5.14.1 Facility Description

Kutz Canyon Processing Plant (KCPP) is a natural gas processing facility located approximately 3.5 miles south of Bloomfield, in San Juan County, New Mexico at latitude 36° 40' 11", longitude -107° 57' 42". It is owned and operated by Harvest Four Corners, LLC, and currently operates under Title V Operating Permit No. P097-R4, which expires on January 3, 2028. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 43.2 miles.

The function of the facility is to remove ethane and heavier hydrocarbons from natural gas through refrigerating lean oil absorption and cryogenic processes. The facility is authorized for continuous operation, and its total potential to emit is 603.3 tons per year of NO_X and 1.4 tons per year of SO_2.

7.5.14.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for eight (8) combustion turbines at KCPP that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.14.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
1	SCR	$6,000	3-4	20	None
	DLN	$6,000	2-3	20	None
	Replacement	$27,000	3-4	30	None
2	SCR	$8,000	3-4	20	None
	DLN	$7,000	2-3	20	None
	Replacement	$33,000	3-4	30	None
3	SCR	$11,000	3-4	20	None
	DLN	$11,000	2-3	20	None
	Replacement	$54,000	3-4	30	None
4	SCR	$8,000	3-4	20	None
	DLN	$8,000	2-3	20	None
	Replacement	$38,000	3-4	30	None
5	SCR	$9,000	3-4	20	None
	DLN	$9,000	2-3	20	None
	Replacement	$45,000	3-4	30	None
6	SCR	$8,000	3-4	20	None
	DLN	$16,000	2-3	20	None
	Replacement	$76,000	3-4	30	None
19	SCR	$8,000	3-4	20	None
	DLN	$10,000	2-3	20	None
	Replacement	$37,000	3-4	30	None
20	SCR	$10,000	3-4	20	None
	DLN	$12,000	2-3	20	None
	Replacement	$46,000	3-4	30	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
All Units	Electrification	$18,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.14.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	SCR	46.4
2	SCR	38.0
4	SCR	36.9
5	SCR	33.0
6	SCR	38.7
19	SCR	30.1
20	SCR	24.3

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
1	DLN	Less stringent than SCR
2	DLN	Less stringent than SCR
4	DLN	Less stringent than SCR
5	DLN	Less stringent than SCR
19	DLN	Less stringent than SCR

NMED's FFA did not identify any cost-effective controls for KCPP Unit 3. Therefore, NMED determined that reasonable progress does not require new controls on this unit.

7.5.15 Hilcorp Energy Company – San Juan Basin Gas Plant

7.5.15.1 Facility Description

San Juan Basin Gas Plant (SJBGP) is a natural gas processing facility located approximately 2 miles northeast of Bloomfield in San Juan County, New Mexico at latitude 36° 43' 57", longitude -107° 57' 59". It is owned and operated by Hilcorp Energy Company and currently operates under Title V Operating Permit No. P124-R4, which expires on March 10, 2028. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 39.6 miles.

The function of the facility is to extract and process natural gas liquids and residue gas products from field gas. The facility is authorized for continuous operation, and its total potential to emit is 1050.1 tons per year of NO_X and 18.3 tons per year of SO_2.

7.5.15.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for seven (7) combustion turbines at SJBGP that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.15.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
1	DLN	$351,000	2-3	20	None
	SCR	$10,000	3-4	20	None
	Replacement	$124,000	3-4	30	None
2	DLN	$237,000	2-3	20	None
	SCR	$10,000	3-4	20	None
	Replacement	$113,000	3-4	30	None
3	DLN	-$4,990,000 [2]	2-3	20	None
	SCR	$10,000	3-4	20	None
	Replacement	$130,000	3-4	30	None
4	DLN	$9,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$30,000	3-4	30	None
5	DLN	$9,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$30,000	3-4	30	None
6	DLN	$8,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$26,000	3-4	30	None
7	DLN	$9,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$28,000	3-4	30	None
All Units	Electrification	$31,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.
[2] Negative cost effectiveness is an artifact of NMED's method for calculating this value and does not accurately represent the cost effectiveness of the control. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and were not considered further.

NMED also elected to evaluate the ATS at SJBGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED concluded that a FFA of potential control measures for SO_2 for the ATS was not required because alternatives to the existing TO are either inferior, presumptively not cost effective, or both.

7.5.15.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	SCR	66.9
2	SCR	72.3
3	SCR	66.5
4	SCR	44.5
5	SCR	44.0
6	SCR	48.7
7	SCR	45.5

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
4	DLN	Less stringent than SCR
5	DLN	Less stringent than SCR
6	DLN	Less stringent than SCR
7	DLN	Less stringent than SCR

As noted above, NMED did not conduct a FFA of potential control measures for SJBGP's ATS. Because the alternatives to the existing TO are either inferior, presumptively not cost effective, or both, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.16 IACX Roswell, LLC – Bitter Lake Compressor Station

7.5.16.1 Facility Description

Bitter Lake Compressor Station (BLCS) is a natural gas compressor station located 13.3 miles northeast of Roswell in Chaves County, New Mexico at latitude 33° 33' 11", longitude -104° 23' 27". It is owned and operated by IACX Roswell, LLC, and is currently authorized as a synthetic minor source under New Source Review Permit No. 0274-M8. The facility previously operated as a major source under Title V Operating Permit No. P047-R3, which was cancelled at IACX's request on March 13, 2020. The shortest distance to the boundary of the nearest Class I Area, Salt Creek Wilderness Area, is approximately 1.1 miles.

The function of the facility is to gather casinghead gas from multiple wells and compress the gas using natural gas-fired compressor engines. The facility is authorized for continuous operation, and its total potential to emit is 79.6 tons per year of NO_X and 1.5 tons per year of SO_2.

7.5.16.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for two (2) 2SLB RICE at BLCS that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.16.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
C-891	LEC	-$9,000 [(2)]	2	20	None
	Replacement	$70,000	3-4	30	None
C-893	LEC	-$10,000 [(2)]	2	20	None
	Replacement	$82,000	3-4	30	None
All Units	Electrification	$46,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.
[(2)] Negative cost effectiveness is an artifact of NMED's method for calculating this value and does not accurately represent the cost effectiveness of the control. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and were not considered further.

7.5.16.3 Control Measures Determination

NMED's FFA did not identify any cost-effective controls for BLCS Units C-891 or C-893. Therefore, NMED determined that reasonable progress does not require new controls on either of these units. However, as discussed in Section 8.2.3, both units are already equipped with LEC, which was a major, if not the deciding factor in the outcome of NMED's analyses. As a result, NMED determined that continued use of the existing controls on these units is necessary for reasonable progress.

7.5.17 Oxy USA WTP Limited Partnership – Oxy Indian Basin Gas Plant

7.5.17.1 Facility Description

Indian Basin Gas Plant (IBGP) is a natural gas processing facility located 14.5 miles west of Carlsbad in Eddy County, New Mexico at latitude 32° 27' 50", longitude -104° 34' 27". It is owned and operated by Oxy USA WTP Limited Partnership and currently operates under Title V Operating Permit No. P103-R3, which expires on November 1, 2024. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 21.2 miles.

The function of the facility is to remove hydrogen sulfide, carbon dioxide, condensate and water from raw natural gas to make commercial natural gas. The facility also extracts natural gas products (propane and butane) from natural gas. The facility is authorized for continuous operation, and its total potential to emit is 363.0 tons per year of NO_X and 87.1 tons per year of SO_2.

7.5.17.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for three (3) CT at IBGP that met the tier two screening criteria described in Chapter 6. NMED also performed a FFA for all technically feasible control options for the ATS at IBGP due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.17.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
ES-06/07	DLN	$9,000	2-3	20	None
	SCR	$12,000	3-4	20	None
	Replacement	$27,000	3-4	30	None
ES-08/09	DLN	$9,000	2-3	20	None
	SCR	$12,000	3-4	20	None
	Replacement	$28,000	3-4	30	None
ES-10/11	DLN	$10,000	2-3	20	None
	SCR	$13,000	3-4	20	None
	Replacement	$38,000	3-4	30	None
All CT	Electrification	$31,000	4-6	25	None
ATS	Redundant Compression	$25,000	2-3	20	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.17.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
ES-06/07	DLN	36.5
ES-08/09	DLN	35.0
ES-10/11	DLN	29.0

NMED's FFA did not identify any cost-effective controls for the ATS at IBGP. Therefore, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.18 Public Service Company of New Mexico – San Juan Generating Station

7.5.18.1 Facility Description

San Juan Generating Station (SJGS) is a former 1,800 MW coal-fired electric power plant located 3 miles north of Waterflow in San Juan County, New Mexico at latitude 36° 48' 07", longitude -108° 26' 20". It is owned by Public Service Company of New Mexico (PNM) and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Chapter 6 in 2019. However, PNM subsequently shut down SJGS on or about November 1, 2022, and submitted an administrative permit revision closing NSR Permit No. 0063-M12R3 and voluntarily discontinuing Title V Operating Permit No. P062-R4M1 on December 27, 2022. PNM's demolition and remediation plan for the facility was approved by the San Juan County Commission on March 7, 2023, and demolition was initiated on July 10, 2023, with the majority of the work expected to be completed by the end of 2025.

7.5.18.2 Summary of Four-Factor Analysis

NMED originally selected SJGS' two coal-fired boilers for an analysis of potential control measures for NO_X and SO_2 in the second planning period. However, because SJGS has since been shut down and demolition is currently underway, NMED did not perform a FFA of potential control measures for these units. There is no more effective control for boilers than retirement, which reduces emissions by 100 percent. Therefore, NMED has determined that SJGS' boilers are already effectively controlled by virtue of their retirement, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

7.5.18.3 Control Measures Determination

Because they are already effectively controlled, NMED determined that reasonable progress does not require new controls on the two retired boilers at SJGS.

7.5.19 Targa Midstream Services, LLC – Eunice Gas Processing Plant

7.5.19.1 Facility Description

Eunice Gas Processing Plant (EGPP) is a natural gas processing facility located one mile southeast of Eunice in Lea County, New Mexico at latitude 32° 25' 28", longitude -103° 08' 50". It is owned by Versado Gas Processors, LLC and operated by Targa Midstream Services, LLC, and currently operates under Title V Operating Permit No. P109-R3M1, which expires on November 29, 2024. [164] The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 73.5 miles.

The function of the facility is to receive field natural gas, perform dehydration and removal of carbon dioxide and hydrogen sulfide, and separate natural gas liquids. The facility is authorized for continuous operation, and its total potential to emit is 2606.0 tons per year of NO_X and 482.0 tons per year of SO_2.

7.5.19.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for two (2) industrial boilers and seven (7) 2SLB RICE at EGPP that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors for these units is discussed in detail in Section C.5.19.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts (1)
B-01	FGR	$3,000	2-3	30	None
	LNB	$3,000	2-3	30	None
	SCR	$17,000	2-3	30	None
	Replacement	$8,000	3-4	30	None
B-02	FGR	$3,000	2-3	30	None
	LNB	$3,000	2-3	30	None
	SCR	$17,000	2-3	30	None

[164] Targa submitted a timely application to renew Title V Operating Permit No. P109-R3M1 on November 28, 2023. At the time of preparation of this Regional Haze SIPr Rd2 (2019-2028), NMED had not taken final action on the application.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
	Replacement	$8,000	3-4	30	None
C-01	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-02	LEC	$2,000	2-3	20	None
	Replacement	$3,000	3-4	30	None
C-03	LEC	$2,000	2-3	20	None
	Replacement	$3,000	3-4	30	None
C-04	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-05	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-06	LEC	$2,000	2-3	20	None
	Replacement	$3,000	3-4	30	None
C-07	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-01, C-02, C-03	Electrification	$2,000	4-6	25	None
C-04, C-05, C-06	Electrification	$2,000	4-6	25	None
C-07 and C-13	Electrification	$3,000	4-6	25	None

[1] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

NMED also evaluated the ATS at EGPP due to the potential for significant SO_2 emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED concluded that a FFA of potential control measures for SO_2 for the ATS was not required because the most effective ATS control available – an AGI well with redundant compression – is already being utilized at EGPP.

7.5.19.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
B-01	LNB	23.5
B-02	LNB	23.5
C-01	Replacement	194.5
C-02	Replacement	165.7
C-03	Replacement	162.4
C-04	Replacement	185.3
C-05	Replacement	195.2

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
C-06	Replacement	157.5
C-07	Replacement	180.0

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
B-01	FGR	Less stringent than LNB
B-01	Replacement	Same stringency as LNB but less cost-effective
B-02	FGR	Less stringent than LNB
B-02	Replacement	Same stringency as LNB but less cost-effective
C-01	LEC	Less stringent than replacement
C-01	Electrification	Categorically excluded
C-02	LEC	Less stringent than replacement
C-02	Electrification	Categorically excluded
C-03	LEC	Less stringent than replacement
C-03	Electrification	Categorically excluded
C-04	LEC	Less stringent than replacement
C-04	Electrification	Categorically excluded
C-05	LEC	Less stringent than replacement
C-05	Electrification	Categorically excluded
C-06	LEC	Less stringent than replacement
C-06	Electrification	Categorically excluded
C-07	LEC	Less stringent than replacement
C-07	Electrification	Categorically excluded

As noted above, NMED did not conduct a FFA of potential control measures for EGPP's ATS. Because the most effective control available – an AGI well with redundant compression – is already being utilized at EGPP, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.20 Targa Midstream Services, LLC – Monument Gas Plant

7.5.20.1 Facility Description

Monument Gas Plant (MGP) is a natural gas processing facility located 2.8 miles west of Monument in Lea County, New Mexico at latitude 32° 36' 38", longitude -103° 18' 44". It is owned by Versado Gas Processors, LLC and operated by Targa Midstream Services, LLC, and currently operates under Title V Operating Permit No. P110-R3M1, which expires on April 12, 2025. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 68.2 miles.

The function of the facility is to process natural gas through inlet separation, an amine system for acid gas removal (carbon dioxide and hydrogen sulfide), dehydration for water removal, and the separation of methane from natural gas liquids. The facility is authorized for continuous operation, and its total potential to emit is 1012.8 tons per year of NO_X and 372.9 tons per year of SO_2.

7.5.20.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for seven (7) 2SLB RICE at MGP that met the tier two screening criteria described in Chapter 6. NMED's analysis of the four statutory factors is discussed in detail in Section C.5.20.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
C-01	LEC	$11,000	2-3	20	None
	Replacement	$8,000	3-4	30	None
C-02	LEC	$5,000	2-3	20	None
	Replacement	$4,000	3-4	30	None
C-04	LEC	$20,000	2-3	20	None
	Replacement	$12,000	3-4	30	None
C-05	LEC	$4,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-06	LEC	$16,000	2-3	20	None
	Replacement	$7,000	3-4	30	None
C-24	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-28	LEC	$14,000	2-3	20	None
	Replacement	$13,000	3-4	30	None
C-01, C-02	Electrification	$6,000	4-6	25	None
C-04, C-05, C-06	Electrification	$6,000	4-6	25	None
C-24	Electrification	$4,000	4-6	25	None
C-28	Electrification	$33,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

NMED also evaluated the ATS at MGP due to the potential for significant SO_2 emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). NMED concluded that a FFA of potential control measures for SO_2 for the ATS was not required because the most effective ATS control available – an AGI well with redundant compression – is already being utilized at MGP.

7.5.20.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
C-01	Replacement	36.2
C-02	Replacement	79.4
C-05	Replacement	95.6
C-06	Replacement	30.8
C-24	Replacement	167.0

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
C-01	Electrification	Categorically excluded
C-02	LEC	Less stringent than replacement
C-02	Electrification	Categorically excluded
C-04	Electrification	Categorically excluded
C-05	LEC	Less stringent than replacement
C-05	Electrification	Categorically excluded
C-06	Electrification	Categorically excluded
C-24	LEC	Less stringent than replacement
C-24	Electrification	Categorically excluded

NMED's FFA did not identify any cost-effective controls for MGP Unit C-28. Therefore, NMED determined that reasonable progress does not require new controls on this unit.

As noted above, NMED did not conduct a FFA of potential control measures for MGP's ATS. Because the most effective control available – an AGI well with redundant compression – is already being utilized at MGP, NMED determined that reasonable progress does not require new controls for the ATS.

7.5.21 Targa Midstream Services, LLC – Saunders Gas Plant

7.5.21.1 Facility Description

Saunders Gas Plant (SGP) is a former natural gas processing facility located 15 miles northwest of Lovington in Lea County, New Mexico at latitude 33° 03' 26", longitude -103° 36' 27". It is owned by Versado Gas Processors, LLC and operated by Targa Midstream Services, LLC (Targa), and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Chapter 6 in 2019. However, Targa subsequently idled the facility and later decided to shut down gas plant operations at SGP permanently. On May 30, 2024, Targa submitted an administrative permit revision removing all of the units NMED selected for an analysis of potential control measures for NO_X and/or SO_2 from the facility's NSR and Title V permits and voluntarily discontinuing the Title V. The company intends to re-authorize the few remaining sources not selected for analysis under an oil and gas general construction permit.

7.5.21.2 Summary of Four-Factor Analysis

Because Targa has shut down gas plant operations at SGP, removed all of the units NMED selected for an analysis of potential control measures for NO_X and/or SO_2 from the facility's NSR and Title V permits, and discontinued the Title V, NMED did not perform a FFA of potential control measures for any of these units. There is no more effective control than retirement, which reduces emissions by 100 percent. Therefore, NMED has determined that all of the units selected for an analysis of potential control measures for NO_X and/or SO_2 are already effectively controlled by virtue of their retirement, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

7.5.21.3 Control Measures Determination

Because they are already effectively controlled, NMED determined that reasonable progress does not require new controls on any of the units selected for analysis at SGP.

7.5.22 Tri-State Generation and Transmission Association, Inc. – Prewitt Escalante Generating Station

7.5.22.1 Facility Description

Prewitt Escalante Generating Station (PEGS) is a former 268 MW coal-fired electric power plant located 4 miles north of Prewitt in McKinley County, New Mexico at latitude 35° 24' 57", longitude -108° 04' 58". It is owned by Tri-State Generation and Transmission Association, Inc. (Tri-State), and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Chapter 6 in 2019. However, Tri-State subsequently shut down PEGS on August 31, 2020, and NMED voluntarily discontinued its Title V permit (Permit No. P012-R3) as of September 28, 2020. The plant is currently being decommissioned.

7.5.22.2 Summary of Four-Factor Analysis

NMED originally selected PEGS' main boiler for an analysis of potential control measures for NO_X and SO_2 in the second planning period, and its auxiliary boiler and plant heating boiler for an analysis of potential control measures for NO_X. However, because PEGS has since been shut down and is in the process of being decommissioned, NMED did not perform a FFA of potential control measures for any of these units. The main boiler is already effectively controlled by virtue of its retirement due to the shutdown of PEGS; ownership and operation of the auxiliary boiler has been transferred to a nearby minor source, removing it from consideration during the second planning period; and NMED has sufficient information to conclude that there are no cost effective controls for the plant heating boiler without performing a full four-factor analysis. NMED's evaluation of PEGS' boilers is described in detail in Section C.4.22 of Appendix C.

7.5.22.3 Control Measures Determination

Because they are already effectively controlled, have been transferred to an exempt source, or have no cost-effective controls available, NMED determined that reasonable progress does not require new controls on any of the boilers at PEGS.

7.5.23 Xcel Energy – Cunningham Station Power Plant

7.5.23.1 Facility Description

Cunningham Station Power Plant (CSPP) is a 487 MW electric power plant located 12.5 miles west of Hobbs in Lea County, New Mexico at latitude 32° 42' 44", longitude -103° 21' 13". It is owned and operated by Southwestern Public Service Company, a subsidiary of Xcel Energy, and currently operates under Title V Operating Permit No. P080-R4, which expires on April 9, 2026. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 69.4 miles.

The function of the facility is to provide commercial electric power using boilers and turbines fueled with natural gas. The facility is authorized for continuous operation, and its total potential to emit is 4,072.5 tons per year of NO_X and 155.8 tons per year of SO_2.

7.5.23.2 Summary of Four-Factor Analysis

NMED performed a FFA for all technically feasible control options for NO_X for two (2) utility boilers and two (2) combustion turbines at CSPP that met the tier two screening criteria described in Chapter 6.[165] NMED's analysis of the four statutory factors is discussed in detail in Section C.5.23.5 of Appendix C and the results are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	SCR	$7,000	2.5	30	None
2	SCR	$5,000	2.5	30	None
3	WI	$35,000	1.5	15	None
	SCR	$36,000	2.5	20	None
	Replacement	$237,000	3-4	30	None
4	WI	$26,000	1.5	15	None
	SCR	$33,000	2.5	20	None
	Replacement	$312,000	3-4	30	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

7.5.23.3 Control Measures Determination

Based on its analysis of the four statutory factors, the cost effectiveness threshold described in Section 7.3, and the control selection criteria described in Section 7.4, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	SCR	270.0
2	SCR	781.4

This determination only applies should either of these units operate beyond the end of the second planning period. If Xcel retires Units 1 and 2 on schedule, reasonable progress does not require new controls on either of these units as they will cease operating before controls could be installed.

NMED's FFA did not identify any cost-effective controls for CSPP Units 3 or 4. Therefore, NMED determined that reasonable progress does not require new controls on either of these units.

7.6 Estimated Emissions Reductions

Estimated total emissions reductions from sources subject to analysis in the second planning period are summarized below. These include reductions due to cost-effective controls NMED has determined are necessary to make reasonable progress, reductions due to unit retirements that occurred or are scheduled to occur during the second planning period, and reductions due to controls that have already been installed during the second planning period.

[165] Based on Xcel's current retirement schedule, neither of the boilers at CSPP is expected to operate beyond the end of the second planning period, which would preclude the installation of new controls. However, because the current retirement schedule is not a federally enforceable requirement, NMED evaluated the boilers as a backstop in case their retirement dates slip and one or both units continue to operate beyond 12/31/2028.

Table 7-1: Estimated emissions reductions in the second planning period.

Facility	Estimated Realized Reductions from Unit Retirements or Previously Installed Controls (ton/yr)		Estimated Pending Reductions from New Controls Required for Reasonable Progress (ton/yr)
	NO_X	**SO_2**	**NO_X**
Denton Gas Plant	---	708	---
Artesia Gas Plant	---	---	---
Eunice Gas Plant [166]	321.6	1,392.9	---
Linam Ranch Gas Plant	---	---	---
Blanco Compressor Station A	---	---	93.8
Pecos River Compressor Station	---	---	182.6
Washington Ranch Storage Facility	---	---	---
Blanco C&D Compressor Station	---	---	866.1
Chaco Gas Plant	---	---	118.3
South Carlsbad Compressor Station	---	---	135.7
Jal #3 Gas Plant	25.1	154.4	---
Mountainair Compressor Station No. 7	---	---	1284.5
Roswell Compressor Station No. 9	---	---	644.7
Kutz Canyon Processing Plant	245.4	---	247.4
San Juan Basin Gas Plant	---	---	388.4

Indian Basin Gas Plant	---	---	100.5
San Juan Generating Station	7,007.4	1,558.5	---
Eunice Gas Processing Plant [167]	492	308.2	1287.6
Monument Gas Plant	---	112.2	409
Saunders Gas Plant	632	284.8	---
Prewitt Escalante Generating Station	2,313.4	829.2	---
Cunningham Station Power Plant	1,168.2 (1)	---	---
Subtotals	**12,205.1**	**5,348.2**	**5,758.6**
Total Estimated NO_X Reductions	**17,963.7**		
Total Estimated SO_2 Reductions	**5,348.2**		

(1) Estimated reductions from unit retirements at Cunningham Station Power Plant have only been partially realized. Unit 1 has been shut down, but Unit 2 is still operating and is scheduled to be retired in 2027.

[166] DCP Operating Company LP – Eunice Gas Plant as discussed in Section 7.5.3.

[167] Targa Midstream Services, LLC - Eunice Gas Processing Plant as discussed in Section 7.5.19.

Chapter 8: Long-term Strategy for Second Planning Period

8.1 Regulatory Requirements

The Regional Haze Rule requires that this Regional Haze SIPr Rd 2 (2019-2028) contain "a long-term strategy that addresses regional haze visibility impairment for each mandatory Class I Federal area within the state and for each mandatory Class I Federal area located outside the state that may be affected by emissions from the state. The long-term strategy must include the enforceable emissions limitations, compliance schedules, and other measures that are necessary to make reasonable progress, as determined pursuant to [40 CFR § 51.308(f)(2)(i) through (iv)]." [168]

8.2 Measures Necessary to Make Reasonable Progress

As required by the Regional Haze Rule, NMED evaluated the emission reduction measures that are necessary to make reasonable progress toward natural visibility conditions in Class I Areas in New Mexico, as well as in Class I Areas outside New Mexico that may be affected by emissions from New Mexico, considering the four statutory factors described in 40 CFR § 51.308(f)(2)(i). Chapter 7 of this Regional Haze SIPr Rd 2 (2019-2028) provides a summary of NMED's four-factor analyses and reasonable progress control measures determinations for all units selected for analysis in the second planning period.

NMED initially identified 133 units requiring an analysis of potential control measures for NO_X and/or SO_2 in the second planning period. These include two-stroke lean burn engines (2SLB RICE), four-stroke lean burn engines (4SLB RICE), four-stroke rich burn engines (4SRB RICE), combustion turbines (CT), industrial and utility boilers, and amine treatment systems (ATS). However, after NMED completed its source screening, four facilities permanently shut down and several more retired one or more emissions units NMED had originally selected for analysis. NMED also identified a number of units that are already effectively controlled (for reasons other than retirement) or that did not require an analysis of potential control measures for other reasons. This left 91 units requiring a four-factor analysis. Of these, NMED identified 50 units with cost effective controls based on its $10,000/ton cost effectiveness threshold value. Applying the decision-making approach described in Section 7.4, NMED determined that reasonable progress requires new controls on all of these units.

8.2.1 Emissions limitations and compliance deadlines

As discussed in Section 7.4.3, NMED's reasonable progress control measures determinations are not prescriptive. Instead of mandating the installation of specific controls, NMED is imposing new emissions limitations in this Regional Haze SIPr Rd 2 (2019-2028) commensurate with controls deemed necessary for reasonable progress and leaving it up to facilities to determine how to comply. This approach is intended to give facilities the flexibility to consider factors beyond the four statutory factors considered by NMED when deciding how to comply with Regional Haze requirements. NMED is also establishing compliance deadlines for the installation of reasonable progress controls (or equivalent alternatives) to ensure facilities come into compliance before the end of the second planning period. Emissions limitations and compliance deadlines for the 50 units for which NMED identified reasonable progress controls are summarized in Table 8-1.

[168] 40 CFR § 51.308(f)(2).

Table 8-1. Emissions Limitations and Compliance Deadlines for Reasonable Progress Controls.

Facility	AI No.	Unit No.	Source Type	Reasonable Progress Control	NO_X Emission Limitation	Compliance Deadline [1]
Blanco Compressor Station A	1147	A11	2SLB RICE	Replacement w/ New RICE	0.5 g/bhp-hr	3 years

South Carlsbad Compressor Station	218	1	CT	Dry Low NO_X Combustion	15 ppmvd @ 15% O_2	2 years
South Carlsbad Compressor Station	218	2	CT	Dry Low NO_X Combustion	15 ppmvd @ 15% O_2	2 years

[1] Compliance deadlines are expressed in years after final approval of this Regional Haze SIPr Rd 2 (2019-2028) by EPA.

[2] Emission limitation represents a 80% reduction from the current actual emission rate (65.2 lb/hr @ 100% load).

[3] Emission limitation represents a 80% reduction from the current actual emission rate (66.6 lb/hr @ 100% load).

[4] Emission limitation represents a 80% reduction from the current actual emission rate (121.1 lb/hr @ 100% load).

[5] Emission limitation represents a 90% reduction from the current actual emission rate (120.7 lb/hr @ 100% load). As noted in Section 7.5.23, this unit is not expected to operate beyond the end of the second planning period based on Xcel's current retirement schedule. The new limit is a backstop that only applies if service life is extended beyond 12/31/2028. Compliance with this emission limitation shall be determined on a 30-day rolling average basis.

[6] Emission limitation represents a 90% reduction from the current actual emission rate (300.5 lb/hr @ 100% load). As noted in Section 7.5.23, this unit is not expected to operate beyond the end of the second planning period based on Xcel's current retirement schedule. The new limit is a backstop that only applies if service life is extended beyond 12/31/2028. Compliance with this emission limitation shall be determined on a 30-day rolling average basis.

[7] Emission limitation represents a 80% reduction from the current actual emission rate (16.7 lb/hr @ 100% load).

[8] Emission limitation represents a 80% reduction from the current actual emission rate (17.7 lb/hr @ 100% load).
[9] Emission limitation represents a 80% reduction from the current actual emission rate (14.1 lb/hr @ 100% load). As noted in Section C.4.14 of Appendix C, the average adjusted emissions of identical Units 1-3 and Units 5-6 were used as a surrogate for Unit 4, as NMED was unable to locate a recent emissions test for report for this unit.
[10] Emission limitation represents a 80% reduction from the current actual emission rate (11.9 lb/hr @ 100% load).
[11] Emission limitation represents a 80% reduction from the current actual emission rate (11.8 lb/hr @ 100% load).
[12] Emission limitation represents a 80% reduction from the current actual emission rate (15.6 lb/hr @ 100% load). As noted in Section C.4.14 of Appendix C, the most recent testing of Units 19 and 20 was conducted at very low load. Therefore, instead of adjusting reported emissions to 100 percent load based on an assumed linear relationship between emissions and load, NMED used a surrogate emission factor based on the heat input capacity (MMBtu/hr) of these units and a vendor-provided emission rate expressed in lb/MMBtu.
[13] Emission limitation represents a 80% reduction from the current actual emission rate (15.6 lb/hr @ 100% load). As noted in Section C.4.14 of Appendix C, the most recent testing of Units 19 and 20 was conducted at very low load. Therefore, instead of adjusting reported emissions to 100 percent load based on an assumed linear relationship between emissions and load, NMED used a surrogate emission factor based on the heat input capacity (MMBtu/hr) of these units and a vendor-provided emission rate expressed in lb/MMBtu.
[14] 44.74 ton/yr is a multi-unit emission limitation applicable to Units 701, 702 and 703 combined. If TWP replaces these units with CT and the replacement ratio is not 1:1, the emission limitation will apply to all replacement units combined, regardless of their number. Compliance with this emission limitation shall be determined on a 12-month rolling sum basis.
[15] Based on manufacturer's specifications for Capstone C200 Microturbine.
[16] Emission limitation represents a 80% reduction from the current actual emission rate (36.4 lb/hr @ 100% load).
[17] Emission limitation represents a 80% reduction from the current actual emission rate (40.5 lb/hr @ 100% load).
[18] 29 ton/yr is a multi-unit emission limitation applicable to Units 903 and 904 combined. If TWP replaces these units with CT and the replacement ratio is not 1:1, the emission limitation will apply to all replacement units combined, regardless of their number. Compliance with this emission limitation shall be determined on a 12-month rolling sum basis.
[19] Emission limitation represents a 80% reduction from the current actual emission rate (19.8 lb/hr @ 100% load).
[20] Emission limitation represents a 80% reduction from the current actual emission rate (21.2 lb/hr @ 100% load).
[21] Emission limitation represents a 80% reduction from the current actual emission rate (19.4 lb/hr @ 100% load).
[22] Emission limitation represents a 80% reduction from the current actual emission rate (13.9 lb/hr @ 100% load).
[23] Emission limitation represents a 80% reduction from the current actual emission rate (13.7 lb/hr @ 100% load).
[24] Emission limitation represents a 80% reduction from the current actual emission rate (15.2 lb/hr @ 100% load).
[25] Emission limitation represents a 80% reduction from the current actual emission rate (14.4 lb/hr @ 100% load).

Emissions limitations for reasonable progress controls generally correspond to vendor-quoted, guaranteed post-control emission rates or, in the case of replacement, to the emission limits for new natural gas-fired spark ignition engines in 20.2.50 NMAC. Emissions limitations for selective catalytic reduction are based on current actual emissions and the assumed control efficiency (80% or 90%, depending on the unit).

To determine compliance deadlines, NMED assumed that facilities will begin working on project approval, budgeting and design while EPA approval of this Regional Haze SIPr Rd 2 (2019-2018) is still pending, shortening the time necessary for compliance once approval is granted. Therefore, for reasonable progress controls with an estimated compliance time of 2-3 years, NMED set the compliance deadline two (2) years after final approval of this SIPr by EPA. For reasonable progress controls with an estimated compliance time of 3-4 years, NMED set the compliance deadline three (3) years after final approval of this SIPr by EPA. Assuming this SIPr is approved by EPA by December 31, 2025, these deadlines will ensure that all reasonable progress controls are installed by the end of the second planning period.

To make the emissions limitations and compliance deadlines in Table 8-1 federally enforceable, NMED has included them in a proposed rule, 20.2.68 NMAC, which will be incorporated into this Regional Haze SIPr Rd 2 (2019-2028) following adoption of the rule and SIPr by the Environmental Improvement Board. A copy of the proposed rule, which also includes monitoring, recordkeeping, and reporting provisions to make the new emissions limitations practicably enforceable, is included in Appendix G.

8.2.2 Facility shutdowns and unit retirements

After NMED completed its source screening, four facilities permanently shut down and several more retired one or more emissions units NMED had originally selected for analysis. These actions resulted in the permanent retirement of 34 units selected for an analysis of potential control measures for NO_X and/or SO_2 in the second planning period. Because there is no more effective control than retirement, which reduces emissions by 100 percent, NMED determined that these units are effectively controlled by virtue of their retirement and forwent a four-factor analysis. The units in question have all been removed from their respective construction permits or the permits have been closed altogether, obviating the need for emissions limitations and compliance deadlines. Table 8.2 lists all retired units and the date they were removed from their respective construction permits or the permits were closed. Proposed rule 20.2.68 NMAC prohibits NMED from reauthorizing any of these units as a regulated emission source in any future construction permit modification issued by the department without a new analysis of the emission control measures necessary to make reasonable progress and an EPA-approved revision of this Regional Haze SIPr Rd 2 (2019-2028).

Table 8-2. Retired Units and Retirement Mechanism/Date.

Facility	AI No.	Unit No.	Source Type	Retirement Mechanism	Permit No.	Date

[1] The ATS at Denton Gas Plant comprised Units 005 and 007.
[2] The ATS at Eunice Gas Plant comprised Units Amine-01, 31, 111, and 113.
[3] The ATS at Saunders Gas Plant comprised Units A-01, F-01, F-03, and I-01.

8.2.3 In-place emission controls

NMED determined that a number of emissions units evaluated for reasonable progress controls are already effectively controlled by in-place emission controls. These include Units 29, 30, 31, and 32B at DCP Operating Company's Linam Ranch Gas Plant, which are equipped with DLN; [169] Units 1 and 2 at El Paso Natural Gas Company's Washington Ranch Storage Facility, which are equipped with LEC; and Units C-891 and C-893 at IACX Roswell's Bitter Lake Compression Station, which are also equipped with LEC. The current, controlled emission rates for these units are significantly lower than emission rates for comparable units at other facilities without any controls. This was a major, if not the deciding factor in the outcome of NMED's four-factor analyses for these units. Therefore, the in-place controls on these units are necessary for reasonable progress, and NMED is imposing new emissions limitations in this Regional Haze SIPr Rd 2 (2019-2028) to ensure their continued use. The new limits for these units are listed in Table 8-3 and included in proposed rule 20.2.68 NMAC to make them federally enforceable.

Table 8-3. New Emissions Limitations for Units With In-Place Controls Necessary for Reasonable Progress.

Facility	AI No.	Unit No.	Source Type	NO_X Emission Limitation
Bitter Lake Compressor Station	14	C-891	2SLB RICE	3.0 g/bhp-hr
Bitter Lake Compressor Station	14	C-893	2SLB RICE	3.0 g/bhp-hr
Linam Ranch Gas Plant	589	29	CT	15 ppmvd @ 15% O_2
Linam Ranch Gas Plant	589	30	CT	25 ppmvd @ 15% O_2
Linam Ranch Gas Plant	589	31	CT	25 ppmvd @ 15% O_2
Linam Ranch Gas Plant	589	32B	CT	25 ppmvd @ 15% O_2
Washington Ranch Storage Facility	220	1	2SLB RICE	3.0 g/bhp-hr
Washington Ranch Storage Facility	220	2	2SLB RICE	3.0 g/bhp-hr

NMED also determined that the amine treatment systems at several facilities are effectively controlled by in-place emission controls, specifically, acid gas injection (AGI) wells with redundant compression. These include DCP Operating Company's Linam Ranch Gas Plant, ET Gathering & Processing's Jal #3 Gas Plant, and Targa Midstream Services' Eunice Gas Processing Plant and Monument Gas Plant. The NSR permits for these facilities include conditions requiring that all emissions from their respective amine treatment units be routed to the AGI well at all times (except during authorized SSM and malfunction flaring events) and not emitted directly to the atmosphere, that a backup compressor be operationally available to inject acid gas into the AGI well at all times, and that the backup compressor have sufficient capacity to accept the entire acid gas stream during maintenance or failure of the primary compressor. Because these in-place controls are necessary for reasonable progress, NMED is incorporating NSR permit conditions pertaining to them into this Regional Haze SIPr Rd 2 (2019-2028) to ensure their continued use. Table 8-4 lists all incorporated NSR permit conditions pertaining to in-place controls necessary for reasonable progress.

[169] As noted in Section C.4.4 of Appendix C, DCP is in the advanced stages of upgrading Unit 32B with DLN to comply with 20.2.50 NMAC. Therefore, NMED's base case assumes DLN has already been installed on this unit, making it an in-place control for purposes of regional haze.

Table 8-4. Incorporated NSR Permit Conditions Pertaining to In-Place Controls Necessary for Reasonable Progress.

Facility	AI No.	Permit No.	Condition No.
Linam Ranch Gas Plant	589	39-M9	A208.A. Monument Gas Plant	610	110-M11R2	A210.A. AGI Operations (Unit AGI controlling AM-01)

8.3 Consideration of Additional Factors for Long-term Strategy

The Regional Haze Rule requires that NMED must consider the following additional factors in developing its long-term strategy: [170]

- Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment;
- Measures to mitigate the impacts of construction activities;
- Source retirement and replacement schedules;
- Basic smoke management practices for prescribed fire used for agricultural and wildland vegetation management purposes and smoke management programs; and
- The anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions over the period addressed by the long-term strategy.

A description of how NMED considered these additional factors is provided in Sections 8.3.1 through 8.3.5.

[170] 40 CFR § 51.308(f)(2)(iv).

8.3.1 Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment

The Regional Haze Rule requires states to consider emission reductions due to ongoing air pollution control programs in their long-term strategies. These programs include new source performance standards, national emissions standards for hazardous air pollutants, national onroad and nonroad emissions standards, the cross-state air pollution rule, and other national rules that limit the emissions of pollutants that may contribute to visibility impairment. Emission reductions due to ongoing programs were considered through their incorporation into WRAP's projected 2028OTBa2 emissions inventory, which was used to model aerosol light extinction and develop Reasonable Progress Goals (RPGs) for New Mexico federal Class I Areas.

After WRAP compiled the projected 2028OTBa2 emissions inventory and completed its modeling analyses, New Mexico adopted a pair of rules that will further reduce emissions contributing to visibility impairment in New Mexico Class I Areas. The first, 20.2.50 NMAC – Oil and Gas Sector – Ozone Precursor Pollutants, is a state-only rule establishing emissions standards and other requirements applicable to certain crude oil and natural gas production and processing equipment in counties that exceed ninety-five percent of the national ambient air quality standard for ozone.[171] The second, 20.2.91 NMAC – New Motor Vehicle Emission Standards, adopts the latest California vehicle emission standards and requirements, including requirements pertaining to the delivery of an increasing percentage of zero-emission vehicles for sale in New Mexico. As discussed in Section 12.3, NMED has committed in this Regional Haze SIPr Rd 2 (2019-2028) to continue to submit annual inventories of pollutants, including those reasonably anticipated to cause or contribute to visibility impairment, pursuant to 40 CFR § 51.308(f)(6)(v). The emissions reductions due to these new rules will be captured in future inventories and considered in the next planning period.

8.3.2 Measures to mitigate the impact of construction activities

NMED did not select construction activities as a source category for an analysis of control measures for reasonable progress for the second planning period. As part of its process to select sources for four-factor analysis, NMED reviewed IMPROVE-based light extinction info for the most impaired days and clearest days, presented in Chapter 4. The IMPROVE-based light extinction budget for coarse mass indicates it comprises a smaller total contribution to extinction at New Mexico Class I Areas compared to ammonium sulfates and nitrates. NMED developed a strategy to look at the combined SO_2 and NO_X emissions, which are precursors to sulfates and nitrates, from major Title V point sources (See Chapter 6). NMED consulted with FLMs on this approach in 2019 and received a favorable response on its source selection methodology. Moreover, inventories in New Mexico for construction activities are not nearly as well developed as they are for larger point sources. NMED may choose to further evaluate construction activities in a future planning period.

8.3.3 Source retirement and replacement schedules

The Regional Haze Rule requires states to consider source retirement and replacement schedules in their long-term strategies. Similar to emission reductions due to ongoing air pollution control programs,

[171] Currently, 20.2.50 NMAC applies to sources in Chaves, Doña Ana, Eddy, Lea, Rio Arriba, Sandoval, San Juan, and Valencia Counties. These counties encompass the Permian and San Juan Basins, which are the primary oil and gas production regions in New Mexico.

known source retirement and replacement schedules were considered through their incorporation into WRAP's projected 2028OTBa2 emissions inventory, which was used to model aerosol light extinction and develop Reasonable Progress Goals (RPGs) for New Mexico federal Class I Areas. More recent retirements were considered as part of NMED's four-factor analyses and reasonable progress control measures determinations and are discussed in Section 8.2.2.

8.3.4 Basic smoke management practices for prescribed fire used for agricultural and wildland vegetation management purposes and smoke management programs

NMED administers a comprehensive Smoke Management Program (SMP) developed to meet the requirements of the Regional Haze Rule.[172] The SMP is applicable in all of New Mexico, excluding Tribal lands and Bernalillo County, which are separate air quality jurisdictions, and helps control prescribed fire-related emissions of VOCs, NO_X, elemental carbon, organic carbon, and $PM_{2.5}$. 20.2.65 NMAC – Smoke Management, provides the enforcement mechanism for the SMP and requires that most prescribed burning in New Mexico be conducted in accordance with rule requirements, including: the reporting of emissions for use in emissions inventories; consideration of alternatives to burning; use of enhanced smoke management techniques recommended by the WRAP; and use of specific emission reduction techniques.

8.3.5 Anticipated Net Effect on Visibility Due to Projected Changes in Point, Area, and Mobile Source Emissions Over the Period Addressed by the Long-term Strategy.

The anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions is demonstrated through WRAP's modeling of U.S. anthropogenic contributions to aerosol light extinction for New Mexico federal Class I Areas. The results of this modeling are shown in Figure 8-1 through Figure 8-9. WRAP's modeling was conducted before NMED completed its four-factor analyses and therefore does not reflect expected emission reductions due to the reasonable progress control measures described in Section 8.2. As such, modeled U.S. anthropogenic contributions to aerosol light extinction for the 2028OTBa2 scenario are likely overstated.

[172] Information on NMED's Smoke Management Program is available at https://www.env.nm.gov/air-quality/smp/.

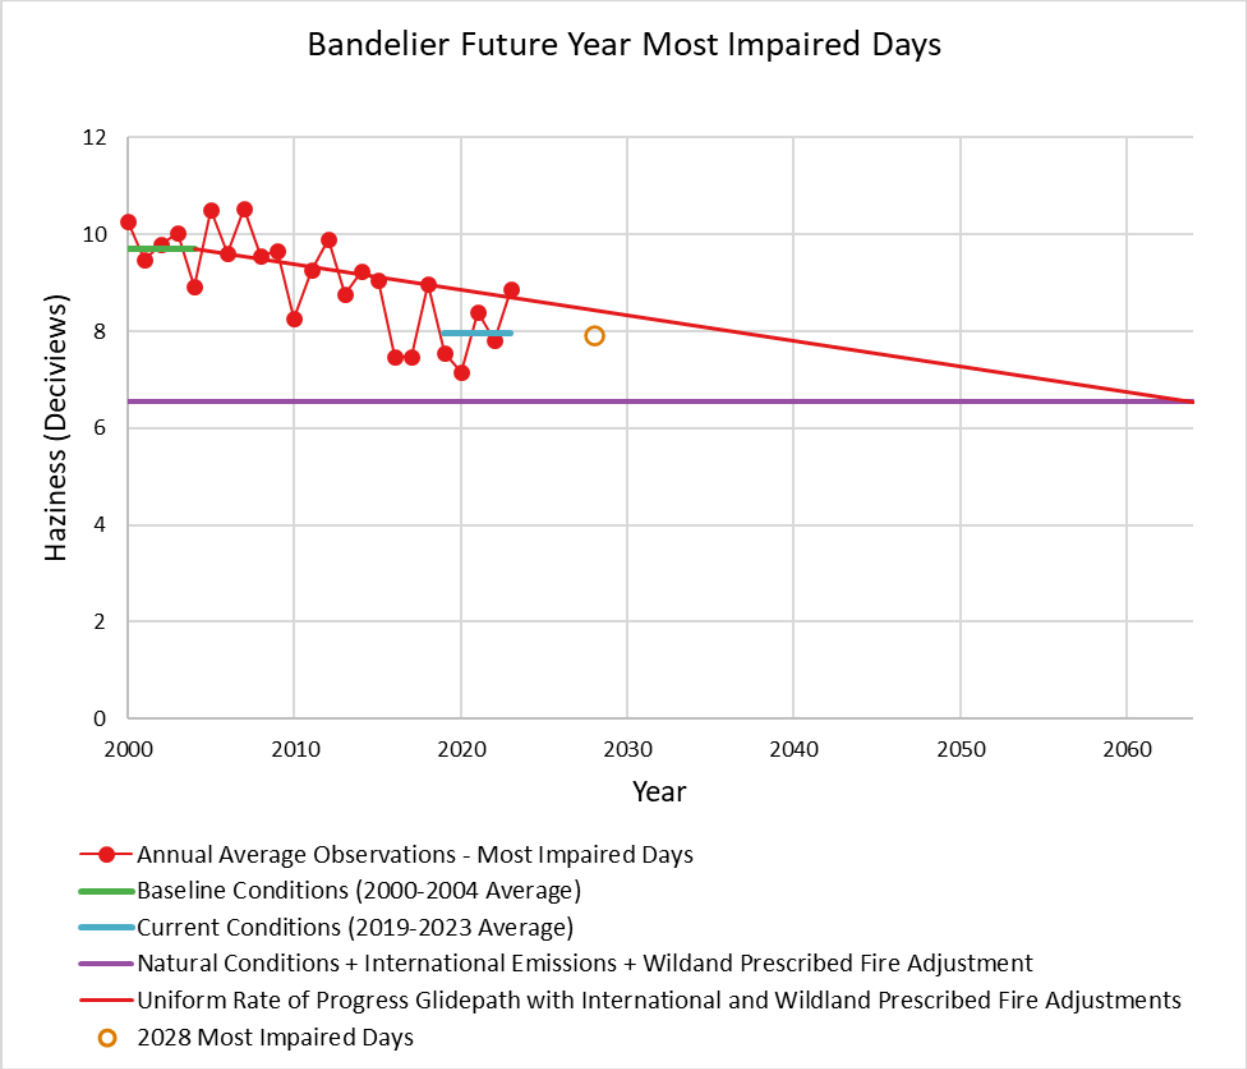
Chapter 9: Regional Scale Modeling to Set Reasonable Progress Goals for 2028

9.1 Regulatory Requirements

The Regional Haze Rule requires that states establish reasonable progress goals (expressed in deciviews) that reflect the visibility conditions that are projected to be achieved by the end of the implementation period as a result of the long-term strategy. [173]

9.2 Modeled Future Year Most Impaired Days for New Mexico Class I Areas



Sections 9.2.1 to 9.2.8 (and corresponding Figure 9-1 to Figure 9-8) illustrate the reasonable progress goals as modeled future year most impaired days (MID) for each Class I Area in New Mexico. Modeled future year MID are based on the Western Regional Air Partnership (WRAP) 2028 'On the Books' modeling scenario (2028OTBa2). [174] This modeling scenario includes regulations that were reported to WRAP as already adopted by regulatory agencies as of September 2020.

[173] 40 CFR 51.308(f)(3)(i)

Chapter 10: Glidepath Checks for New Mexico Class I Areas and Robust Demonstration

10.1 Regulatory Requirements

The Regional Haze Rule requires the long-term strategy to provide a pathway towards an improvement in visibility for the most impaired days since the baseline period and ensure no degradation in visibility for the clearest days since the baseline period. [175]

The Regional Haze Rule requires that any state containing a Class I Area with a slower rate of improvement than the Uniform Rate of Progress (URP) must provide a robust demonstration [176]. This robust demonstration should include the criteria used to determine which sources were evaluated and how the four-factors required by 40 CFR 51.308(f)(2)(i) were taken into consideration in selecting the measures for inclusion in its long-term strategy. This obligation does not require states to demonstrate their long-term strategy will be sufficient to be on the URP glide path; rather, states should demonstrate that they have taken all reasonable measures to improve visibility in the Class I Area.

10.2 Uniform Rate of Progress Glidepath Check for Most Impaired Days at each Class I Area in New Mexico

Section 9.2 shows the reasonable progress goals as modeled future year most impaired days for each Class I Area in New Mexico. Modeled future year most impaired days are based on the WRAP 2028 'On the Books' modeling scenario (2028OTBa2) [177]. This modeling scenario includes regulations that regulatory agencies already adopted as of September 2020. The future year visibility on the MID at each Class I Area in New Mexico is projected to be below the URP glidepath adjusted for international emissions and wildland prescribed fire, except for Salt Creek Wilderness area (see Section 9.2.6). Salt Creek Wilderness area is projected to be above the URP glidepath in the future year (2028). Section 10.3 is a robust demonstration for Salt Creek Wilderness area.

10.3 Robust Demonstration for Salt Creek Wilderness Area

Salt Creek Wilderness area is projected to be above the uniform rate of progress glidepath in 2028 (according to the 2028 WRAP modeling), and New Mexico contains sources contributing to visibility impairment in the Class I Area. Therefore, a robust demonstration that all reasonable measures have been taken to improve visibility is required.

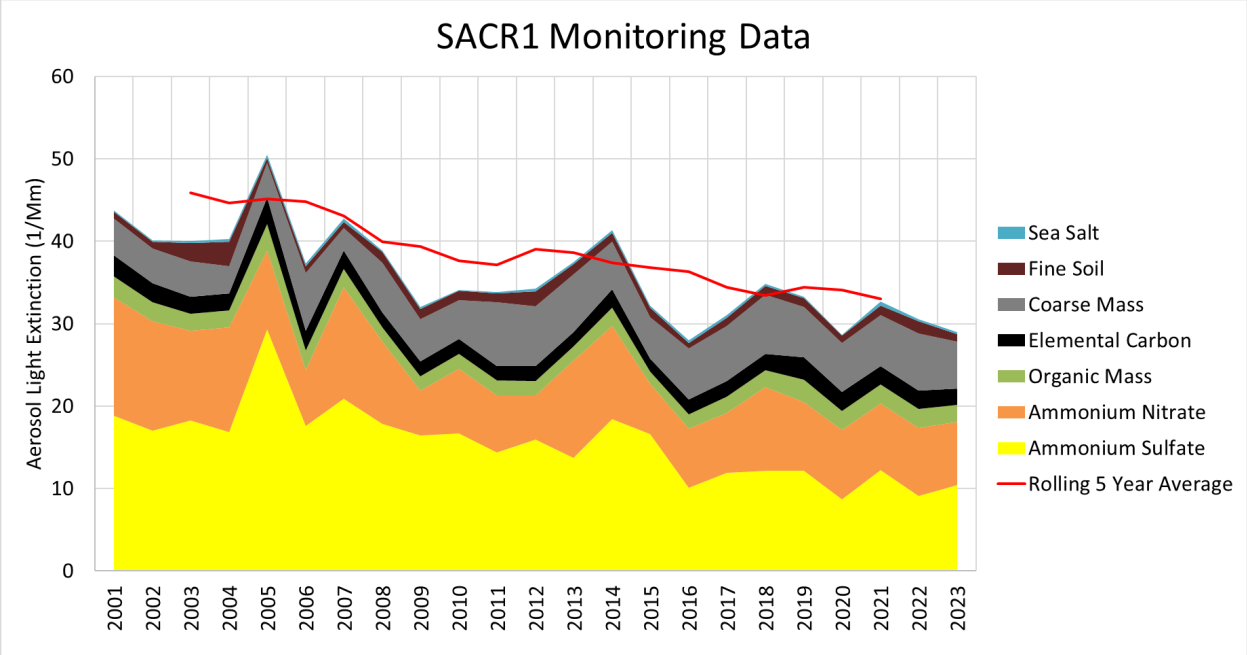
10.3.1 Monitoring Data at Salt Creek Wilderness Area

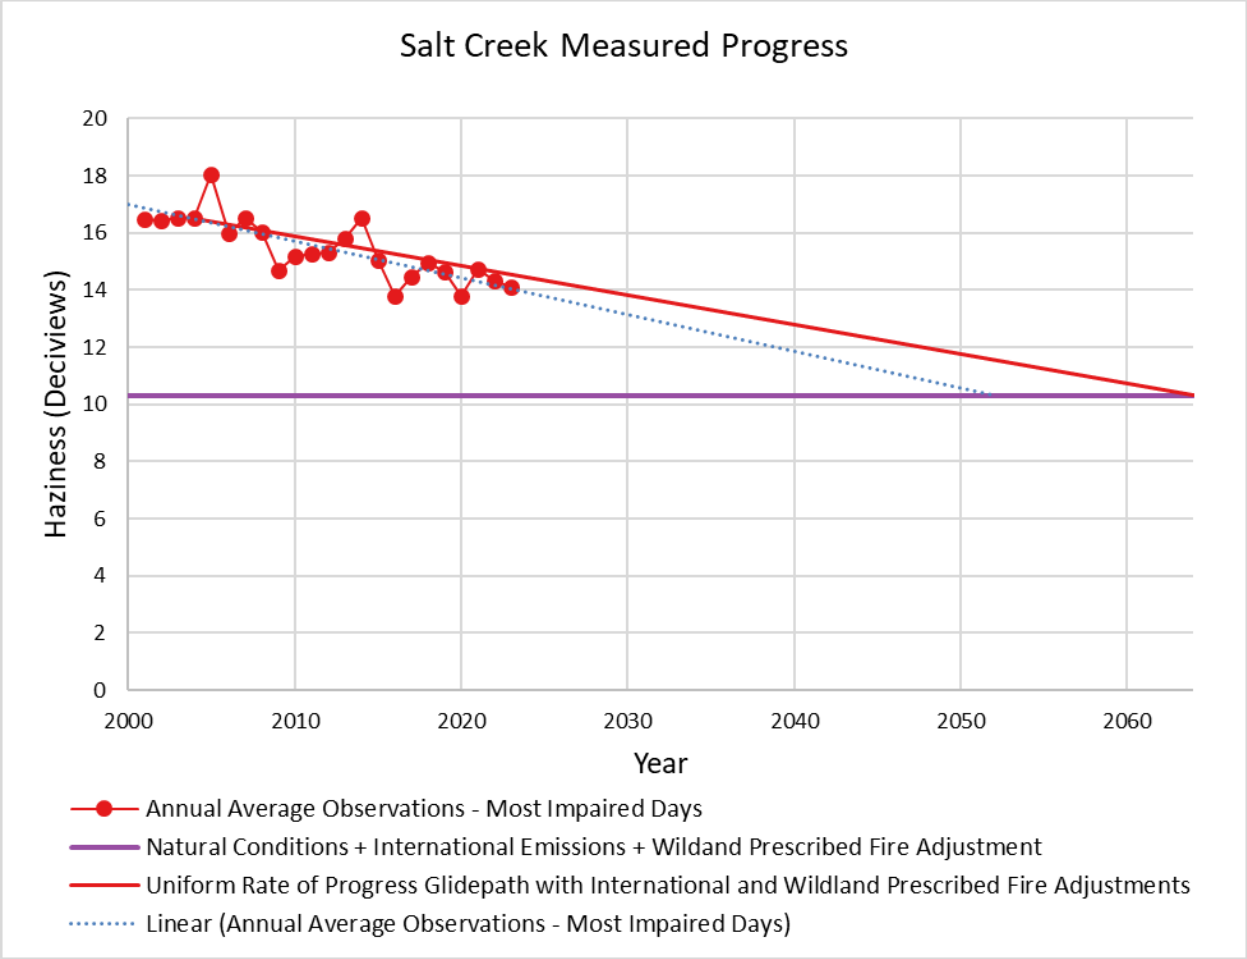
The IMPROVE monitoring site for Salt Creek Wilderness Area is discussed In Section 3.3.6 of this Regional Haze SIPr Rd 2 (2019-2028). Monitoring data (Figure 10-1) shows that the primary components of light extinguishing aerosol at SACR1 are ammonium sulfate (31.8% for the 2019-2023 average) and ammonium nitrate (24.7% for the 2019-2023 average) with smaller contributions from Course Mass (18.7% for the 2019-2023 average) and Organic Mass (13.7% for the 2019-2023 average). The rolling five-year average of aerosol light extinction is steadily improving from 2001 to 2023, suggesting that

[175] 40CFR 51.308(f)(3)(i)
[176] 40 CFR 51.308(f)(3)(ii)(A)
[177] https://westar.org/tribal-data-work-group/#tab-id-6

visibility in the Class I Area is improving. Figure 10-2 shows the extrapolation of the improvement trend at SACR1 from the current MID (2001 – 2023) period to the regional haze endpoint adjusted for international emissions and wildland prescribed fire. This extrapolation predicts that if the current trend continues SACR1 will reach the endpoint in 2052, well before the 2064 end of the Regional Haze program.

Figure 10-1 Aerosol Light Extinction for the 20% Most Impaired Days at SACR1.





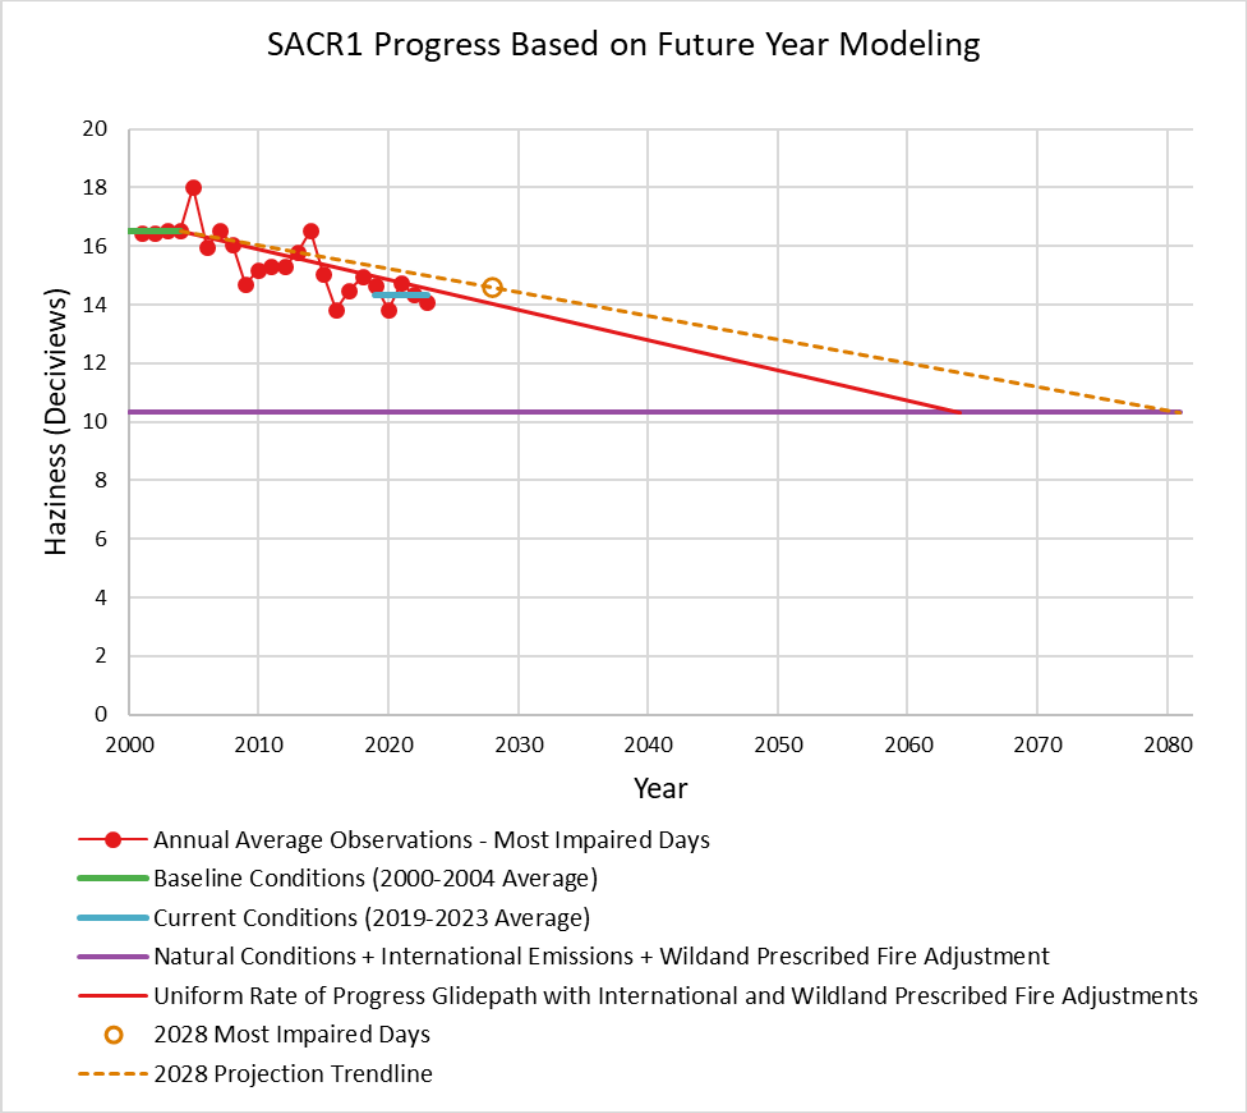


Figure 10-2 Extrapolation of Visibility Improvement at SACR to the Regional Haze Endpoint Based on IMPROVE Monitoring.

10.3.2 Future Year Visibility and Projection to Attainment of the Regional Haze Endpoint at Salt Creek Wilderness Area

The 2017 Regional Haze Rule, 40 CFR 51.308(f)(3)(ii)(A) requires that a state containing a Class I Area which is not projected be below the Uniform Rate of Progress in 2028 must provide to the public an assessment of the number of years it will take to attain natural visibility conditions at the Class I Area at the rate of progress projected for the Long Term Strategy for the Implementation Period. The future year modeled haziness at Salt Creek Wilderness Area is projected to be above the URP Glidepath, adjusted for International Emissions and Wildland Prescribed Fire (Figure 10-3). Extrapolation of this trend from the 2000-2004 baseline period through the future year modeled value to the regional haze endpoint adjusted for international emissions and wildland prescribed fire shows that SACR1 is predicted to reach the endpoint in 2081, 17 years after 2064.

Figure 10-3 Extrapolation of Visibility Improvement the Regional Haze Endpoint Based on Future Year Modeling.

10.3.3 Source Sectors Affecting Visibility at Salt Creek Wilderness Area

Salt Creek Wilderness Area is located in the southeastern area of New Mexico, just outside of the Permian Basin. The Permian Basin is an oil and gas region which has had increasing productivity in recent years. Figure 10-4 shows the location of Salt Creek Wilderness Area (SACR1), the location of the Permian Basin and sub-basins, and the Area of Influence (AOI) predicted for SACR1. The AOI is the percentage air parcels that arrive at SACR1 on the 2014-2018 most impaired days traveling from a location, expressed as residence time. The AOI for SACR1 covers the southeastern part of New Mexico, western Texas, and small areas along the Mexico border and of western Oklahoma.

WRAP $(NH_4)_2SO_4$ source apportionment (Figure 10-5) shows that approximately 36% of anthropogenic $(NH_4)_2SO_4$ at SACR on the 20% most impaired days is from sources in New Mexico, with U.S. states outside of WRAP ('USnonWRAP') contributing approximately 59%, and small contributions from other WRAP states. WRAP NH_4NO_3 source apportionment (Figure 10-6) shows that approximately 63% of

anthropogenic NH_4NO_3 at SACR on the 20% most impaired days is from sources in New Mexico, with U.S. states outside of WRAP contributing approximately 33%, and small contributions from other WRAP states. WRAP source apportionment modeling only included U.S. anthropogenic emissions.

A large percentage of the area of influence (Figure 10-4) overlaps with the geographic extent of the Permian Basin in both New Mexico and Texas, suggesting that oil and gas sources will have an impact on visibility at SACR. The importance of the impact of oil and gas emissions at SACR is shown in the WRAP modeling. WRAP $(NH_4)_2SO_4$ source apportionment (Figure 10-5) shows that approximately 39% of anthropogenic $(NH_4)_2SO_4$ at SACR on the 20% most impaired days is from the oil and gas sector, with an additional 29% originating from Electric Generating Units (EGUs), 23% from Non-EGU point sources, and smaller amounts from the remaining sectors. WRAP NH_4NO_3 source apportionment (Figure 10-6) also shows the largest contribution from the oil and gas sector (76%) with a smaller contribution from mobile sources (12%). Other source sectors contribute small amounts to visibility impairment at SACR.

Figure 10-4 Area of Influence Surrounding Salt Creek Wilderness Area.

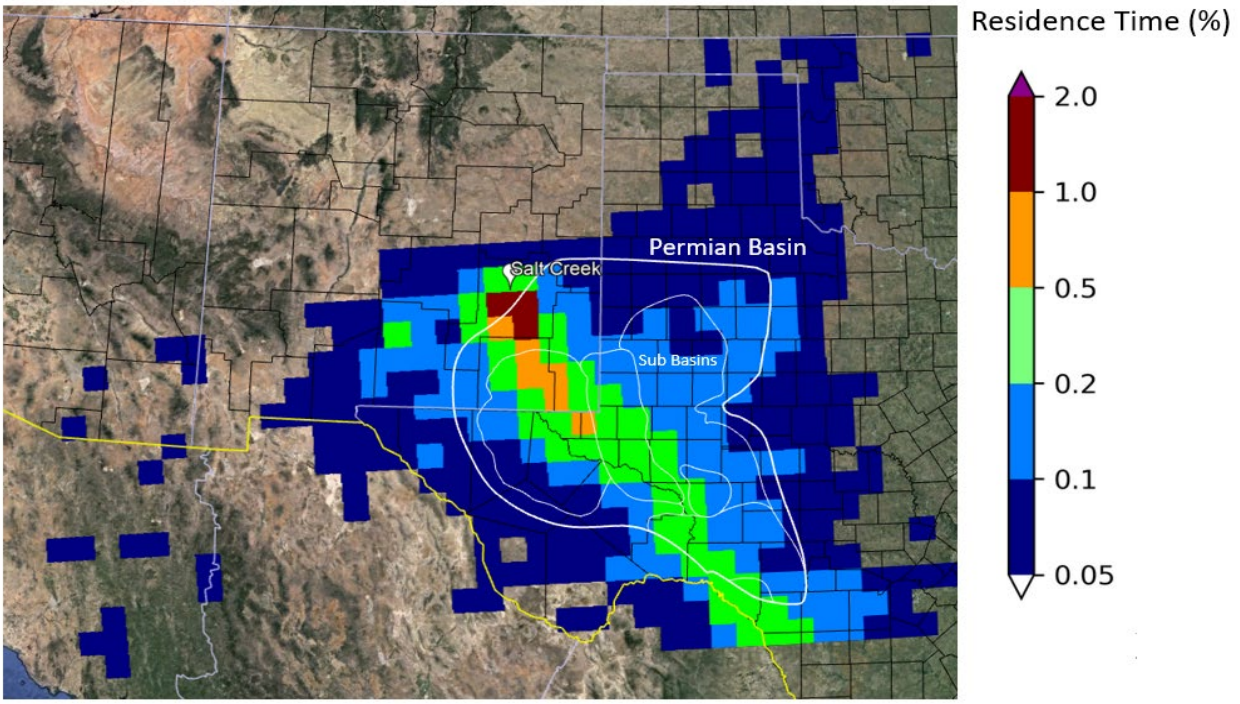

Figure 10-5 WRAP $(NH_4)_2SO_4$ Source Apportionment for Salt Creek on the 20% Most Impaired Days.

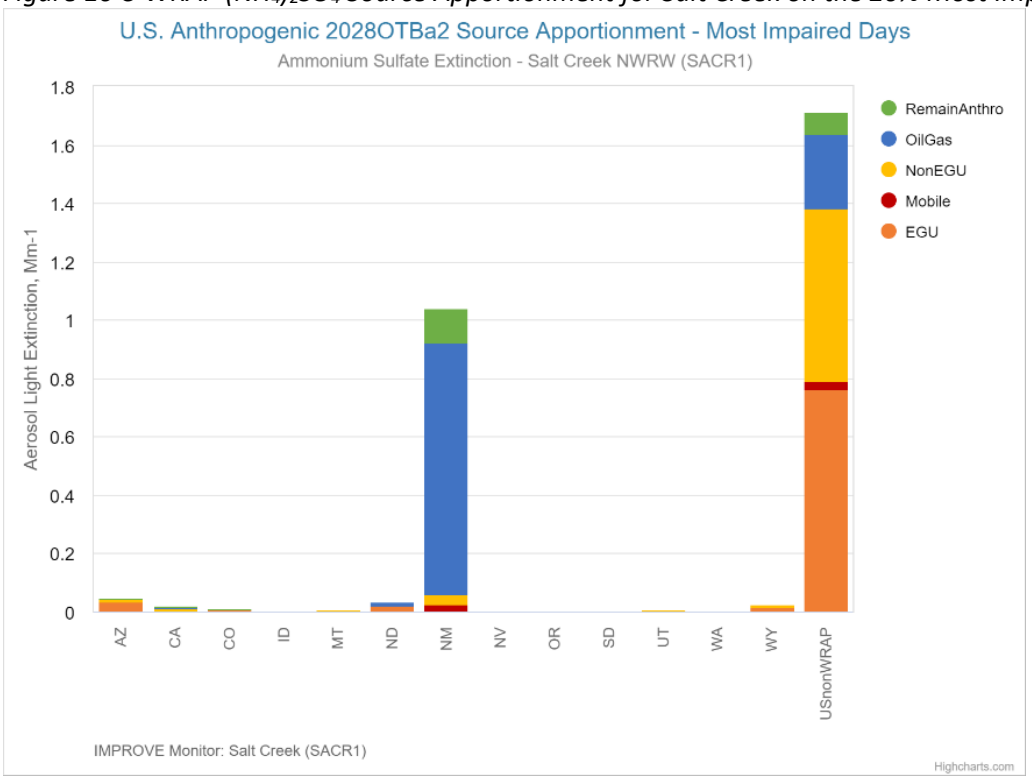

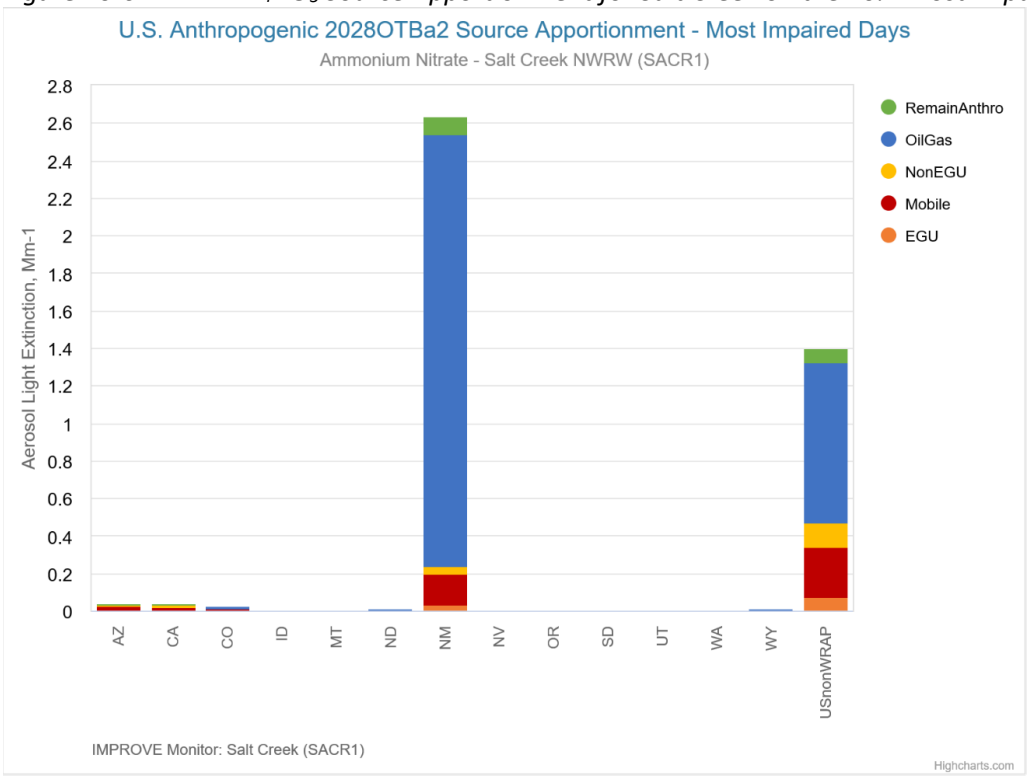

Figure 10-6 WRAP NH_4NO_3 Source Apportionment for Salt Creek on the 20% Most Impaired Days.

10.3.4 Emissions Reductions at Sources Contributing to Visibility Impairment at Salt Creek Wilderness Area

10.3.4.1 Control Measures for Facilities Selected for Four-Factor Analysis in the Permian Basin Area

Sources located in the Permian Basin that were selected by NMED for evaluation (Chapter 6) that underwent a four-factor analysis and control measure determination (Chapter 7) include: Denton Gas Plant, Eunice Gas Plant, Linam Ranch Gas Plant, Pecos River Compressor Station, Washington Ranch Storage Facility, South Carlsbad Compressor Station, Jal #3 Gas Plant, Bitter Lake Compressor Station, Roswell Compressor Station No. 9, Indian Basin Gas Plant, Eunice Gas Processing Plant, Monument Gas Plant, Saunders Gas Plant, and Cunningham Station Power Plant. From these facilities, a combined total of 61 units (or systems) have proposed limitations as part of reasonable progress in NMED's long-term strategy for the second planning period.

10.3.4.2 Emissions Reductions Due to Compliance and Enforcement Settlements in the Second Planning Period

In addition to the "measures necessary to make reasonable progress," discussed in Section 10.3.4.1, NMED has also issued several compliance orders above and beyond what was part of the source selection process. While these additional facilities/sources were not considered to be necessary for reasonable progress, these additional compliance orders for oil and gas facilities, located in the Permian Basin, have a direct impact on visibility-impairing pollution. These are mentioned here as additional weight of evidence that NMED is prioritizing the mitigation of anthropogenic sources of visibility impairing pollution in the area of influence of Salt Creek Wilderness Area.

April 29, 2024 – Ameredev Settlement – This settlement agreement, due to the cessation of excess emissions and a yet-to-be-determined mitigation project, will result in reductions of NO_X and other pollutants that cannot be quantified at this time.

March 27, 2023 – Matador Production Company – This Consent Decree, due to a program of engine replacement, is estimated to result in an additional reduction of 77 tons of NO_X over the next three years.

10.3.5 Summary and Visibility Outlook at Salt Creek Wilderness Area

NMED reviewed the IMPROVE monitoring trends through 2023 at Salt Creek Wilderness Area and observed that monitored IMPROVE visibility (in deciviews) is trending closer to aligning with the uniform rate of progress for most impaired days than the 2028 modeling indicates. The 2028 reasonable progress goals (as estimated in deciviews) are based on the 2028 OTBa2 WRAP modeling scenario, that most likely does not fully take into consideration most of the additional control measures being mandated in NMED's SIP Revision - Long-term strategy. Even so, in Section 10.3.2, NMED has calculated the number of years it would potentially take to attain the natural visibility conditions, [178] if visibility improvement were to continue at the rate of progress, based on the WRAP 2028 OTBa2 scenario. [179] EPA's guidance reads that "a state could provide within its SIP submission a narrative explanation of how the state has already conducted the source selection and control measures analyses in such a manner

[178] This included NMED's adjustment of the glidepath for international anthropogenic emissions and prescribed fire.

[179] 40 CFR 51.308(f)(3)(ii)

that addresses the [robust demonstration requirements]." [180] This is the case with the NMED SIP Revision as demonstrated in Section 10.3.4.

10.4 No Degradation Check for New Mexico Class I Areas

Section 9.3 shows the reasonable progress goals as modeled future year clearest days for each Class I Area in New Mexico. The future year visibility on the clearest days is projected to be below the no degradation limit at all Class I Areas in New Mexico. This demonstrates that the long-term strategy provides for no degradation in visibility at all New Mexico Class I Areas for the clearest days since the baseline period. [181]

[180] EPA Regional Haze SIP Guidance, pp. 50 to 51.
[181] 40CFR 51.308(f)(3)(i)

Chapter 11: Coordination and Discussions with Other Parties

The U.S. Environmental Protection Agency's (EPA) August 2019 Guidance on Regional Haze State Implementation Plans for the Second Implementation Period includes a Step 8a – "Additional Requirements for Regional Haze SIPs - Coordination and Discussions with Other Parties." [182]

EPA's guidance provides a roadmap for how states can satisfy some of the Regional Haze Rule requirements pertaining to coordination, specifically, as it pertains to:

- Consultation with other states;
- Consultations, notification and information sharing between New Mexico and Federal Land Managers (FLMs);
- Discussions with the Environmental Protection Agency (EPA); and
- Discussions with Tribes.

Because the pollutants that lead to regional haze can originate from sources located across broad geographic areas, EPA has encouraged the states and Tribes across the U.S. to address visibility impairment from a regional perspective, through Regional Planning Organizations (RPOs). New Mexico belongs to the Western Regional Air Partnership (see Figure 11-1).

Figure 11-1: Regional Planning Organizations.

As described in Chapter 1, these organizations evaluate technical information to better understand how their states and Tribes impact national parks and wilderness areas (Class I Areas) across the country, pursue the development of regional strategies to reduce emissions of pollutants that cause visibility

[182] EPA Regional Haze SIP Guidance, pp. 52 to 56.

impairment, and help states meet the consultation requirements of the Regional Haze Rule. Because the content of SIPs may affect air quality in and around Tribal land, EPA has indicated it recognizes the value in EPA, states, and multi-state organizations maintaining a dialogue with Tribes through all stages of developing regional haze SIPs.[182]

In 2018, WRAP's Regional Haze Planning Work Group formed specific subcommittees for the second planning period to develop Regional Haze data sets and recommendations on how to use the data.

11.1 Coordination with Local Jurisdictions and Other States

Because of the scope and design of the Regional Haze Rule, NMED prepared this Regional Haze SIPr Rd 2 (2019-2028) in close cooperation with the City of Albuquerque Environmental Health Department (EHD). Under state and local law, EHD prepares SIPs applicable to Albuquerque and Bernalillo County, proposing them for consideration by the Albuquerque - Bernalillo County Air Quality Control Board. [183] Separately, NMED prepares SIPs for the rest of the state and proposes them for consideration by the New Mexico Environmental Improvement Board (EIB). [184] Upon adoption by the EIB, NMED submits SIPs to EPA for final approval.

Coordination with other Western Region states has been mainly through WRAP. In addition to this broader-level coordination, NMED has also met informally with states in the Four-Corners region, including Arizona Department of Environmental Quality (Arizona DEQ), Utah Department of Environmental Quality (Utah DEQ), and Colorado Department of Public Health and Environment (CDPHE) as a group through the Four Corners Air Quality Group. NMED has also met one-on-one with the Texas Commission on Environmental Quality (TCEQ), Arizona DEQ, Utah DEQ, and CDPHE to help check in and coordinate the development of our respective Regional Haze draft SIPs.

In 2021, TCEQ reached out to NMED for a series of consultations, which primarily focused on sharing information from TCEQ on their modeling and draft SIP long-term strategy for reasonable progress. NMED provided some feedback, including suggestions that Texas consider further evaluating some of the sources impacting the Permian Basin area. At that time, WRAP had yet to complete the photochemical modeling that was part of the WRAP work plan, and NMED had yet to decide on its draft long-term strategy. NMED did share its source selection with TCEQ during the 2021 coordination. NMED's communication to TCEQ during this phase, prior to NMED's first draft SIPr Rd 2, is provided for reference in Appendix E.

Contiguous states, by their geographic proximity, have some potential interstate emissions impacts; however, for the purposes of second period Regional Haze planning, NMED did not make any specific requests for other states to require control measures at specific facilities. Likewise, no neighboring state or other state requested that NMED require controls at sources regulated by NMED. Communications and interactions with other states related to Regional Haze planning were primarily informal and consisted of information sharing. The suite of tools WRAP developed to help states address potential impacts of interstate emissions was mostly qualitative in nature. NMED used a qualitative tool, Q/d, for source screening, as discussed in Chapter 6. Other qualitative tools that later became available on source apportionment and estimating areas of influence are weight of evidence supporting NMED's long-term strategy and robust demonstration.

[183] NMSA 1978 §§ 74-2-5 and 74-2-5.1; ROA 1994 §§ 9-5-4 and 9-5-1-5; Bernalillo County Code §§ 30-33 and 30-34.
[184] NMSA 1978 §§ 74-2-5 and 74-2-5.1.

As part of the external outreach process, NMED shared the FLM review draft SIP revision - version 2024-05-20, with all five contiguous states (Texas, Arizona, Utah, Colorado, and Oklahoma), as well as the City of Albuquerque on June 20, 2024. NMED requested feedback by July 19, 2024. Only Arizona DEQ and TCEQ provided responses to NMED. The Arizona DEQ response on July 16, 2024, stated that they do not have comments or requests for NMED. TCEQ submitted a comment letter. Both responses are included in Appendix E. Neither Arizona DEQ, TCEQ, nor any other state has asked NMED for any additional sources to be analyzed or any specific control measures to be implemented at any source in New Mexico in order to meet their reasonable progress goals.

11.2 Consultation, Notification and Information Sharing between New Mexico and Federal Land Managers

NMED began coordination on the second planning period with its federal land manager (FLM) partners early in 2019, working together to determine which sources would be selected to undergo further evaluation for the long-term strategy. NMED continued to meet informally with FLMs from 2019 to the present to discuss various aspects of technical planning. NMED was also highly involved in and regularly participated in the in-depth Western Regional Air Partnership regional planning process which included FLMs, EPA, states, local agencies, and Tribes. Informal check-ins with the U.S. National Park Service and U.S. Forest Service occurred more recently, in the fall of 2023. Upon completion, a FLM review draft Regional Haze SIPr Rd 2 (2019-2028) was distributed to FLMs on May 20, 2024 to begin the formal FLM review period.

NMED values coordination with FLM and other partners in the Regional Haze Program. As part of the coordination and consultation with FLMs for the second planning period, NMED has followed the requirements for FLM coordination mandated by the Clean Air Act and Regional Haze Rule.

- Following a formal FLM review period, which began on May 20, 2024, and ended July 26, 2024, all comments received were considered before a revised draft Regional Haze SIPr Rd 2 (2019-2028) was developed in advance of NMED's public hearing process [185].
- An informational overview and summary webinar on the plan was held exclusively for FLMs on June 6, 2024, to provide a platform for initial questions and answers. All partner FLMs were in attendance for this event. A second meeting was scheduled by the National Park Service (NPS) on July 11, 2024, where they provided feedback on the FLM review draft prior to submitting formal written comments. Representatives from the U.S. Fish and Wildlife Service, U.S. Forest Service, and EPA were also in attendance for this meeting and were able to provide feedback.
- NMED followed the additional requirement from 42 USC § 7491(d) that NMED shall include a summary of the conclusions and recommendations of the federal land managers in the public hearing notice on the proposed Regional Haze SIPr Rd 2 (2019-2028). [186]
- Appendices E and F provide documentation of key communications between NMED and FLMs.
- Before submitting an EIB-adopted plan to EPA Region 6, NMED provided a description on how comments provided by the FLMs were addressed in the Regional Haze SIPr Rd 2 (2019-2028). [187]
- NMED values coordination between FLMs and other partners in the Regional Haze Program and plans to continue coordinating with FLMs on maintaining and improving visibility at Class I Areas. [188]

[185] 40 CFR § 51.308(i)(2).
[186] 42 USC § 7491(d).
[187] 40 CFR § 51.308(i)(3).
[188] 40 CFR § 51.308(i)(4).

11.3 Discussions with Environmental Protection Agency

NMED began discussions with its EPA regional office (Region 6) about New Mexico's plans and progress in developing a Regional Haze SIPr Rd 2 (2019-2028) early and discussions continued throughout the SIP development process. In these discussions, EPA has provided feedback to the state on how the provisions of the Regional Haze Rule and the recommendations in EPA guidance can be applied in the context of New Mexico's SIP. EPA has shared EPA technical products, as appropriate and relevant. NMED has encouraged collaboration between EPA Region 6 and New Mexico's regional planning organization (WRAP).

As part of the external review process, NMED shared the FLM review draft with EPA Region 6 on May 23, 2024. NMED provided through July 26, 2024, for EPA to provide feedback. NMED granted EPA an additional extension to July 30, 2024, at which time EPA submitted comments to NMED. NMED also provided a public review draft SIP revision and draft new Regional Haze rule to EPA Region 6 on August 26, 2024. EPA provided NMED additional comments related to the draft new rule, NMAC 20.2.68 – Regional Haze Requirements, on September 9, 2024. EPA's comments are included in Appendix E.

11.4 Coordination with Tribes, Nations, and Pueblos

While there are no specific state-Tribal consultation requirements set by federal legislation, NMED recognizes the State of New Mexico is home to many Tribes, Nations, and Pueblos and values coordinating with Tribes on projects that may impact air quality in and around Tribal land.

NMED conducted additional outreach to Tribal leaders in New Mexico, notifying them of the availability of the draft SIP revision. A letter was sent via email to the following Tribes, Nations, and Pueblos on June 10, 2024, which provided a link to the draft Regional Haze SIPr Rd 2 (2019-2028) and notifying them of upcoming engagement opportunities. These meetings were conducted online via Webex on June 18 and June 20, 2024, which saw several members of Tribal leadership and environmental department representatives in attendance. Copies of the letters transmitted to Tribal leaders and environmental contacts are provided in Appendix E. Further communication and engagement opportunities were offered both in the letter and during the webinar.

- Fort Sill Apache Tribe
- Ute Mountain Ute Tribe

11.5 Industry Specific Engagement on Sources Selected for Four-Factor Analysis

NMED engaged directly with industry as part of the outreach program. Updates on the Regional Haze SIPr Rd 2 (2019-2028) progress were provided as milestones were met, or as otherwise necessary. Outreach began with source selection notifications in 2019, [189] and communication with industry has been ongoing since that date. Whenever key updates or milestones were reached, industry members were notified. In May 2023, NMED contacted all affected companies and offered to meet with them to discuss any new updates or plans regarding selected sources to help NMED finalize its four-factor analyses. Copies of these communications to affected companies are included in Appendix E. Meetings were held between May 2023 to November 2023 with all companies that requested to meet including: DCP Operating Company, El Paso Natural Gas Company, Enterprise Field Services, ET Gathering & Processing, Transwestern Pipeline Company, Harvest Four Corners, Hilcorp Energy Company, IACX Roswell, Targa Midstream Services, and Xcel Energy. NMED shared draft final cost evaluations with all affected companies in early December 2023, and accepted feedback from them through January 15, 2024. Several facilities requested meetings with the department early in 2024, which allowed additional opportunities to receive comments and provide more information regarding the content of these documents. NMED also shared a public review draft Regional Haze SIPr Rd 2 on August 26, 2024, and requested feedback and comment. Advance notice was provided to affected industry of public review draft availability, as coordination with industry is an important element of the SIPr development process. NMED received comments during the August 26,2024 – September 20, 2024 public review period from DCP Operating Company, El Paso Natural Gas Company (EPNG), Enterprise Field Services, and Public Services Company of New Mexico. Clarifying questions were also asked by Transwestern Pipeline and answered by NMED. After the conclusion of the public review draft comment period, EPNG requested an additional meeting with NMED to discuss their comments further and provide recommendations concerning potentially affected EPNG facilities/units. Subsequently, NMED met with EPNG on October 22, 2024, to listen to their suggestions and recommendations. Comments received from industry during the public review period are included in Appendix E.

11.6 General Outreach, Education, and Stakeholder Engagement

In partnership with City of Albuquerque-EHD, NMED conducted introductory Regional Haze planning public webinars in 2019-2020. Additional stakeholder webinars were hosted by NMED in 2023. NMED also has maintained a Regional Haze planning website at https://www.env.nm.gov/air-quality/reg-haze/ and provided announcements regarding regional haze planning through its listservs.

NMED distributed a public review draft SIPr (2019-2028) and a draft new companion rule, 20.2.68 NMAC – Regional Haze Requirements, in August 2024, for review and comment by members of the public, industry and other stakeholders. During this phase, two public information webinars were hosted by NMED to provide an overview on the public review drafts and receive feedback and questions from stakeholders. NMED received comments on the public review drafts from Sierra Club, Wild Earth Guardians, and Western Environmental Law Center. These comments are included in Appendix E.

[189] See Appendix E

11.7 Overarching Responses to Comments Received.

At the conclusion of the FLM consultation period, NMED received substantive comments from the U.S. National Park Service (NPS) and EPA Region 6. See Appendix E for EPA comments, and Appendix F for the formal FLM comments. The NPS comments were largely focused on concerns regarding NMED's evaluation of selective catalytic reduction (SCR) for natural gas-fired combustion turbines. NMED carefully considered the comments and revised its SCR analyses in response, resulting in some changes to its control measures determinations and long-term strategy. By and large, other FLM comments commended NMED on engagement, source selection, and the long-term strategy. A summary of the FLMs' conclusions and recommendations follows:

- U.S. National Park Service – "We greatly appreciate NMED's FLM early and frequent consultation engagement process. We also commend your approach for source selection, agree with not using visibility benefits in potential control measure determinations, and generally support criteria used in Reasonable Progress determinations. We are providing comments on NMED's approach to selective catalytic reduction (SCR) costs and/or feasibility review along with recommendations for specific facility determinations. Overall, the NPS finds your plan to be clear, concise, and well-organized with significant reductions proposed at 13 facilities in New Mexico." (7/26/24)
- U.S. Forest Service – "We are satisfied with the document as provided and offer no suggestions for change beyond the informal suggestions to clarify language that were shared via email on July 19th, 2024. We appreciate the opportunity to work closely with the New Mexico Environment Department. The Forest Service compliments you on your hard work and dedication to significant improvement in our nation's air quality values and visibility." (7/19/24)[190]
- U.S. Fish and Wildlife Service – indicated the SIP was one of, if not the best, of all that had been reviewed thus far. (7/11/24)

EPA Region 6 also commented on the regulatory mechanism for making the emissions limitations and other measures in the draft SIP federally enforceable. NMED determined that promulgating a new rule containing the emissions limitations, compliance deadlines, and other measures necessary for reasonable progress was the best option. NMED drafted a new rule, 20.2.68 NMAC – Regional Haze Requirements, [191] as a companion to the SIP. Other recommendations by EPA on strengthening parts of the SIP were determined to require considerable additional analysis which would result in further delay and would not have a substantive effect on the proposed long-term strategy or robust demonstration. NMED's source selection, as required by the Regional Haze rule, was made in 2019 and was discussed frequently with WRAP and other stakeholders. FLMs were consulted with at that time and agreed on the source selection. This step determined the analysis required for the subsequent steps, including the four-factor analysis and the control measure determinations developed for the long-term strategy. FLMs have applauded NMED's source selection and EPA has informally commented that our source selection was adequate. The full content of EPA's recommendations to NMED are available in Appendix E.

NMED received other informal comment letters from TCEQ and the Ute Mountain Ute Tribe, included in Appendix E. The comments from TCEQ provided supplemental information on emissions inventories in Texas. NMED is part of the Western Regional Air Partnership (WRAP) and relied on emissions inventories

[190] NMED revised the draft SIP to incorporate all the USFS Informal comments related to U.S. National Forest descriptions and the IMPROVE monitoring network.

[191] See Appendix G

and modelling provided by the WRAP to prepare this SIP revision. Information provided from TCEQ in this comment letter, 7/16/24, came after the WRAP completed its work plan for the second planning period and finalized the WRAP Technical Support System (TSS). See Appendix A and B for more information on the WRAP TSS. NMED also appreciates the engagement and comments from the Ute Mountain Ute Tribe. The comments were primarily on the embedded progress report and do not substantively affect NMED's process or determinations made for this second planning period SIP revision. NMED did not make changes to the public review draft SIP in response to either of these sets of comments.

During the general stakeholder outreach process, the National Parks Conservation Association and other environmental groups also engaged with NMED and provided comments during the development of this Regional Haze SIPr Rd 2 (2019-2028). NMED appreciates the engagement and feedback from NPCA, other environmental groups, and all the other stakeholders that have participated in the stakeholder engagement process.

Nine organizations, including five affected companies, three environmental advocacy groups, a federal land manager, and EPA submitted comments on the public review drafts of New Mexico's Regional Haze plan and new companion rule. The review period spanned August 26 – September 20, 2024. NMED held two stakeholder engagement webinars (9/9) and (9/10) during the review period. All comments submitted during the public review period are included in Appendix E.

Additional comments were submitted to NMED as part of the engagement process after the petition, involving all parties that submitted entries of appearance in the hearing. These comments are also included in Appendix E.

NMED weighed the evidence provided in comments and then made revisions to the proposed plan and rule in cases where the evidence supported those revisions. Substantive revisions included:

- NMED revised the assumed NO_X removal efficiency of SCR for certain units based on feedback from industry.
- NMED revised the methodology used for adjusting estimated costs from previous year dollars to 2024 dollars based primarily on feedback from industry.
- NMED updated the bank prime interest rate from 8.5% to 7.5%, the current overnight lending rate as of December 2024, based on feedback from environmental groups and industry.

In addition to the changes described above, NMED has made a number of non-substantive revisions to NMED's proposed regional haze SIP revision. These include correcting typographical errors, providing further explanation in various places at the request of EPA, and providing additional time for one unit to come into compliance with a new emission limit that reflects a control the owner is currently installing for compliance with 20.2.50 NMAC.

Chapter 12: Monitoring Strategy and Other Elements

12.1 Regulatory Requirements

The U.S. Environmental Protection Agency's (EPA) August 2019 Guidance on Regional Haze State Implementation Plans for the Second Implementation Period includes a final section for "Additional requirements for regional haze SIPs." [192] This section is a "catch-all" for Regional Haze Rule requirements that have not already been addressed elsewhere in EPA's Guidance. That section lists three requirements: a) Consultation and discussions with other parties, which is covered in Chapter 11 of this Regional Haze SIPr Rd 2 (2019 – 2028); b) Progress report elements, which is covered in Chapter 5; and c) Monitoring strategy and other elements, which is covered in this chapter. The specific regulatory requirements that this chapter addresses are as follows:

1) An assessment of the current monitoring strategy necessary for measuring, characterizing, and reporting of regional haze visibility impairment that is representative of all Class I Areas within New Mexico; for determining the contribution of emissions from within New Mexico to regional haze visibility impairment at Class I Areas in other States; for reporting all visibility monitoring data to the EPA Administrator at least annually; and for any other measure–including reporting and recordkeeping–necessary to assess and report on visibility. [193]
2) The provisions for a statewide inventory of emissions of pollutants that are reasonably anticipated to cause or contribute to visibility impairment in any Class I Area; and a commitment to update the inventory periodically. [194]

12.2 Assessment of Current Monitoring Strategy

The Regional Haze Rule requires that "The State must submit with the implementation plan a monitoring strategy for measuring, characterizing, and reporting of regional haze visibility impairment that is representative of all mandatory Class I Federal areas within the State. Compliance with this requirement may be met through participation in the Interagency Monitoring of Protected Visual Environments (IMPROVE) network." [195]

The primary monitoring network for regional haze, both nationwide and in New Mexico, is the IMPROVE network. IMPROVE network operations are governed by a Steering Committee that guides the management of the monitoring network and the collection of data for use in complying with the Regional Haze Rule. The IMPROVE Steering Committee consists of representatives from 10 voting member organizations. These organizations include:

- U.S. Forest Service (USFS);
- National Park Service (NPS);
- U.S. Fish and Wildlife Service (FWS);
- Bureau of Land Management (BLM);
- Environmental Protection Agency (EPA);
- National Oceanic & Atmospheric Administration (NOAA);
- National Association of Clean Air Agencies (NACAA);
- Northeast States for Coordinated Air Use Management (NESCAUM);

[192] EPA Regional Haze SIP Guidance, pp. 52 to 56.
[193] 40 CFR § 51.308(f)(6)(ii), (iv) and (vi).
[194] 40 CFR § 51.308(f)(6)(v).
[195] 40 CFR § 51.308(f)(6).

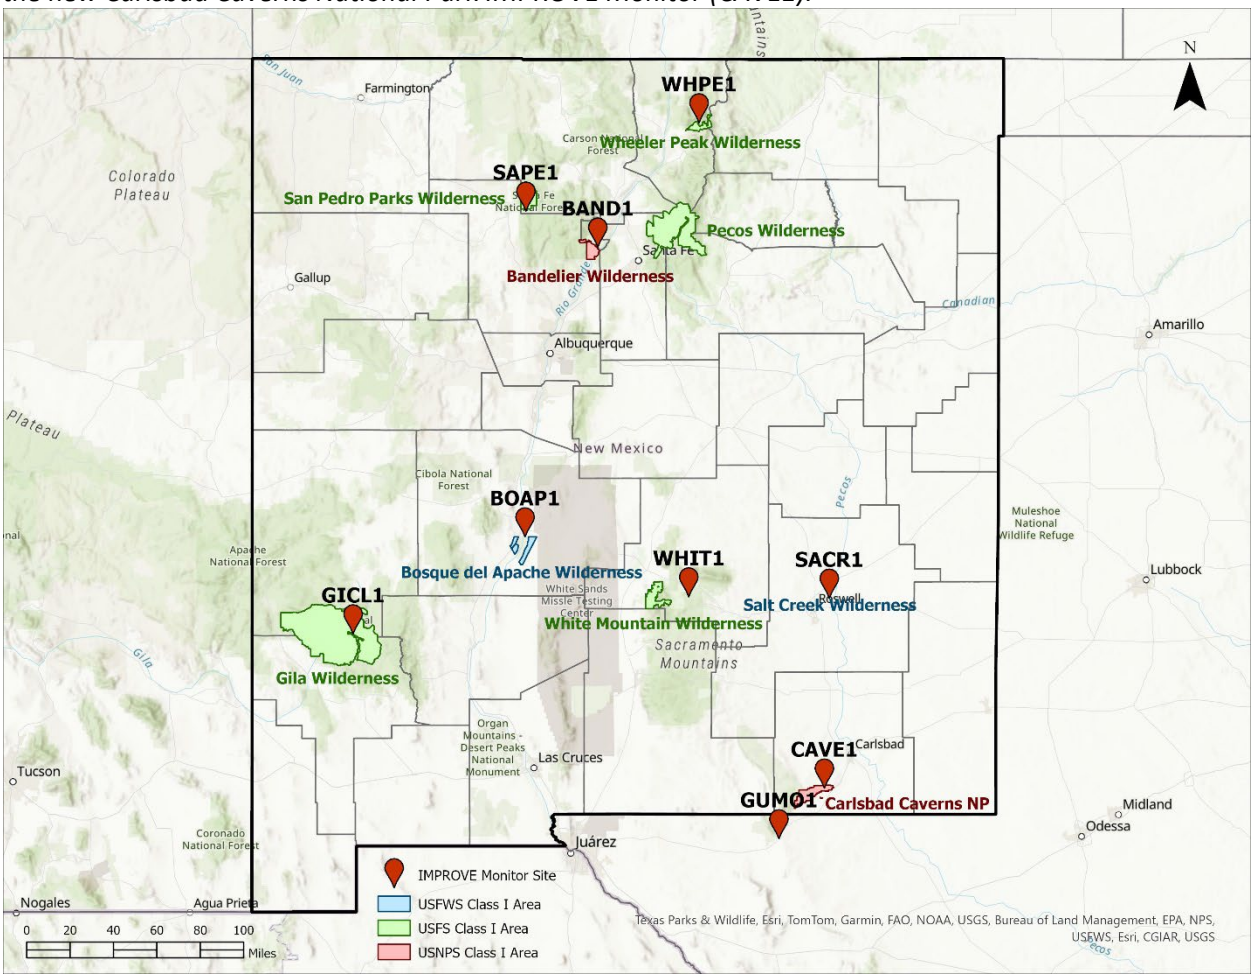
- Western States Air Resources Council (WESTAR); and
- Mid-Atlantic Regional Air Management Association (MARAMA).

Members of the Steering Committee are appointed by their organizations and serve an indefinite term determined by their organization. The Steering Committee also has three non-voting associate members:

- Arizona Department of Environmental Quality;
- Environment and Climate Change Canada; and
- Republic of Korea Ministry of Environment.

WESTAR is the agency that represents New Mexico's interests on the IMPROVE Steering Committee along with those of its other members.[196] The existing IMPROVE network was deemed adequate to assess whether our RPGs are being met so no additional monitoring sites are needed at this time. The Steering Committee allocates monitoring resources, which come from several agencies. The IMPROVE program arranges for the operation of monitors, the analysis of samples, and the validation and posting of the data on the internet. EPA takes associated program support funds for IMPROVE monitor sites from the annual State and Tribal Assistance Grant budgets, then allocates the remaining grant amount to states. EPA doesn't withhold different amounts from each state for the 110 IMPROVE sites. For FY 2023 and FY 2024, about $4 million of $PM_{2.5}$ monitoring funds was proposed to support visibility monitoring at 110 IMPROVE sites and two sites collocated with Clean Air Status and Trends Network monitoring sites.[197]

Given that IMPROVE monitoring data from 2000 – 2004 serves as the baseline for the Regional Haze Program, the future regional haze monitoring strategy must necessarily be based on – or directly comparable to – the current IMPROVE monitoring program. IMPROVE measurements provide the only long-term record available for tracking visibility improvement or degradation and, therefore, New Mexico intends to continue relying on the IMPROVE monitoring program for complying with the monitoring requirements in the Regional Haze Rule. The IMPROVE monitoring program's practice of providing data directly to EPA satisfies the requirements in sections 51.308(f)(6)(iv) and (vi) of the Regional Haze Rule.[198]



There are eight IMPROVE monitors in New Mexico and one in Texas that provide visibility information for New Mexico's Class I Areas. These monitors and the New Mexico Class I Areas they represent are listed in Table 12-1 below, and their locations are shown in Figure 12-1. The WHPE1 monitor provides data for both the Pecos Wilderness Area and Wheeler Peak Wilderness Area. The GUMO1 monitor provided visibility monitoring information for Carlsbad Caverns National Park prior to the establishment of the CAVE1 monitor in 2017.

[196] WESTAR members include the air quality program managers from the 15 westernmost states: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, North Dakota, Oregon, South Dakota, Utah, Washington, and Wyoming.
[197] Ibid. Page 25 of 31.

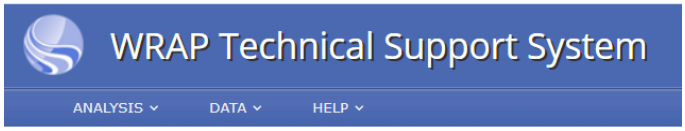
GUMO1 (Texas)	Carlsbad Caverns National Park	NPS

Figure 12-1: Map Showing IMPROVE Monitor Sites Representing New Mexico's Class I Areas, Including the new Carlsbad Caverns National Park IMPROVE Monitor (CAVE1).

12.3 Statewide Inventory of Emissions

The Regional Haze Rule requires that the implementation plan must also provide for "A statewide inventory of emissions of pollutants that are reasonably anticipated to cause or contribute to visibility impairment in any mandatory Class I Federal area. The inventory must include emissions for the most recent year for which data are available, and estimates of future projected emissions. The State must also include a commitment to update the inventory periodically." [199]



The State of New Mexico prepares annual and triennial emission inventories in compliance with the Consolidated Emissions Reporting Rule (CERR), promulgated by EPA in 2002 [200] and codified at 40 CFR Part 51 Subpart A, thereby satisfying the requirement to provide for the preparation of an emissions inventory for the most recent year for which data are available. [201] NMED will continue to submit annual inventories of pollutants, including those reasonably anticipated to cause or contribute to visibility impairment.

Estimates of future projected emissions for regional haze planning are typically developed by EPA and Multi-Jurisdictional Organizations such as the Western Regional Air Partnership (WRAP), with state coordination. For the second planning period WRAP developed several future year emissions inventory projections for western states that were made available publicly through the WRAP Technical Support System (TSS). [202]

[199] 40 CFR § 51.308(f)(6)(v).
[200] 67 Fed. Reg. 39602 (June 10, 2002)(Consolidated Emissions Reporting).

Contents **Page Number**

1.0 Purpose 2

2.0 Background 2

3.0 Emissions Scenarios 5

4.0 References 24

1.0 Purpose:

The Western Regional Air Partnership and Western Air Quality Study (WRAP-WAQS) 2014 Regional Haze modeling platform is the latest of a series of regional modeling efforts supporting western U.S. air quality planning and management. The WRAP technical analyses follow the Environmental Protection Agency's (EPA) Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.5, and Regional Haze (November 2018) and the Technical Support Document for EPA's updated 2028 regional haze modeling (September 2019). The analyses fulfill the objectives of the WRAP 2018-2019 Workplan as updated and approved by the WRAP Board on April 3, 2019 and have been collectively designed, implemented, and reviewed by the WRAP Technical Steering Committee and its workgroups and subcommittees.

The Western Regional Air Partnership (WRAP) Technical Support System (TSS) hosts the visibility monitoring, emissions, and air quality modeling analyses that support the 15 western states in developing regional haze state implementation plans (SIPs). This reference document describes the WRAP emissions and modeling analyses and illustrates how the TSS products can be applied and interpreted to support the 2028 visibility progress demonstrations for western U.S. Class I areas.

2.0 Background:

The Regional Haze Rule requires states to demonstrate progress every ten years toward the Clean Air Act goal of no manmade visibility impairment. EPA guidance for tracking visibility progress (December 2018) defines a visibility impairment tracking metric (measured in deciview) using observations from the Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring network sites that represent Class I areas. EPA defined in the Regional Haze Rule and guidance a Uniform Rate of Progress glidepath for the 20% most impaired days as the straight line from the 2000-2004 IMPROVE 5-year average baseline to EPA estimates of future natural visibility conditions, plotted at 2064. In the first regional haze planning period, 2000-2018, EPA guidance interpreted most impaired days as those days with highest total haze. States were required to demonstrate visibility progress by 2018 compared to the Uniform Rate of Progress glidepath for the haziest days and no degradation of visibility on the clearest days from the 2000-2004 IMPROVE 5-year average baseline. Visibility on the clearest days improved between 2000 and 2018 across the Class I areas in the western U.S. However, smoke from wildfire and wildland prescribed fire events and dust events on the haziest days made tracking the visibility benefits due to reducing U.S. anthropogenic emissions more difficult.

For the second regional haze implementation period, 2018-2028, states are required to demonstrate visibility progress by 2028 for the most impaired days and no visibility degradation for the clearest days. EPA guidance (December 2018) defined most impaired days as those days

with the highest fractional contribution to aerosol light extinction from anthropogenic sources. EPA statistical methods use IMPROVE measurements of carbon and crustal materials to separate contributions from episodic extreme natural events (e.g., wildfire or dust) from routine natural and anthropogenic contributions. Ammonium sulfate and ammonium nitrate are assigned primarily to anthropogenic emissions with smaller contributions from routine natural sources. This statistical approach does not separate contributions due to U.S. anthropogenic emissions from those of international anthropogenic emissions. Since states do not have authority to reduce international emissions, WRAP conducted source apportionment modeling analyses to evaluate U.S. anthropogenic contributions to haze and progress in reducing U.S. anthropogenic contributions to haze over time.

Table 1 summarizes the emissions and modeling scenarios, source apportionment runs, and alternative visibility progress analyses that were performed to support state regional haze planning.

3.0 Emissions Scenarios:

2014v2 Base Year for WRAP Regional Haze Modeling

The WRAP 2014v2 inventory was based on the 2014v2 National Emissions Inventory (NEI) plus updates provided by western states through WRAP Regional Haze workgroup's Emissions and Modeling Protocol subcommittee.

Table 2 defines the WRAP 2014v2 sector-specific data sources. WRAP states replaced the 2014v2 NEI source sectors as listed below:

- California Air Resources Board (CARB) provided emissions for all anthropogenic sectors in California.
- WRAP states updated emissions for electric generating units (EGU), non-EGU point sources, and onroad mobile.
- The WRAP Oil and Gas Workgroup and its contractor Ramboll, Inc., defined a Roadmap for updating oil and gas inventories and delivered updated 2014 emissions (October 2018) for Colorado, Montana, New Mexico, North Dakota, South Dakota, Utah, and Wyoming (emissions for remaining WRAP states remain as in the EPA 2014v2 platform).
- The WRAP Fire and Smoke Work Group (FSWG) updated the 2014NEIv2 BlueSky/SmartFire emissions.
- Natural emissions were developed by WRAP for 2014v2 and held constant at 2014v2 levels for the Representative Baseline and future year scenarios.
- All other WRAP emissions sectors and all Non-WRAP emissions for WRAP 2014v2 were based on the EPA 2014 modeling platform.

Table 2. Data sources for WRAP emissions sectors for the 12-km 12WUS2 and 36-km US domains for the 2014v2, Representative Baseline (RepBase2) and 2028OTBa2 model scenarios.

1. WRAP-RepBase2-EGU and WRAP-2028OTBa2-EGU include changes/corrections/updates from WESTAR-WRAP states
2. WRAP-RepBase2-O&G and WRAP-2028OTBa2-O&G both include corrections for WESTAR-WRAP states.
3. O&G for other WRAP states and Non-WRAP states use EPA-2016v1 assumptions for 2028OTBa2 and unit-level changes provided by WESTAR-WRAP states.
4. WRAP-2014v2 Non-EGU Point is used for RepBase2 and 2028OTBa2, with source specific updates provided by WESTAR-WRAP states.
5. WRAP-2028-MOBILE is used for On-Road and Non-Road sources for the 12WUS2 domain.
6. EPA-2016v1 and EPA-2028v1 are used for On-Road and Non-Road Mobile for the 36km US domain.
7. Non-Point emissions use 2014v2 emissions for RepBase2 and 2028OTBa2 scenarios, including state-provided corrections.
8. RepBase fires are used for both RepBase2 and 2028OTBa2

Representative Baseline (RepBase2)

The Representative Baseline (RepBase2) emissions scenario updates the 2014v2 inventory to account for changes and variation in emissions between 2014 and 2018 for key WRAP source sectors, as defined by the WRAP Emissions and Modeling Protocol subcommittee. The RepBase inventory was delivered in February 2020 as listed below.

- California Air Resources Board (CARB) used the same source sector emissions as defined for 2014v2.
- The WRAP EGU Emissions Analysis Project developed a comprehensive database for fossil fuel electric generating units in 13 continental western states, including operating characteristics and emissions, for the period circa 2014-2018. Methods are defined in Center for New Energy Economy's analysis of WRAP fossil-fueled Electric Generating Units for Regional Haze Planning and Ozone Transport Contribution (June 2019.)
- The WRAP Oil and Gas Workgroup and its contractor, Ramboll, Inc., developed the circa-2014 baseline oil and gas inventory to apply to the RepBase inventory.
- The WRAP Fire and Smoke Work Group (FSWG) worked with states, tribes, federal land managers and Air Sciences, Inc., to define 2014 to 2018 wildfire emissions for the Continental U.S. (36-km modeling grid) to represent a broader range of fire conditions (Representative Fire) than the single year 2014, as reported in Fire Emissions Inventories for Regional Haze Planning: Methods and Results (April 2020).
- All other emissions sectors used the EPA 2016v1 platform for RepBase.

During state review of the Representative Baseline emissions, some errors and duplicate records were identified. WRAP states revised select EGU, non-EGU point, and oil and gas emissions for a revised Representative Baseline (RepBase2). Data sources for RepBase2 emissions, as delivered in September 2020, are defined in **Table 2.** Emissions sectors that changed between 2014v2 and RepBase2 are defined in **Table 4**.

The RepBase2 WRAP Point source emissions are available to download on the WRAP Regional Haze Planning Work Group webpage. Note that these point source emissions files are not identical to the SMOKE emissions model outputs that are posted on the TSS.

WRAP methods are further defined in Ramboll Inc.'s Run Specification Sheet for Representative Baseline (RepBase2) and 2028 On-the-Books (2028OTBa2) CAMx Simulations.

2028 On the Books Inventory (2028OTBa2)

The WRAP 2028OTBa emissions inventory projection followed the methods applied by EPA in the September 2019 Technical Support Document for updated 2028 regional haze modeling. The WRAP states updated source sectors to account for implementation by 2028 of all applicable federal and state requirements for U.S. anthropogenic emissions as listed below:

- California Air Resources Board (CARB) provided 2028OTB projections from 2014v2 for all anthropogenic source sectors.

- WRAP states worked with western utilities and the Center for New Energy Economy to project EGU emissions for 2028 On the Books, as reported in Analysis of EGU Emissions for Regional Haze Planning and Ozone Transport Contribution (June 2019).

- The WRAP Oil and Gas workgroup and its contractor, Ramboll, Inc., projected 2028 Oil and Gas area and point source emissions for WRAP states as reported in Revised Final Report: 2028 Future Year Oil and Gas Emission Inventory for WESTAR-WRAP States, March 2020 version.

  Table 3. 2028 On the Books Oil and Gas emissions by WESTAR-WRAP State split into Tribal and Non-Tribal mineral ownership, for Nitrogen Oxides and Volatile Organic Compounds (tons/year) from Revised Final Report: 2028 Future Year Oil and Gas Emission Inventory for WESTAR-WRAP States, March 2020

State	NOx Emissions (tons/year)		VOC Emissions (tons/year)

WY	24,162	171	109,152	438
Total	**259,690**	**33,815**	**751,403**	**110,023**

- WRAP 2028 CAMx-ready emissions for on-road and non-road mobile sources, including off-shore shipping, rail and airports are reported in Mobile Source Emissions Inventory 2028 Projections Project.

- Wildfire, Wildland Prescribed fire, and agricultural fires for the 2028OTBa inventory were identical to RepBase fires.

In September 2020, the WRAP states made revisions to select EGU, non-EGU, and oil and gas emissions for the WRAP states in the updated 2028OTBa2 projection. EPA 2016v1 emissions were

assigned to some source sectors for WRAP, non-WRAP, Canada and Mexico in lieu of EPA 2028v1 emissions to provide more conservative assumptions for the 2028OTBa2 projection. 2028OTBa2 data sources are listed in **Table 2** and 2028OTBa2 emissions sectors that changed emissions compared to RepBase2 are listed in **Table 4**.

WRAP methods are further defined in the Run Specification Sheet for Representative Baseline (RepBase2) and 2028 On-the-Books (2028OTBa2) CAMx Simulations. Note that these point source emissions files are not identical to the SMOKE emissions model outputs that are posted on the TSS. Also, point sources on Tribal lands are listed separately from state point sources.

The 2028OTBa2 WRAP Point source emissions are available to download on the WRAP Regional Haze Planning Work Group (wrapair2.org) webpage. Note that these point source emissions files are not identical to the SMOKE emissions model outputs that are posted on the TSS.

2028 Potential Additional Controls (PAC2)

Some, but not all, western states defined Potential Additional Controls beyond the On the Books controls to evaluate the potential visibility response in 2028. The states and source categories for additional potential controls are defined in **Table 5**.

Table 5. WESTAR-WRAP States and source sectors modified in the 2028 Potential Additional Controls (PAC2) modeling scenario compared to 2028OTBa2.

2028PAC2 changes to 2028OTBa2	AZ	CA	CO	ID	MT	NV	NM	ND	OR	SD	UT	WA	WY
EGU - point	x				x	x	x	x	x				
Non-EGU point				x		x	x		x			x

On-road Mobile		x											

Point source emissions spreadsheets for the 2028OTBa2 and PAC2 emissions scenarios, after data review by WESTAR-WRAP states completed October 9,2020, are found on the WRAP Regional Haze Planning Workgroup webpage.

Future Wildfire Sensitivity 1

In addition to the 2014v2 and Representative Baseline/2028 On the Books fire scenarios, the WRAP Fire and Smoke Work Group (FSWG) defined a future wildfire sensitivity (FFS1) (not specific to any single future year) as an alternative to using 2014-2018 wildfire activity data for 2028 visibility projections. The future wildfire emissions are used with 2028OTBa2 emissions for all other emissions sectors.

Modeling a range of future fire emissions will help visualize potential future impacts from this sector. The purposes of this sensitivity are to determine:

- how changes in wildfire activity change the projected 2028 visibility response to US anthropogenic emissions using the regional haze tracking metric
- monthly variation in future wildfire impacts compared to the 2028OTBa2 reference case.

Methods for the future wildfire sensitivity (FFS1) are described in Air Sciences' report Fire Emissions Inventories for Regional Haze Planning: Methods and Results (April 2020) and summarized in the modeling Specification Sheet for Future Fire Sensitivities (August 2021). As summarized in **Table 6**, future wildfire acreage and emissions may be greater than or less than those of the RepBase2/2028OTBa2 emissions scenarios. Emissions from wildland prescribed fire and agricultural burns were the same in FFS1 as for the RepBase2/2028OTBa2 scenarios.

Table 6. Comparison of fire emissions in continental WESTAR-WRAP states for the Wildfire (FFS1) modeling sensitivity, relative to the RepBase2/2028OTBa2 scenarios by fire event, acres burned, tons of fuel consumed, and $PM_{2.5}$ emissions, as well as differences in percent.

	Wildfire (FFS1)				RepBase2 / 2028OTBa2				Percent Difference

Future Wildland Prescribed Fire Sensitivity 2

The WRAP Fire and Smoke workgroup defined a no-year future wildland prescribed fire sensitivity (FFS2) as an alternative to using 2014-2018 RepBase2 activity data for 2028 visibility projections.

U.S. land management agencies intend to increase the acres burned by wildland prescribed fire in future years to reduce the vegetation that fuels high-intensity wildfires. The purposes of this sensitivity were to determine:

- how changes in wildland prescribed fire could change the 2028 visibility projections that are used in regional haze planning.
- monthly variation in future wildfire impacts compared to the 2028OTBa2 reference case.

Methods for the future wildland prescribed fire sensitivity (FFS2) are described in Air Sciences' report Fire Emissions Inventories for Regional Haze Planning: Methods and Results (April 2020) and summarized in the modeling Specification Sheet for Future Fire Sensitivities. The FFS2 wildland prescribed fire events were tied to the same geographic ecoregions and dates as the RepBase2 burns. The acreages of the FFS2 events were randomly selected and emissions were recalculated. As summarized in **Table 7**, future wildland prescribed fire acreage and emissions may be greater than or less than those defined for the RepBase2/2028OTBa2 emissions scenarios. Wildfire events and agricultural burns are held the same as for RepBase2/2028OTBa2 scenarios.

Table 7. Comparison of fire emissions in continental WESTAR-WRAP states for the Wildland Prescribed fire (FFS2) modeling sensitivity, relative to the RepBase2/2028OTBa2 scenarios by fire event, acres burned, tons of fuel consumed, $PM_{2.5}$ emissions, and percent differences.

	Prescribed Burning (FFS2)				RepBase2 / 2028OTBa2				Percent Difference

2002 Hindcast Emissions

The purposes of the Dynamic Evaluation and 2002 Hindcast emissions were:

- test the CAMx 2014v2 model platform's ability to project observed air quality changes in response to observed emissions changes between the 2000-2004 baseline and the 2014-2018 (RepBase2) planning period at western U.S. IMPROVE monitors.
- evaluate U.S. Anthropogenic emissions rate of progress between 2002 and 2028OTBa2 to define a modeled U.S. Anthropogenic visibility rate of progress by 2028.

Methods for the 2002 Hindcast are described in the Run Specification Sheet for Dynamic Evaluation – 2002 CAMx Simulation and Analysis. TheRepBase2 emissions were hindcast to the 2002 base year using the current inventory methods and 2002 activity data. Natural and non-US emissions were held the same as RepBase2 so that all changes in air concentrations and visibility between 2002 and RepBase2 were attributable to changes in U.S. anthropogenic emissions.

Emission Scenarios Comparison:

Annual emissions (tons per year) for ammonia (NH3), carbon monoxide (CO), nitrogen oxides (NOx), particulate matter less than 2.5 micrometers (PM2.5), particulate matter less than 10 micrometers (PM10), sulfur dioxide (SO2), and volatile organic compounds (VOC) for 13 continental U.S. western states, 14 anthropogenic source groups, and 6 natural source categories for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 emissions scenarios can be downloaded from the TSS Emissions Express Tools. The emissions data displayed on the Technical Support System are composited from more detailed pollutant emissions records (to be displayed on the Intermountain West Data Warehouse), as defined in **Table 8** below.

Table 8. Pollutant Emissions displayed on the WRAP Technical Support System and summarized on Intermountain West Data Warehouse.

Final – January 2021

Modeled Pollutant Emissions	Pollutant Code	Technical Support System (TSS) Pollutant Emissions	Pollutant Code
Carbon Monoxide	CO	Carbon Monoxide	CO
Nitrogen Oxides	NOx = NO+NO2+HONO	Nitrogen Oxides	NOx
Sulfur Dioxide	SO2	Sulfur Oxides	SO2
Volatile Organic Compound	VOC	Volatile Organic Compound	VOC
Ammonia	NH3	Ammonia	NH3
Sulfuric Acid	SULF		
Total Particulate Matter less than 2.5 mm (PM2.5)	PM2.5 = POA + PEC + PNO3 + PSO4 + PNH4 + Elements + FPRM	Total Particulate Matter less than 2.5 mm	PM2.5

Particulate Organic Carbon	POA		
Particulate Elemental Carbon	PEC		
Nitrate	PNO3		
Sulfate	PSO4		
Ammonium	PNH4		
Elements	PFE + PMN + PK + PCA + PMG + PAL + PSI + PTI		
"Remaining" Fine Particulate Matter	FPRM		
Coarse Particulate Matter	CPRM		
Particulate Matter less than 10 mm	CPRM + PM2.5	Particulate Matter less than 10 mm	PM10
Sea salt	PCL + NA		

Examples of emissions results that are displayed in TSS Emissions Express Tools # 1-4 are illustrated below.

2017 National Emissions Inventory (NEI) data also can be displayed in TSS Emissions Express Tools # 1-3.

- To display emissions values, below each chart # 1-3, select to show "+ chart data".

Figures 1a-1c illustrate NOx, SO2, and PM2.5 emissions, respectively, for all anthropogenic emissions sectors for WESTAR-WRAP states for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 emission scenarios (TSS Emissions Express Tool # 1).

Figures 2a-2c illustrate NOx, SO2, and PM2.5 emissions, respectively, for Oil and Gas Point sources (one of 14 anthropogenic source sectors that can be selected for display) for WESTAR-WRAP states and the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 emission scenarios (TSS Emissions Express Tool # 2)**.**

Figures 3a-3d illustrate total NOx emissions for the 2014v2, RepBase2, and 2028OTBa2 scenarios, and the 2017 National Emissions Inventory, respectively, for the 13 continental WESTAR-WRAP states as pie charts of the 14 anthropogenic source sectors (TSS Emissions Express Tool # 3). SO2 and PM2.5 charts are similar format, not displayed in this document.

Tables 8 and 10 display State Emissions Totals (tons/year) for NOx and SO2, respectively, for 16 emissions sectors and the 2014v2, RepBase2, 2028OTBa2 and 2028PAC2 emissions scenarios (TSS Emissions Express Tool # 4).

Figure 1a. Annual Nitrogen oxide (NOx) emissions (tons per year) for the 13 continental WESTAR-WRAP states and 14 anthropogenic source groups for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 scenarios. TSS Emissions Express Tool # 1.

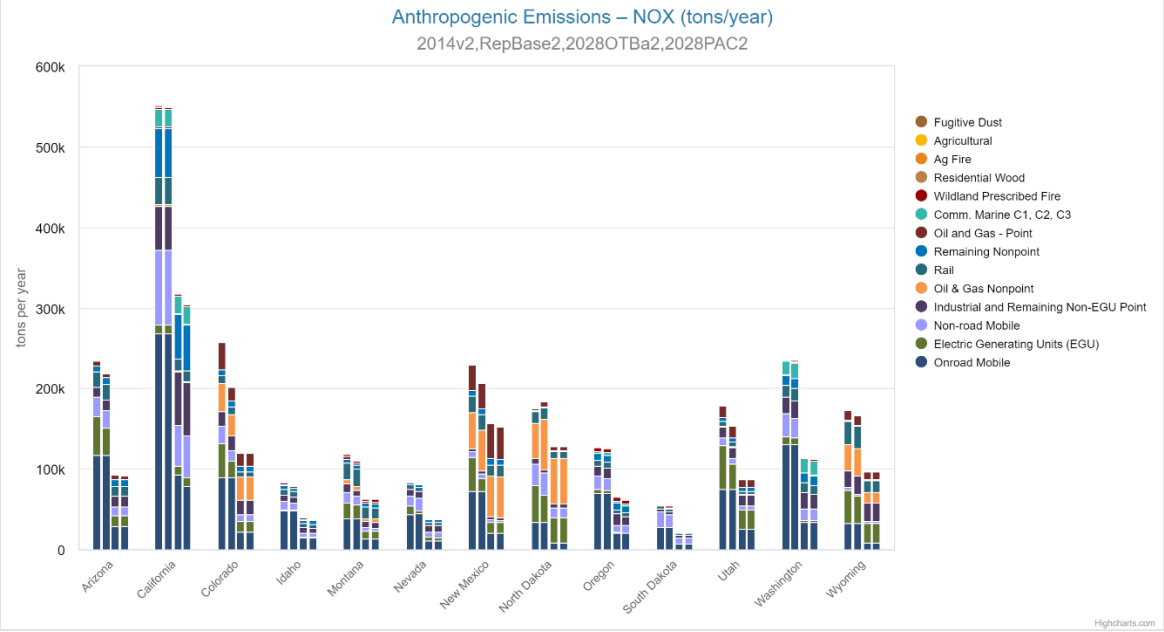

Figure 1b. Annual Sulfur dioxide (SO2) emissions (tons per year) for the 13 continental WESTAR-WRAP states and 14 anthropogenic source groups for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 scenarios. TSS Emissions Express Tool # 1.

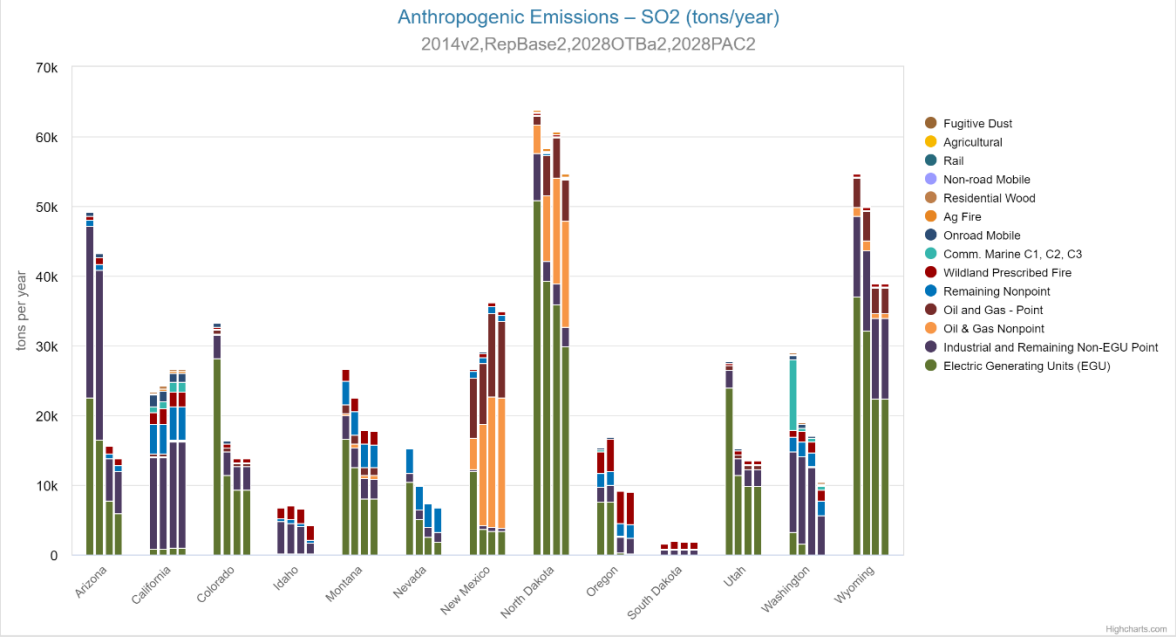

Figure 1c. Annual emissions (tons per year) for Particulate matter less than 2.5 micrometers (PM2.5) for the 13 continental WESTAR-WRAP states and 14 anthropogenic source groups for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 scenarios. TSS Emissions Express Tool # 1.

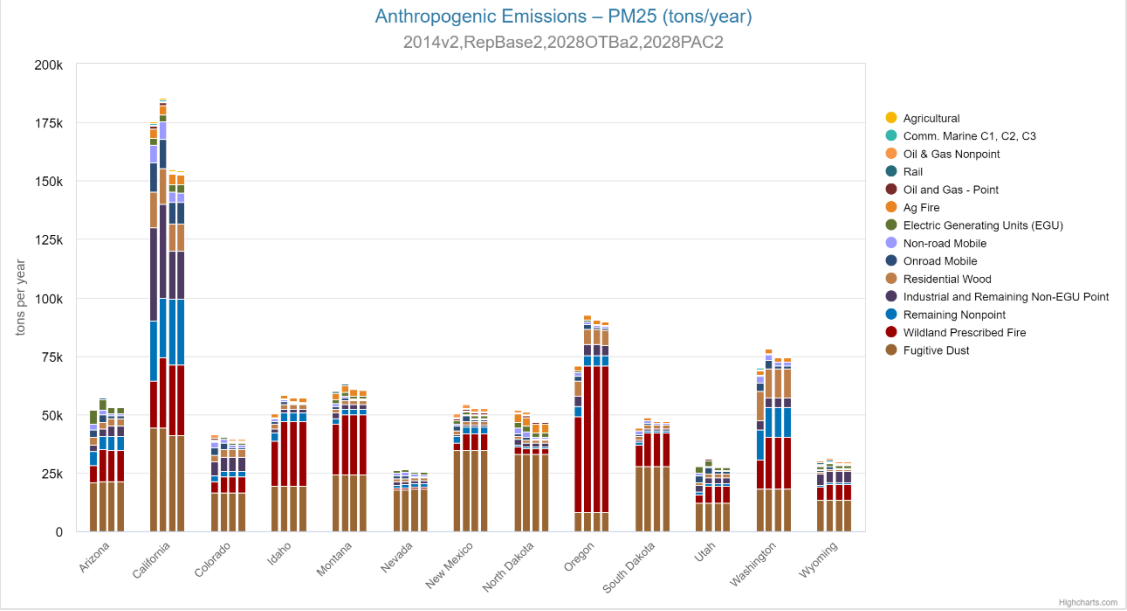

Figure 2a. Annual Nitrogen Oxide (NOx) emissions (tons per year) for Oil and Gas Point sources (1 of 14 anthropogenic source group selection options) in the 13 continental WESTAR-WRAP states for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 scenarios. TSS Emissions Express Tool # 2.

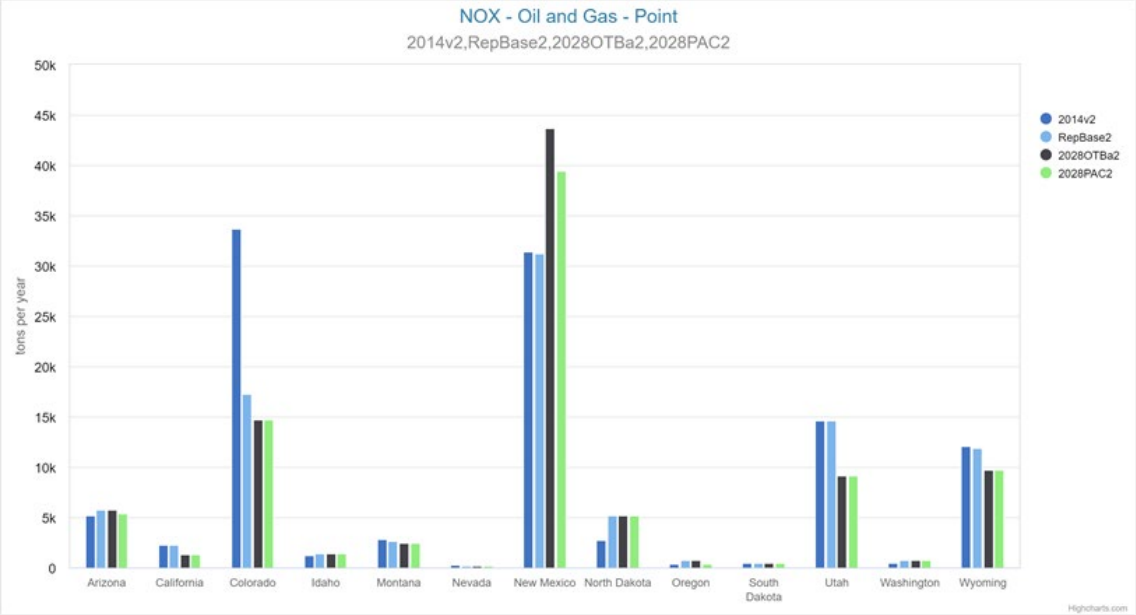

Figure 2b. Annual Sulfur dioxide (SO2) emissions (tons per year) for Oil and Gas Point sources (1 of 14 anthropogenic source group selection options) in the 13 continental WESTAR-WRAP states for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 scenarios. [TSS Emissions Express Tool] # 2.

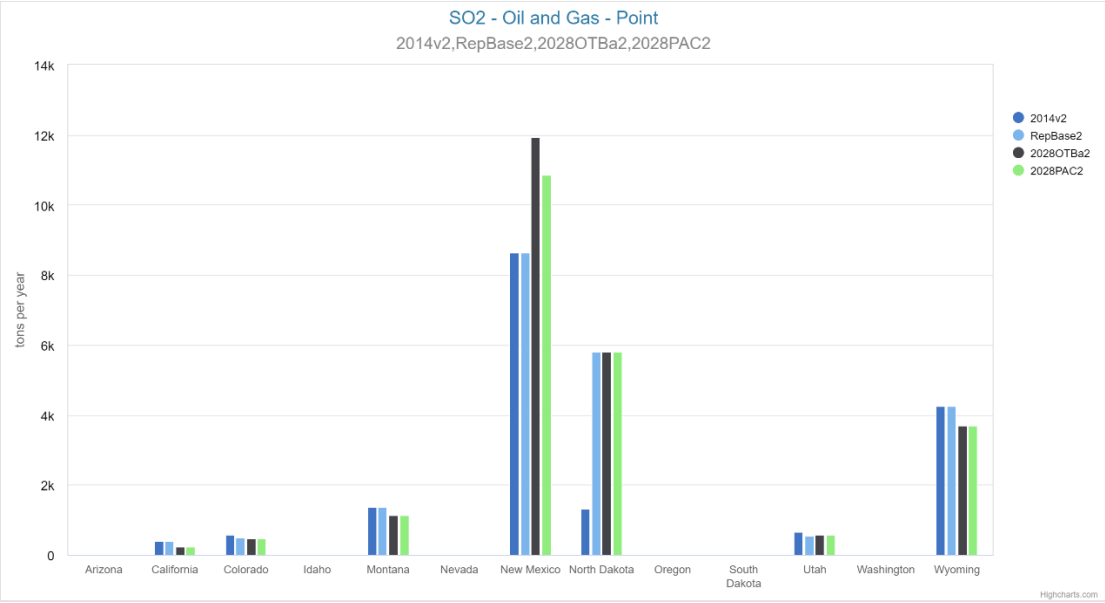

Figure 2c. Annual emissions (tons per year) for Particulate matter less than 2.5 micrometers (PM2.5) for Oil and Gas Point sources (1 of 14 anthropogenic source group selection options) in the 13 continental WESTAR-WRAP states for the 2014v2, RepBase2, 2028OTBa2, and 2028PAC2 scenarios. [TSS Emissions Express Tool] # 2.

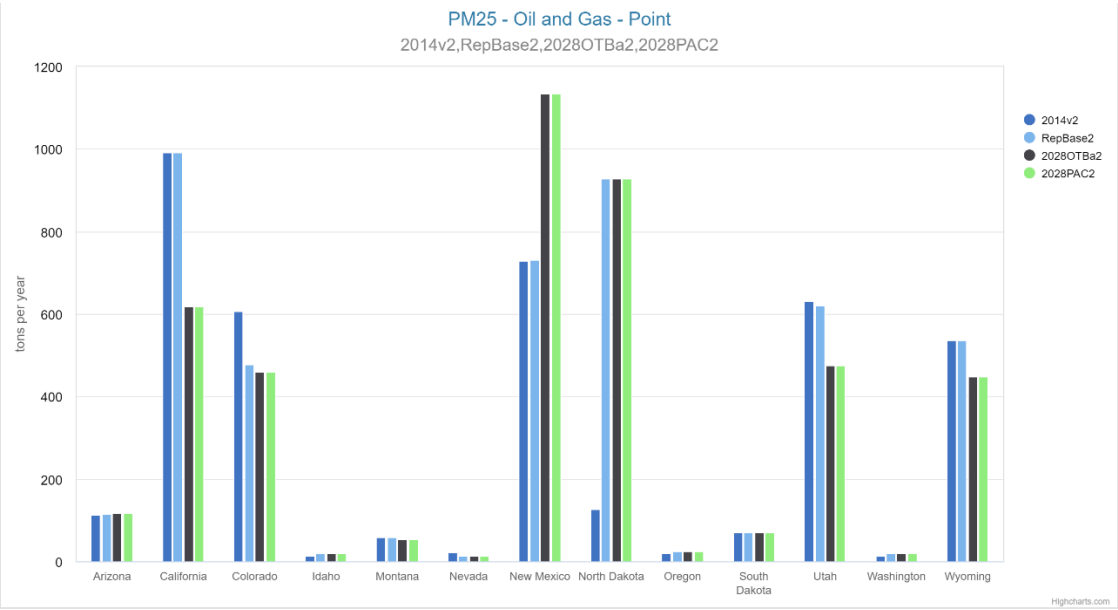

Figure 3a. 2014v2 annual Nitrogen oxide (NOx) emissions (tons per year) totaled for the 13 continental WESTAR-WRAP states for 14 anthropogenic source groups, [TSS Emissions Express Tool] # 3.

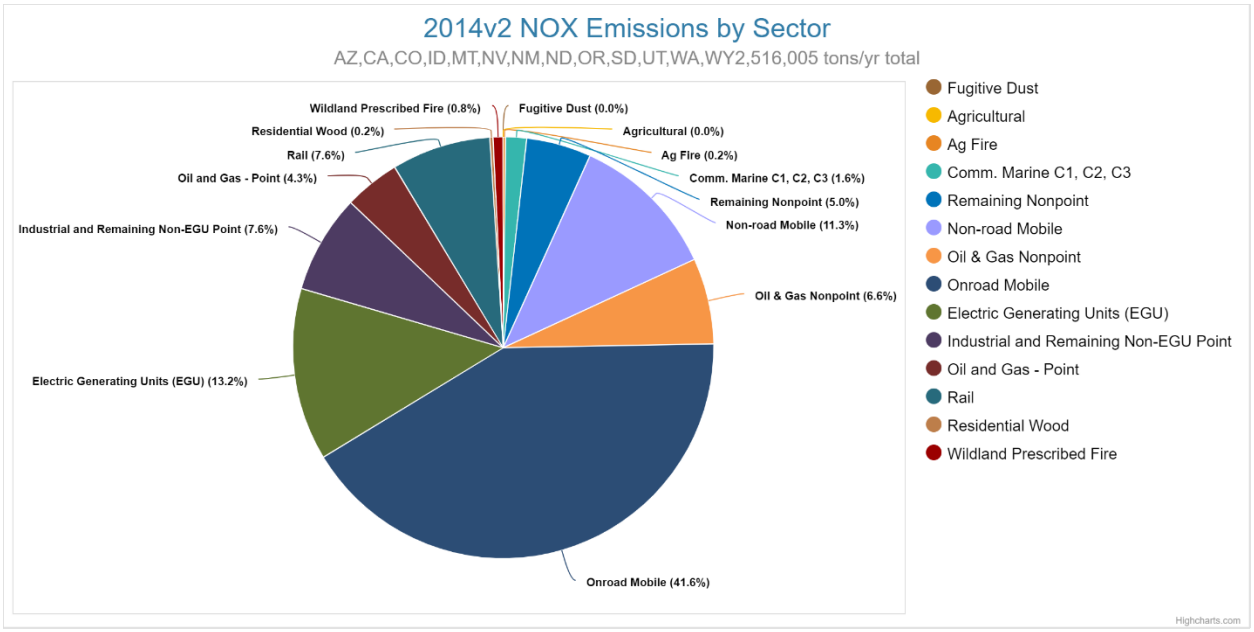

Figure 3b. Representative Baseline (RepBase2) annual Nitrogen oxide (NOx) emissions (tons per year) totaled for the 13 continental WESTAR-WRAP states for 14 anthropogenic source groups, [TSS Emissions Express Tool] # 3.

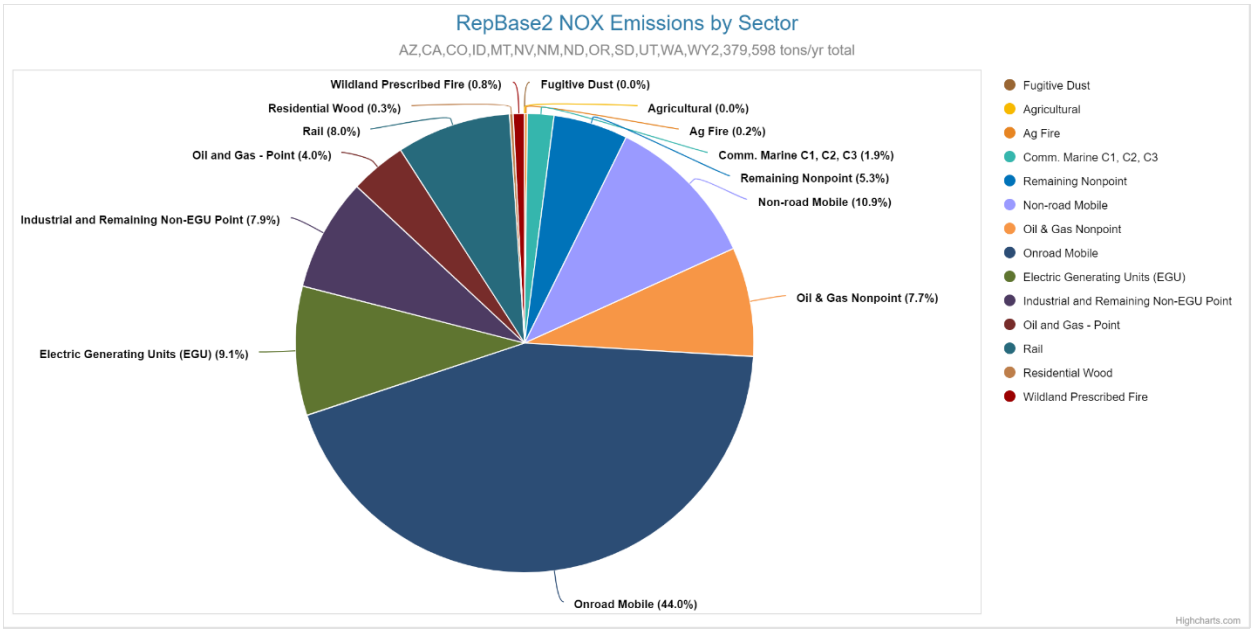

Figure 3c. 2028 On the Books (2O28OTBa2) annual Nitrogen oxide (NOx) emissions (tons per year) totaled for the 13 continental WESTAR-WRAP states for 14 anthropogenic source groups, [TSS Emissions Express Tool]# 3.

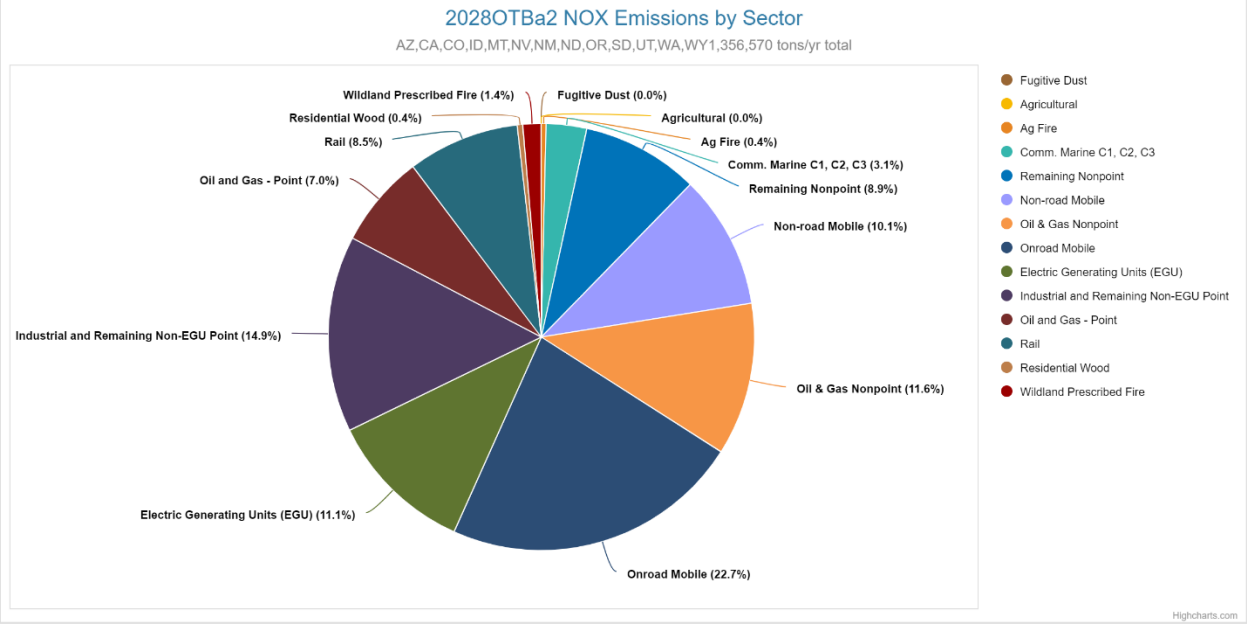

Figure 3d. National Emissions Inventory 2017 (NEI_2017) annual Nitrogen oxide (NOx) emissions (tons per year) totaled for the 13 continental WESTAR-WRAP states for 14 anthropogenic source groups, [TSS Emissions Express Tool]# 3.

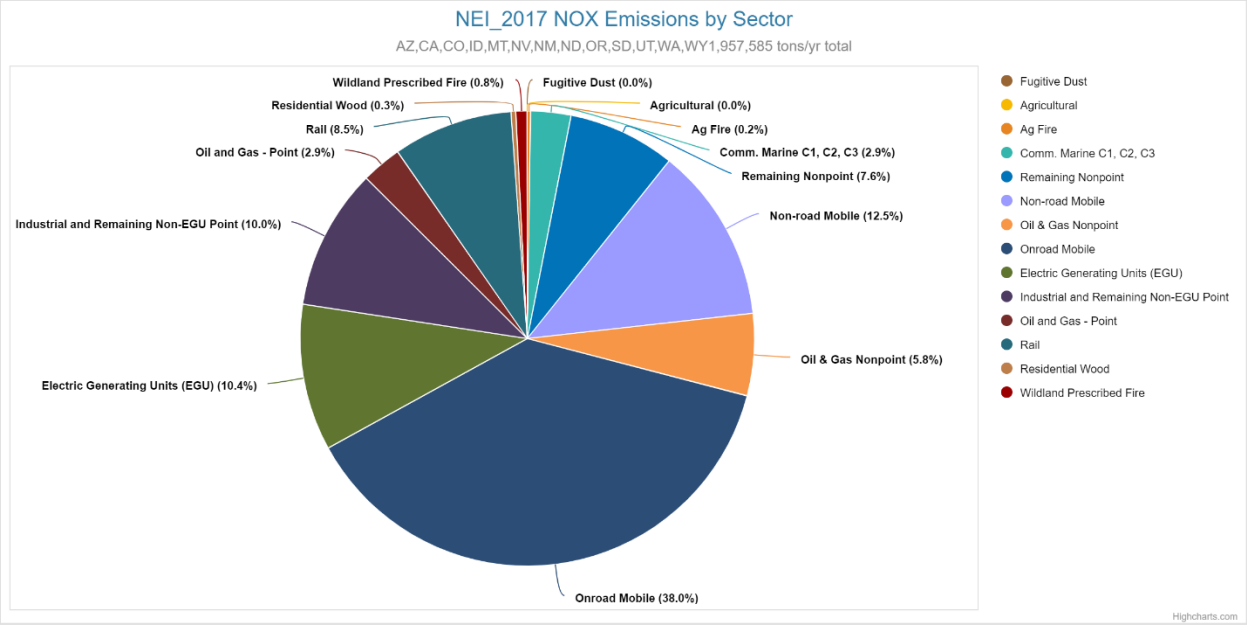

Table 9. Colorado Nitrogen oxide (NOx) emissions (tons/year) for 2014v2, Representative Baseline 2, 2028 On the Books (2028OTBa2), and 2028 Potential Additional Controls (2028PAC2) scenarios and 16 emissions sectors TSS Emissions Express Tool #4.

1.0 Purpose:

The Western Regional Air Partnership and Western Air Quality Study (WRAP-WAQS) 2014 Regional Haze modeling platform is the latest of a series of regional modeling efforts supporting western U.S. air quality planning and management. The WRAP technical analyses follow the Environmental Protection Agency's (EPA) Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.5, and Regional Haze (November 2018) and the Technical Support Document for EPA's updated 2028 regional haze modeling (September 2019). The analyses fulfill the objectives of the WRAP 2018-2019 Workplan as updated and approved by the WRAP Board on April 3, 2019 and have been collectively designed, implemented, and reviewed by the WRAP Technical Steering Committee and its workgroups and subcommittees.

The Western Regional Air Partnership (WRAP) Technical Support System (TSS) hosts the visibility monitoring, emissions, and air quality modeling analyses that support the 15 western states in developing regional haze state implementation plans (SIPs). This reference document describes the WRAP emissions and modeling analyses and illustrates how the TSS products can be applied and interpreted to support the 2028 visibility progress demonstrations for western U.S. Class I areas.

2.0 Background:

The Regional Haze Rule requires states to demonstrate progress every ten years toward the Clean Air Act goal of no manmade visibility impairment. EPA guidance for tracking visibility progress (December 2018) defines a visibility impairment tracking metric (measured in deciview) using observations from the Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring network sites that represent Class I areas. EPA defined in the Regional Haze Rule and guidance a Uniform Rate of Progress glidepath for the 20% most impaired days as the straight line from the 2000-2004 IMPROVE 5-year average baseline to EPA estimates of future natural visibility conditions, plotted at 2064. In the first regional haze planning period, 2000-2018, EPA guidance interpreted most impaired days as those days with highest total haze. States were required to demonstrate visibility progress by 2018 compared to the Uniform Rate of Progress glidepath for the haziest days and no degradation of visibility on the clearest days from the 2000-2004 IMPROVE 5-year average baseline. Visibility on the clearest days improved between 2000 and 2018 across the Class I areas in the western U.S. However, smoke from wildfire and wildland prescribed fire events and dust events on the haziest days made tracking the visibility benefits due to reducing U.S. anthropogenic emissions more difficult.

For the second regional haze implementation period, 2018-2028, states are required to demonstrate visibility progress by 2028 for the most impaired days and no visibility degradation for the clearest days. EPA guidance (December 2018) defined most impaired days as those days with the highest fractional contribution to aerosol light extinction from anthropogenic sources. EPA statistical methods use IMPROVE measurements of carbon and crustal materials to separate contributions from episodic extreme natural events (e.g., wildfire or dust) from routine natural and anthropogenic contributions. Ammonium sulfate and ammonium nitrate are assigned primarily to anthropogenic emissions with smaller contributions from routine natural sources. This statistical approach does not separate contributions due to U.S. anthropogenic emissions from those of international anthropogenic emissions. Since states do not have authority to reduce international emissions, WRAP conducted source apportionment modeling analyses to evaluate U.S. anthropogenic contributions to haze and progress in reducing U.S. anthropogenic contributions to haze over time.

Table 1 summarizes the emissions and modeling scenarios, source apportionment runs, and alternative visibility progress analyses that were performed to support state regional haze planning.

***** fire *is* paired in space *and* time with RepFire activity; this sensitivity scenario gives potential future Wildland Prescribed fire contribution relative to 2028OTBa2
******Dynamic Evaluation compare US anthropogenic contributions for 2002 Hindcast, RepBase2, and 2028OTBa2 to demonstrate alternative rate of visibility improvement

3.0 Emissions Scenarios:

The WRAP 2014v2 inventory was based on the 2014v2 National Emissions Inventory (NEI) plus updates provided by western states through WRAP Regional Haze workgroup's Emissions and Modeling Protocol subcommittee.

Table 2 defines the emissions data sources used for the WRAP 2014v2, Representative Baseline (RepBase2), and 2028 On the Books (2028OTBa2) emissions scenarios. Sector-specific data sources and assumptions are discussed in the companion TSS Emissions References document (September 2021). Future fire emissions sensitivities and 2002 hindcast emissions are also detailed in the TSS Emissions References document.

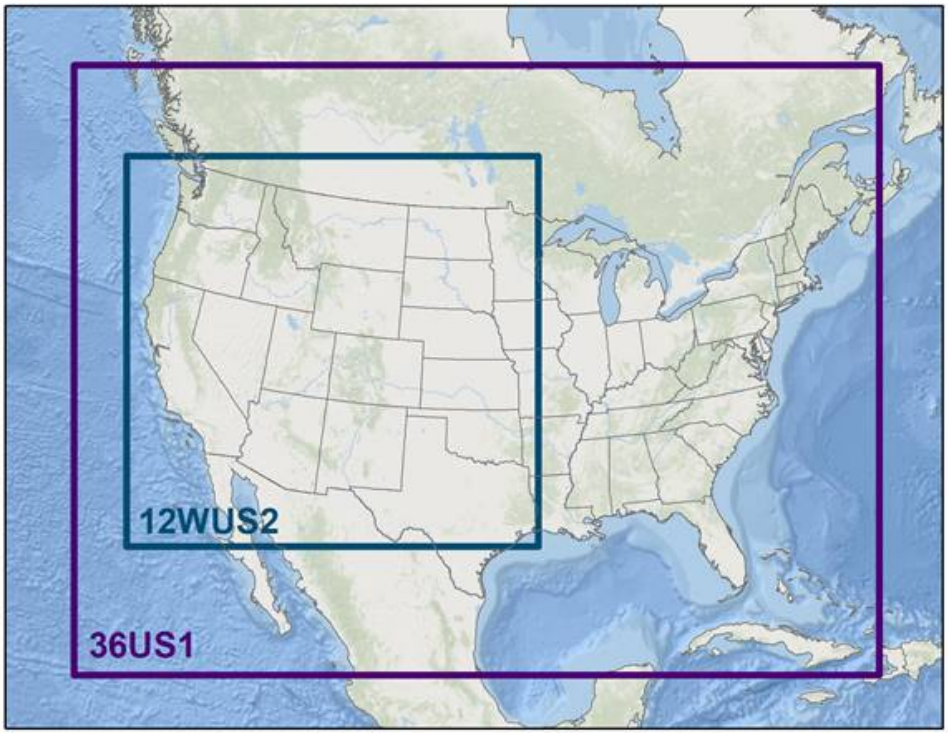

Table 2. Data sources for WRAP emissions sectors for the 12-km 12WUS2 and 36-km US domains for the 2014v2, Representative Baseline (RepBase2) and 2028 On the Books (2028OTBa2) scenarios.

4.0 Model Development:

The WRAP-WAQS 2014 modeling platform was developed and performed by Ramboll, Inc., under contract to WESTAR-WRAP. The 2014 modeling platform used the Weather Research and Forecasting (WRF) meteorological model, the Sparse Matrix Operator Kernel Emissions (SMOKE) model and the Comprehensive Air Quality Model with Extensions (CAMx) to project air quality for the 2014 base year. The Goddard Earth Observing System global chemical model (GEOS-Chem) provided global boundary conditions for the regional CAMx model for the 2014 base year. The CAMx 2014v2 final model configuration is defined in Table 1 of the WRAP-WAQS 2014 modeling platform webpage. CAMx version 7beta 6 was used for the 2014v2 model performance run, while CAMx version 7.0 was used for the subsequent model scenarios. **Figure 1** below illustrates the CAMx 36-km modeling domain covering the Continental United States and the 12-km modeling domain covering the western states.

Figure 1. 36-km continental U.S. (36US1) and 12-km western U.S. (12US2) modeling domains used in the WRAP-WAQS 2014 modeling platform.

In addition to the 2014v2 model year, model runs were made using 2014 meteorology and with Representative Baseline (2014-2018, RepBase2), 2028 On the Books (2028OTBa2), 2028 Potential Additional Controls (2028PAC2), 2002 Hindcast, and Future Fire Sensitivities emission scenarios. Details are provided in model run specification sheets:

- Representative Baseline (RepBase2) and 2028 On the Books (2028OTBa2) CAMx simulations
- Dynamic Evaluation – 2002 Simulations
- Future Fire Sensitivity Simulations

5.0 WRAP-WAQS 2014v2 model performance

The WRAP-WAQS 2014v2 modeling platform webpage includes statistical model performance measures compared to EPA goals and criteria, spatial data plots and timeseries plots for the aerosol species listed below. For aerosol species concentrations, CAMx 2014v2 model outputs are compared to 2014 observations from the IMPROVE, Chemical Speciation Network (CSN) and Clean Air Status and Trends (CASTNET) monitoring network.

- Ozone model performance is reported on the Intermountain West Data Warehouse.

CAMx 2014v2 performance was evaluated using the EPA Atmospheric Model Evaluation tool (AMET) to compare model outputs to 2014 ambient air quality measurements (in μg/m3) for:

- Particulate matter less than 2.5 micrometers (PM2.5)
- Nitrate (NO3)
- Sulfate (SO4)
- Organic mass from carbon (OMC)
- Elemental carbon (EC)
- Fine soil (Soil)
- Coarse mass (particulate matter between 2.5 and 10 micrometers).
- Seasalt: performance is tracked separately for Sodium and Chloride

For example, **Figures 2a to 2d** are spatial plots of the Normalized Mean bias statistic for the winter months January - March and Summer months July – September, for Nitrate and Sulfate, respectively. IMPROVE sites are illustrated as circles, CSN sites as triangles, and CASTNET sites as squares. In Winter, Nitrate is overpredicted in the Pacific Northwest and CA and underpredicted in the northern plains. Performance is generally mixed in the Rocky Mountains and Southwestern interior. In Summer, Nitrate is overpredicted in the Pacific Northwest and under predicted in CA. Sulfate is generally overpredicted in the Pacific Northwest in winter and underpredicted in the Southwest in summer.

Figure 2a. Normalized mean bias for 2014v2 modeled Nitrate compared to the IMPROVE, CSN, and CASTNET monitoring networks for Winter (Jan – Mar). (2014v2 MPE summary)

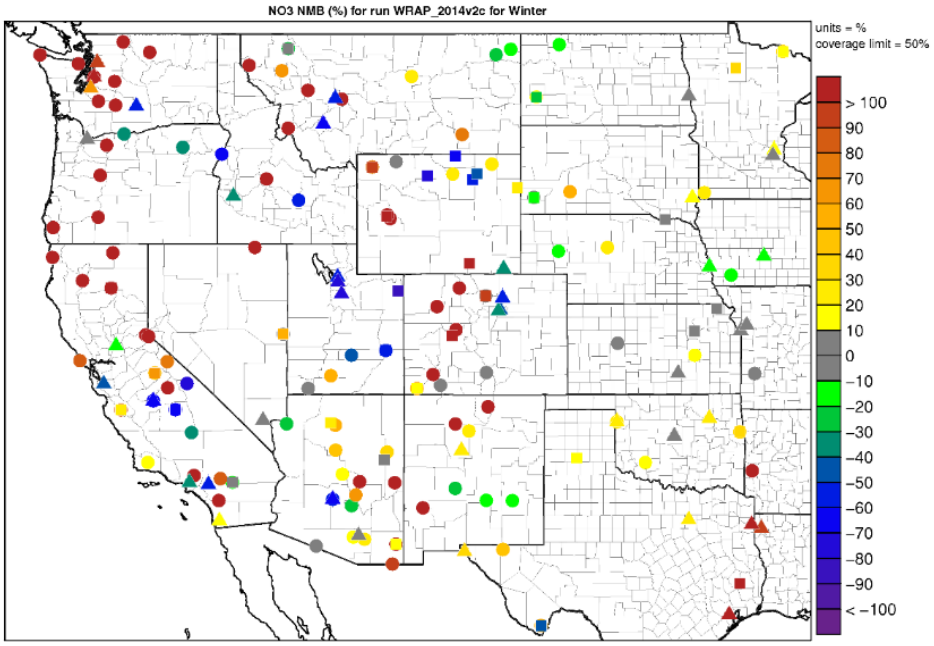

Figure 2b. Normalized mean bias for 2014v2 modeled Nitrate compared to the IMPROVE, CSN, and CASTNET monitoring networks for Summer (Jul – Sep). (2014v2 MPE summary)

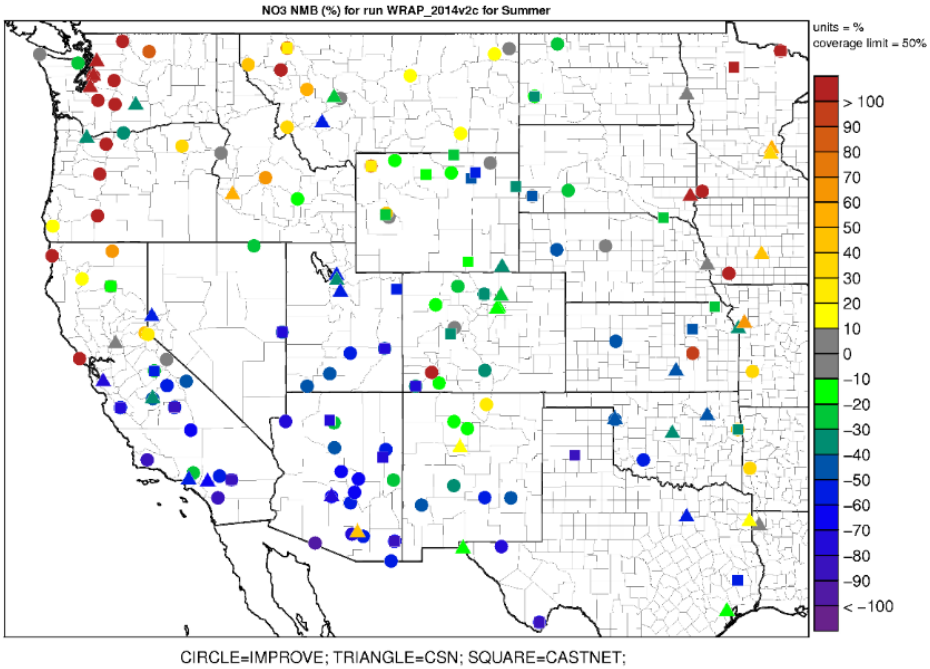

Figure 2c. Normalized mean bias for 2014v2 modeled Sulfate compared to the IMPROVE, CSN, and CASTNET monitoring networks for Winter (Jan – Mar). (2014v2 MPE summary)

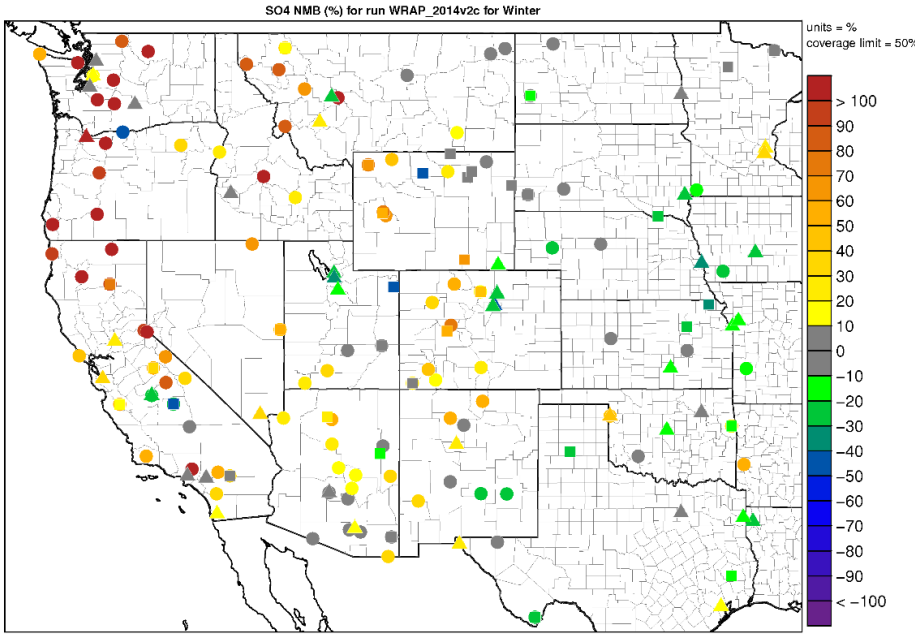

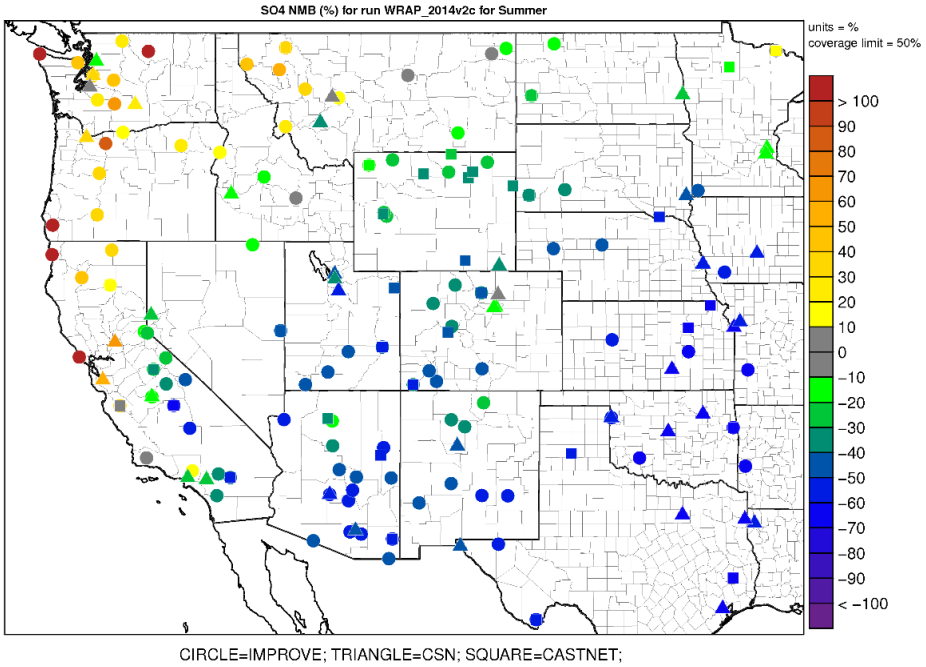

Figure 2d. Normalized mean bias for 2014v2 modeled Sulfate compared to the IMPROVE, CSN, and CASTNET monitoring networks for Summer (Jul – Sep). (2014v2 MPE summary)

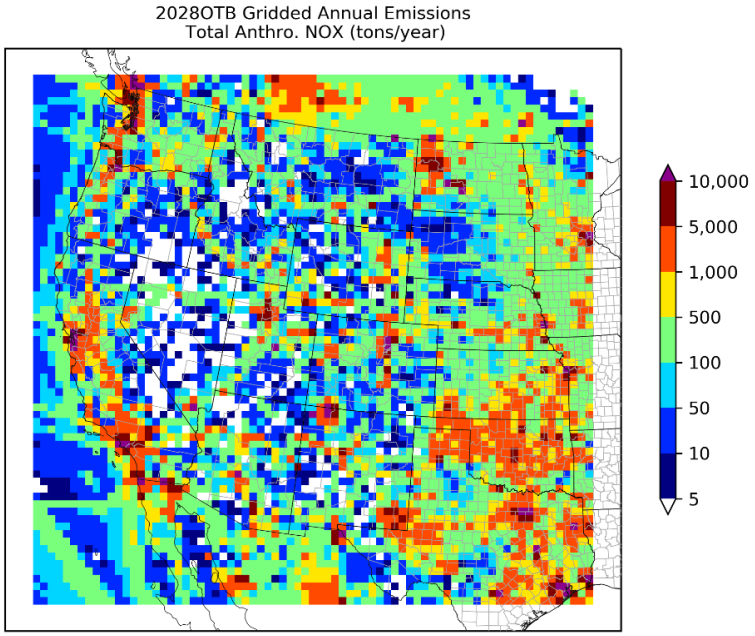
CAMx 12-km gridded annual anthropogenic nitrogen oxide and anthropogenic sulfur dioxide emissions (tons per year) for 2028OTBa emissions (from the WRAP 2028 Weighted Emissions Potential analyses) are mapped in **Figures 3a and 3b**.

Figure 3a. 2028 On the Books CAMx gridded 12-km annual anthropogenic nitrogen oxide emissions (tons per year) (Weighted Emissions Potential)



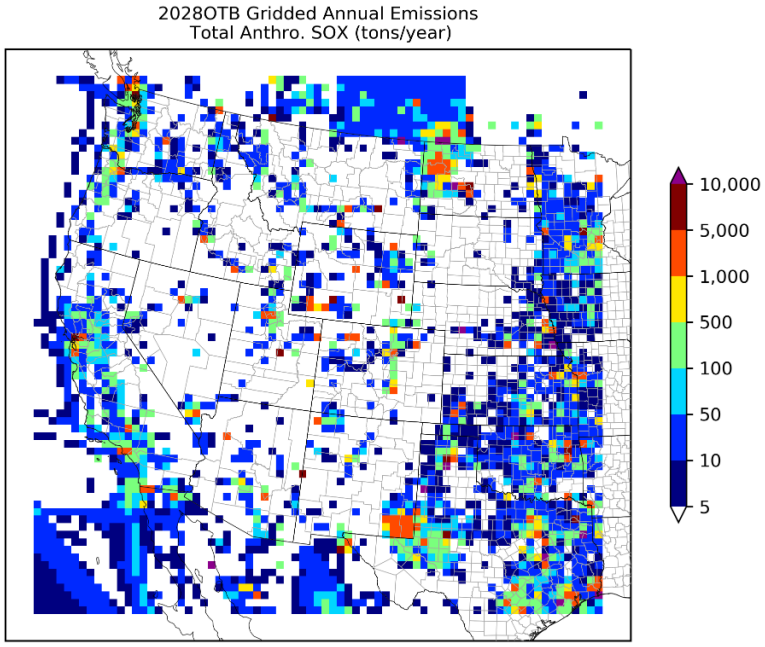


Figure 3b. 2028 On the Books CAMx gridded 12-km annual anthropogenic sulfur oxides emissions (tons per year) (Weighted Emissions Potential)

6.0 Model Comparisons to Observations

Yellowstone National Park, in a fire-dominated ecosystem in the northern Rocky Mountains, and Mesa Verde National Park, in a drier southwestern ecosystem, are used as example Class I areas to interpret WESTAR-WRAP 2014v2 model performance, source contributions to haze, and projected visibility progress by 2028.

Comparisons of 2014 IMPROVE observations to the 2014v2, RepBase2, and 2028OTBa2 model scenarios are illustrated in **Figures 7a through 7d** (TSS Modeling Express Chart #1) for IMPROVE monitors in Yellowstone (YELL2) and Mesa Verde (MEVE1) National Parks, respectively. The charts display speciated aerosol light extinction for the averages of the most impaired days or clearest days. These are absolute model results; the model outputs are not adjusted to IMPROVE data. Comparison of 2014 IMPROVE observations to 2014v2 model results illustrates the accuracy of the model performance on the selected days. Comparison of the 2014v2, RepBase2, and 2028OTBa2 model scenario results demonstrates the aerosol responses to changes in emissions across these scenarios. Natural, fire, and international emissions are held constant at RepBase2 levels in 2028OTBa2, so the only differences between the two scenarios are due to changes in U.S. anthropogenic emissions.

Interpretation: Comparing 2014 IMPROVE observations to 2014v2 model results on most impaired days (**Figures 7a and 7b**) at both YELL2 and MEVE1, ammonium sulfate, elemental carbon, and coarse mass are under predicted, while ammonium nitrate and organic carbon are over predicted. At both YELL2 and MEVE1 organic carbon is slightly higher in RepBase2 than 2014v2; this reflects changes for wildfire emissions in the RepBase2 scenario. At both YELL2 and MEVE1 ammonium nitrate shows small reductions between the RepBase2 and 2028OTBa2 scenarios, all other aerosol species show little change.

On the clearest days at both YELL2 and MEVE1 (**Figure 7c and 7d**) all aerosol species are overestimated, likely because aerosol concentrations are very low and small differences in light extinction are reflected as large percentage differences.

TSS Modeling Express charts for the clearest days are formatted the same as for the most impaired days and will not be displayed in this document forward.

Figure 4a. Model Scenarios Compared to 2014 IMPROVE Observations for Aerosol Light Extinction (Mm^{-1}) on the most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Chart #1

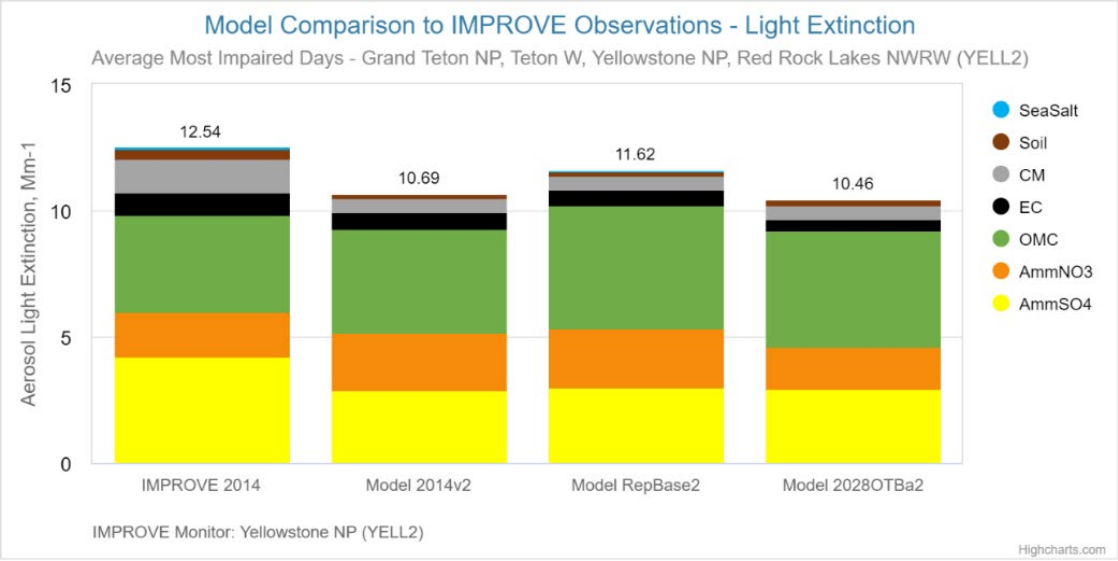

Figure 4b. Model Scenarios Compared to 2014 IMPROVE Observations for Aerosol Light Extinction (Mm^{-1}) on the most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Chart #1

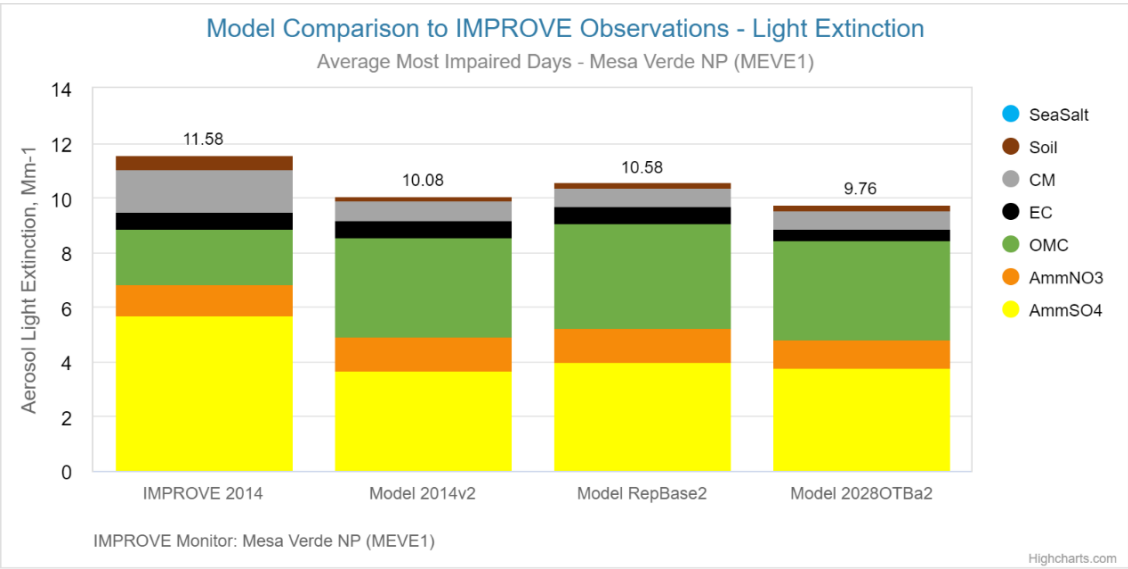

Figure 4c. Model Scenarios Compared to 2014 IMPROVE Observations for Aerosol Light Extinction (Mm^{-1}) on the clearest days at the Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Chart #1

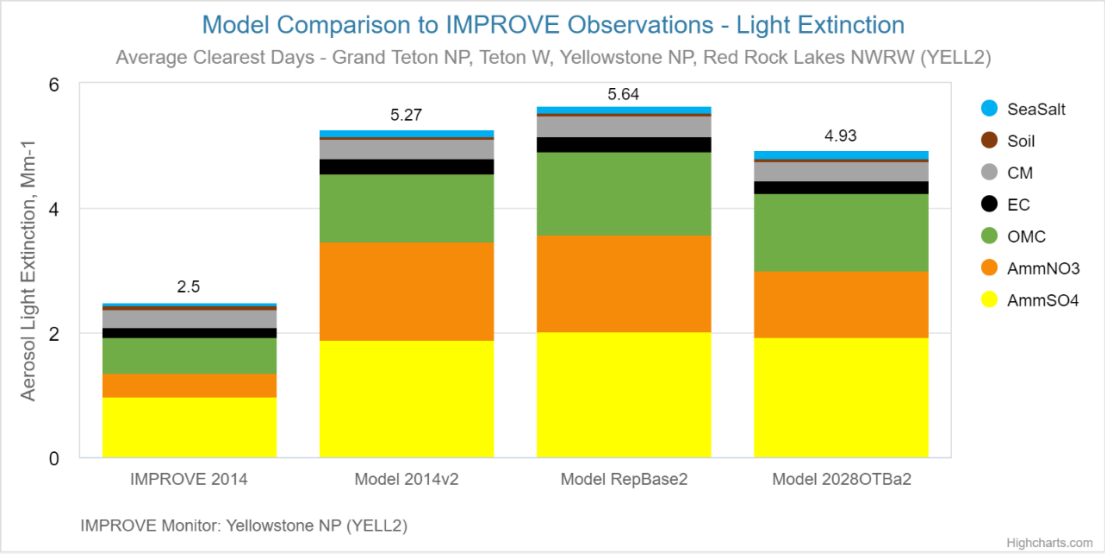

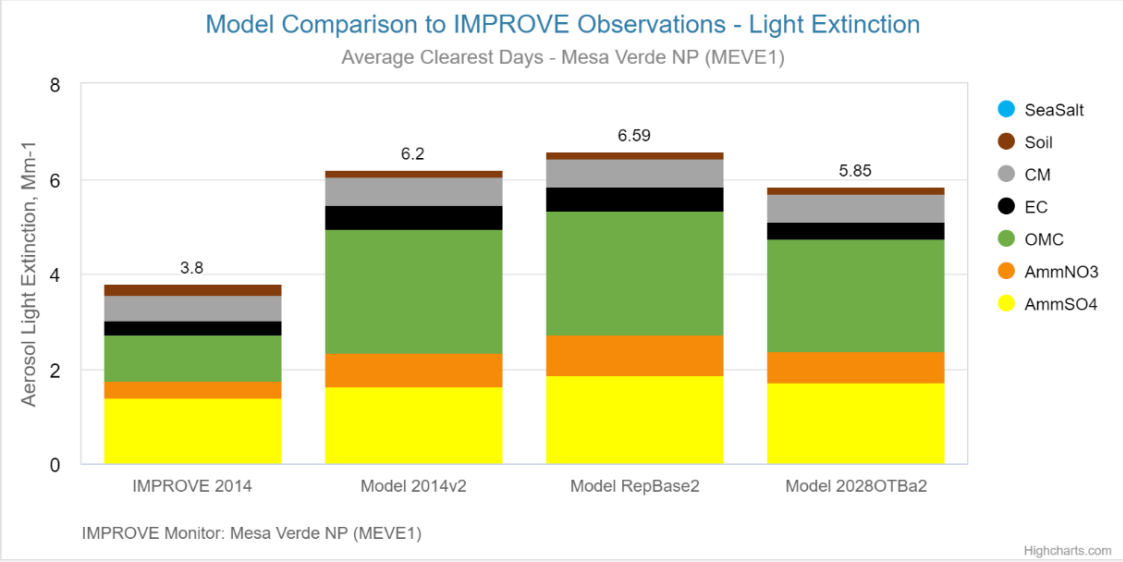

Figure 4d. Model Scenarios Compared to 2014 IMPROVE Observations for Aerosol Light Extinction (Mm^{-1}) on the clearest days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Chart #1

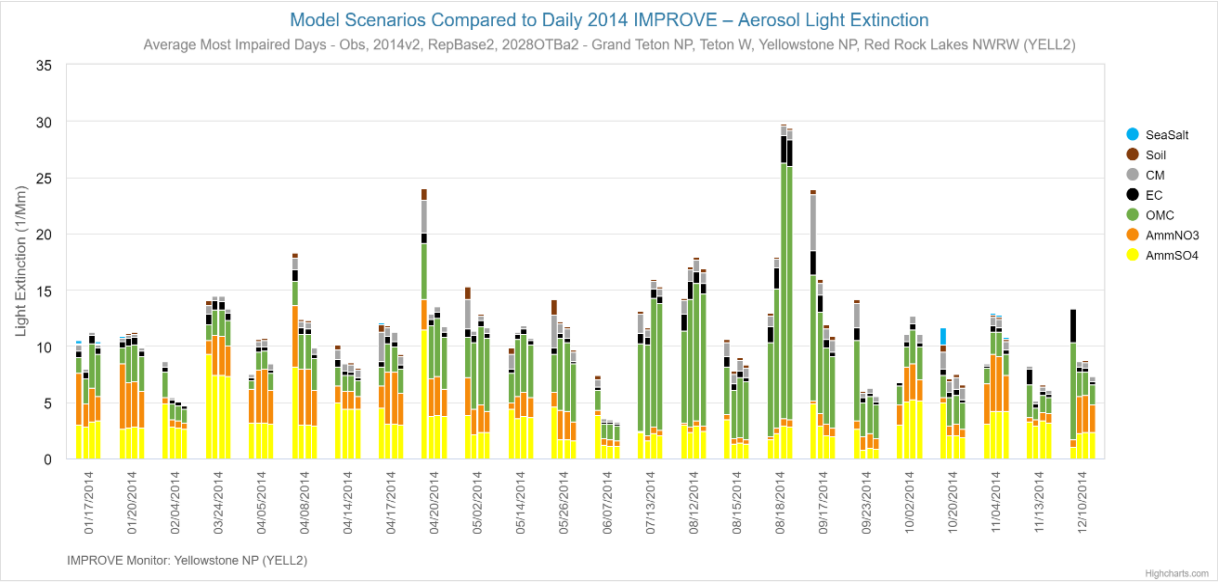
Figures 5a and 5b display TSS Modeling Express Chart #2 for daily 2014 IMPROVE most impaired days at Yellowstone (YELL2) and Mesa Verde (MEVE1) National Parks, respectively, compared to the 2014v2, RepBase2, and 2028OTBa2 model scenarios.

Interpretation: Overall, comparing 2014 IMPROVE data to the 2014v2 modeled aerosol light extinction, CAMx showed credible skill for most impaired days at YELL2 and MEVE1. Maximum IMPROVE daily aerosol extinction on most impaired days is 24 Mm^{-1} at YELL2 and 20 Mm^{-1} at MEVE1. Daily ammonium nitrate (AmmNO3) is well represented on most impaired days at these two sites. On a few most impaired days at both YELL2 and MEVE1, 2014v2 modeled ammonium sulfate (AmmSO4) is more than 50% lower than IMPROVE observations. Under estimates of coarse mass are likely due to poor model skill in representing windblown dust. At both sites, organic carbon (OMC) is a large fraction of total aerosol extinction on several 2014 IMPROVE most impaired days. OMC is somewhat over predicted on several days. Differences in OMC on the most impaired days between the 2014v2 and RepBase2 scenarios are likely due to differences in wildfire activity assumptions for RepBase2 (covering the period the 2014 to 2018) compared to the single year 2014v2. Differences in total aerosol extinction between RepBase2 and 2028OTBa2 are small on all most impaired days, indicating little visibility progress.

Figure 5a. Model Scenarios Compared to 2014 IMPROVE Observations for Aerosol Light Extinction (Mm^{-1}) on most impaired days at the Yellowstone National Park (YELL1) IMPROVE monitor. TSS Modeling Express Chart #2



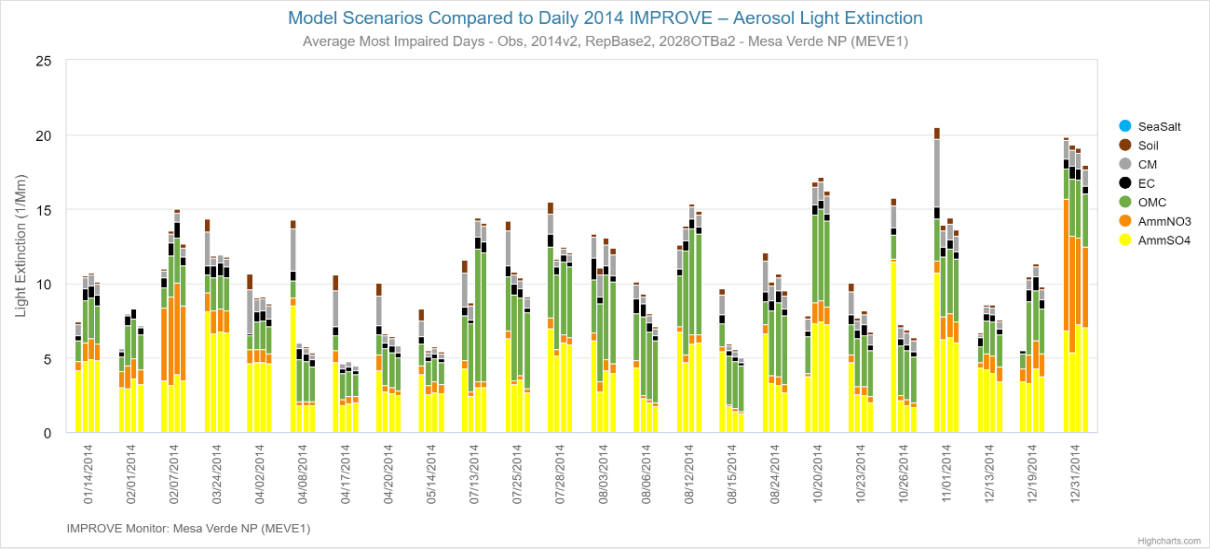


Figure 5b. Model Scenarios Compared to 2014 IMPROVE Observations for Aerosol Light Extinction (Mm^{-1}) on most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Chart #2

7.0 2028 Visibility Projections

2028 visibility projections for the most impaired or clearest days are calculated following EPA guidance for ozone, PM2.5 and regional haze modeling (November 2018) using the EPA default projection method and using two WRAP alternative projection methods that are intended to reduce aerosol contributions from sources other than U.S. anthropogenic emissions on the most impaired days.

The EPA recommended projection procedures are used for all three WRAP projection methods (see WRAP Procedures for Making Visibility Projections and Adjusting Glidepaths, March 2021 final draft.) EPA's Software for the Model Attainment Test (SMAT) was used to perform the projection calculations. CAMx model results are used in a relative sense, meaning that the aerosol concentrations are scaled to the IMPROVE monitoring data for the 2014-2018 period. The fractional differences between the 2028OTBa2 and the RepBase2 modeled aerosol concentrations are used to define scaling factors, also called relative response factors (RRFs), that are calculated for each aerosol species on each 2014 IMPROVE most impaired day (or clearest day) and then averaged for all most impaired days (or clearest days). These average relative response factors are multiplied by the daily aerosol concentration on each most impaired day or clearest day for the IMPROVE 2014-2018 5-year period to define daily projected aerosol concentrations, as indicated by the equations below.

$$\text{Relative Response Factor, } RRF_{SO4} = \sum 2028OTBa2_{SO4} / \sum RepBase2_{SO4}$$

$$Projected_SO4_{2028OTBa2} = IMPROVE_SO4_{2014\text{-}2018} \times RRF_{SO4}$$

The daily projected 2028 aerosol concentrations for each of the 2014-2018 IMPROVE most impaired days (or clearest days) are converted to light extinction and then converted to deciview. The daily deciview values are averaged for each year and the annual averages are averaged for the 5-year period to define the 2028 visibility projections. The three WRAP projection methods:

- The **EPA default projection method** follows EPA guidance without deviation.
- The **EPA without fire projection method** uses the same 2014 IMPROVE most impaired days as the EPA default projection method. RepBase2 and 2028OTBa2 modeled source apportionment results are used to identify and remove modeled aerosol contributions from U.S. wildfire, U.S. wildland prescribed fire, and Non-U.S. (Canada and Mexico) fire on these days. After modeled fire contributions have been removed from the daily aerosol values, the EPA default projection procedures are used to calculate the relative response factors and 2028 visibility projections.
- The **Modeled MID projection method** selects the modeled RepBase2 days with the highest fraction of modeled U.S. anthropogenic contributions as the modeled most impaired days for both the RepBase2 and 2028OTBa2 scenarios. RepBase2 and 2028OTBa2 modeled source apportionment results are used to remove the fire contributions from the modeled most impaired days before calculating relative response factors and 2028 visibility projections.

In TSS Modeling Express Chart #3 users can choose to illustrate, for one, two, or three projection methods, for either the most impaired days or clearest days, the visibility projections for 2028 On the Books (2028OTBa2) or 2028 Potential Additional Controls (2028PAC2) in aerosol light extinction. These aerosol contributions are the basis for the 2028 visibility projections in deciview that define the regional haze tracking metric and are displayed in TSS TSS Modeling Express Chart #4 (see Section 8.0). Changes in aerosol species extinction across the 2028 projection scenarios and methods illustrate which aerosol species are responsible for the projected changes in the regional haze visibility tracking metric in deciviews.

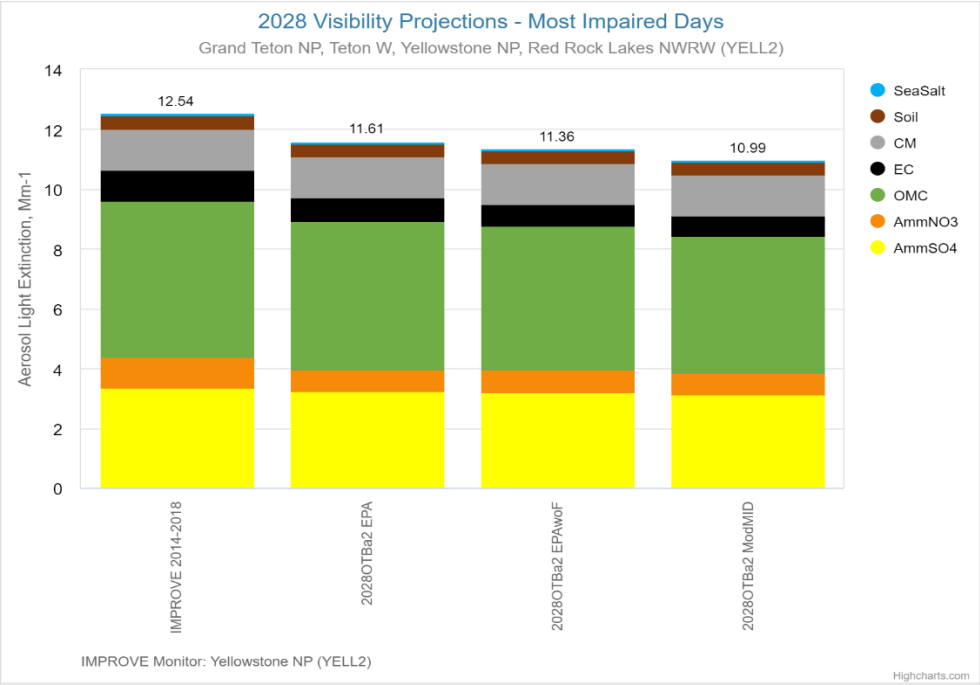
Figures 6a and 6b illustrate the IMPROVE 2014-2018 aerosol contributions and the 2028OTBa2 visibility projections in aerosol light extinction using the 3 WRAP projection methods for Yellowstone and Mesa Verde National Parks, respectively.

Interpretation: For YELL2, AmmNO3, OMC, and EC are projected to decrease between the 2014-2018 IMPROVE observations and modeled 2028OTBa2 following the EPA default projection methods. The EPA without fire method has slight decreases in OMC and EC compared to the EPA default method, while the Modeled MID method, which selects different days as most impaired, has slight decreases in OMC, EC, and AmmSO4 (0.3 Mm^{-1}). At MEVE1, AmmNO3 and AmmSO4 are reduced slightly between 2014-2018 IMPROVE observations and

2028OTBa2 projections using EPA default methods. The EPA without fire and Modeled MID methods display slight changes to OMC and EC compared to the EPA default method. As will be illustrated under Section 10.0 Regional Source Apportionment, biogenic and anthropogenic sources of carbon are significant and unchanged fractions of OMC and EC at these two sites. Thus, for these two sites, removing fire contributions from most impaired days only changes a fraction of the total carbon and the EPA without fire projection method has only small changes in the 2028 visibility projection.

Nonetheless, WRAP recommended that EPA without fire projection method be the default 2028 visibility projection displayed because this method removes the contributions of fire on the most impaired days and most closely focuses on anthropogenic contributions to haze.

Figure 6a. 2028 Visibility Projections on most impaired days in Aerosol Light Extinction (Mm^{-1}) compared to 2014-2018 IMPROVE observations for Yellowstone National Park (YELL2). TSS Modeling Express Chart #3



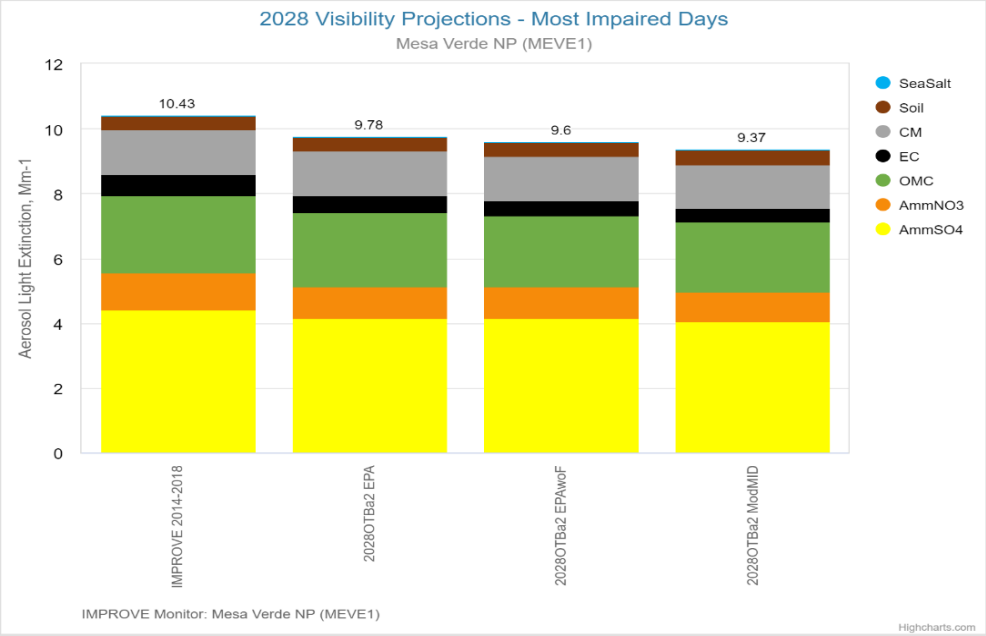


Figure 6b. 2028 Visibility Projections on most impaired days in Aerosol Light Extinction (Mm^{-1}) compared to 2014-2018 IMPROVE observations for Mesa Verde National Park (YELL2). TSS Modeling Express Chart #3

8.0 Visibility Projections compared to the Uniform Rate of Progress Glidepath

TSS Modeling Express Chart #4 displays 2028 visibility projections in deciview compared IMPROVE measurements for the period 2000-2018 and to the Uniform Rate of Progress (URP) glidepath as defined by EPA guidance (Dec 2018). The 2028 visibility projections in deciview are calculated from aerosol concentrations and extinction as described in Section 7. Users can also select to display chart data by aerosol light extinction for individual species or Total Light Extinction.

The URP glidepath is constructed (in deciviews) for the 20% most impaired days (MID) or clearest days using observations from the IMPROVE monitoring site representing a Class I area. The URP glidepath starts with the IMPROVE most impaired days for the 2000-2004 5-year baseline and draws a straight line to estimated natural conditions displayed for the year 2064. For clearest days, the goal is no degradation of visibility from the 2000-2004 5-year baseline, therefore the glidepath for clearest days is a straight line from the 2000-2004 baseline to 2064. In the second regional haze planning period, 2064 natural visibility condition estimates use the 15-year average of natural conditions on IMPROVE most impaired days in each year 2000-2014. IMPROVE annual average values are presented in this chart as points. IMPROVE 5-year average values are presented as solid lines covering the periods 2000-2004 and 2014-2018.

The 2028OTBa2 and 2028PAC2 visibility projections were processed using EPA's Software for the Model Attainment Test (SMAT) for the three WRAP projection methods described in Section 7 (see also WRAP Procedures for Making Visibility Projections and Adjusting Glidepaths, March 2021 final draft):

- EPA default projection method
- EPA without fire projection method
- Modeled MID projection method

2028 On the Books (2028OTBa2) and 2028 Potential Additional Controls (2028PAC2) visibility projections in deciview are illustrated as points that can be compared to the Uniform Rate of Progress glidepath. A state can select among the 2028 projection methods to define a 2028 Reasonable Progress Goal (RPG) for a Class I area for Regional Haze planning purposes.

The 2028 visibility projection is compared to the URP Glidepath at 2028 to determine whether visibility at the Class I areas is projected to be on, above, or below the URP Glidepath. Comparison of 2028 projections to the URP Glidepath defines how well the modeled trend in visibility tracks the straight-line uniform rate of progress to 2064. EPA guidance (August 2019) clarifies that the URP Glidepath is not a bright line test for reasonable visibility progress by 2028 and describes additional considerations for defining reasonable progress. Uncertainties in the glidepath assumptions are discussed in the U.S. Anthropogenic Emissions Rate of Progress (September 2021) document.

Figures 7a and 7b display TSS Modeling Express Chart #4 results for the 2028OTBa2 scenario for Yellowstone and Mesa Verde National Parks, respectively. Users could choose to also display results for the 2028PAC2 control scenario. Regional source apportionment data discussed in Section 10 will assist interpretation of 2028 visibility projections displayed in Chart #4.

Interpretation: For YELL2 (**Figure 7a**), the IMPROVE annual average deciview for the most impaired days varies widely between 2000 to 2018 and the 2000-2018 monitoring trend line (blue line) is above the URP Glidepath (red line). The IMPROVE 2014-2018 5-year average deciview for the most impaired days intersects the URP glidepath. The 2028OTBa2 visibility projections for all 3 WRAP methods are above the URP glidepath, although the EPA without fire and Modeled MID projection methods yield slightly lower 2028 projections than the EPA default projection. The IMPROVE annual average deciview for the clearest days show steady improvement between 2000 and 2018 and the 2028OTBa2 projection indicates further improvement on the clearest days.

At MEVE1 (**Figure 7b**) the IMPROVE annual average deciview for the most impaired days shows a consistent reduction between 2000 and 2018. The IMPROVE 2000-2018 monitoring trendline and the IMPROVE 2014-2018 5-year average deciview for the most impaired days are well below the URP glidepath. All 3 projection methods for 2028OTBa2 are also well below the URP

glidepath. The clearest days at MEVE1 also show continuous improvement and the 2028OTBa2 projections are below the 2014-2018 5-year average deciview.

Figure 7a. 2028 Visibility Projections for clearest days and most impaired days, compared to the Uniform Rate of Progress Glidepath at the Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Chart #4

Figure 7b. 2028 Visibility Projections for clearest days and most impaired days, compared to the Uniform Rate of Progress Glidepath at the Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Chart #4

In general, western Class I areas near urban areas or major point sources demonstrate visibility improvement in the IMPROVE monitoring data between 2000 to 2018 and the 2028 visibility projections are below the URP glidepath. Ammonium nitrate and ammonium sulfate are major contributors on most impaired days at many of these sites, including Mesa Verde NP (see **Figure 6b**). Class I areas near oil and gas development do not display as much visibility improvement by 2028OTBa2 as more remote sites. Class I areas where carbon is a significant fraction of aerosol contributions on most impaired days, including Yellowstone NP (see **Figure 6a**) show more variable visibility progress in the IMPROVE monitoring data 2000-2018 and in the 2028 visibility projections.

Clearest days at all western Class I areas have improved between 2000 and 2018 and are projected to continue to improve by 2028 at almost all western Class I areas.

EPA Volcanic adjustment (August 2021) for IMPROVE monitors at Hawai'i Volcano (HAVO1) and Haleakalā (HALE1) National Parks:

EPA defined an adjustment to ammonium sulfate to account for episodic volcanic events at Hawai'i Volcano (HAVO1) and Haleakalā (HALE1) National Parks. EPA's adjustment follows the same methodology as defined in December 2018 guidance to account for episodic extreme fire or dust events using IMPROVE measurements of carbon or crustal materials. EPA's adjustment for volcanic contributions uses IMPROVE daily ammonium sulfate measurements for the years 2000-2014, defines the average 95th percentile value for each year, and selects the lowest annual value as the threshold to assign ammonium sulfate daily measurements above that threshold as episodic volcanic (natural) contributions. After accounting for episodic volcanic contributions to ammonium sulfate, impairment is calculated following EPA guidance. By assigning maximum ammonium sulfate values as natural rather than anthropogenic, the days that are defined as most impaired by anthropogenic contributions shift. Ammonium sulfate still dominates the most impaired days, suggesting that not all volcanic contributions are accounted for using a 95th percentile threshold.

In addition to the volcanic adjustment, to assure a complete IMPROVE data set for Haleakalā National Park, EPA also applied data substitution methods to merge data from two separate IMPROVE monitor locations that have represented the Haleakalā NP Class I area over the 2000-2018 period (HALE1 and Haleakala Crater, HACR1). The combined data set is referred to as HALE_RHTS.

EPA also provided 2028 visibility projections for the volcano adjusted data sets, HAVO1_VADJ and HALE_RHTS_VADJ, as described in EPA's Technical Support Document for Updated 2028 Regional Haze Modeling for Hawaii, Virgin Islands, and Alaska (August 2021). EPA 2028 visibility projections for HAVO1_VADJ and HALE_RHTS_VADJ are displayed in aerosol extinction in TSS Modeling Express Chart #20 (equivalent to TSS Modeling Chart #3). TSS Modeling Express Chart #21 (equivalent to TSS Modeling Chart #3) displays 2028 visibility projections in deciview

for HAVO1_VADJ and HALE_RHTS_VADJ, the 2000-2018 volcano-adjusted monitoring data, estimated natural conditions in 2064, and the Uniform Rate of Progress for the volcano adjusted data for the most impaired days or clearest days at these two Class I areas.

TSS Modeling Express Tool #8 displays a table for each state listing all federal Class I areas in that state comparing the 2014-2018 5-year average IMPROVE observations to the 2028OTBa2 and 2028PAC2 visibility projections in deciview, calculated using the 3 WRAP projection methods. **Table 11** illustrates the 2028 visibility projection results for the state of Colorado. Note that Colorado did not define Potential Additional Controls for sources in Colorado for 2028PAC2, nonetheless, small changes in visibility were projected for 2028PAC2 due to PAC2 control assumptions in other WRAP states.

Table 11. 2028 Visibility Projections for the most impaired days at Class I areas in Colorado for the 2028 On the Books (2028OTBa2) and 2028 Potential Additional Controls (2028PAC2) model scenarios and 3 WRPA projection methods. TSS Modeling Express Tool #8

1) U.S. EPA. December 2018. Technical Guidance on Tracking Visibility Progress for the Second Implementation Period of the Regional Haze Program. EPA-454/R-18-010

9.0 Adjustments to the Uniform Rate of Progress Glidepath

EPA guidance (December 2018) allows a State to propose an adjustment to the URP glidepath to account for visibility contributions from anthropogenic emissions outside the U.S. or from emissions from wildland prescribed fires that meet specific land management objectives and apply basic smoke management practices. The EPA Administrator may approve proposed

adjustments to the URP glidepath that follow "scientifically valid data and methods." EPA's regional haze modeling Technical Support Document (September 2019) demonstrates adjustments to the 2064 endpoint of the URP glidepath using source apportionment results for international anthropogenic or wildland prescribed fire emissions from the EPA 2028 model scenario.

WRAP methods to adjust the 2064 endpoints for the URP glidepath to account for international emissions or wildland prescribed fire emissions are described in detail in WRAP Procedures for Making Visibility Projections and Adjusting Glidepaths (March 2021). The WRAP adjustments to the URP glidepath are based on 2028OTBa2 source apportionment results for international anthropogenic and wildland prescribed fire. Consistent with the methods evaluated in the EPA Technical Support Document, WRAP evaluated five approaches using 2028OTBa2 source apportionment results to adjust the 2064 endpoints. 2028 source apportionment results were applied in a relative sense (model results normalized to 2028 visibility projections) or an absolute sense (unadjusted absolute model results). 2064 endpoints were defined using IMPROVE natural conditions estimated for 2000-2014 or using 2028 source apportionment results for natural source contributions.

After review of the initial glidepath adjustment results, WRAP recommended that adjustment of the URP glidepath for Class I areas in western states use 2028 source apportionment results in a relative sense and use EPA estimated natural conditions for the 2064 endpoint for one of two options:

- International anthropogenic contribution normalized to IMPROVE monitoring data and added to EPA estimated natural conditions (International).
- International anthropogenic plus Wildland Prescribed fire combined contributions normalized to IMPROVE monitoring data and added to EPA estimated natural conditions (International + wildland Rx fire)

Note that wildland prescribed fire events in the 2028 OTBa2model scenario reflect the same events as modeled for 2014v2. Wildland prescribed fire events may not occur on most impaired days in 2014v2. Location, timing, frequency, magnitude, and duration of wildland prescribed fire events vary geographically, seasonally, and year to year. Therefore, interpretation of wildland prescribed fire contributions on most impaired days for the 2028OTBa2 source apportionment results and for the 2064 adjustment to the URP glidepath is uncertain.

TSS Modeling Express Chart #5 illustrates the Regional Haze Uniform Rate of Progress (URP) Glidepath as defined by EPA guidance and the two WRAP alternative glidepath end point adjustments for 2064 (International, International + Wildland Prescribed Fire.)

The URP glidepath (in deciviews) for most impaired days and the optional glidepath adjustments all start from the 2000-2004 5-year baseline for most impaired days and draw a straight line to estimated natural conditions in 2064. All 2064 endpoints use EPA estimates of natural conditions based on 2000-2014 IMPROVE data. Annual average deciview for 2000 to

2018 most impaired days are illustrated as points. IMPROVE 2000-2004 and 2014-2018 5-year average deciview values are illustrated as solid lines. Users can choose to display 2028OTBa2 and/or 2028PAC2 visibility projections for 1-3 projection methods and to display 2064 endpoint without adjustment or adjustment for either international anthropogenic emissions or international anthropogenic plus wildland prescribed fire emissions. The 2028OTBa2 EPA without fire projection method is the default setting for purposes of comparing 2028 visibility projections to the adjustment glidepath.

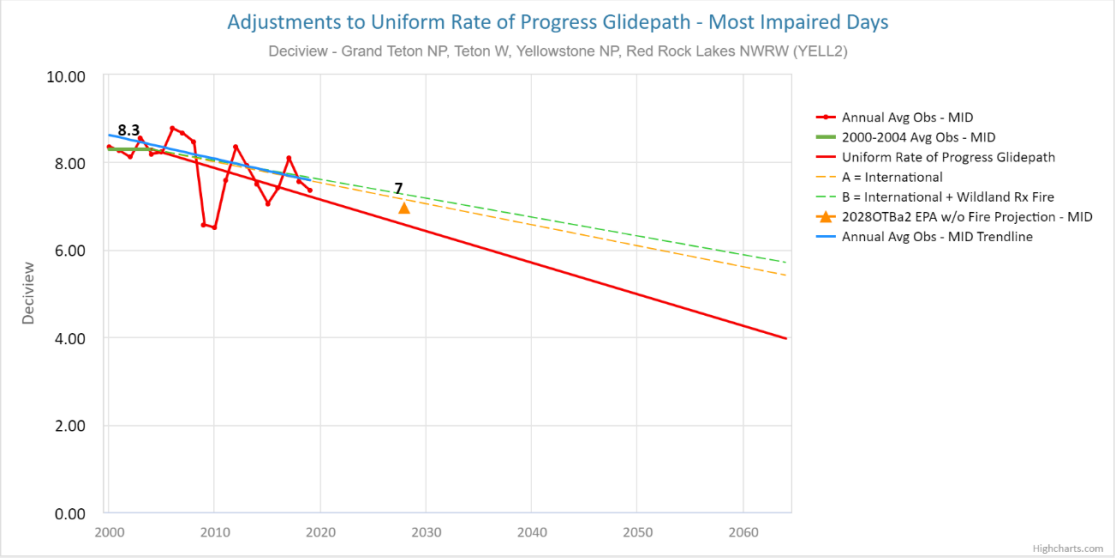
Figures 8a and 8b illustrate examples of TSS Modeling Express Chart #5 for Yellowstone (YELL2) and Mesa Verde (MEVE1) National Parks.

Interpretation: At YELL2, the 2028OTBa2 EPA without fire projection is above the URP glidepath. Adding International anthropogenic contributions to the 2064 endpoint raises the adjusted glidepath in 2028 to be above the 2028OTBa2 EPA without fire projection value. The second adjustment to the 2064 endpoint (adding wildland prescribed fire contribution to the international anthropogenic contribution) slightly raises the slope of the glidepath compared to international emissions alone.

At MEVE1, the 2028 visibility projection is below the URP glidepath. Adjustment of the 2064 endpoint for the international anthropogenic contribution raises the slope of the glidepath; adjustment for wildland prescribed fire has a negligible change to the adjusted glidepath.

At most Class I areas in the western U.S., application of the recommended methods to adjust the 2064 endpoint raises the slope of the URP glidepath. Western states will independently determine whether or not to use the URP glidepath adjustments in their regional haze planning.

Figure 8a. 2028 Visibility Projections compared to adjustments to the Uniform Rate of Progress Glidepath for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Chart #5.



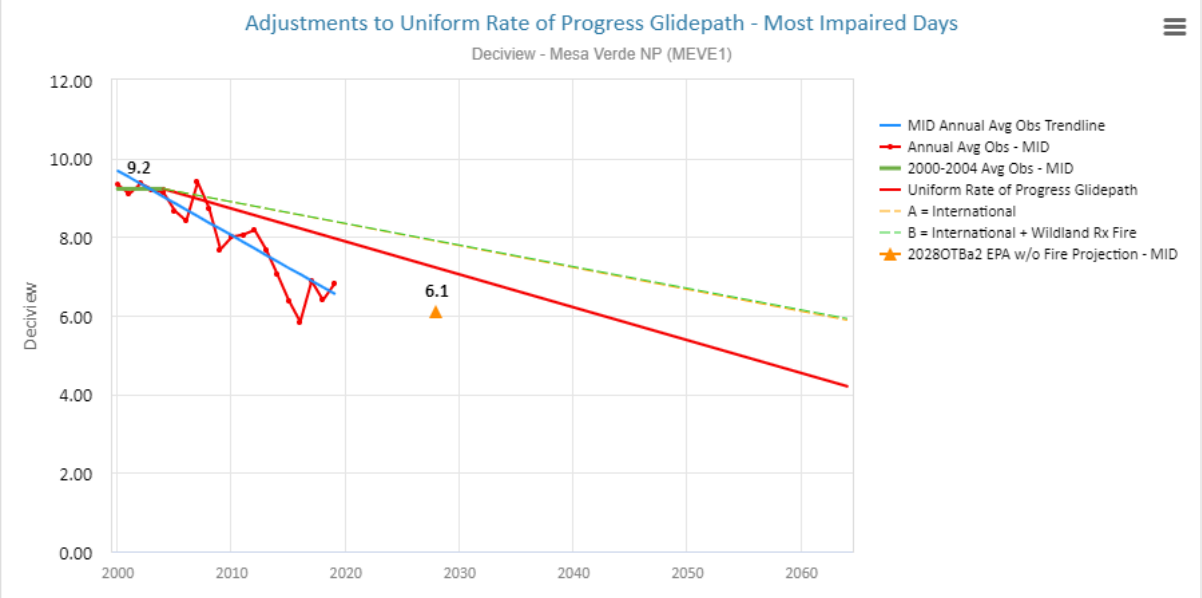


Figure 8b. 2028 Visibility Projections compared to adjustments to the Uniform Rate of Progress Glidepath for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. [TSS Modeling Express Chart] #5

10.0 Regional (High-level) Source Apportionment

WRAP Source Apportionment methods are described in the run specification sheet for [High-Level and Low-Level Source Apportionment Modeling] using the RepBase2 and 2028OTBa2 model scenarios (September 2020).

Purpose: Regional source apportionment results for U.S. anthropogenic, international anthropogenic, fire, and natural source contributions at each IMPROVE site representing western Class I areas were used as follows:

- Modeled most impaired days (ModMID) were defined based on RepBase2 source apportionment results. ModMID days were ranked by modeled U.S. anthropogenic contributions as a fraction of total aerosol light extinction. ModMID days are used as one of the WRAP alternative 2028 projection methods (see Section 7).
- 2028OTBa2 modeled international and U.S. wildland prescribed fire contributions were used as an option to adjust the 2064 endpoint of the URP glidepath for the most impaired days (see Section 9).
- Along with 2002 Hindcast scenario, RepBase2 and 2028OTBa2 regional source apportionment results for total aerosol light extinction were used to define a U.S. Anthropogenic Emissions Rate of Progress (see Section 12).

The CAMx photochemical model version 7.0 with the Particle Source Apportionment tool (PSAT) was applied at a regional level to separate U.S. anthropogenic contributions from those of fire, natural, and international anthropogenic contributions for the representative baseline period (2014-2018, RepBase2) and a future year, 2028OTBa2. CAMx with PSAT tracked gaseous and particle air emissions from sources through atmospheric dispersion, photochemical reactions, and transport to receptors (the 12-km modeling grid cell where the IMPROVE monitor is located), as defined in **Table 12**. Aerosol concentrations at the receptor include the direct products of primary gaseous and particle emissions and secondary aerosol formation.

Source contributions were defined for the following aerosols:

- Ammonium nitrate (AmmNO3)
- Ammonium sulfate (AmmSO4)
- Organic mass from carbon (OMC)
    - Primary Organic Aerosol (POA)
    - Secondary Organic Aerosols
        - Anthropogenic (SOAA)
        - Biogenic (SOAB)
- Primary Elemental Carbon (EC)
- Primary Fine Soil
- Primary Coarse Mass
- Seasalt

Table 12. PSAT emissions tracers mapped to IMPROVE aerosol species at the model receptor

PSAT Tracer Description	IMPROVE Species Name (TSS label)	Mapping between IMPROVE and PSAT species (concentration in μg/m3)	Notes
Particulate Sulfate (PS4)	Ammonium Sulfate (AmmSO4)	AmmSO4 = 1.375 * PS4	Factor 1.375 converts sulfate ion to fully neutralized ammonium sulfate
Particulate Nitrate (PN3)	Ammonium Nitrate (AmmNO3)	AmmNO3 = 1.29 * PN3	Factor 1.29 converts nitrate ion to fully neutralized ammonium nitrate
Primary Elemental Carbon (PEC)	Elemental Carbon (EC)	EC = PEC	
Primary Organic Aerosol (POA)	Organic Mass from Carbon (OMC)	OMC = POA +SOAA + SOAB	Secondary Organic Aerosols (SOA) are not explicitly tracked by source group. SOA are derived from AVRG concentration files and are operationally assigned to anthropogenic (SOAA) or biogenic (SOAB) source groups. All SOAA is assigned to U.S. anthropogenic source category and all SOAB is assigned to Natural source category.
Aluminum (PAL)	Fine Soil (Soil)	Soil = 2.2*PAL + 2.49*PSI + 1.63*PCA + 2.42*PFE + 1.94*PTI	Soil mapping is consistent with IMPROVE definition
Silicon (PSI)			
Calcium (PCA)			
Iron (PFE)			
Titanium (PTI)			
Coarse Crustal PM (PCC)	Coarse Mass (CM)	CM = PCC + PCS	
Other Coarse Particulate (PCS)			
Chloride (PCL)	Sea Salt	Sea Salt = 1.8 * PCL	Chloride is not tracked by Source Apportionment. It is obtained from the AVRG concentration files. All Chloride is assigned to sea salt. All sea salt is assigned to the "natural" source group. All other source group contributions to sea salt are 0.

Due to computational constraints, the secondary organic aerosols (SOA) family of reactive tracers were not used to track SOA at the receptor; rather SOA were operationally assigned to anthropogenic (SOAA) or biogenic (SOAB) contributions based on the chemical signatures (e.g., isoprene was assigned as biogenic in origin; benzene was assigned as anthropogenic in origin.) For purposes of compositing regional source categories, all SOAA were assigned to the U.S. anthropogenic source category and all SOAB were assigned to the Natural source category.

Regional source apportionment results for RepBase2 and 2028OTBa2 aerosol light extinction are displayed in TSS Modeling Express Tools # 10-16 for 15 source groups that are composited into 6 source categories as listed below. Abbreviations correspond to the source labels used in TSS Modeling Express Tools #10-16.

- U.S. Anthropogenic (USAnthro)
    - U.S. anthropogenic (AntUS)
    - U.S. agricultural fire (AgfireUS)
    - Secondary Organic Aerosol-Anthropogenic (SOAA)
    - Commercial Marine Vessels (CMVUS)
    - U.S. anthropogenic contributions from outside the CAMx 36-km domain boundary as defined by the GEOS-Chem global model. (BC-US)
- U.S. Wildfire (WFUS)
- U.S. Wildland Prescribed fire (RxUS)
- Canadian and Mexican fires (OthFr)
- Natural
    - Natural (Nat)
    - Secondary Organic Aerosol -Biogenic (SOAB)
    - Natural contributions from outside the CAMx 36-km domain boundary as defined by the GEOS-Chem global model. (BC-Nat)
- International Anthropogenic (IntlAnthro)
    - International Anthropogenic contributions from outside the CAMx 36-km domain boundary as defined by the GEOS-Chem global model. (BC-Int)
    - Canadian Anthropogenic (AntCAN)
    - Mexican Anthropogenic (AntMEX)
    - Commercial Marine vessels – International (beyond 200km from U.S. coast) (CMV_nonUS)

Users can choose to display source apportionment results in TSS Modeling Express Tools # 10-16 for most impaired days (EPA default 2014 IMPROVE days), modeled most impaired days, or clearest days. Charts in this document provide examples for 2014 IMPROVE most impaired days only.

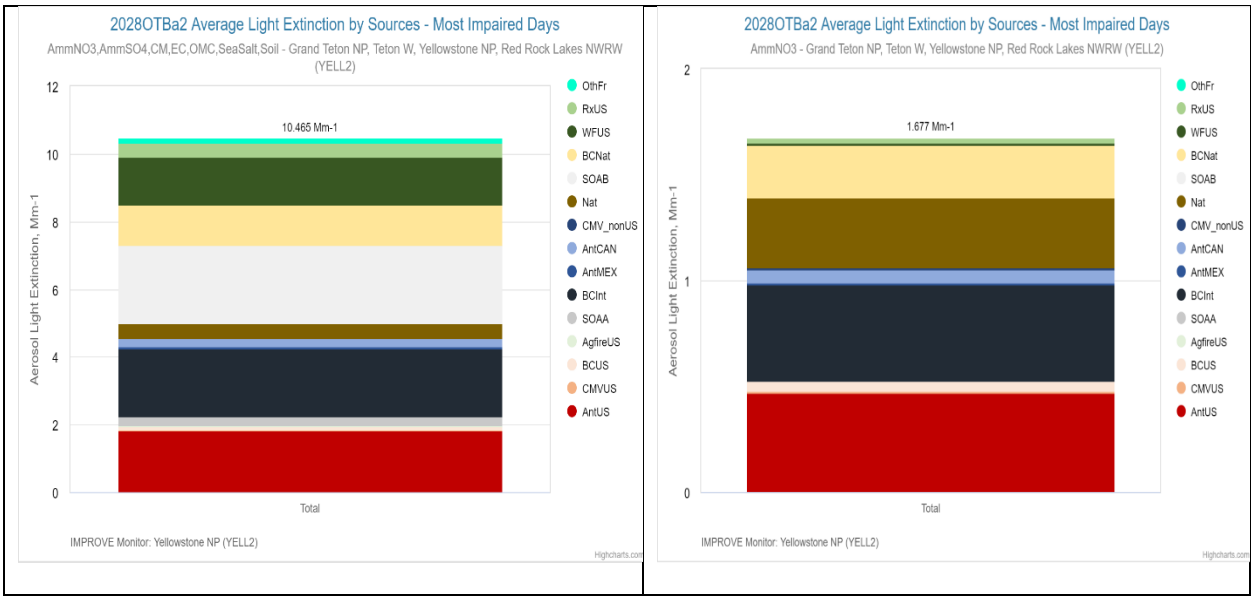
Users can choose to display source apportionment results for total aerosol extinction or for individual aerosols species extinction.

Modeled source contributions to light extinction in TSS Modeling Express Tools # 10-16 are not normalized to IMPROVE monitoring data. Model performance should be considered when interpreting source apportionment results. Average and daily model performance for most impaired days as displayed in TSS Modeling Express Tool # 1 and 2 provide insight to confidence to place in source apportionment results for individual aerosol species.

TSS Modeling Express Tool # 10 defines in a single stacked barchart the light extinction contributions from 15 source groups for the RepBase2 or 2028OTBa2 model scenarios. **Figures 9a and 9b** illustrate regional source apportionment for 2028OTBa2 for Yellowstone NP (YELL2) and Mesa Verde NP (MEVE1), respectively.

Interpretation: At YELL2, U.S. anthropogenic emissions in 2028OTBa2 are projected to contribute less than 20% of total aerosol light extinction (left chart) and less than 30% of extinction due to AmmNO3 extinction (right chart). At MEVE1, U.S. anthropogenic emissions in 2028OTBa2 are projected to contribute less than 30% of total extinction (left) and 54% of AmmNO3 extinction (right).

Figure 9a. 2028OTBa2 Regional Source Apportionment for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor for 15 source group contributions to total aerosol light extinction (Mm^{-1}) (left) or to Ammonium nitrate light extinction (right). TSS Modeling Express Tool # 10.



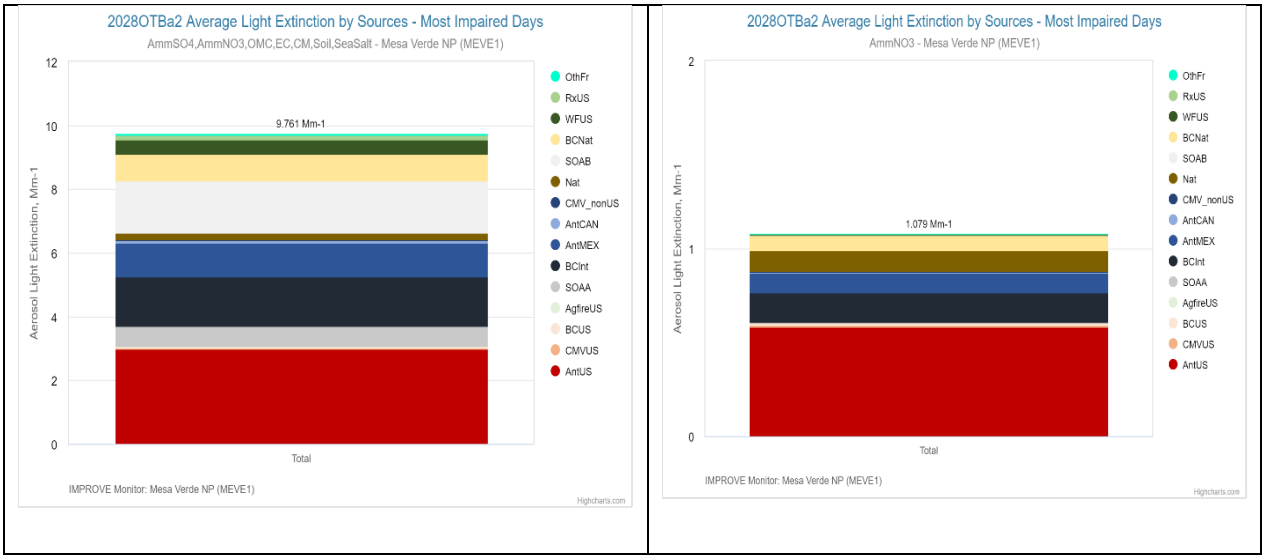


Figure 9b. 2028OTBa2 Regional Source Apportionment for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor for 15 source group contributions to total aerosol light extinction (Mm^{-1}) (left) or to Ammonium nitrate light extinction (right). TSS Modeling Express Tool # 10.

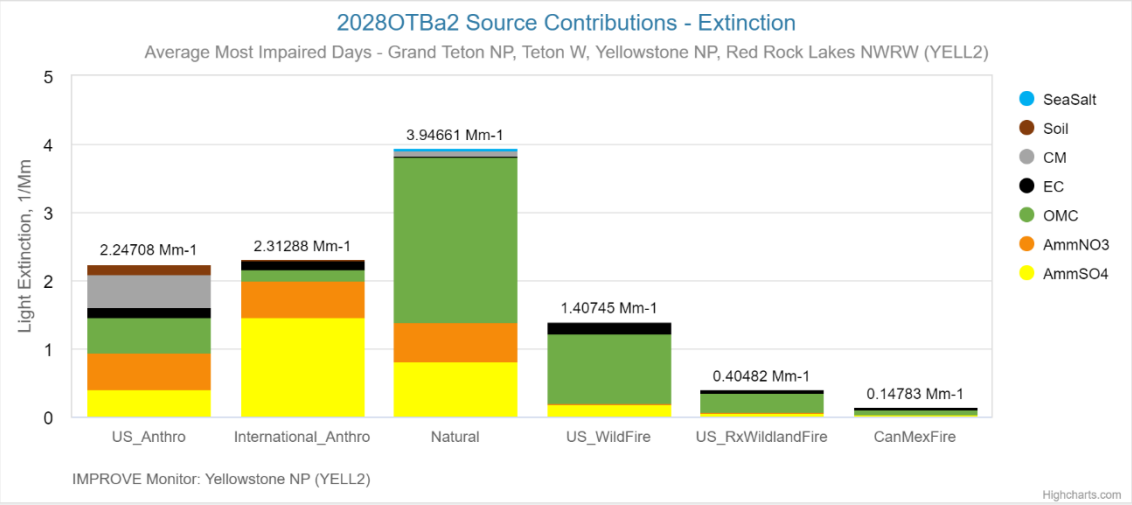

TSS Modeling Express Tool # 11, illustrated in **Figure 10a** for YELL2 and **Figure 10b** for MEVE1, displays speciated aerosol light extinction on most impaired days for RepBase2 or 2028OTBa2, by pollutant, for each of 6 source categories.

Interpretation: For YELL2, in 2028OTBa2, the natural source category is the largest source contribution, even on the most impaired days. Organic carbon dominates the natural and fire categories. International anthropogenic source contributions are equal to U.S. anthropogenic contributions and smaller than natural plus fire contributions. Ammonium sulfate and ammonium nitrate dominate the international anthropogenic category. For U.S. anthropogenic contributions, ammonium nitrate, ammonium sulfate, organic carbon, and coarse mass are projected to have similar contributions. U.S. wildland prescribed fire has very small contributions at YELL2.

The 2028OTBa2 visibility projections for YELL2 are projected to be above the URP glidepath (see **Figure 7a**, TSS Modeling Express Tool # 4) because U.S. anthropogenic sources are a smaller fraction of total aerosol extinction compared to natural, international, and fire contributions. Adding the 2028OTBa2 international contribution to the 2064 endpoint raises the URP glidepath above the 2028OTBa2 visibility projection for YELL2 (see **Figure 8a**, TSS Modeling Express Tool # 5). Adding 2028OTBa2 wildland prescribed fire to the 2064 endpoint has a very small impact on the slope of the URP glidepath because U.S. wildland prescribed fire has a small contribution to total aerosol extinction.

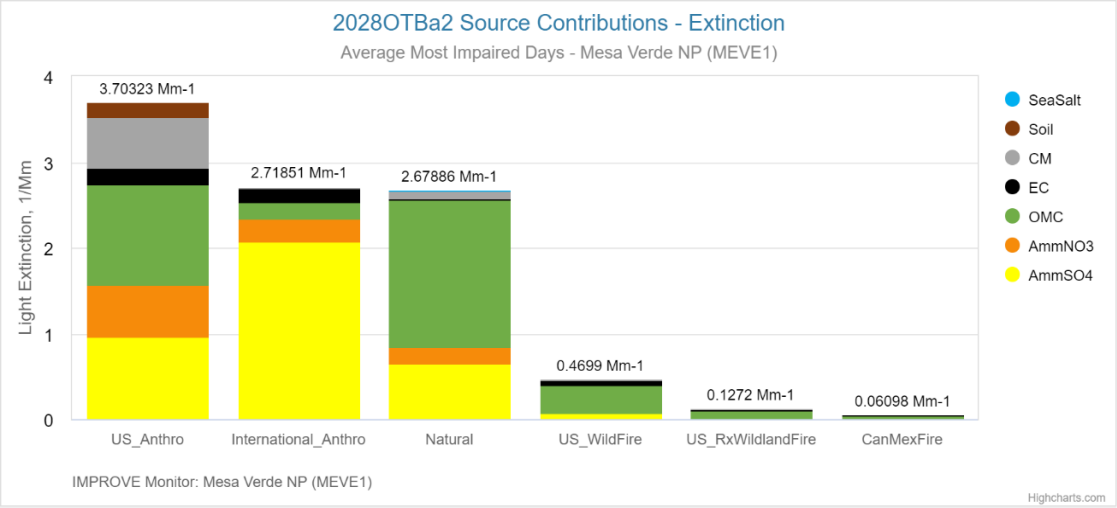

Figure 10a. 2028OTBa2 Regional Source Apportionment of Speciated Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor for U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories, with component species contributions. TSS Modeling Express Tool # 11.

Interpretation: For MEVE1, in 2028OTBa2, U.S. anthropogenic emissions have the largest contributions to total aerosol extinction, divided between ammonium sulfate, ammonium nitrate, organic carbon, and coarse mass (**Figure 10b**). International anthropogenic and natural sources have equivalent, somewhat smaller contributions than U.S. anthropogenic sources. International anthropogenic contributions are dominated by ammonium sulfate, while natural sources and fires are dominated by organic carbon. U.S. wildland prescribed fire has very small contributions at MEVE1.

The 2028OTBa2 visibility projections for MEVE1 are projected to be below the URP glidepath (see **Figure 10a**, TSS Modeling Express Tool # 4) because U.S. anthropogenic sources are a larger fraction of total aerosol extinction compared to natural, international, and fire contributions and changes in the U.S. anthropogenic emissions between RepBase2 and 2028OTBa2 are reflected in changes to 2028OTBa2 visibility projections. Adding the 2028OTBa2 international contribution to the 2064 endpoint raises the URP glidepath for MEVE1 (see **Figure 11a**, TSS Modeling Express Tool # 5). Adding 2028OTBa2 wildland prescribed fire to the 2064 endpoint has a very small impact on the slope of the URP glidepath because U.S. wildland prescribed fire has a small contribution to total aerosol extinction.

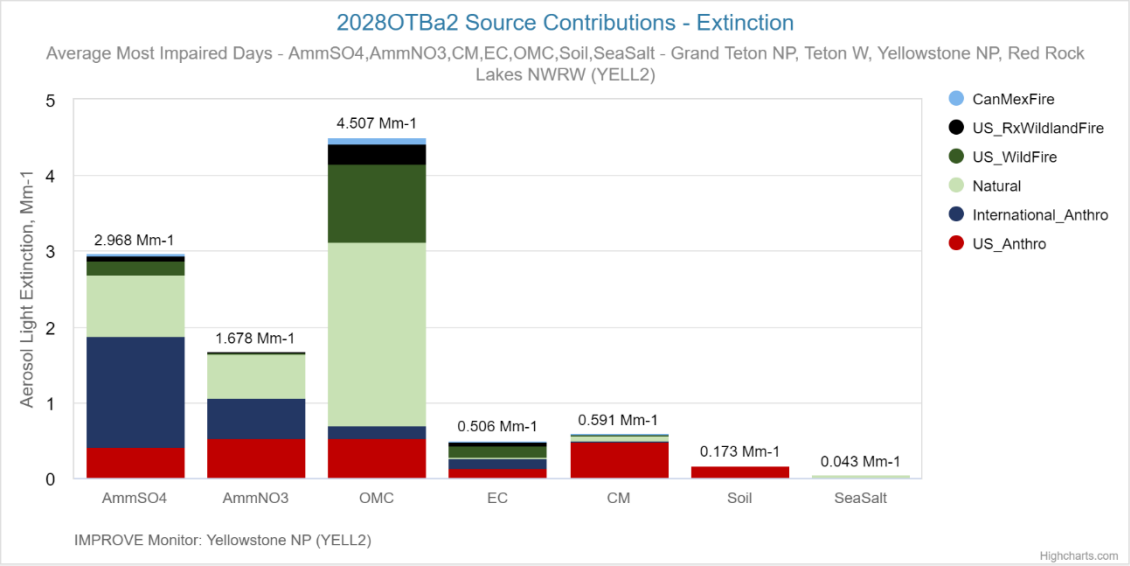
Figure 10b. 2028OTBa2 Regional Source Apportionment of Speciated Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor for U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories, with component species contributions. TSS Modeling Express Tool # 11.

TSS Modeling Express Tool # 12 illustrated in **Figure 11a** for Yellowstone NP, YELL2, and **Figure 11b** for Mesa Verde NP, MEVE1, displays speciated aerosol light extinction on most impaired days for RepBase2 or 2028OTBa2, by source category, for each of 7 pollutants.

Interpretation: At YELL2, in 2028OTBa2, on the most impaired days, organic carbon is the largest contributor to total aerosol extinction and natural and fire sources are the largest contributors to organic carbon. International anthropogenic emissions are the largest contributor to AmmSO4. Natural, international anthropogenic, and U.S. anthropogenic emissions have comparable contributions to AmmNO3.

At MEVE1, in 2028OTBa2, on most impaired days, AmmSO4 and organic carbon are the largest contributors to total aerosol extinction. International emissions are the largest contributor to AmmSO4 and natural emissions are the largest contributor to organic carbon. U.S. anthropogenic emissions are the second largest contributors to AmmSO4 and organic carbon.

Figure 11a. 2028OTBa2 Regional Source Apportionment of Speciated Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor for 7 pollutants, with component U.S. Anthropogenic, International anthropogenic, Natural, and Fire contributions to each pollutant. [TSS Modeling Express Tool] # 12.



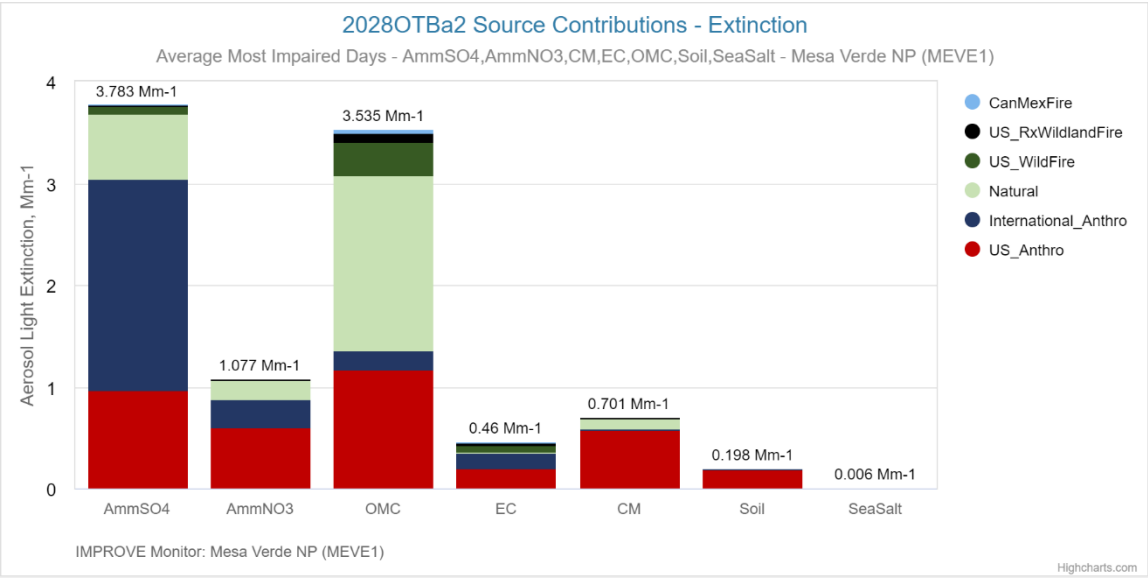


Figure 11b. 2028OTBa2 Regional Source Apportionment of Speciated Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor for 7 pollutants, with component U.S. Anthropogenic, International anthropogenic, Natural, and Fire contributions to each pollutant. [TSS Modeling Express Tool] # 12.

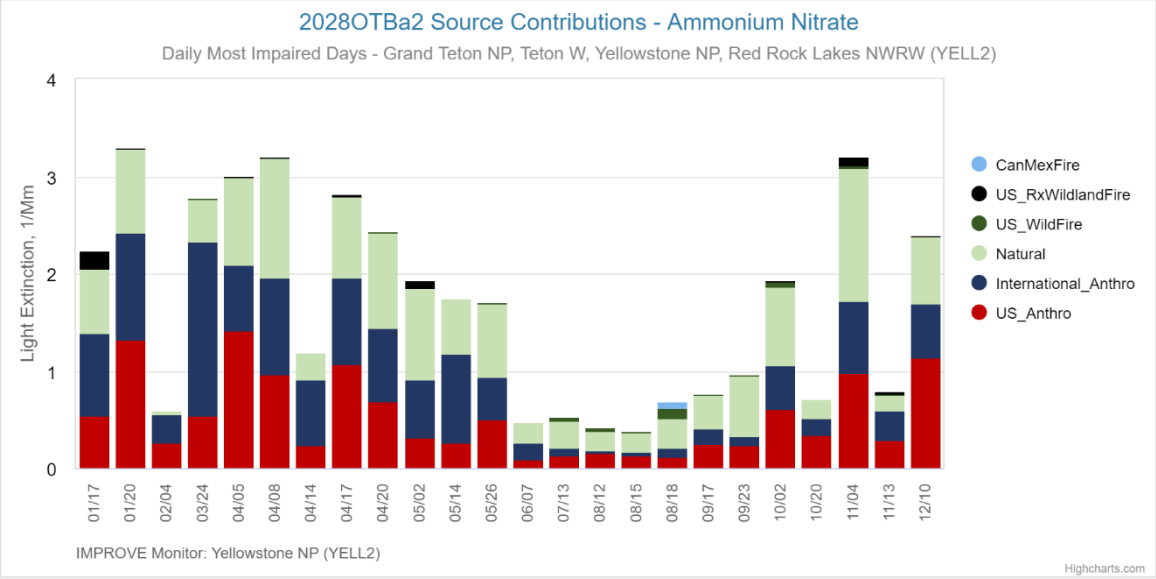
TSS Modeling Express Tool # 13 illustrated in **Figure 12a** for Yellowstone NP (YELL2) and **Figure 12b** for Mesa Verde NP (MEVE1), displays aerosol light extinction on individual 2014 IMPROVE most impaired days for RepBase2 or 2028OTBa2 source apportionment, by source category.

Interpretation: Comparing Figures 15a and 15b, U.S. anthropogenic contributions in 2028OTBa2 are a larger fraction of daily aerosol light extinction at Mesa Verde NP than at Yellowstone NP. U.S. anthropogenic contributions dominate on the two most impaired days with the highest total aerosol extinction at MEVE1. At YELL2, international anthropogenic and natural sources are equal or greater contributors to daily aerosol light extinction than U.S. anthropogenic sources. These source apportionment results are consistent with the 2028OTBa2 visibility projections for these two sites (see **Figure 7a**, TSS Modeling Express Tool # 4).

Figure 12a. 2028OTBa2 Regional Source Apportionment of Aerosol Light Extinction (Mm^{-1}) for 2014 IMPROVE daily most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor for U.S. Anthropogenic, International anthropogenic, Natural, and Fire emissions. TSS Modeling Express Tool # 13.



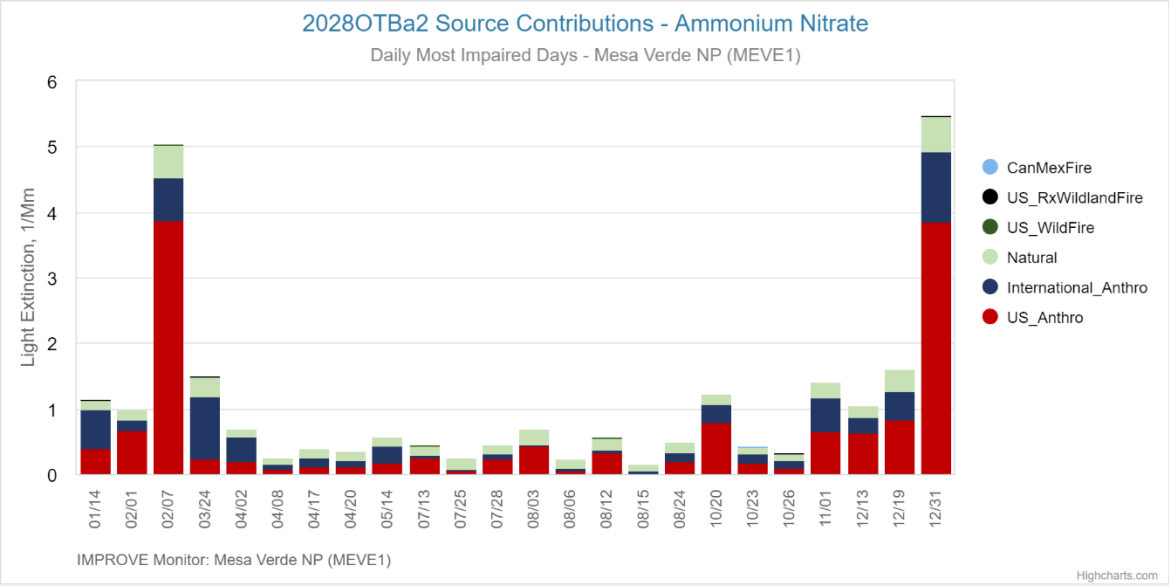


Figure 12b. 2028OTBa2 Regional Source Apportionment of Aerosol Light Extinction (Mm^{-1}) for daily 2014 IMPROVE most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor for U.S. Anthropogenic, International anthropogenic, Natural, and Fire emissions. TSS Modeling Express Tool # 13.

TSS Modeling Express Tool # 14 illustrated in **Figures 13a and 13b** for Yellowstone NP (YELL2) and **Figures 13c and 13d** for Mesa Verde NP (MEVE1) displays RepBase2 or 2028OTBa2 source apportionment results as a treemap (used to display hierarchal data.) Source categories are displayed in block colors with component source groups outlined within each source category total. Users can choose to display source apportionment results for total aerosol light extinction or single aerosol species extinction. Results in Figures 13a and 13c display total aerosol light extinction for 2028OTBa2; results in Figures 13b and 13d display light extinction due to AmmNO3 for 2028OTBa2.

Interpretation: at YELL2, for total aerosol extinction, natural sources are the largest contributors. International anthropogenic and U.S. anthropogenic have similar contributions, and wildfire is also an important source contribution. For AmmNO3, Natural, International anthropogenic and U.S. anthropogenic sources have very similar contributions. As shown in Figure 9a, at YELL2, U.S. anthropogenic emissions in 2028OTBa2 are projected to contribute less than 20% of total aerosol light extinction and less than 30% of extinction due to AmmNO3. These low fractions mean that it is more difficult to demonstrate changes visibility in response to changes in U.S. anthropogenic emissions.

At MEVE1, U.S. anthropogenic emissions are the largest source category for total aerosol extinction and for extinction due to AmmNO3 (Figures 13c, 13d). Visibility is more likely to respond to changes in U.S. anthropogenic emissions at MEVE1 than at YELL2.

Figure 13a. 2028OTBa2 Regional Source Apportionment of Total Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Yellowstone National Park (YELL2) for source groups contributing to U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories. [TSS Modeling Express Tool] # 14.

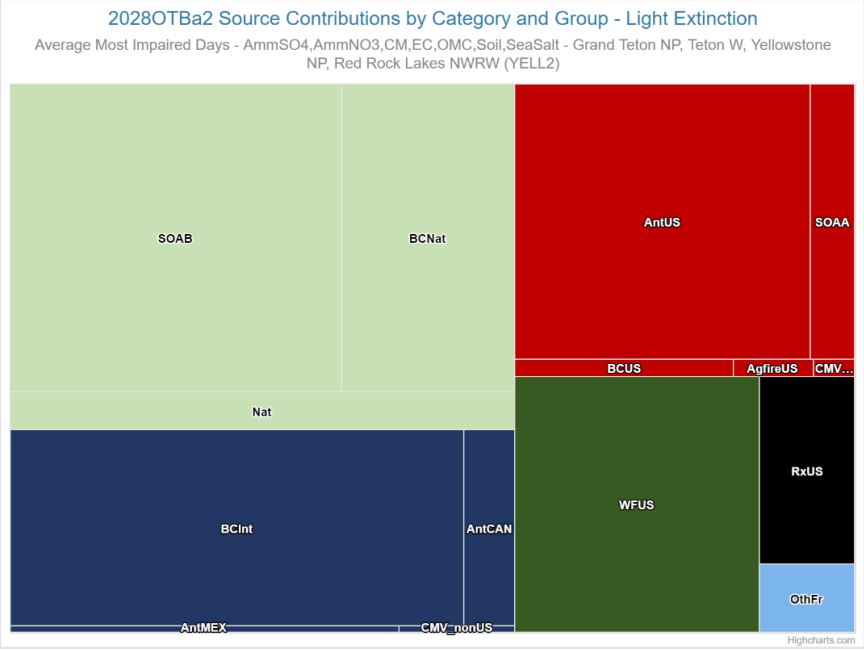

Figure 13b. 2028OTBa2 Regional Source Apportionment of Aerosol Light Extinction (Mm^{-1}) due to Ammonium nitrate for most impaired days at the Yellowstone National Park (YELL2) for source groups contributing to U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories. [TSS Modeling Express Tool] # 14.

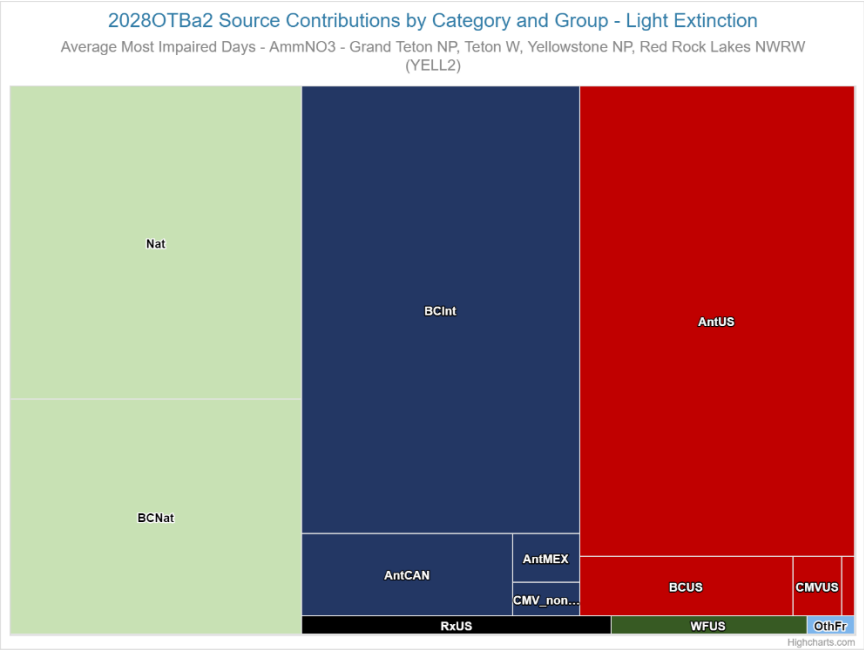

Figure 13c. 2028OTBa2 Regional Source Apportionment of Total Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Mesa Verde National Park (MEVE1) for source groups contributing to U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories. [TSS Modeling Express Tool] # 14.

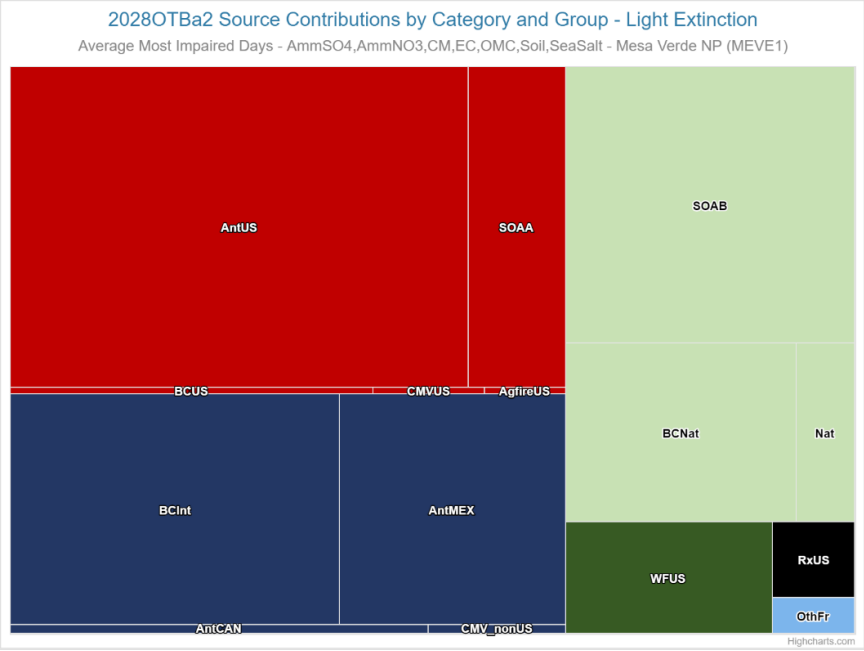

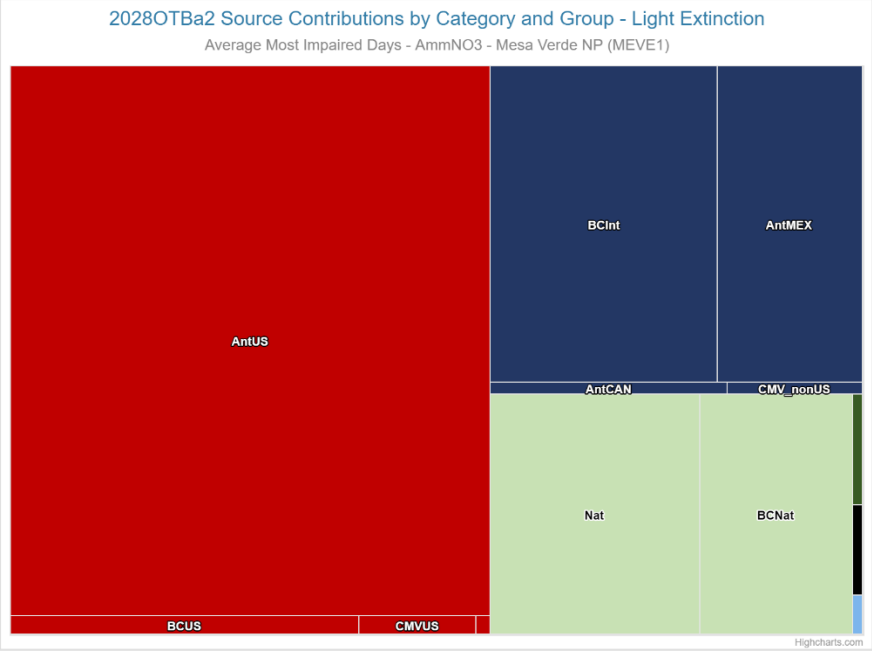

Figure 13d. 2028OTBa2 Regional Source Apportionment of Aerosol Light Extinction (Mm^{-1}) due to Ammonium Nitrate for most impaired days at the Mesa Verde National Park (MEVE1) for source groups contributing to U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories. [TSS Modeling Express Tool] # 14.

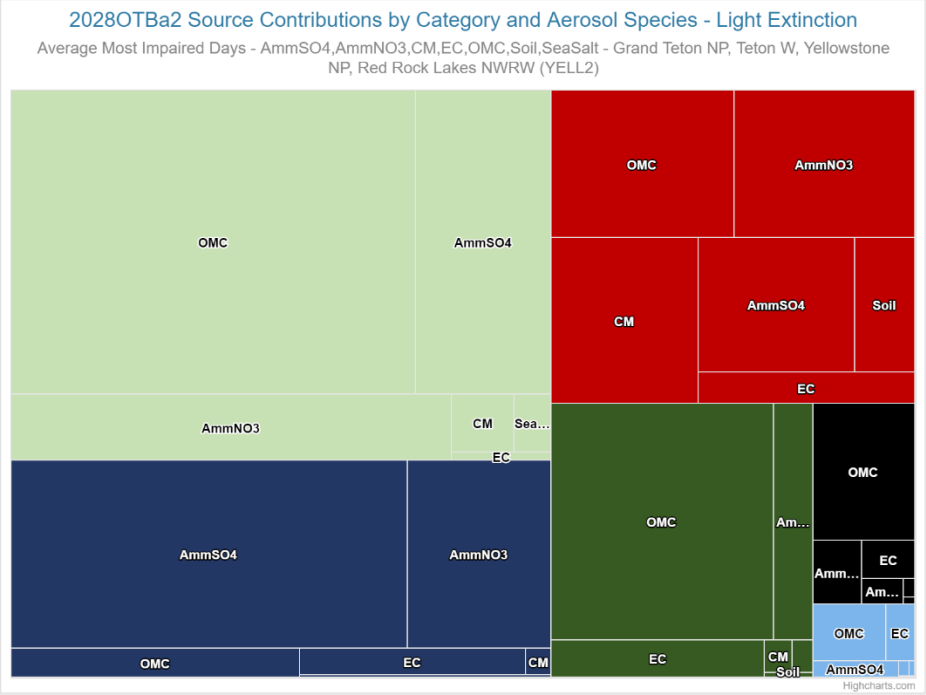
TSS Modeling Express Tool # 15 illustrated in **Figure 14a** for Yellowstone NP (YELL2) and **Figure 14b** for Mesa Verde NP (MEVE1), displays RepBase2 or 2028OTBa2 source apportionment results as a treemap (used to display hierarchal data.) Source categories are displayed in block colors with component aerosol species contributions outlined within each source category total. Users can choose to display source apportionment results for total aerosol light extinction or single aerosol species extinction. Results in Figures 14a and 14b display total aerosol light extinction for 2028OTBa2.

The same data are presented in TSS Modeling Express Tool #11 (Figures 10a and 10b.)

Interpretation: the tree map shows the aerosol species contributions to each source category. At both YELL2 and MEVE1, OMC is a large fraction of U.S. anthropogenic contributions, in addition to AmmNO3 and AmmSO4. OMC is also a large fraction of natural and fire contributions.

Figure 14a. 2028OTBa2 Regional Source Apportionment of Total Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Yellowstone National Park (YELL2) for aerosol species contributions to U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories. TSS Modeling Express Tool # 15.



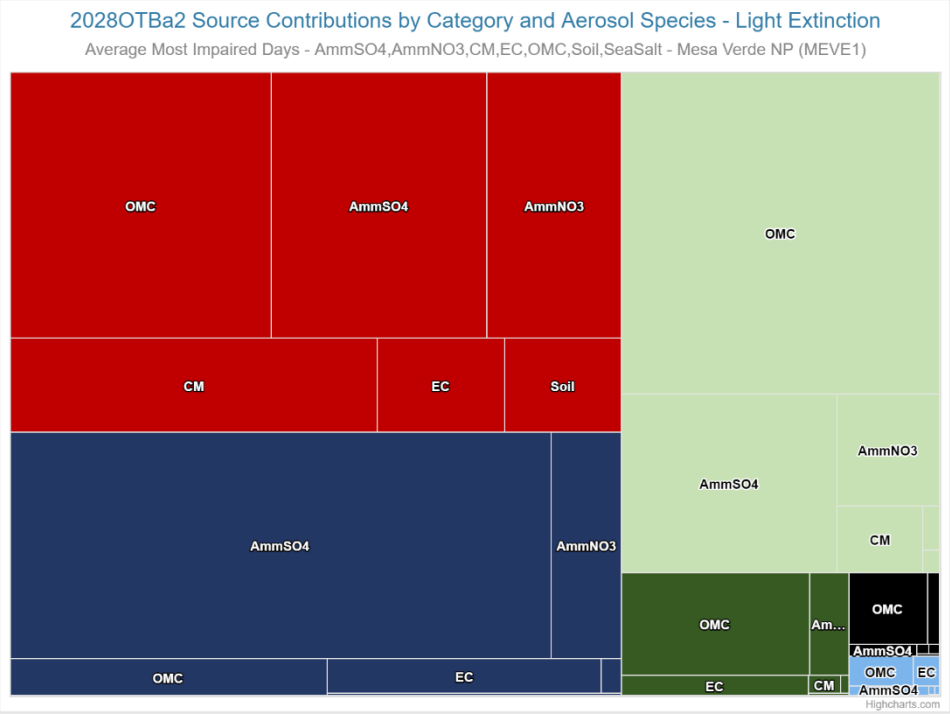


Figure 14b. 2028OTBa2 Regional Source Apportionment of Total Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Mesa Verde National Park (MEVE1) for aerosol species contributions to U.S. Anthropogenic, International anthropogenic, Natural, and Fire source categories. TSS Modeling Express Tool # 15.

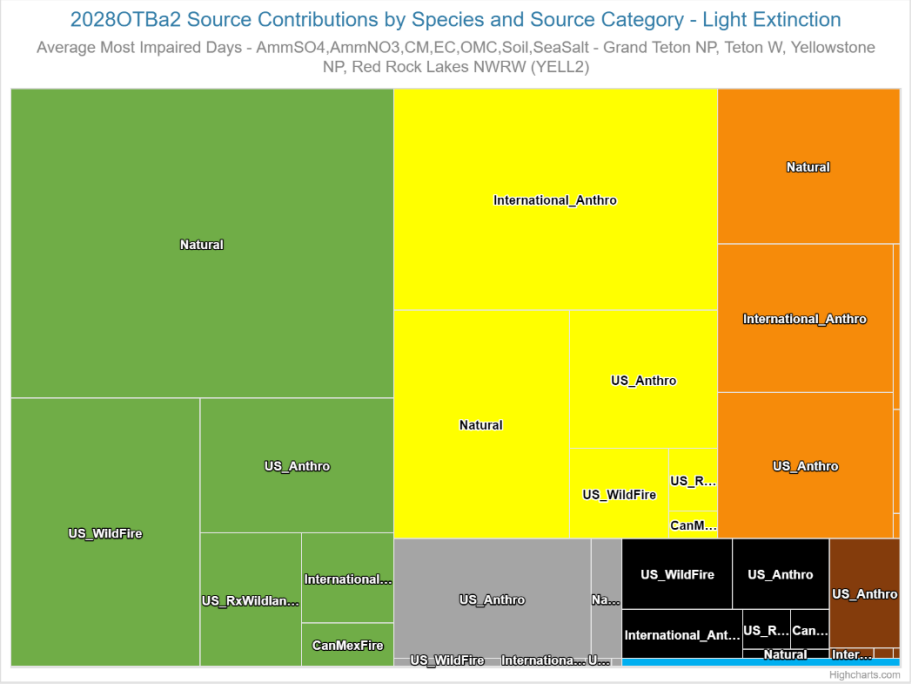
TSS Modeling Express Tool # 16 illustrated in **Figure 15a** for Yellowstone NP (YELL2) and **Figure 15b** for Mesa Verde NP (MEVE1), displays RepBase2 or 2028OTBa2 source apportionment results as a treemap (used to display hierarchal data.) Aerosol species contributions are displayed in block colors with component source groups outlined within each aerosol species. total. Users can choose to display source apportionment results for total aerosol light extinction or single aerosol species extinction. Results in Figures 15a and 15b display total aerosol light extinction for 2028OTBa2.

The same data are presented in TSS Modeling Express Tool #12 (Figures 11a and 11b.)

Interpretation: at YELL2, U.S. anthropogenic contributions are the third most important for OMC, AmmSO4, and AmmNO3. At MEVE1 U.S. anthropogenic contributions are the largest factor for AmmNO3 and the second largest for AmmSO4 and OMC.

Figure 15a. 2028OTBa2 Regional Source Apportionment of Total Aerosol Light Extinction (Mm^{-1}) for most impaired days at Yellowstone National Park (YELL2) for source category contributions to individual aerosol species. [TSS Modeling Express Tool] # 16.



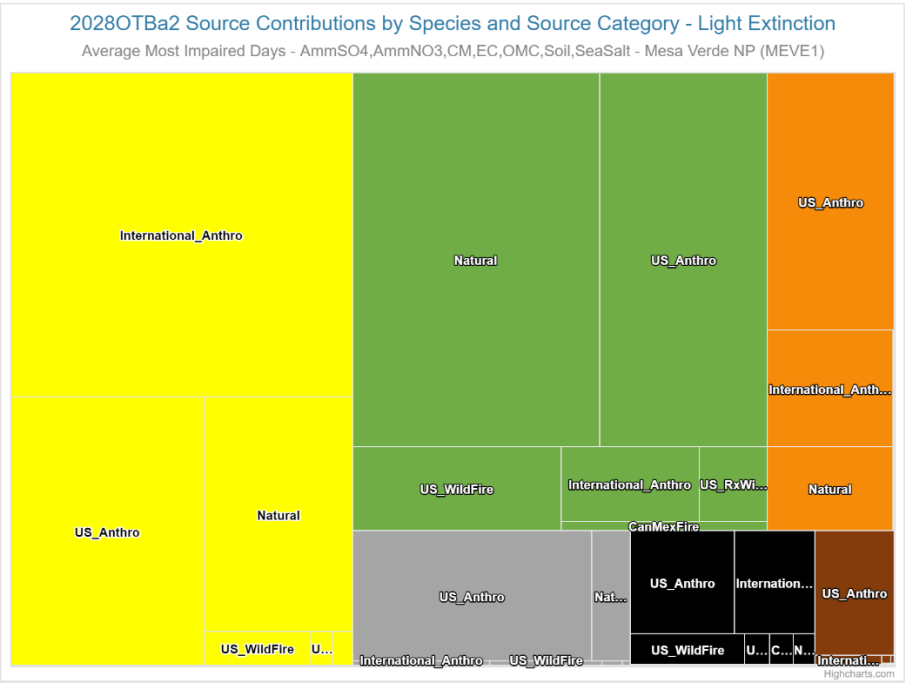


Figure 15b. 2028OTBa2 Regional Source Apportionment of Total Aerosol Light Extinction (Mm^{-1}) for most impaired days at Mesa Verde National Park (MEVE1) for source category contributions to individual aerosol species. [TSS Modeling Express Tool] # 16.

11.0 State and Sector (Low-level) Source Apportionment

For the future year 2028OTBa2 model scenario, PSAT was applied to further define U.S. anthropogenic contributions to AmmNO3 and AmmSO4 aerosols at western Class I areas from each of 13 WESTAR-WRAP states and all other non-WRAP U.S. states combined. Methods are further detailed in the run specification sheet for High-Level and Low-Level Source Apportionment Modeling using the RepBase2 and 2028OTBa2 model scenarios (September 2020).

State contributions to AmmNO3 and AmmSO4 were subdivided into five anthropogenic source categories:

- electric generating units (EGU)
- oil and gas (area plus point sources) (OilGas)
- remaining point sources (non-EGU)
- Mobile onroad, nonroad, rail, and commercial marine vessels (CMV 1, 2, and 3 within 200 km of U.S. coast) (Mobile)
- remaining anthropogenic sources (including Fugitive dust, Agriculture, Agricultural fire, residential wood combustion, and all remaining nonpoint sources)

For each Class I area, these results identify which source sectors and states are projected to have the greatest contributions in 2028OTBa2 to visibility impairment due AmmSO4 and AmmNO3. These results can assist states to prioritize which emissions reductions strategies might be most effective in improving visibility at western Class I areas.

The state and sector source apportionment results in TSS Modeling Express Tools # 9 are absolute model outputs; results are not normalized to IMPROVE monitoring data. Users can choose to display state and sector source apportionment results for most impaired days (EPA default 2014 IMPROVE days), modeled most impaired days, or clearest days. This document provides examples for most impaired days only.

TSS Modeling Express Tool # 9 illustrated in **Figures 16a and 16b** for Yellowstone NP (YELL2) and **Figures 16c and 16d** for Mesa Verde NP (MEVE1), displays RepBase2 or 2028OTBa2 source apportionment results for western states and source sectors for AmmNO3 or AmmSO4 light extinction, respectively.

Interpretation: at YELL2 PSAT projects that AmmNO3 contributions from individual states are 0.2 Mm^{-1} or less. PSAT identifies mobile sources from several western states as the most important U.S. anthropogenic contributors to AmmNO3 at YELL2 (**Figure 16a**). Idaho is shown as having the largest contributions to AmmNO3 from mobile, non-EGU and area sources.

For AmmSO4 at YELL2, PSAT projects that individual state contributions are small (0.15 Mm-1 or less). Non-EGU, EGU, and area sources in several states are identified as contributors.

Figure 16a. 2028OTBa2 State and Sector Source Apportionment of Ammonium Nitrate Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. [TSS Modeling Express Tool](#) # 9

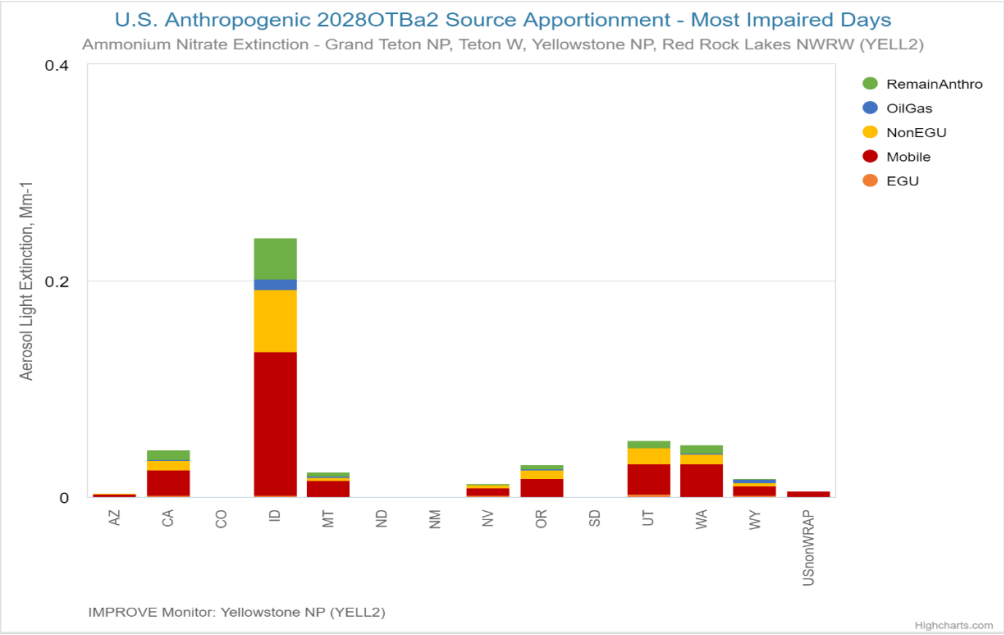

Figure 16b. 2028OTBa2 State and Sector Source Apportionment of Ammonium Sulfate Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. [TSS Modeling Express Tool](#) # 9

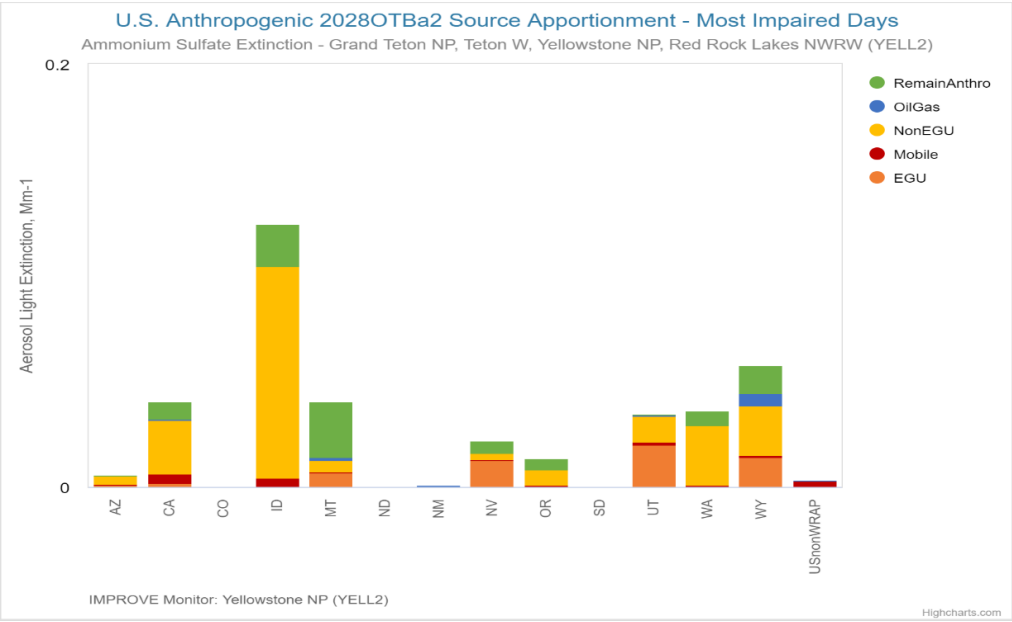

Figure 16c. 2028OTBa2 State and Sector Source Apportionment of Ammonium Nitrate Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. [TSS Modeling Express Tool] # 9

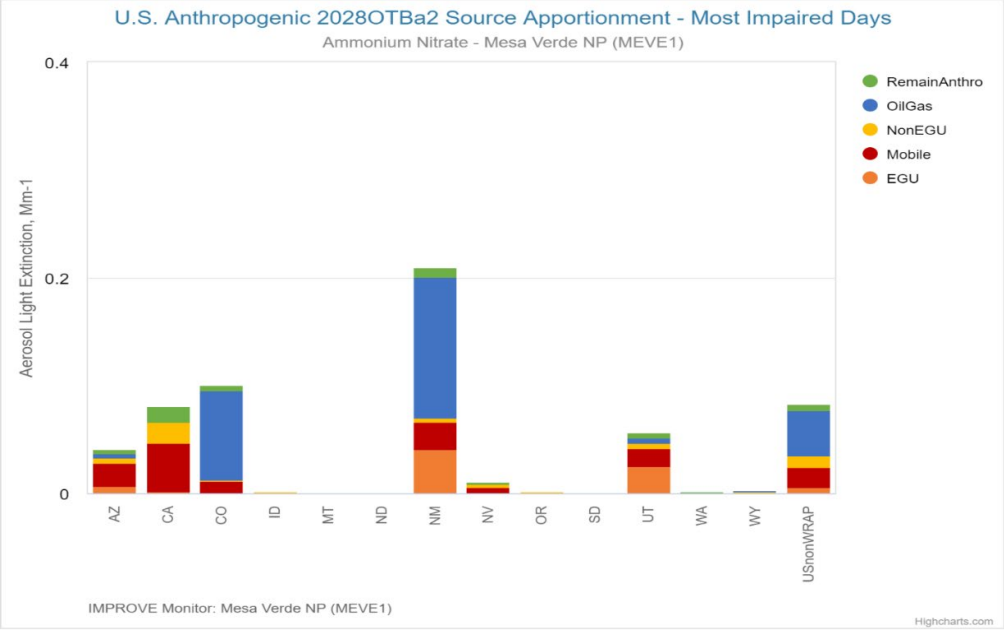

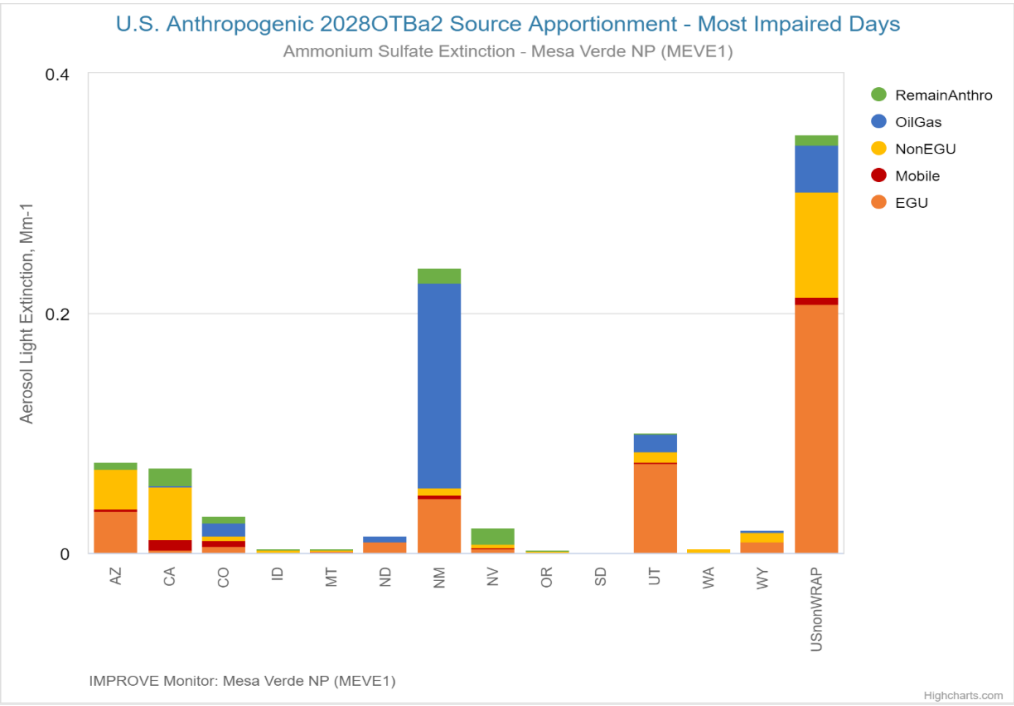

Figure16d. 2028OTBa2 State and Sector Source Apportionment of Ammonium Sulfate Aerosol Light Extinction (Mm^{-1}) for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. [TSS Modeling Express Tool] # 9

At MEVE1, AmmNO3 contributions from individual states are 0.2 Mm^{-1} or less. Oil and gas in NM, CO, and non-WRAP states are major contributors; oil and gas on tribal lands is included in the state contributions (see Table 3 in Section 3 of the TSS Emissions Reference document for breakdown of tribal vs non-tribal NOx emissions.) EGU and mobile source sectors are also contributors to AmmNO3. EGU from non-WRAP states and oil and gas in NM are the largest contributors to AmmSO4 at MEVE1. Weighted Emissions Potential plots for MEVE1 confirm the Four Corners region and Arizona as the highest transport area for AmmNO3 and that EGU in Texas contribute to AmmSO4 loadings.

In general, at western Class I areas mobile emissions and oil and gas emissions are significant contributors to AmmNO3, while electric generating units and remaining point sources are more important source categories for AmmSO4.

12.0 Weighted Emissions Potential

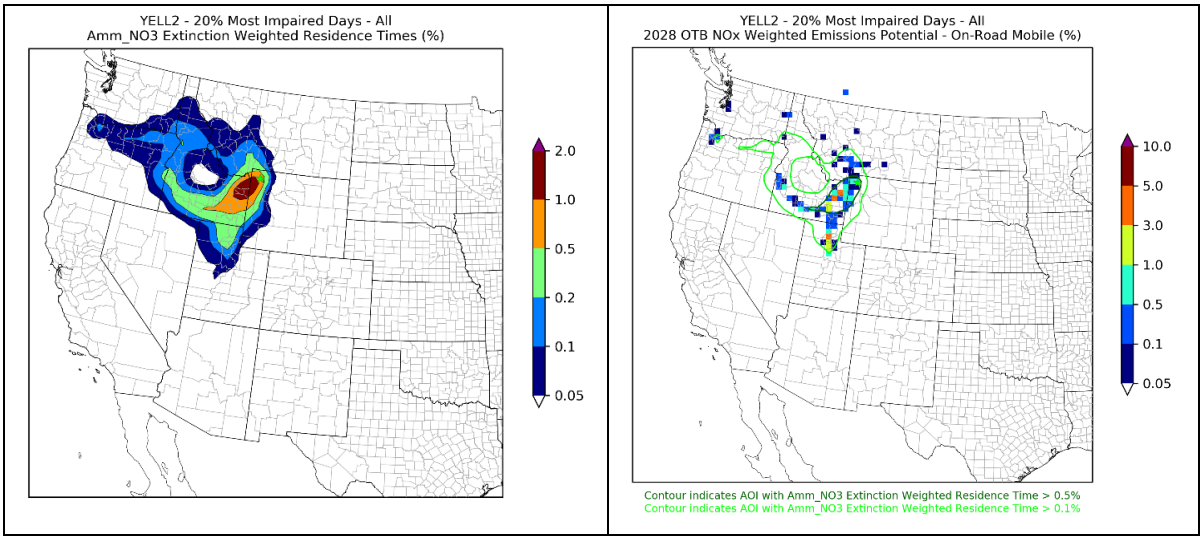
WRAP 2028 Weighted Emissions Potential maps were developed to illustrate the geographic areas of greatest emissions influence for aerosol extinction on most impaired days at 76 IMPROVE monitors representing 116 Class I areas in the 13 WESTAR-WRAP states and neighboring states. 72-hour back trajectory analyses (defined every 6 hours for multiple start heights) for most impaired days for the 5-year period 2014-2018 were used to define frequency of atmospheric transport. Gridded 2028 modeled emissions in 36-km grid cells, residence time defined by back trajectory transport frequency, residence time weighted aerosol extinction for most impaired days (also called area of influence), and weighted emission potential for gridded emissions can be downloaded from the Weighted Emissions Potential webpage. The weighted emissions potential defines relative source importance for each Class I area. These analyses provide weight of evidence in support of state and sector source apportionment results in Section 11.0.

Figure 17a (left) displays the areas of highest influence from NOx emissions, weighted by AmmNO3 extinction on the most impaired days for YELL2, highlighted in burgundy and orange elliptical shapes overlaying eastern Idaho and western Wyoming. **Figure 17a (right)** displays the individual 36-km model grid cells, color graded by importance of mobile source NOx emissions for AmmNO3 extinction on most impaired days at YELL2 (burgundy, orange, and green grid cells have the highest importance). **Figure 17b (left)** displays areas of highest influence from SO2 emissions, weighted by AmmSO4 extinction on the most impaired days for YELL2.

Interpretation: The Weighted Emissions Potential maps agree with the PSAT results (Section 11.0) for YELL2 and MEVE1. For YELL2 the geographic area of influence is similar for AmmNO3 and AmmSO4 extinction (**Figures 17a, left and 17b, left**.) For mobile sources, the highest contributors to AmmNO3 extinction on most impaired days at YELL2 include the mobile source corridors in Idaho and grid cells in Montana, Utah, Oregon and Washington (**Figure 17a, right**). Non-Electric generating point sources (non-EGU) in several states are seen as important

contributors to AmmSO4 extinction on most impaired days at YELL2 (**Figure 17b right**). These results agree with PSAT results that identify mobile sources as largest contributors to AmmNO3 (**Figure 16a**) and non-EGU point sources as largest contributors to AmmSO4 extinction at YELL2 (**Figure 16b**).

Figure 17a. 2028OTBa2 Extinction Weighted Residence Time for Ammonium Nitrate (AmmNO3) Light Extinction (Mm^{-1}) (left) and NOx Weighted Emissions Potential for On-Road Mobile sources (right) for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. Weighted Emissions Potential



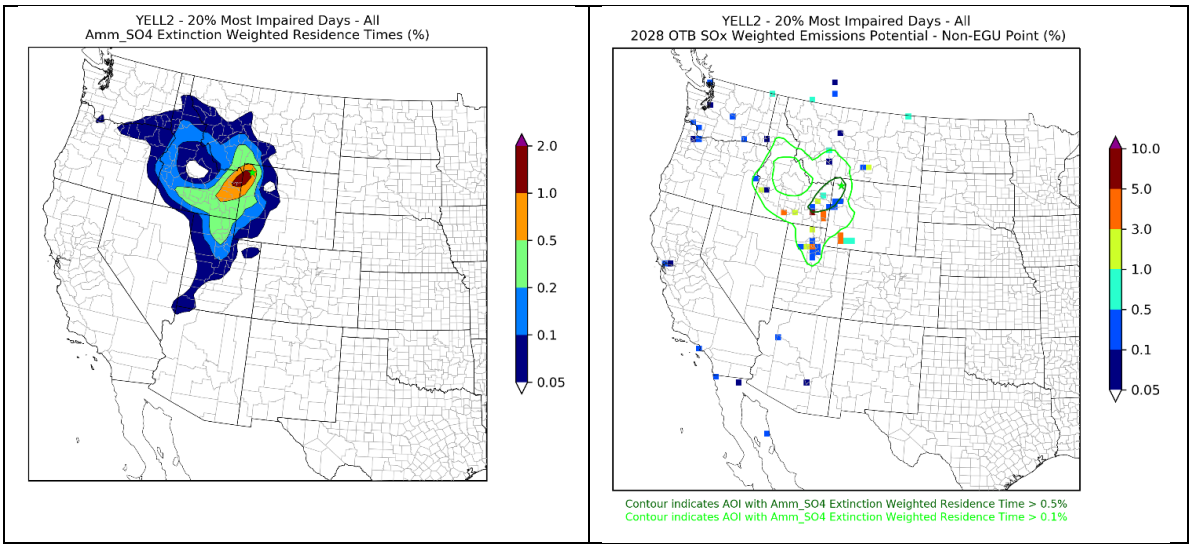


Figure 17b. 2028OTBa2 Extinction Weighted Residence Time for Ammonium Sulfate (AmmSO4) Light Extinction (Mm^{-1}) (left) and SO2 Weighted Emissions Potential for Non-Electric Generating Point sources (right) for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. Weighted Emissions Potential

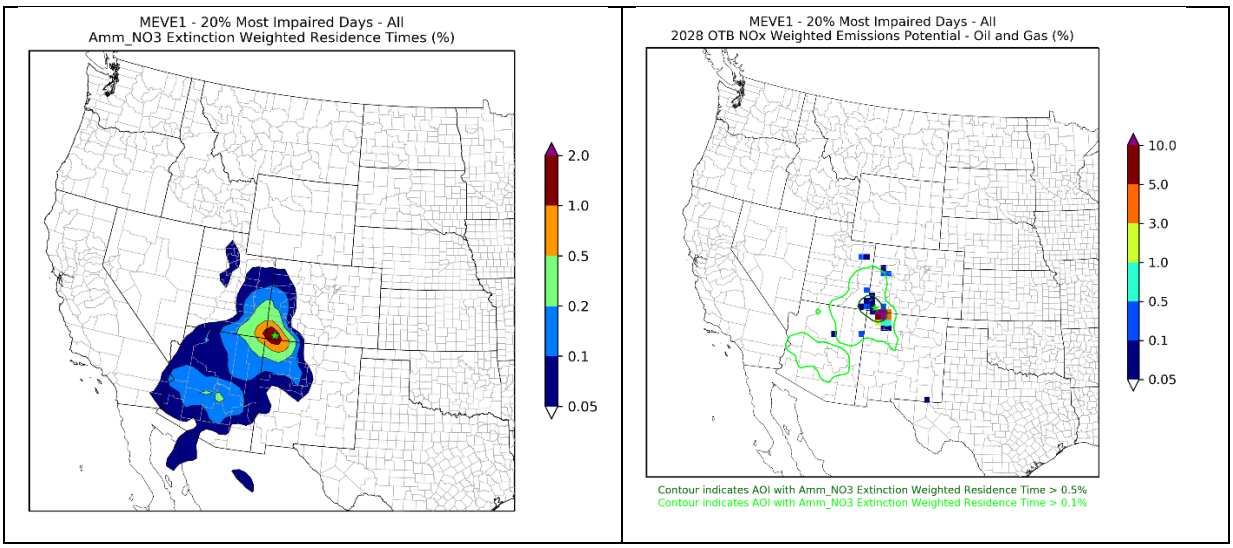
For MEVE1, **Figure 17c, left** display the geographic areas of highest influence for NOx emissions, weighted by AmmNO3 extinction on the most impaired days. In **Figure 17c, right** the areas of highest influence are outlined in dark green and light green boundaries and oil and gas point and area sources contributions to AmmNO3 are defined in color-graded 36-km grid cells. **Figure 17d, left** displays a very similar geographic area of influence for SO2 emissions, weighted by AmmSO4 extinction on most impaired days. **Figure 17d, right** illustrates that electric generating units that influence AmmSO4 extinction at MEVE1 on most impaired days are geographically dispersed and not restricted to the geographic area of highest influence for total AmmSO4.

Figure 17c. 2028OTBa2 Extinction Weighted Residence Time for Ammonium Nitrate (AmmNO3) Light Extinction (Mm^{-1}) (left) and NOx Weighted Emissions Potential for On-Road Mobile sources (right) for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. Weighted Emissions Potential



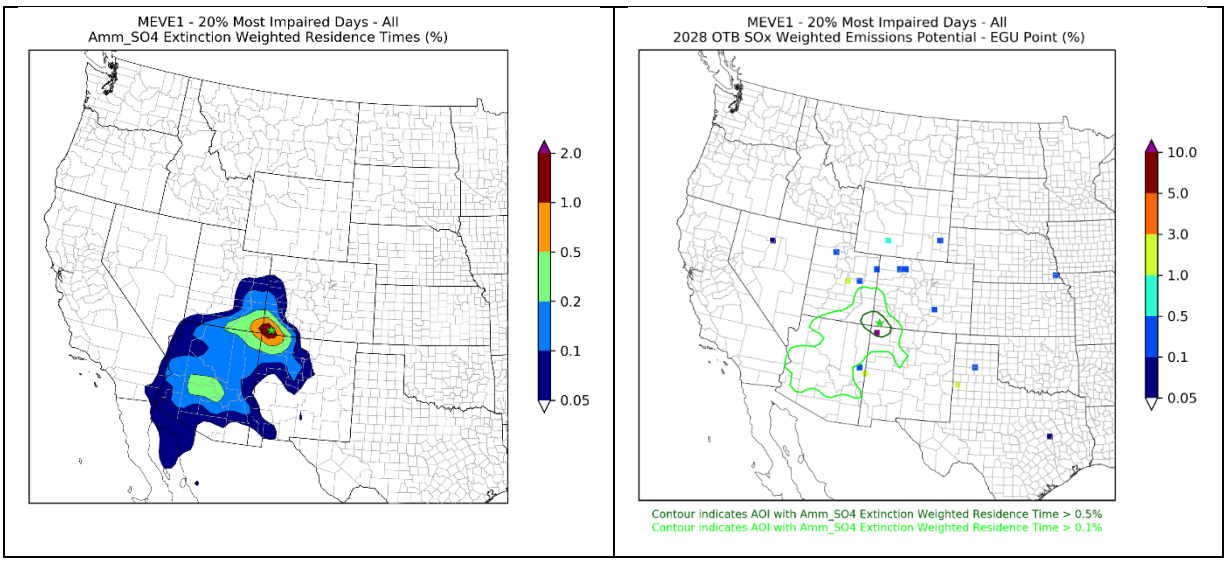


Figure 17d. 2028OTBa2 Extinction Weighted Residence Time for Ammonium Sulfate (AmmSO4) light Extinction (Mm^{-1}) (left) and SO2 Weighted Emissions Potential for Electric Generating Units (EGU) sources (right) for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. Weighted Emissions Potential

The area of greatest influence for AmmNO3 extinction on most impaired days at MEVE1 (**Figure 17c, left)** is centered over the Four Corners area. In **Figure 17c, right** the area of greatest influence is outlined in the dark green elliptical boundary over the Four Corners and the lighter green boundary over portions of the four states: AZ, CO, NM, and UT. On the same plot, the 36-km grid cells are color coded by importance of NOx emissions from oil and gas area and point sources. The oil and gas contributions are primarily located within the inner dark green area of influence.

The areas of greatest influence for AmmSO4 extinction on most impaired days at MEVE1 are illustrated in **Figure 17d, left** and **17d, right.** The areas of influence are similar to those for AmmNO3 extinction at MEVE1. The EGU plot illustrates emissions from elevated EGU point sources can influence visibility at a distant Class I area even if transport from the EGU point source is infrequent. These maps are consistent with the PSAT state and sector source apportionment for AmmNO3 and AmmSO4 at MEVE1 (Section 11.0)

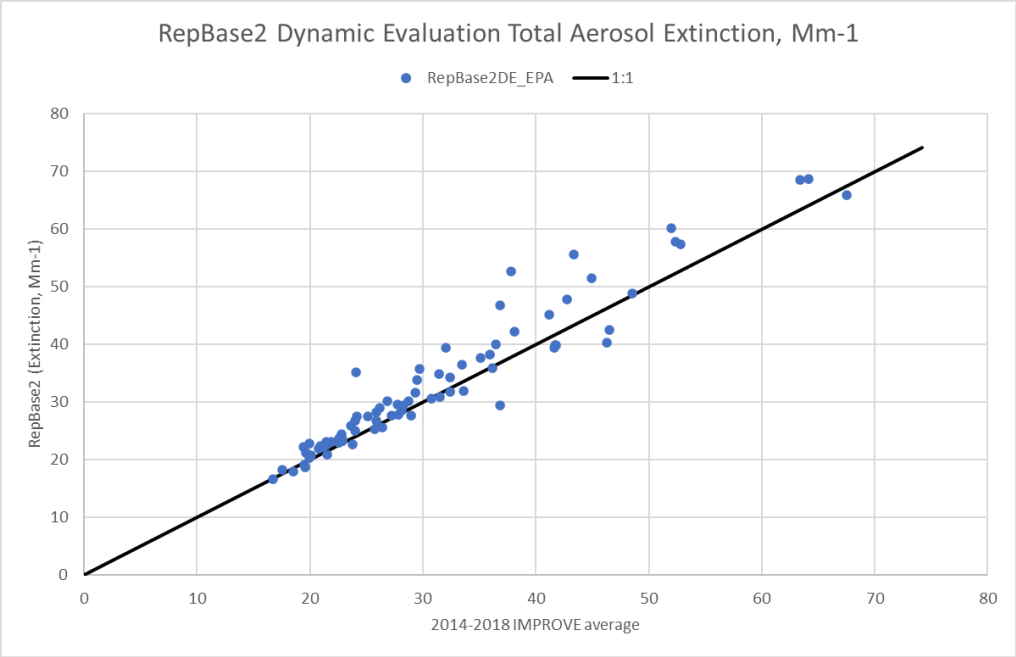
13.0 Dynamic Model Evaluation

As part of the WRAP-WAQS 2014 modeling study, a dynamic model evaluation was conducted to test the model's ability to project changes in ambient aerosol visibility extinction at IMPROVE monitoring sites in response to changes in U.S. anthropogenic emissions. To conduct the dynamic model evaluation, in addition to the 2014v2, RepBase2 and 2028OTBa2 model

scenarios already discussed, an additional scenario representing U.S. anthropogenic emissions for 2002 (2002 Hindcast) was run using the CAMx-PSAT photochemical grid model platform with 2014 meteorology and RepBase2 emissions for all other natural, fire, and international source groups. Only U.S. anthropogenic emissions changed between the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios. 2002 U.S. Anthropogenic emissions were back cast from the 2014 National Emissions Inventory (NEI) using scaling factors based on EPA's NEI trends for most sectors, with exceptions that California Air Resources Board provided 2014 to 2002 scaling factors for California, and western states supplied 2002 emissions for point sources (electric generating units (EGU), oil and gas point sources, and other non-EGU point sources.) Methods for the 2002 Hindcast are further defined in the U.S. Anthropogenic Emissions Rate of Progress document (September 2021).

The dynamic model evaluation applied the same future year projection methods defined by Environmental Protection Agency modeling guidance (December 2018) to project 2014-2018 visibility from the 2002 Hindcast forward to the RepBase2 scenario. Relative response factors for each aerosol species were calculated (RepBase2 model results divided by 2002 Hindcast model results) and then multiplied by 2000-2004 IMPROVE observations for each species to project RepBase2 visibility. Model projected RepBase2 aerosol light extinction closely matched IMPROVE observed light extinction for 2014-2018 5-year average (**Figure 18a**). This confirmation increases confidence that the CAMx model and EPA projection methods can produce credible 2028 visibility projections. Backward projections of 2002 visibility from RepBase2 (relative response factors calculated as 2002 Hindcast divided by RepBase2 and then multiplied by 2014-2018 IMPROVE observations) had larger discrepancies from 2000-2004 IMPROVE observations than forward projections from 2002 to RepBase2, but still showed good agreed for most western IMPROVE sites (**Figure 18b**). The larger discrepancies for the 2002 Hindcast are likely due to a combination of (i) using RepBase2 levels of fire and international emissions for the 2002 Hindcast model run that differed from the actual emissions that contributed to 2000-2004 IMPROVE observations and (ii) using scaling factors to calculate 2002 Hindcast emissions from 2014v2 National Emissions Inventory that introduces errors for U.S. anthropogenic emissions (e.g., over estimating 2002 emissions for Commercial Marine Vessel emissions). A future dynamic model evaluation may want to back cast natural, fire and international emissions as well as U.S. anthropogenic emissions.

Figure 18a. Dynamic Model Evaluation applying EPA projection methods and comparing total aerosol light extinction for 2014-2018 IMPROVE observations (x-axis) to modeled RepBase2 (y-axis) for Class I areas in the 13 western states. U.S. Anthropogenic Emissions Rate of Progress



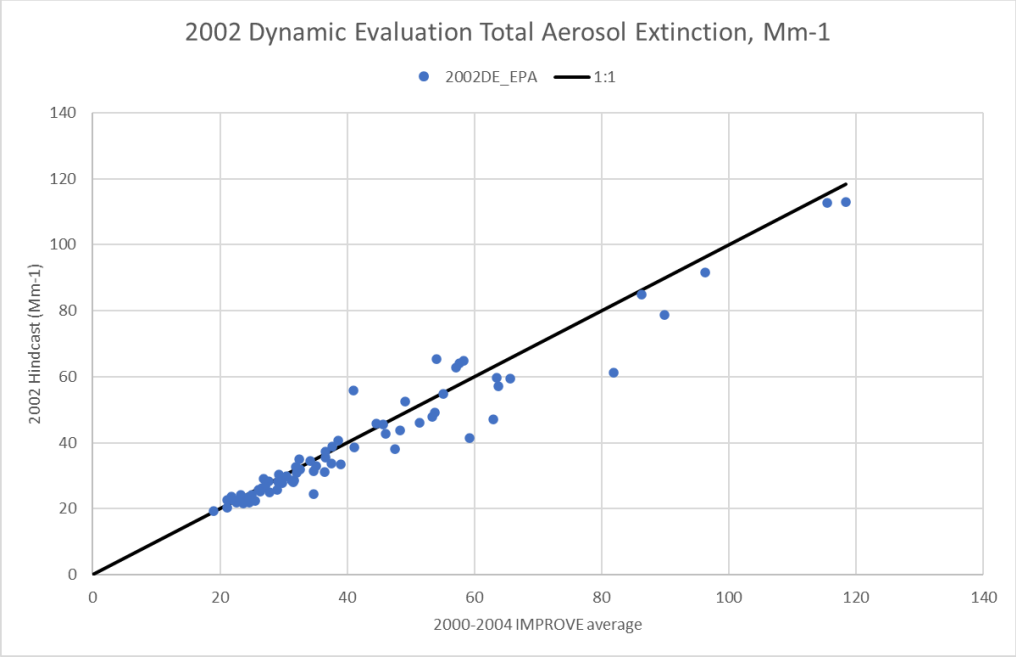


Figure 18b. Dynamic Model Evaluation applying EPA projection methods and comparing total aerosol light extinction for 2000-2004 IMPROVE observations (x-axis) to modeled 2002 Hindcast (y-axis) for Class I areas in the 13 western states. U.S. Anthropogenic Emissions Rate of Progress

14.0 U.S. Anthropogenic Emissions Rate of Progress

WRAP has defined a U.S. Anthropogenic Emissions Rate of Progress to demonstrate visibility progress at western Class I areas due to changes in U.S. Anthropogenic emissions between the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios. Methods for the 2002 Hindcast, RepBase2 and 2028OTBa2 scenario development are further defined in the WRAP-WAQS run specification sheets

- Representative Baseline v2 and 2028OTBa2
- U.S. Anthropogenic Emissions Rate of Progress

The URP glidepath represents total haze from all source contributions on most impaired days. In the western U.S., haze is caused by international, natural, and fire emissions as well as U.S. anthropogenic emissions. Uncertainties in the URP glidepath construction are further described in the U.S. Anthropogenic Emissions Rate of Progress webpage.

The objective of the U.S. Anthropogenic Emissions Rate of Progress is to isolate the contributions of U.S. anthropogenic emissions to visibility at Class I areas in the WESTAR-WRAP states and to demonstrate the progress in improving visibility in response to changes in U.S. anthropogenic emissions between the 2002 Hindcast, RepBase2, and 2028OTBa2 scenarios.

- Only U.S. anthropogenic emissions change in the three model scenarios.
    - Any differences in aerosol extinction between the 2002, RepBase2, and 2028OTBa2 scenarios are due to changes in U.S. anthropogenic emissions.
    - We have greatest confidence in U.S. anthropogenic emissions.

- All other emissions (natural, fire, and international) are held constant at RepBase2 levels for the 2002 Hindcast and 2028OTBa2 scenarios.
    - Because RepBase2 international, fire, and natural emissions are used in the 2002 Hindcast scenario, the 2002 Hindcast results are not fully comparable to the 2000-2004 IMPROVE monitoring data.

- The source apportionment model results are not adjusted to the IMPROVE monitoring data.

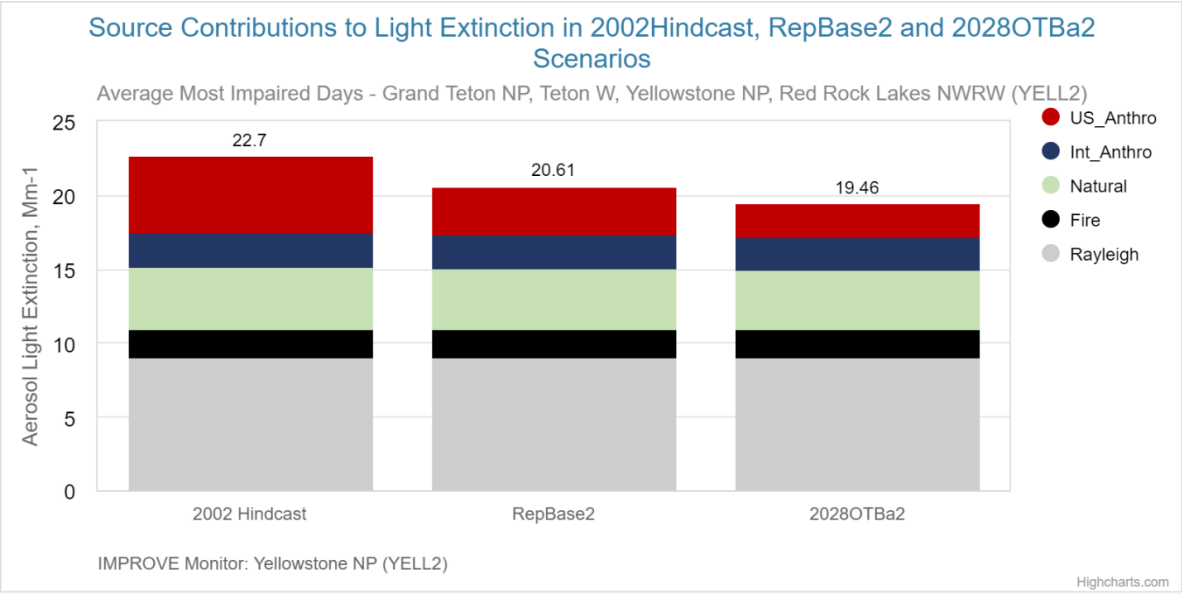
- The U.S. Anthropogenic Emissions Rate of Progress is intended as an alternative to adjusting the 2064 endpoint of the URP glidepath using 2028 source apportionment results for international and U.S. wildland prescribed fire, per EPA guidance.

TSS Modeling Express Tool # 6, illustrated in **Figures 19a and 19b** displays US Anthropogenic, International Anthropogenic, Natural, Fire, and Rayleigh contributions to total light extinction for the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios for the IMPROVE monitors at Yellowstone (YELL2) and Mesa Verde (MEVE1) National Parks, respectively.

Interpretation: at YELL2 U.S. Anthropogenic contributions are projected to be reduced by 2 Mm^{-1} (39%) between 2002 Hindcast and RepBase2 and by 1 Mm^{-1} (30%) between RepBase2 and 2028OTBa2. This rate of progress is below the straight line drawn from 2002 U.S. anthropogenic contribution to zero U.S. anthropogenic contribution in 2064. This is in contrast to conclusions following EPA guidance, where 2028OTBa2 visibility projections for YELL2 are not below the URP glidepath (Section 8.0). The modeled rate of U.S. anthropogenic progress is below the glidepath to no U.S. anthropogenic contribution.

At MEVE1, U.S. anthropogenic contributions are projected to be reduced by 3 Mm^{-1} (41%) between 2002 Hindcast and RepBase2 and by 0.8 Mm^{-1} (18%) between RepBase2 and 2028OTBa2. This rate of progress is below the straight line drawn from 2002 U.S. anthropogenic contribution to zero U.S. anthropogenic contribution in 2064.

Figure 19a. Contributions to Aerosol Light Extinction from U.S. Anthropogenic, International Anthropogenic, Natural, and Fire emissions, plus Rayleigh light scattering, for the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios for most impaired days at Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Tool # 6



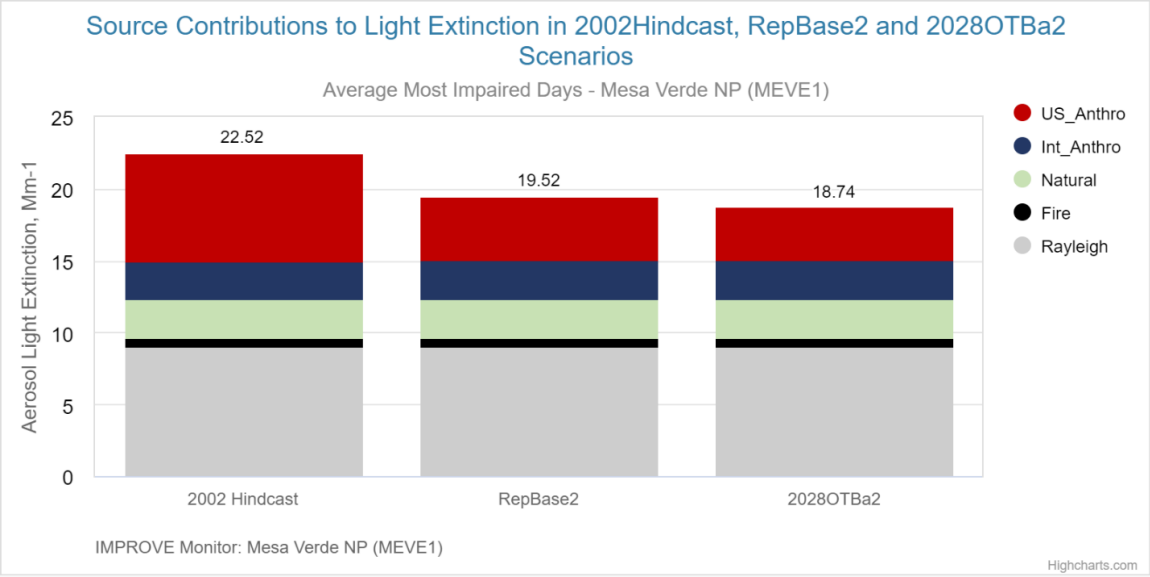


Figure 19b. Contributions to Aerosol Light Extinction from U.S. Anthropogenic, International Anthropogenic, Natural, and Fire emissions, plus Rayleigh light scattering, for the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios for most impaired days at Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Tool # 6

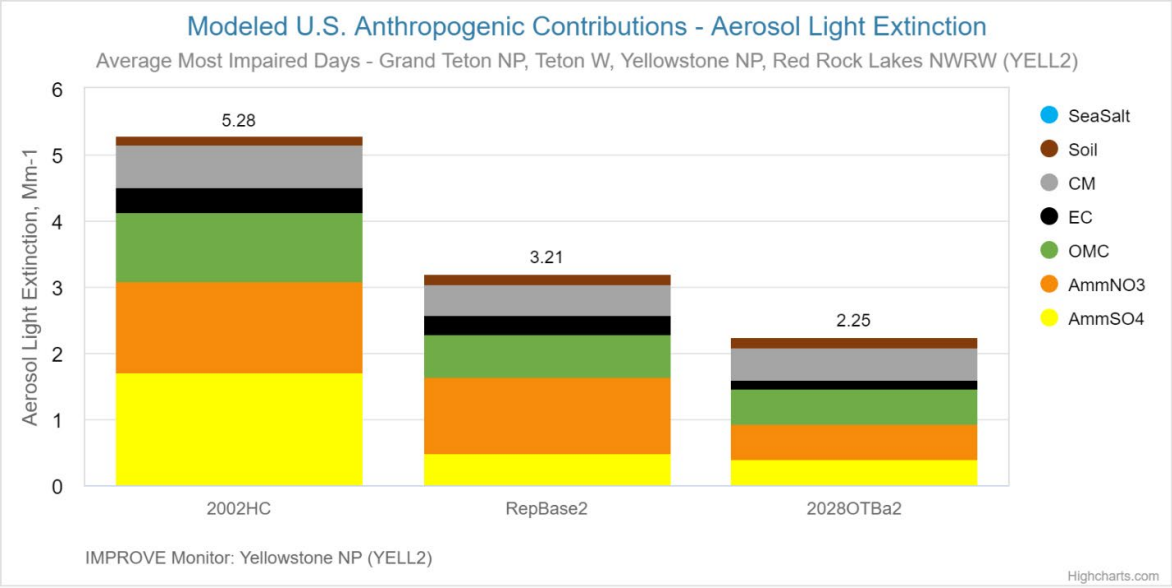
TSS Modeling Express Tool # 7, illustrated in **Figures 20a and 20b** displays aerosol species contributions to just the U.S. Anthropogenic fraction of total light extinction for the 2002 Hindcast, RepBase2 and 2028OTBa2 model scenarios for the IMPROVE monitors at Yellowstone (YELL2) and Mesa Verde (MEVE1) National Parks, respectively.

- TSS Chart 7 does not address aerosol light extinction from sources other than U.S. Anthropogenic contributions.
- The source apportionment model results are not adjusted to the IMPROVE monitoring data.

Interpretation: at both YELL2 and MEVE1, reductions in U.S. anthropogenic contributions between 2002 Hindcast and RepBase2 are primarily due to reductions in AmmSO4 and OMC. At YELL2, reductions projected to occur between RepBase2 and 2028OTBa2 are primarily due to reductions in AmmNO3. At MEVE1, reductions in U.S. anthropogenic contributions between RepBase2 and 2028OTBa2 are projected due to small reductions in AmmNO3 and AmmSO4.

Figure 20a. U.S. Anthropogenic Contributions to Speciated Aerosol Light Extinction for the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios for most impaired days at Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Tool # 7



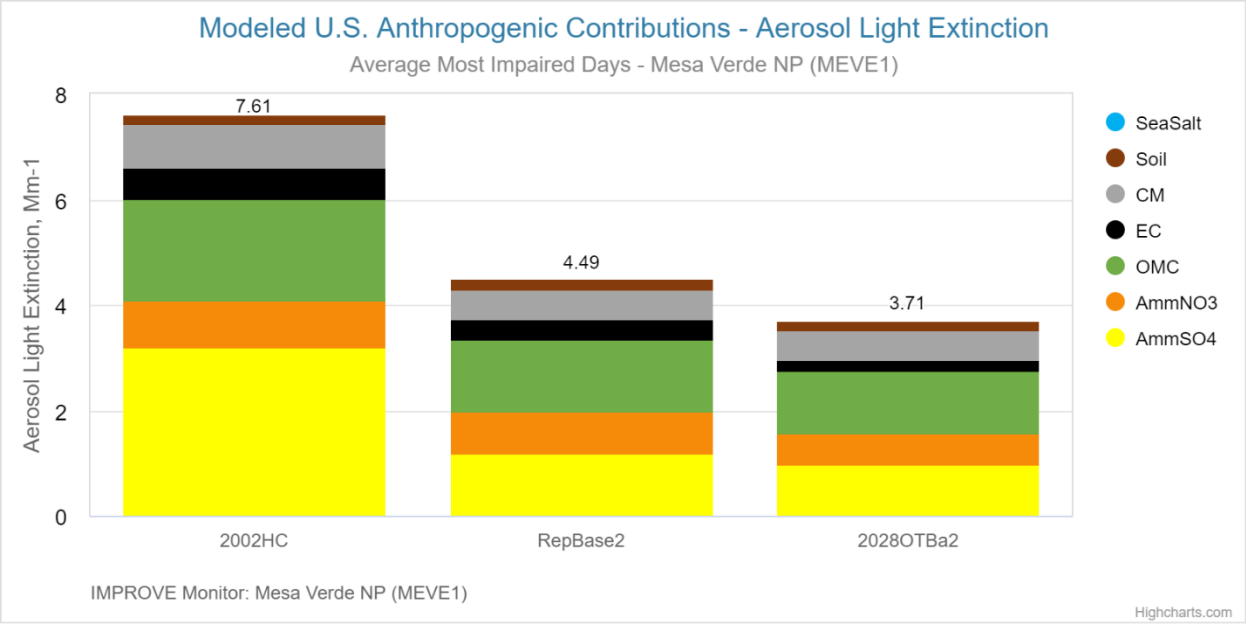


Figure 20b. 2028 U.S. Anthropogenic Contributions to Speciated Aerosol Light Extinction for the 2002 Hindcast, RepBase2, and 2028OTBa2 model scenarios for most impaired days at Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Tool # 7

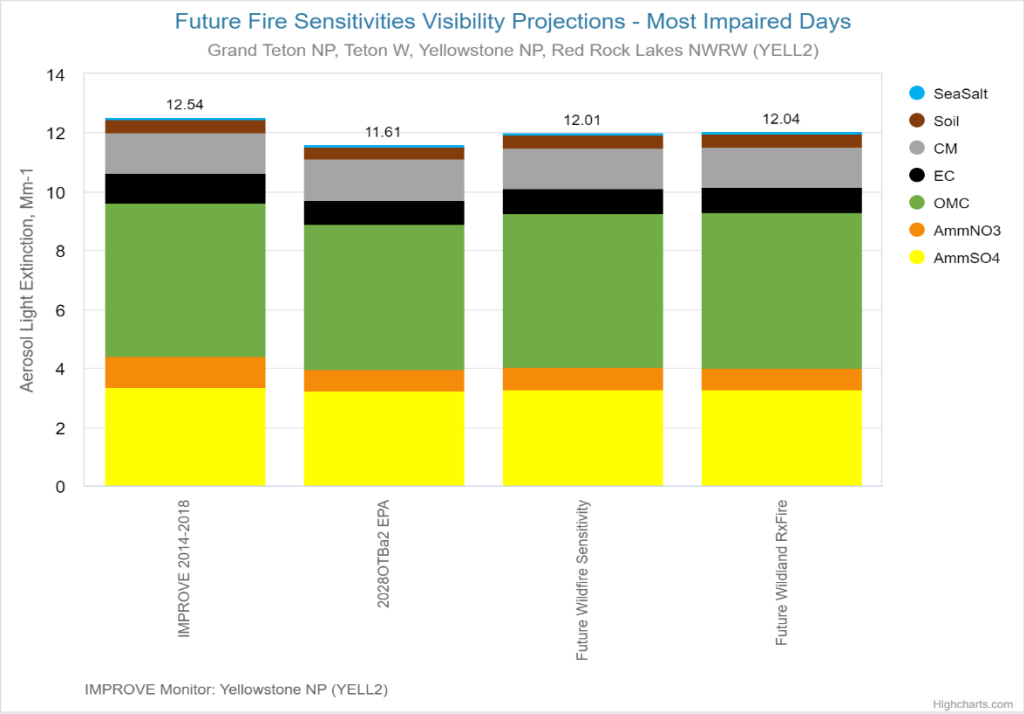
15.0 Future Fire Sensitivities

Future fire sensitivities added wildfire emissions (FFS1) or wildland prescribed fire emissions (FFS2) as two potential future variations in fire activity that are not specific to any single future year. The fire sensitivities are added to the 2028OTBa2 reference case scenario to replace historic fire emissions used in the RepBase2 and 2028OTBa2 scenarios. All other 2028OTBa2 emissions: U.S. anthropogenic, international, natural, and non-US fire emissions are held constant. The only differences between the 2028OTBa2 and the fire sensitivities are due to the FFS1 and FFS2 assumptions.

- **FFS1** examines the effects of potential future changes in the timing, frequency, and intensity in terms of acres burned for **wildfires** compared to the Representative Baseline fires.
- **FFS2** examines the effects of potential future enhanced forest management practices defined as increases in **wildland prescribed burns**.

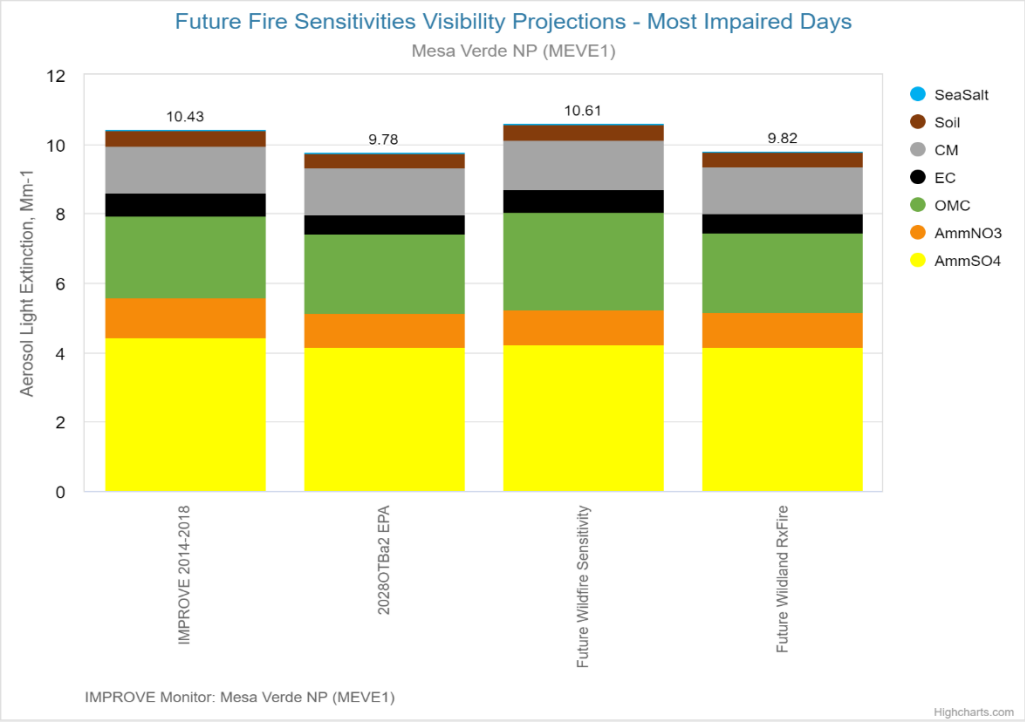
Emissions development of the future fire sensitivities is described in the Air Sciences, Inc. report Fire Emissions Inventories for Regional Haze Planning: Methods and Results (April 2020).



Modeling procedures are detailed in the run specification sheet for the Future Fire Simulations (August 2021).

TSS Modeling Express Tool # 18, illustrated in **Figures 21a and 21b**, displays IMPROVE 2014-2018 aerosol light extinction (Mm^{-1}) compared to the 2028 visibility projections for the 2028OTBa2, Future Wildfire Sensitivity, and Future Wildland Prescribed Fire Sensitivity scenarios for the IMPROVE monitors at Yellowstone (YELL2) and Mesa Verde (MEVE1) National Parks, respectively.

In TSS Modeling Express Tool # 18, fire sensitivities have been processed through the EPA Software for Modeled Attainment Test (normalized to IMPROVE 2014-2018 observations) to test the impact of changing fire regimes on 2028 regional haze visibility projections. The fire sensitivities for wildfire and wildland prescribed fire are compared to the 2028OTBa2 visibility projections for most impaired days or clearest days.



Interpretation: Added fire activity does not necessarily occur on 2014 IMPROVE most impaired days. The impacts of changing fire activity on the regional haze metrics are site-specific and may be small. IMPROVE 2014-2018 observations are included in TSS Modeling Express Tool #18 as the baseline data used with the relative response factors to calculate the 2028 visibility projections. At YELL2 (**Figure 21a)**, the 2028OTBa2 visibility projection shows small decreases in AmmNO3, OMC, and EC compared to 2014-2018 observations. The Future Wildfire Sensitivity and the Future Wildland Prescribed fire sensitivity show minor increases in OMC that can be attributed to changes in fire activity on some most impaired days in these sensitivities.

Figure 21a. IMPROVE 2014-2018 aerosol light extinction (Mm^{-1}) compared to the 2028 visibility projections (following EPA guidance) for the 2028OTBa2, Future Wildfire Sensitivity, and Future Wildland Prescribed Fire Sensitivity scenarios for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Tool # 18

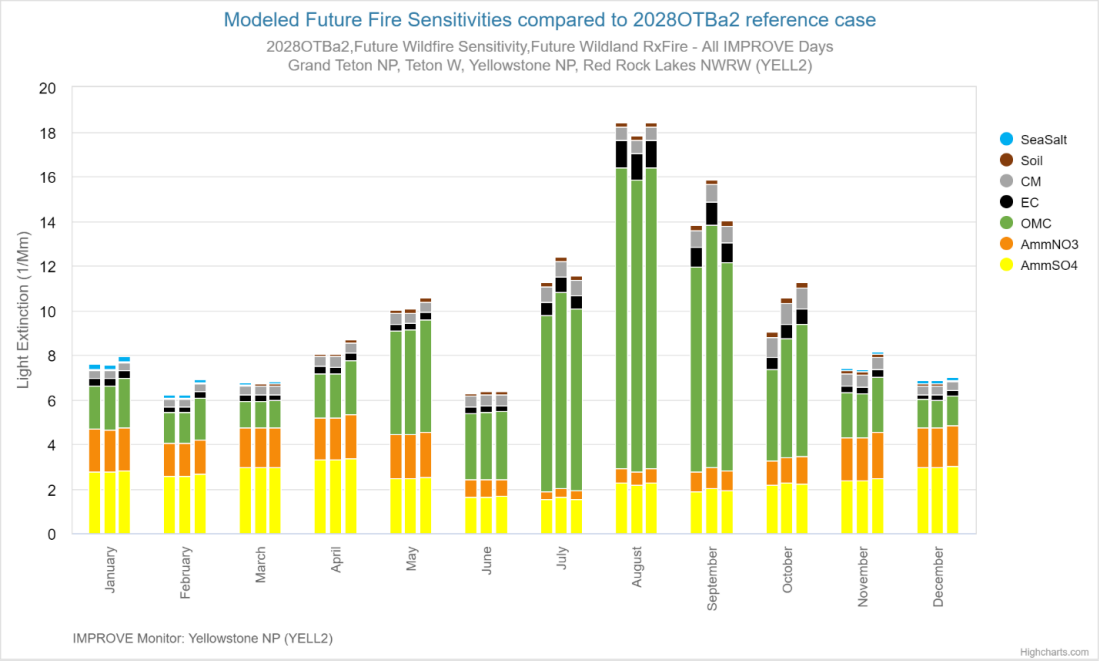
At MEVE1 (**Figure 21b**), OMC is a smaller contributor on most impaired days than at YELL2. 2028OTBa2 visibility projection shows small decreases in AmmSO4 and AmmNO3 compared to the 2014-2018 IMPROVE observations. OMC increases in the Future Wildfire sensitivity indicating increased fire emissions on some most impaired days for this sensitivity. OMC is little changed in the Future Wildland Prescribed fire sensitivity compared to 2028OTBa2.

Figure 21b. IMPROVE 2014-2018 aerosol light extinction (Mm^{-1}) compared to the 2028 visibility projections (following EPA guidance) for the 2028OTBa2, Future Wildfire Sensitivity, and Future Wildland Prescribed Fire Sensitivity scenarios for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Tool # 18

TSS Modeling Express Tool # 19, illustrated in **Figures 22a and 22b**, displays absolute model results (not adjusted to IMPROVE observations) for 2028OTBa2 and the future fire sensitivities as monthly averages for all IMPROVE sample collection days. This chart illustrates when changes in wildfire or wildland prescribed fire activity are projected to occur and how the changes affect visibility compared to the 2028OTBa2 fire assumptions. These results are not 2028 visibility projections (adjusted to IMPROVE data) for regional haze planning purposes.

Interpretation: at YELL2 (**Figure 22a**) in several months there are small differences in AmmSO4, AmmNO3, and OMC between the 2028OTBa2 scenario and the Future Fire Sensitivities. The Future Wildfire Sensitivity is higher than 2028OTBa2 in July, September and October, while the Future Wildland Prescribed Fire Sensitivity is higher in January, February, April, May, October, and November. Not all the fire activity changes occurred on most impaired days so the impacts on the 2028 visibility projections are small.

Figure 22a. Monthly average aerosol extinction (Mm^{-1}) for the 2028OTBa2, Future Wildfire Sensitivity, and Future Wildland Prescribed Fire Sensitivity scenarios for most impaired days at the Yellowstone National Park (YELL2) IMPROVE monitor. TSS Modeling Express Tool # 19



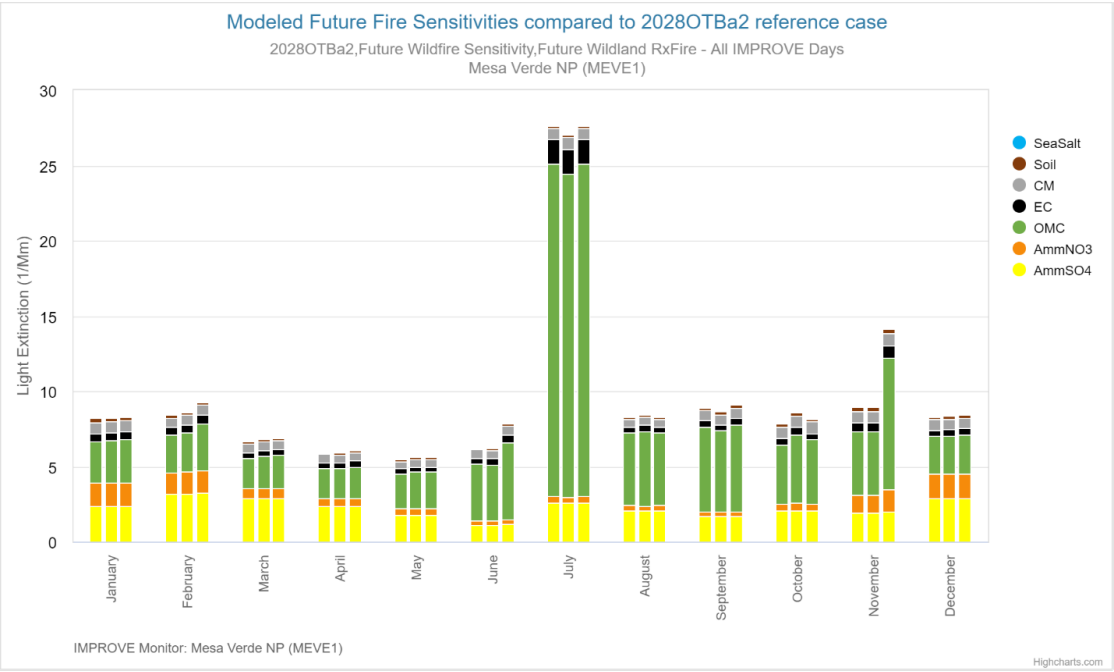


Figure 22b. Monthly average aerosol extinction (Mm^{-1}) for the 2028OTBa2, Future Wildfire Sensitivity, and Future Wildland Prescribed Fire Sensitivity scenarios for most impaired days at the Mesa Verde National Park (MEVE1) IMPROVE monitor. TSS Modeling Express Tool # 19

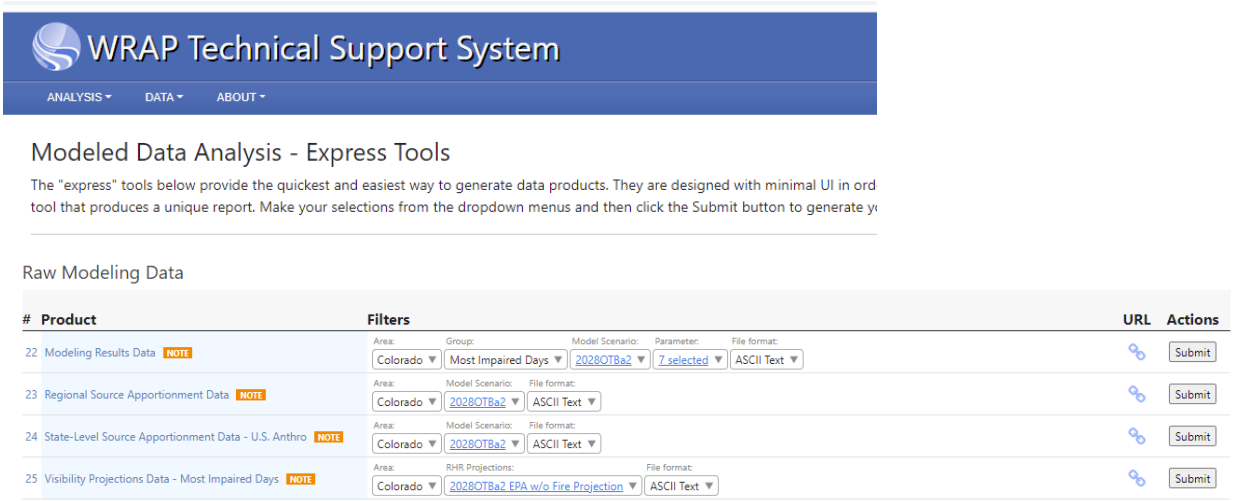

At MEVE1 (**Figure 22b**) the Future Wildfire Sensitivity shows very slight monthly differences compared to the 2028OTBa2 scenario, even though the Future Wildfire visibility projection has slightly higher OMC than the 2028OTBa2 projection (**Figure 21b**). This suggests that wildfire activity added on a few most impaired days was offset by decreased wildfire activity on other days in the monthly averages. The Future Wildland Prescribed Fire Sensitivity in June and November show slightly higher OMC than 2028OTBa2, but little change in the 2028 visibility projection.

At some western Class I areas, the added future fire sensitivities have larger impacts than seen as these two sites. Fires will continue to be a major contributor to haze in western states, however the regional haze tracking metric may not be the best measure of changes in future fire activity.

16.0 Modeling Data files

Raw modeling data files can be downloaded from the TSS Modeling Express Tools #22-25 as illustrated below. Data are sorted by geographic area, by IMPROVE data groups, Model scenarios, pollutant parameters, and regional haze projection methods. Data can be downloaded as ASCII text, Microsoft Excel, or JSON format.

Appendix C: Four-Factor Analyses and Control Measures Determinations Technical Support Document

C.1 Introduction

The Regional Haze Rule requires states to evaluate and determine the emission reduction measures that are necessary to make reasonable progress toward natural visibility conditions in Class I Areas in New Mexico, as well as in Class I Areas outside New Mexico that may be affected by emissions from New Mexico. In determining which measures are necessary to make reasonable progress, states are required to consider four statutory factors, including "the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source."[1] Hence, these evaluations are commonly referred to as four-factor analyses (FFA).

This Technical Support Document briefly describes NMED's process for selecting sources for an evaluation of potential control measures, identifies the different types of equipment evaluated and the controls available for each, and then provides detailed descriptions of NMED's four-factor analyses and control measures determinations for all selected sources. FFA supporting documentation is provided in Appendix D. Additional facility information, including printable facility reports and downloadable documents, is available via NMED's online Air Permit Map, available at https://rsmt.air.net.env.nm.gov/.

C.2 Screened Sources

The Regional Haze Rule requires that each state select emission sources for an analysis of what emission control measures are necessary to make reasonable progress. NMED utilized a two-tiered screening process to select sources for analysis in the second planning period. For tier one, NMED calculated Q/d scores for all Title V facilities in New Mexico (excluding sources on tribal lands) and compared them to a threshold value designed to capture 80 percent of the total NO_X and SO_2 emissions from all New Mexico Title V facilities combined. This resulted in the selection of 23 facilities within the jurisdiction of the Environmental Improvement Board (EIB) for further screening, including:

- Davis Gas Processing – Denton Gas Plant
- DCP Operating Company – Artesia Gas Plant
- DCP Operating Company – Eunice Gas Plant
- DCP Operating Company – Linam Ranch Gas Plant
- El Paso Natural Gas Company – Blanco Compressor Station A
- El Paso Natural Gas Company – Pecos River Compressor Station
- El Paso Natural Gas Company – Washington Ranch Storage Facility
- Enterprise Field Services – Blanco C&D Compressor Station
- Enterprise Field Services – Chaco Gas Plant
- Enterprise Field Services –South Carlsbad Compressor Station
- ET Gathering & Processing – Jal #3 Gas Plant
- Transwestern Pipeline Company – Mountainair Compressor Station No. 7
- Transwestern Pipeline Company – Roswell Compressor Station No. 9
- Harvest Four Corners – Kutz Canyon Processing Plant
- Hilcorp Energy Company – San Juan Basin Gas Plant
- IACX Roswell – Bitter Lake Compressor Station

[1] 40 CFR 305(f)(2)(i).

- Oxy USA WTP Limited Partnership – Indian Basin Gas Plant
- Public Service Company of New Mexico – San Juan Generating Station
- Targa Midstream Services – Eunice Gas Processing Plant
- Targa Midstream Services – Monument Gas Plant
- Targa Midstream Services – Saunders Gas Plant
- Tri-State Generation and Transmission Association – Prewitt Escalante Generating Station
- Xcel Energy – Cunningham Station Power Plant

For tier two, NMED identified all emissions units at these facilities with the potential to emit more than 10 pounds per hour of NO_X or SO_2. Due to resource constraints, NMED decided to focus on these units, as they are the most significant sources of NO_X and SO_2 at the selected facilities.[2] This resulted in the selection of approximately 122 units for an analysis of what emission control measures are necessary in order to make reasonable progress. NMED also elected to evaluate the amine treatment systems (ATS) at 11 facilities due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams.

After NMED completed its source screening, four of the selected facilities permanently shut down and have since been or are in the process of being decommissioned and/or demolished. These include Davis Gas Processing's Denton Gas Plant, DCP Operating Company's Eunice Gas Plant, Public Service Company of New Mexico's San Juan Generating Station, and Tri State Generation and Transmission Association's Prewitt Escalante Generating Station. Four additional facilities have since retired one or more emissions units NMED originally selected for analysis, including ET Gathering & Processing's Jal #3 Gas Plant, Harvest Four Corners' Kutz Canyon Processing Plant, and Targa Midstream Services' Eunice and Saunders Gas Plants. NMED has also identified a number of units that are already effectively controlled (for reasons other than retirement) or that do not require an analysis of potential control measures for other reasons. These shutdowns, retirements and exclusions reduced the number of units (including ATS) NMED analyzed from 133 to 91.

C.3 Equipment Types Evaluated and Available Controls

The units selected for analysis via the screening process described in Section C.2 comprise reciprocating internal combustion engines (RICE), including two-stroke lean burn (2SLB), four-stroke lean burn (4SLB), and four-stroke rich burn (4SRB) RICE; combustion turbines (CT); industrial and utility boilers; and amine treatment systems (ATS). Before performing a four-factor analysis for any of the selected units, NMED identified all commercially available controls for these types of sources, determined which controls are technically feasible, and assessed, in general terms, the expected control efficiency, compliance time, and energy and non-air quality impacts associated with each technically feasible control.

C.3.1 Two-Stroke Lean Burn Engines

NMED determined that the following controls for reducing NO_X emissions from natural gas-fired 2SLB RICE are commercially available.

[2] NMED exempted units exceeding the 10 pounds per hour threshold that are exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC, or that emit less than five tons per year of NOx or SO_2.

Good Combustion Practices

Good Combustion Practices (GCP) describes the optimal design and proper operation and maintenance (O&M) of an emissions unit. In the case of RICE, GCP typically involves maintenance with trained personnel and includes performing periodic tune-ups and conducting overhauls as appropriate and necessary. A tune-up generally involves conducting an evaluation of existing equipment to determine if any equipment needs to be cleaned, repaired, or replaced.

Optimal design and proper O&M of a RICE maximizes fuel efficiency, minimizes emissions, reduces costs, and improves safety – benefits desirable to owners of RICE. Thus, RICE manufacturers are highly incentivized to design highly optimized units, and owners of existing RICE understand the benefits of following proper O&M schedules and procedures.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- GCP is a technically feasible control option for reducing NO_X emissions from 2SLB RICE.
- The NO_X control efficiency associated with GCP varies significantly as it depends on the age and condition of the unit and what other controls (if any) have been installed.
- The compliance time for GCP is 0-1 years. If a facility does not already implement GCP, up to a year may be necessary to obtain O&M documentation and train personnel.
- There are no energy or non-air quality impacts associated with GCP.

Low-Emission Combustion

Low-Emission Combustion (LEC), aka Clean Burn Technology, refers to a combination of equipment and technologies that minimize the creation of NO_X through higher air-to-fuel ratios and improved engine efficiency. Retrofitting a RICE with LEC can involve one or more engine modifications depending on the target NO_X emissions rate. For example, an LEC retrofit may include (but is not limited to) fuel system enhancements, improved ignition, turbocharger addition, cooling system improvements, addition of an oxidation catalyst, cylinder upgrades, and control system augmentations. For this reason, LEC is sometimes referred to as “layered combustion.”

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- LEC is a technically feasible control option for reducing NO_X emissions from 2SLB RICE.
- The NO_X control efficiency associated with LEC varies significantly as it depends on the existing NO_X emission rate and the target (post-retrofit) emission rate. Manufacturers will typically provide a post-retrofit NO_X emissions warranty, which varies based on make, model, age, and other factors.
- The compliance time for LEC is generally 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.
- An LEC retrofit on a natural gas-fired 2SLB RICE can increase fuel consumption by up to 5 percent which can result in an increase in CO emissions.

Selective Catalytic Reduction

Selective Catalytic Reduction (SCR) is a pollution control measure that uses a catalyst and a selective reactant to convert NO_X into molecular nitrogen and water vapor. Ammonia (NH_3), usually diluted with air or steam, is injected into the exhaust upstream of a catalyst bed. At the catalyst surface, NH_3 reacts with NO_X to form molecular nitrogen and water with the following basic reaction pathways:

$$4NH_3 + 4NO + O_2 \rightarrow 4N_2 + 6H_2O$$

$$4NH_3 + 2NO_2 + O_2 \rightarrow 3N_2 + 6H_2O$$

Typical SCR catalysts include metal oxides (titanium oxide and vanadium pentoxide), noble metals (combinations of platinum and rhodium), zeolites, and ceramics. The catalyst serves to lower the activation energy of these reactions, which allows them to occur at a lower temperature than the exhaust gas. While operating temperatures can range from 350°F to 1,100°F, most SCR systems are designed to operate at temperatures between 600°F and 750°F for conventional (vanadium- or titanium-based) catalysts, and between 470°F and 510°F for platinum-based catalysts.

Design and operation of SCR systems can be challenging as several factors can affect SCR performance and corresponding NO_X reduction efficiency. Residence time, space velocity and the degree of mixing are critical as the reactants must be sufficiently mixed to ensure contact. Ammonia/NO_X ratios must be closely maintained to prevent unreacted ammonia from passing directly through the system ("ammonia slip"), resulting in increased emissions of PM10. If the catalyst bed temperature is too low, the NO_X reduction reactions will not proceed. If the catalyst bed temperature is too high, ammonia will be oxidized to NO and greater NO_X will be emitted than if no controls were present. If excessive temperatures occur for prolonged periods, thermal degradation of the catalyst can occur, resulting in loss of catalyst activity. Catalyst deactivation or "poisoning" can occur when certain elements – such as sulfur, iron, nickel, chrome, calcium, and sodium – present in the exhaust stream react with a platinum catalyst to form compounds which are not catalytically active.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SCR is not a technically feasible control option for 2SLB RICE due to a relatively high amount of lubricating oil leakage (i.e., carryover) into the exhaust. The oil quickly adheres to and poisons the SCR catalyst.

Selective Non-Catalytic Reduction

Selective Non-Catalytic Reduction (SNCR) systems reduce NO_X by injecting a reagent (ammonia or urea) into the high-temperature regions of the exhaust from a combustion unit where the reagent will selectively react with NO_X to produce nitrogen and water. When urea is used as the reagent, it rapidly decomposes – due to the high temperature – to form ammonia before reacting with NO_X in the exhaust stream. While SNCR systems have been predominantly utilized on large industrial and utility-sized boilers, the technology has also been installed on a wide range of other combustion units including solid waste combustors, kilns and furnaces.

Effective design and operation of a SNCR system must carefully account for operating temperature, adequate exhaust/reagent mixing, sufficient residence time (i.e., greater than 0.5 seconds) and pollutant loading. Most notably, the technical feasibility of SNCR is extremely dependent on exhaust temperature, with an effective temperature range of approximately 1,600°F to 2,100°F. If the operating temperature is too low, the NO_X reduction reaction will not occur resulting in unreacted ammonia passing directly through the system ("ammonia slip"), causing increased particulate emissions. If the operating temperature is too high, ammonia will be oxidized to NO and greater NO_X will be emitted than if no controls were present. In addition, proper chemical storage and handling facilities must be built and operated to safely accommodate either reagent.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SNCR is not a technically feasible control option for 2SLB RICE because the exhaust temperature is well below the effective temperature range.

Non-Selective Catalytic Reduction

Non-Selective Catalytic Reduction (NSCR) is a form of pollution control in which a precious metal catalyst (e.g., platinum) is used to promote reactions that reduce NO_X, CO, and hydrocarbon emissions by converting them into less harmful by-products (i.e., nitrogen, water and carbon dioxide). NSCR systems, also referred to as "three-way catalysts," are most commonly used to control tailpipe emissions in automobiles.

NSCR is most effective when the combustion unit is operated within a narrow band of near-stoichiometric fuel-to-air ratios, and conversion efficiency declines very rapidly when the unit is operated outside of that narrow band. Closed-loop control systems are necessary with NSCR because of the conflicting requirements for effective NO_X reduction and hydrocarbon oxidation. The control system must prevent the NO_X reduction catalyst from becoming fully oxidized, yet replenish the oxygen storage material to maintain its function as an oxidation catalyst.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- NSCR operating conditions limit its application to combustion processes with a fuel rich (no excess oxygen) firing zone, such as rich-burn RICE. Therefore, NSCR is not a technically feasible control option for 2SLB RICE.

Replacement with a New RICE

Current-generation RICE have significantly lower NO_X emissions rates than those manufactured 20 plus years ago. Many of the RICE subject to Regional Haze in New Mexico are more than 50 years old, and some are more than 70 years old. NMED and EPA agree that replacing an old RICE with a new, like-kind or functionally equivalent, more efficient, lower emitting RICE is within the scope of Regional Haze and thus an option states can consider when evaluating potential controls for 2SLB RICE.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Replacement with a new RICE is a technically feasible control option for reducing NO_X emissions from 2SLB RICE.
- The NO_X control efficiency associated with RICE replacement varies significantly as it depends on the NO_X emission rate of the existing unit and that of the replacement unit. Consistent with the emission standards for new natural gas-fired RICE in 20.2.50 NMAC, the NO_X emission rate of a replacement RICE would typically be in the 0.3 to 0.5 g/bhp-hr range.
- NMED believes a reasonable compliance time for RICE replacement is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with RICE replacement. NMED understands that, in limited circumstances, the electricity demand of a facility could increase following RICE replacement.

Electrification

Natural gas compression technology has advanced significantly since many of the RICE subject to Regional Haze in New Mexico were installed. Several manufacturers now offer zero-emitting gas compression systems powered by electric motor drives (EMD). The use of EMD, commonly referred to as electrification, in the gas compression industry is becoming more prevalent as operators realize the lifecycle costs of EMD-powered systems can be considerably less than those of traditional systems powered by fossil fuel-fired RICE.

Based on a review of various information provided by EMD manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Electrification is a technically feasible control option for reducing NO_X emissions from 2SLB RICE.
- The NO_X control efficiency associated with electrification is 100 percent. EMD do not emit NO_X or any other pollutants.
- NMED believes a reasonable compliance time for electrification is 4-6 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; up to 1 year for installation, commissioning, and start-up; and up to 2 years for the design and construction of associated electricity infrastructure (new distribution lines and substation upgrades). This does not account for any facility-specific challenges that would prolong implementation.
- Electrification, inherent to its design, significantly increases a facility's electricity demand.
- The economic feasibility of electrification at a particular facility is highly dependent on two factors, the availability of requisite utility-supplied electricity and the distance from the facility to the nearest electrical substation. If a facility does not have access to utility-supplied electricity or the facility's existing electricity infrastructure cannot support at least one EMD unit, the cost of electrification is significant. For example, the estimated cost of installing new distribution lines from a substation to a facility is typically more than $750,000 per mile (2024$).

Retirement

When a facility's operational plans can accommodate retiring an emissions unit, doing so is a simple and effective control option. Retirement, in this context, means permanently shutting down a unit and forgoing its capacity by not replacing it, which reduces emissions by 100 percent. Retirement is a technically feasible control option for any type of emissions unit, including 2SLB RICE. NMED believes a reasonable compliance time for retirement is 1-2 years depending on a facility's requisite planning time and operational flexibility. More time will be necessary when a facility needs a unit to satisfy anticipated near-term capacity requirements relative to a facility with excess capacity. There are no energy or non-air quality impacts associated with retirement.

C.3.2 Four-Stroke Lean Burn Engines

NMED determined that the following controls for reducing NO_X emissions from natural gas-fired 4SLB RICE are commercially available.

Good Combustion Practices

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- GCP is a technically feasible control option for reducing NO_X emissions from 4SLB RICE.
- The NO_X control efficiency associated with GCP varies significantly as it depends on the age and condition of the unit and what other controls (if any) have been installed.
- The compliance time for GCP is 0-1 years. If a facility does not already implement GCP, up to a year may be necessary to obtain O&M documentation and train personnel.
- There are no energy or non-air quality impacts associated with GCP.

Low-Emission Combustion

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- LEC is a technically feasible control option for reducing NO_X from 4SLB RICE.
- The NO_X control efficiency associated with LEC varies significantly as it depends on the existing NO_X emission rate and the target (post-retrofit) emission rate. Manufacturers will typically provide a post-retrofit NO_X emissions warranty, which varies based on make, model, age, and other factors.
- The compliance time for LEC is generally 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.
- An LEC retrofit on a natural gas-fired 4SLB RICE can increase fuel consumption by up to 5 percent which can result in an increase in CO emissions.

Selective Catalytic Reduction

See Section C.3.1 for a description of this technology

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- By virtue of its design, lubricating oil does not leak into the exhaust of a 4SLB RICE. Therefore, SCR is a technically feasible control option for reducing NO_X emissions from 4SLB RICE.
- A well designed and operated SCR system can (in general) reduce NO_X emissions by more than 90 percent. However, for units that operate intermittently, such as natural gas compressor drivers, NO_X removal efficiency may be lower when the system is below the optimum temperature following cold starts. Depending on such a unit's annual operating profile, the average NO_X removal efficiency of SCR could reasonably vary from approximately 75 to 85 percent.
- Because SCR reactors can be fairly large, physical space limitations at existing facilities can necessitate significant modifications to a building's structure to accommodate SCR. The addition of SCR can also require considerable modifications to existing ductwork. Any such modifications are expected to appreciably increase the capital costs of implementing SCR.
- NMED believes a reasonable compliance time for SCR is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- Operation of SCR on a 4SLB RICE would likely result in a small increase in fuel consumption as additional power would be needed to force exhaust through the catalyst bed. Additionally, electricity is needed to operate SCR.

Selective Non-Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SNCR is not a technically feasible control option for 4SLB RICE because the exhaust temperature is well below the effective temperature range.

Non-Selective Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- NSCR operating conditions limit its application to combustion processes with a fuel rich (no excess oxygen) firing zone, such as rich-burn RICE. Therefore, NSCR is not a technically feasible control option for 4SLB RICE.

Replacement with a New RICE

Current-generation RICE have significantly lower NO_X emissions rates than those manufactured 20 plus years ago. Many of the RICE subject to Regional Haze in New Mexico are more than 50 years old, and some are more than 70 years old. NMED and EPA agree that replacing an old RICE with a new, like-kind or functionally equivalent, more efficient, lower emitting RICE is within the scope of Regional Haze and thus an option states can consider when evaluating potential controls for 4SLB RICE.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Replacement with a new RICE is a technically feasible control option for reducing NO_X emissions from 4SLB RICE.
- The NO_X control efficiency associated with RICE replacement varies significantly as it depends on the NO_X emission rate of the existing unit and that of the replacement unit. Consistent with the emission standards for new natural gas-fired RICE in 20.2.50 NMAC, the NO_X emission rate of a replacement RICE would typically be in the 0.3 to 0.5 g/bhp-hr range.
- NMED believes a reasonable compliance time for RICE replacement is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with RICE replacement. NMED understands that, in limited circumstances, the electricity demand of a facility could increase following RICE replacement.

Electrification

Natural gas compression technology has advanced significantly since many of the RICE subject to Regional Haze in New Mexico were installed. Several manufacturers now offer zero-emitting gas compression systems powered by electric motor drives (EMD). The use of EMD, commonly referred to as electrification, in the gas compression industry is becoming more prevalent as operators realize the lifecycle costs of EMD-powered systems can be considerably less than those of traditional systems powered by fossil fuel-fired RICE.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Electrification is a technically feasible control option for reducing NO_X emissions from 4SLB RICE.
- The NO_X control efficiency associated with electrification is 100 percent. EMD do not emit NO_X or any other pollutants.

- NMED believes a reasonable compliance time for electrification is 4-6 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; up to 1 year for installation, commissioning, and start-up; and up to 2 years for the design and construction of associated electricity infrastructure (new distribution lines and substation upgrades). This does not account for any facility-specific challenges that would prolong implementation.
- Electrification, inherent to its design, significantly increases a facility's electricity demand.
- The economic feasibility of electrification at a particular facility is highly dependent on two factors, the availability of requisite utility-supplied electricity and the distance from the facility to the nearest electrical substation. If a facility does not have access to utility-supplied electricity or the facility's existing electricity infrastructure cannot support at least one EMD unit, the cost of electrification is significant. For example, the estimated cost of installing new distribution lines from a substation to a facility is typically more than $750,000 per mile (2024$).

Retirement

When a facility's operational plans can accommodate retiring an emissions unit, doing so is a simple and effective control option. Retirement, in this context, means permanently shutting down a unit and forgoing its capacity by not replacing it, which reduces emissions by 100 percent. Retirement is a technically feasible control option for any type of emissions unit, including 4SLB RICE. NMED believes a reasonable compliance time for retirement is 1-2 years depending on a facility's requisite planning time and operational flexibility. More time will be necessary when a facility needs a unit to satisfy anticipated near-term capacity requirements relative to a facility with excess capacity. There are no energy or non-air quality impacts associated with retirement.

C.3.3 Four-Stroke Rich Burn Engines

NMED determined that the following controls for reducing NO_X emissions from natural gas-fired 4SRB RICE are commercially available.

Good Combustion Practices

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- GCP is a technically feasible control option for reducing NO_X emissions from 4SRB RICE.
- The NO_X control efficiency associated with GCP varies significantly as it depends on the age and condition of the unit and what other controls (if any) have been installed.
- The compliance time for GCP is 0-1 years. If a facility does not already implement GCP, up to a year may be necessary to obtain O&M documentation and train personnel.
- There are no energy or non-air quality impacts associated with GCP.

Low-Emission Combustion

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- LEC is a technically feasible control option for reducing NO_X emissions from 4SRB RICE.
- The NO_X control efficiency associated with LEC varies significantly as it depends on the existing NO_X emission rate and the target (post-retrofit) emission rate. Manufacturers will typically provide a post-retrofit NO_X emissions warranty, which varies based on make, model, age, and other factors.
- The compliance time for LEC is generally 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.)
- An LEC retrofit on a natural gas-fired 4SRB RICE can increase fuel consumption by up to 5 percent which can result in an increase in CO emissions.

Selective Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SCR is not a technically feasible control option for 4SRB RICE because SCR's NO_X conversion reactions will not occur in an environment with excess oxygen.

Selective Non-Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SNCR is not a technically feasible control option for 4SRB RICE because the exhaust temperature is well below the effective temperature range.

Non-Selective Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- NSCR is an extremely well-established, cost-effective, and widely used control option for reducing NO_X emissions from 4SRB RICE.
- While NSCR can achieve NO_X reductions of greater than 90 percent on new 4SRB RICE, the NO_X control efficiency of a NSCR retrofit depends on the existing NO_X emission rate and the target (post-retrofit) emission rate.

- NMED believes a reasonable compliance time for NSCR is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- A NSCR retrofit would likely result in a small increase in fuel consumption as additional power would be needed to force exhaust through the device. In addition, periodically replacing the catalyst would result in the disposal of old catalyst.

Replacement with a New RICE

Current-generation RICE have significantly lower NO_X emissions rates than those manufactured 20 plus years ago. Many of the RICE subject to Regional Haze in New Mexico are more than 50 years old, and some are more than 70 years old. NMED and EPA agree that replacing an old RICE with a new, like-kind or functionally equivalent, more efficient, lower emitting RICE is within the scope of Regional Haze and thus an option states can consider when evaluating potential controls for 4SRB RICE.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Replacement with a new RICE is a technically feasible control option for reducing NO_X emissions from 4SRB RICE.
- The NO_X control efficiency associated with RICE replacement varies significantly as it depends on the NO_X emission rate of the existing unit and that of the replacement unit. Consistent with the emission standards for new natural gas-fired RICE in 20.2.50 NMAC, the NO_X emission rate of a replacement RICE would typically be in the 0.3 to 0.5 g/bhp-hr range.
- NMED believes a reasonable compliance time for RICE replacement is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with RICE replacement. NMED understands that, in limited circumstances, the electricity demand of a facility could increase following RICE replacement.

Electrification

Natural gas compression technology has advanced significantly since many of the RICE subject to Regional Haze in New Mexico were installed. Several manufacturers now offer zero-emitting gas compression systems powered by electric motor drives (EMD). The use of EMD, commonly referred to as electrification, in the gas compression industry is becoming more prevalent as operators realize the lifecycle costs of EMD-powered systems can be considerably less than those of traditional systems powered by fossil fuel-fired RICE.

Based on a review of various information provided by RICE manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Electrification is a technically feasible control option for reducing NO_X emissions from 4SRB RICE.
- The NO_X control efficiency associated with electrification is 100 percent. EMD do not emit NO_X or any other pollutants.
- NMED believes a reasonable compliance time for electrification is 4-6 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; up to 1 year for installation, commissioning, and start-up; and up to 2 years for the design and construction of associated electricity infrastructure (new distribution lines and substation upgrades). This does not account for any facility-specific challenges that would prolong implementation.
- Electrification, inherent to its design, significantly increases a facility's electricity demand.
- The economic feasibility of electrification at a particular facility is highly dependent on two factors, the availability of requisite utility-supplied electricity and the distance from the facility to the nearest electrical substation. If a facility does not have access to utility-supplied electricity or the facility's existing electricity infrastructure cannot support at least one EMD unit, the cost of electrification is significant. For example, the estimated cost of installing new distribution lines from a substation to a facility is typically more than $750,000 per mile (2024$).

Retirement

When a facility's operational plans can accommodate retiring an emissions unit, doing so is a simple and effective control option. Retirement, in this context, means permanently shutting down a unit and forgoing its capacity by not replacing it, which reduces emissions by 100 percent. Retirement is a technically feasible option for any type of emissions unit, including 4SRB RICE. NMED believes a reasonable compliance time for retirement is 1-2 years depending on a facility's requisite planning time and operational flexibility. More time will be necessary when a facility needs a unit to satisfy anticipated near-term capacity requirements relative to a facility with excess capacity. There are no energy or non-air quality impacts associated with retirement.

C.3.4 Combustion Turbines

NMED determined that the following controls for reducing NO_X emissions from natural gas-fired CT are commercially available.

Good Combustion Practices

As discussed in Section C.3.1, Good Combustion Practices (GCP) describes the optimal design and proper operation and maintenance (O&M) of an emissions unit. In the case of CT, GCP typically involves maintenance with trained personnel and includes routine inspections, timely and appropriate overhauls, vibration and heat rate analyses, and the use of pipeline quality natural gas. A CT overhaul is generally needed every 4-5 years depending on maintenance, runtime, and other factors and may include testing of the turbine and compressor, rotor removal, a comprehensive inspection of various components (e.g., rotor, blades, bearings, and seals), and replacement of worn components.

Optimal O&M of a CT maximizes useful life and fuel efficiency, minimizes emissions, reduces costs, and improves safety – benefits desirable to owners of CT. Thus, CT manufacturers are highly incentivized to design highly optimized units, and owners of existing CT understand the benefits of following proper O&M schedules and procedures.

Based on a review of various information provided by CT manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- GCP is a technically feasible control option for reducing NO_X emissions from CT.
- The NO_X control efficiency associated with GCP varies significantly as it depends on the age and condition of the unit and what other controls (if any) have been installed.
- The compliance time for GCP is 0-1 years. If a facility does not already implement GCP, up to a year may be necessary to obtain O&M documentation and train personnel.
- There are no energy or non-air quality impacts associated with GCP.

Dry Low NO_X Combustion

Dry Low NO_X combustion (DLN), aka Dry Low Emissions or SoLoNOx,[3] is a technology employed in CT to reduce the production of NO_X during combustion. This is accomplished by creating a homogenous and lean fuel/air mix prior to injection into the combustor. Additionally, DLN systems often utilize sensors and sophisticated control algorithms to continuously monitor and optimize combustion conditions, ensuring minimal NO_X production without compromising turbine performance.

The term DLN collectively refers to a combination of two combustion technologies: conventional diffusion flame combustion at <50 percent load and DLN combustion at higher loads. Flame instability at lower loads is the reason for this hybrid approach. Since NO_X emissions can vary based on load, ambient conditions, CT size, and design of the combustion system, the NO_X emission rate of current generation DLN is often in the 9 to 15 ppm range but can be as high as 25 ppm. Enhanced DLN technology – aka Ultra-Low NO_X – can achieve as low as 5 ppm in certain applications.

The benefits of DLN extend beyond environmental considerations. By reducing NO_X emissions without relying on water or steam injection, DLN systems enhance overall turbine efficiency, leading to improved fuel economy and lower operating costs. These advantages are well understood and widely documented, and DLN is consequently utilized in various industrial and commercial CT applications. Many CT manufacturers assert that current generation DLN is the most efficient and cost-effective approach to minimizing NO_X emissions.

Based on a review of various information provided by CT manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- DLN is a technically feasible control option for reducing NO_X emissions from CT.
- The NO_X control efficiency associated with DLN varies as it depends on the existing NO_X emission rate and the target (post-retrofit) emission rate. Manufacturers will typically provide a post-retrofit NO_X emissions warranty, which varies based on make, model, age, and other factors.
- The general compliance time for DLN is estimated to be 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with DLN.

[3] SoLoNOx refers specifically to Solar Turbines' dry low emissions technology for its Centaur, Mars, Taurus, and Titan gas turbine families.

Water and Steam Injection

Water and steam injection[4] (WSI) has been used since the 1970s as a means of controlling NO_X emissions from CT. Inside a CT, fuel rich zones that create high flame temperatures are the result of the simultaneous mixing of fuel and air and their subsequent combustion. Injecting water or steam into the flame area of the combustor provides a heat sink that lowers the combustion zone temperature and reduces thermal NO_X formation. As the combustion zone temperature decreases, NO_X production decreases significantly.

Water is more efficient for reducing the flame temperature than steam, as the energy required to vaporize the water creates a larger heat sink. Generally, the steam flow required is 1.5-2 times the amount of water required for a given amount of NO_X reduction. WSI systems are designed to a specific "water-to-fuel ratio" which has a direct impact on the controlled NO_X emission rate and is generally controlled by the turbine inlet temperature and ambient temperature.

There are several disadvantages to WSI. First, the thermodynamic efficiency of a CT equipped with WSI will decrease due to the energy required to convert water into steam. Second, the water used must be of high quality (e.g., demineralized water) to prevent deposits and corrosion from occurring in the CT. While many combined cycle facilities may have existing demineralized water treatment on site, existing simple cycle facilities often do not. Third, in the case of remote locations, water availability may be a barrier, particularly in arid environments. Finally, WSI can cause an increase in combustor dynamic pressure which can accelerate wear and reduce the useful life of the CT.

Compared to other NO_X emission control technologies, WSI may have a lower capital cost, but higher variable costs. This can make WSI attractive for peaking combustion turbines or other units that operate infrequently. It is more often applied to smaller frame CT or retrofits of older CT, rather than new mid-sized or large-frame heavy duty turbines.

Based on a review of various information provided by CT manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- WSI is a technically feasible control option for reducing NO_X emissions from some CT models. Notably, Solar Turbines, which manufactured many of the CT subject to Regional Haze in New Mexico, does not offer WSI technology for its turbines based on the superior performance (i.e., lower NO_X emissions) and lower operational cost of its SoLoNOx (DLN) technology.
- Despite being a somewhat antiquated technology, WSI can achieve NO_X emissions below 42 ppm.
- The general compliance time for WSI is estimated to be 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.
- A WSI retrofit on a CT can increase CO emissions and requires notable quantities of demineralized water.

[4] Because of their limited application and similar function, water injection and steam injection are collectively addressed, and referred to herein, as a single technology. Most of this technology description was obtained from Sargent & Lundy, *Combustion Turbine NOx Control Technology Memo* (January 2022).

Selective Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by CT manufacturers and SCR vendors, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SCR is a technically feasible control option for reducing NO_X emissions from CT.
- A well designed and operated SCR system can (in general) reduce NO_X emissions by more than 90 percent. However, for units that operate intermittently, such as natural gas compressor drivers, NO_X removal efficiency may be lower due to decreased efficiency when the system is below the optimum temperature following cold starts. Depending on such a unit's annual operating profile, the average NO_X removal efficiency of SCR could reasonably vary from approximately 75 to 85 percent.
- Because SCR reactors can be fairly large, physical space limitations at existing facilities can necessitate significant modifications to a building's structure to accommodate SCR. The addition of SCR can also require considerable modifications to existing ductwork. Any such modifications are expected to appreciably increase the capital costs of implementing SCR.
- NMED believes a reasonable compliance time for SCR is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- Operation of SCR on a CT would likely result in a small increase in fuel consumption, as additional power would be needed to force exhaust through the catalyst bed. Additionally, electricity is needed to operate SCR.

Selective Non-Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by CT manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SNCR is not a technically feasible control option for CT because the exhaust temperature is well below the effective temperature range.

Replacement with a New CT

Current generation CT have significantly lower NO_X emissions rates than those manufactured 30 plus years ago. The vast majority of CT subject to Regional Haze in New Mexico are more than 30 years old, and a few are more than 70 years old. NMED and EPA agree that replacing an old CT with a new, like-kind or functionally equivalent, more efficient, lower emitting CT is within the scope of Regional Haze and thus an option states can consider when evaluating potential controls for CT.

Based on a review of various information provided by CT manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Replacement with a new CT is a technically feasible control option for reducing NO_X emissions from CT.
- The NO_X control efficiency associated with CT replacement varies significantly as it depends on the NO_X emission rate of the existing unit and that of the replacement unit. Consistent with the emission standards for new natural gas-fired CT in 20.2.50 NMAC, the NO_X emission rate of a replacement CT would typically be in the 9 to 15 ppm range.
- NMED believes a reasonable compliance time for CT replacement is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with CT replacement. NMED understands that, in limited circumstances, the electricity demand of a facility could increase following CT replacement.

Electrification

Natural gas compression technology has advanced significantly since many of the CT subject to Regional Haze in New Mexico were installed. Several manufacturers now offer zero-emitting gas compression systems powered by electric motor drives (EMD). The use of EMD, commonly referred to as electrification, in the gas compression industry is becoming more prevalent as operators realize the lifecycle costs of EMD-powered systems can be considerably less than those of traditional systems powered by fossil fuel-fired CT.

Based on a review of various information provided by CT manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Electrification is a technically feasible control option for reducing NO_X emissions from CT.
- The NO_X control efficiency associated with electrification is 100 percent. EMD do not emit NO_X or any other pollutants.
- NMED believes a reasonable compliance time for electrification is 4-6 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; up to 1 year for installation, commissioning, and start-up; and up to 2 years for the design and construction of associated electricity infrastructure (new distribution lines and substation upgrades). This does not account for any facility-specific challenges that would prolong implementation.
- Electrification, inherent to its design, significantly increases a facility's electricity demand.
- The economic feasibility of electrification at a particular facility is highly dependent on two factors, the availability of requisite utility-supplied electricity and the distance from the facility to the nearest electrical substation. If a facility does not have access to utility-supplied electricity or the facility's existing electricity infrastructure cannot support at least one EMD unit, the cost of electrification is significant. For example, the estimated cost of installing new distribution lines from a substation to a facility is typically more than $750,000 per mile (2024$).

Retirement

When a facility's operational plans can accommodate retiring an emissions unit, doing so is a simple and effective control option. Retirement, in this context, means permanently shutting down a unit and forgoing its capacity by not replacing it, which reduces emissions by 100 percent. Retirement is a technically feasible option for any type of emissions unit, including CT. NMED believes a reasonable compliance time for retirement is 1-2 years depending on a facility's requisite planning time and operational flexibility. More time will be necessary when a facility needs a unit to satisfy anticipated near-term capacity requirements relative to a facility with excess capacity. There are no energy or non-air quality impacts associated with retirement.

C.3.5 Boilers

NMED determined that the following controls for reducing NO_X emissions from natural gas-fired industrial and utility boilers are commercially available.

Good Combustion Practices

As discussed in Section C.3.1, Good Combustion Practices (GCP) describes the optimal design and proper operation and maintenance (O&M) of an emissions unit. In the case of boilers, GCP typically involves maintenance with trained personnel and includes (but is not limited to) routine inspections and tune-ups. A tune-up generally involves conducting an evaluation of existing equipment (e.g., oxygen probes and other instrumentation, burners, dampers, tilt mechanisms, and actuators) to determine if equipment needs to be cleaned, repaired, or replaced. Tune-ups also provide an opportunity to investigate levels of excess air and emissions of NO_X and CO, unusual temperatures and pressures, and leakage. Collected data is analyzed and used to adjust control settings as necessary to achieve optimal combustion and sustainable operation of the unit.

Optimal O&M of a boiler maximizes useful life and fuel efficiency, minimizes emissions, reduces costs, and improves safety – benefits desirable to boiler owners. Thus, boiler manufacturers are highly incentivized to design highly optimized units, and boiler owners understand the benefits of following proper O&M schedules and procedures.

Based on a review of various information provided by boiler manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- GCP is a technically feasible control option for reducing NO_X emissions from a boiler.
- The NO_X control efficiency associated with GCP varies significantly as it depends on the age and condition of the unit and what other controls (if any) have been installed.
- The compliance time for GCP is 0-1 years. If a facility does not already implement GCP, up to a year may be necessary to obtain O&M documentation and train personnel.
- There are no energy or non-air quality impacts associated with GCP.

Staged Combustion (Low NO_X Burners)

A staged combustion process uses more than one combustion zone to optimize combustion and reduce NO_X emissions. In fuel-lean zones, the combustion temperature is lowered, reducing the production of NO_X. In fuel-rich zones, both the combustion temperature and oxygen concentrations are lowered. While

there are several forms of staged combustion (e.g., overfire air, burners out of service, biased burner firing), the most prevalent and effective form for natural gas combustion in a boiler is low NO_X burners (LNB).

LNB on a boiler that is several decades old may have a NO_X emission rate of ~50 ppm, whereas LNB on a new boiler may have a NO_X emission rate of 12 to 15 ppm. The term "ultra-low NO_X burner" (ULNB) has evolved to generally refer to a burner that emits less than 9 ppm NO_X. Several ULNB designs are constructed using composite materials and designed for precise fuel and air premixing prior to injection into the furnace combustion zone. The tolerance of ULNB operating conditions is very tight and must be closely monitored to ensure that the produced emissions are as expected.

Based on a review of various information provided by boiler manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- LNB is a technically feasible control option for reducing NO_X emissions from boilers.
- The NO_X control efficiency associated with LNB varies by boiler model, boiler age, and burner selection. Manufacturers typically provide a target (post-retrofit) NO_X emissions warranty for LNB.
- The general compliance time for LNB is estimated to be 2-3 years. (This does not account for company or facility specific challenges that would prolong implementation.)
- There are no appreciable energy or non-air quality impacts associated with LNB.

Flue Gas Recirculation

As the name suggests, flue gas recirculation (FGR) involves the recirculation of a portion – typically 20 to 30 percent – of the relatively cool exhaust gases back into the boiler combustion zone. The recycled flue gas consists of combustion products which act as inerts during combustion of the fuel/air mixture. FGR reduces NO_X emissions by two mechanisms. Primarily, the recirculated gas acts as a diluent to reduce combustion temperatures, thus suppressing the thermal NO_X formation mechanism. To a lesser extent, FGR also reduces NO_X formation by lowering the oxygen concentration in the primary flame zone. The amount of recirculated flue gas is an important operating parameter influencing NO_X emission reduction potential for boiler systems.

Based on a review of various information provided by boiler manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- FGR is a technically feasible control option for reducing NO_X emissions from boilers.
- Physical space limitations at existing facilities can necessitate significant modifications to a building's structure to accommodate FGR. The addition of FGR can also require considerable modifications to existing ductwork (in configuration and capacity), re-design of a boiler's windbox, enlargement of burner nozzles, and new controls. Any such modifications are expected to appreciably increase the capital costs of retrofitting a boiler with FGR.
- The degree of NO_X reductions achieved with FGR vary considerably depending on the type of fuel and the design of the system. For example, when used in conjunction with LNB, FGR typically reduces NO_X emissions from natural gas-fired boilers by 50-90 percent.

- The general compliance time for FGR is estimated to be 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with FGR.

Selective Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by boiler manufacturers and SCR vendors, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SCR is a technically feasible control option for reducing NO_X emissions from boilers.
- A well designed and operated SCR system can (in general) reduce NO_X emissions by more than 90 percent.
- Because SCR reactors can be fairly large, physical space limitations at existing facilities can necessitate significant modifications to a building's structure to accommodate SCR. The addition of SCR can also require considerable modifications to existing ductwork. Any such modifications are expected to appreciably increase the capital costs of implementing SCR.
- NMED believes a reasonable compliance time for SCR is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- Operation of SCR on a boiler would likely result in a small increase in fuel consumption, as additional power would be needed to force exhaust through the catalyst bed. Additionally, electricity is needed to operate SCR.

Selective Non-Catalytic Reduction

See Section C.3.1 for a description of this technology.

Based on a review of various information provided by boiler manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- SNCR is a technically feasible control option for reducing NO_X emissions from boilers only if the temperature of the boiler exhaust is high enough.

EMx™ (formerly SCONOx)

EMx™ is a proprietary emissions control system, previously offered by Emerachem, designed to reduce NO_X, CO, and VOC. Like SCR, EMx utilizes a catalyst to promote reactions at a temperature lower than what would be required otherwise. However, unlike SCR, EMx simultaneously reduces multiple pollutants without the use of ammonia and thus does not potentially increase PM10 emissions.

According to an Emerchem representative,[5] EMx requires significantly more physical space than a traditional SCR system and would likely cost five to ten times as much.

Following the first commercial installation in 1997, the U.S. EPA designated EMx as BACT and LAER for natural gas-fired CT, and subsequently as Maximum Achievable Control Technology (MACT) for formaldehyde, acetaldehyde, and benzene. Capable of effective operation with exhaust temperatures as low as 300°F, the technology may be well suited for a variety of combustion applications. However, commercial application of EMx has been limited to large-scale CT and reciprocating engine installations. According to publicly available resources, EMx technology has not been employed on a natural gas-fired boiler. As a result, NMED determined that EMx is not a technically feasible control option for reducing NO_X emissions from boilers.

Replacement with a New Boiler

New boilers typically have significantly lower NO_X emission rates than those manufactured 30 plus years ago. All of the boilers subject to Regional Haze in New Mexico are at least 50 years old. NMED and EPA agree that replacing an old boiler with a new, more efficient, lower emitting boiler is within the scope of Regional Haze and thus an option states can consider when evaluating potential controls for boilers.

Based on a review of various information provided by boiler manufacturers and licensed service entities, FFAs completed by other air quality agencies, and discussions with industry representatives, NMED determined that:

- Replacement with a new boiler is a technically feasible control option for reducing NO_X emissions from boilers.
- The NO_X control efficiency associated with boiler replacement varies significantly as it depends on the NO_X emission rate of the existing unit and that of the replacement unit.
- NMED believes a reasonable compliance time for boiler replacement is 3-4 years. This estimate is based on the following timeframes for project development: 1-2 years for project approval, budgeting, and design; up to 1 year for equipment procurement; and up to 1 year for installation, commissioning, and start-up. This does not account for any facility-specific challenges that would prolong implementation.
- There are no appreciable energy or non-air quality impacts associated with boiler replacement.

Electrification

A Boiler is designed to produce useful thermal energy (e.g., steam). It is well-documented and widely understood that using electricity to generate steam is extremely inefficient and cost prohibitive. As a result, NMED determined that electrification is not a technically feasible control option for reducing NO_X emissions from boilers.

Retirement

When a facility's operational plans can accommodate retiring an emissions unit, doing so is a simple and effective control option. Retirement, in this context, means permanently shutting down a unit and forgoing its capacity by not replacing it, which reduces emissions by 100 percent. Retirement is a

[5] During a discussion in 2019 with NMED's contractor.

technically feasible option for any type of emissions unit, including boilers. NMED believes a reasonable compliance time for retirement is 1-2 years depending on a facility's requisite planning time and operational flexibility. More time will be necessary when a facility needs a unit to satisfy anticipated near-term capacity requirements relative to a facility with excess capacity. There are no energy or non-air quality impacts associated with retirement.

C.3.6 Amine Treatment Systems

Natural gas extracted from the earth often contains varying concentrations of hydrogen sulfide (H_2S) and carbon dioxide (CO_2). These compounds are generally considered contaminants to natural gas streams because they can react with water to form corrosive acids. Therefore, natural gas processing plants use amine treatment systems (ATS) typically consisting of an amine treatment unit (ATU) and one or more downstream control devices to remove and dispose of H_2S and CO_2 to protect pipelines from corrosion damage.

An ATU operates by feeding the inlet (i.e., unprocessed) natural gas stream into the bottom of a contactor while simultaneously feeding a lean amine solution into the top of the contactor. The two streams interact in counter flow, resulting in H_2S and CO_2 being stripped from the natural gas stream through amine absorption. The resulting "sweet gas" leaves the top of the contactor containing almost no H_2S. Rich amine leaves the bottom of the contactor and is fed into a stripper column to remove the absorbed H_2S and CO_2 so it can be reused, a process known as regeneration. The resulting "acid gas" stream is then sent to a control device for disposal. When the control device utilizes combustion to dispose of the acid gas stream, the H_2S is converted to sulfur dioxide (SO_2), which is released to the atmosphere along with the CO_2 in the stream.

NMED determined that the following controls for disposing of ATS acid gas streams are commercially available.

Flare[6]

Flaring is a high-temperature oxidation process used to burn waste gases containing combustible components such as volatile organic compounds, natural gas (or methane), carbon monoxide, and hydrogen. The waste gas is piped to a remote, usually elevated location and burned in an open flame in ambient air using a specially designed burner tip, auxiliary fuel, and, in some cases, assist gases like steam or air to promote mixing for nearly complete (e.g., greater than 98 percent) destruction of the combustible components in the gas. Flares are generally categorized by the height of the flare tip (i.e., ground or elevated) and by the method of enhancing mixing at the flare tip (i.e., steam-assisted, air-assisted, pressure-assisted, or non-assisted).

Based on a review of various information provided by facilities, as well as information available from EPA and flare manufacturers, NMED determined that:

- A flare is a technically feasible control option for disposing of ATS acid gas streams.
- If used as the primary control device, a flare is inferior to all other forms of disposal because most of the H_2S in the acid gas stream (typically 98% or more) is converted to SO_2 and emitted

[6] Most of this technology description was obtained from EPA's *Air Pollution Control Cost Manual*, Section 3.2, VOC Destruction Controls, Chapter 1 – Flares (updated August 2019).

into the atmosphere. Therefore, NMED did not evaluate replacing other, existing ATS control devices with a flare.

- Every facility with an ATS evaluated by NMED uses a flare as a secondary control device that only combusts acid gas when a primary control device experiences a startup, shutdown, and maintenance or malfunction (SSM/M) event. Improved flare design might reduce emissions somewhat in this context, but the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during SSM/M events as any modification to the flare would incur considerable costs associated with additional design, engineering, procurement, construction, and testing. Therefore, NMED did not evaluate optimizing existing flares used as a secondary control device.

Sulfur Recovery Unit (with Flare or Incinerator)

A sulfur recovery unit (SRU) converts the H_2S in an ATS acid gas stream to elemental sulfur and water using the Claus Process. A SRU typically involves multiple stages, with each stage consisting of a catalytic reactor, gas reheater, and a condenser/cooler. Depending on the exact configuration, a SRU can convert 90 percent or more of the H_2S in the acid gas stream to elemental sulfur. The "tail gas" exiting the SRU is typically sent to a flare or incinerator to combust any residual H_2S.

Based on a review of various information provided by facilities, and information available from EPA and publicly available resources, NMED determined that:

- A SRU (combined with a flare or incinerator) is a technically feasible control option for disposing of ATS acid gas streams.
- No facility with an ATS evaluated by NMED currently uses a SRU. Many, and possibly all gas processing plants in New Mexico that previously used a SRU have decommissioned them in recent years due to operational concerns and/or compliance issues, some of which resulted in enforcement actions against the facility due to significant excess SO_2 emissions. NMED supports and encourages the transition away from SRUs towards more effective forms of acid gas disposal, such as acid gas injection (AGI) wells. Therefore, NMED did not evaluate replacing other, existing ATS control devices with a SRU.

Thermal Oxidizer[7]

A thermal oxidizer (TO), also known as an incinerator, combusts waste gases in a combustion chamber as opposed to an open flame. The heart of a TO is a nozzle-stabilized flame maintained by a combination of auxiliary fuel, waste gas compounds, and supplemental air added when necessary. Ignition of the waste gas occurs as it passes through the combustion chamber, resulting in the destruction of H_2S and other volatile organic compounds. The exhaust gas from the TO consists primarily of CO_2 and water, plus various combustion products (e.g., SO_2) and any uncombusted hydrocarbons.

[7] Most of this technology description was obtained from EPA's *Air Pollution Control Cost Manual*, Section 3.2, VOC Destruction Controls, Chapter 2 – Incinerators and Oxidizers (updated November 2017).

Based on a review of various information provided by facilities, as well as information available from EPA and publicly available resources, NMED determined that:

- A TO is a technically feasible control option for disposing of ATS acid gas streams.
- Every facility with an ATS evaluated by NMED uses either a TO or an AGI well for acid gas disposal. Where an AGI well is technically feasible, a TO is an inferior control. An ATS with a TO will produce SO_2 emissions during normal operations and during SSM/M flaring events. Conversely, an ATS with an AGI well will produce SO_2 emissions only during SSM/M flaring events. Therefore, NMED did not evaluate replacing an existing AGI well with a TO, as this would increase emissions.

Acid Gas Injection Well

An AGI well is used to inject an ATS acid gas stream into a porous geologic formation (typically comprised of sandstone or limestone) for permanent underground storage. Prior to injection, the gas is pressurized to the required injection pressure using compressors powered by conventional natural gas-fired reciprocating engines or electric motor drives (EMD). During normal operations, an ATS controlled by an AGI well produces no atmospheric emissions of any kind. As such, emissions related to the operation of an ATS with an AGI well are limited to those that occur during SSM/M events, during which the acid gas stream is rerouted to a secondary control device, typically a flare, for disposal.

Based on its experience, a review of various information provided by facilities, and information available from EPA, NMED determined that:

- The technical feasibility of an AGI well is extremely dependent on the geologic characteristics of the potential well site. A subsurface investigation must be performed to determine if a suitable reservoir exists beneath the site. Only where a suitable reservoir exists is an AGI well a technically feasible control option for disposing of ATS acid gas streams.
- An AGI well can significantly reduce the amount of SO_2 released into the atmosphere compared to other forms of acid gas disposal. An ATS with a SRU or TO will produce SO_2 emissions during normal operations and during SSM/M flaring events. Conversely, an ATS with an AGI well will produce SO_2 emissions only during SSM/M flaring events. As a result, NMED has been actively encouraging and promoting the use of AGI wells in place of other controls, especially SRUs, in recent years.
- Because emissions from an ATS with an AGI well depend on the amount of acid gas flared during AGI SSM/M events, reducing the number and duration of SSM/M events can be an effective approach to reducing AGI-related flaring emissions. This can be primarily accomplished in one of two ways: 1) installation of a secondary acid gas compressor to provide backup, redundant compression in the event the primary compressor fails or is taken out of service for maintenance; or 2) implementation of an SSM/M plan which outlines a combination of work practice standards (proper maintenance and operation) consistent with manufacturer recommendations and industry best practices.
- All Title V facilities in New Mexico are already required to establish and implement SSM/M plans. Therefore, for facilities with an AGI well without redundant compression, NMED limited its evaluation to adding redundant compression to reduce AGI-related flaring emissions.

The use of an AGI well with redundant compression is an optimal approach to reducing emissions from an ATS. Therefore, for facilities with an AGI well with redundant compression, NMED did not evaluate alternative controls.

C.4 Four-Factor Analyses and Control Measure Determinations

NMED's four-factor analyses and reasonable progress control determinations for the emissions units selected for analysis via the screening process described in Section C.2 are described below.

C.4.1 Davis Gas Processing – Denton Gas Plant

Denton Gas Plant (DGP) is a former natural gas processing facility previously located 11 miles east of Lovington in Lea County, New Mexico at latitude 33° 2' 38", longitude -103° 10' 15". It was owned and operated by Davis Gas Processing, Inc. (Davis), and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Section C.2 in 2019. However, Davis subsequently shut down DGP on December 1, 2022, and submitted an administrative permit revision closing NSR Permit No. 0065-M8 and voluntarily discontinuing Title V Operating Permit No. P079-R3 on February 2, 2022. Davis demolished the facility shortly thereafter.

NMED originally selected the ATS at DGP (comprising Units 005 and 007) for an analysis of potential control measures for SO_2 in the second planning period due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). However, because DGP has since been shut down and demolished, NMED did not perform a FFA of potential control measures for the ATS. EPA guidance provides that a state may forgo a full FFA if a source is already "effectively controlled" and the state can demonstrate why a FFA would not result in new controls and would therefore be a futile exercise.[8] NMED considers it self-evident that a FFA of potential control measures for a retired unit at a facility that has been shut down and demolished would be futile. There is no more effective control than retirement, which reduces emissions by 100 percent, and the demolition of DGP makes it impossible to add new controls. Therefore, NMED has determined that the ATS is effectively controlled by virtue of its retirement due to the shutdown of DGP, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

Based on when DGP was shut down, the emissions reductions resulting from the retirement of the ATS were realized during the second planning period. Therefore, NMED estimated the SO_2 emissions reductions resulting from the retirement of the ATS by averaging 2016-2021 emissions reported by Davis pursuant to 20.2.73 NMAC. These emissions are summarized below.

Pollutant	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	2020 Emissions (tons)	2021 Emissions (tons)	Average Emissions (ton/yr)
SO_2	951.6	687.6	738.6	541.7	696.0	632.6	708.0

[8] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021) at 5.

C.4.2 DCP Operating Company – Artesia Gas Plant

Resources used in NMED's FFA for the Artesia Gas Plant (AGP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for DCP Operating Company, LP (DCP) and submitted to NMED on or about 11/1/19.
- Additional information provided by DCP on 12/16/19 and 3/3/20.
- A detailed discussion between DCP and NMED on 7/12/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA's Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP Region (March 23, 2020).
- FFAs developed for similar facilities in New Mexico and other states.

C.4.2.1 Facility Description

AGP is a natural gas processing facility located 13 miles east-southeast of Artesia in Eddy County, New Mexico at latitude 32^{o} 45' 18", longitude -104^{o} 12' 36". It is owned and operated by DCP and currently operates under Title V Operating Permit No. P095-R4, which expires on March 8, 2028. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 39.8 miles.

The function of the facility is to process natural gas, including condensate removal, H_2S and CO_2 removal with an amine unit, separation of natural gas liquids through the cryogenic plant, and inlet and residue compression. The facility is authorized for continuous operation, and its total potential to emit is 476.0 tons per year of NO_X and 389.3 tons per year of SO_2.[9]

C.4.2.2 Evaluated Units

NMED elected to evaluate the ATS at AGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at AGP consists of an ATU (Units Amine Contactor and Amine-RS), AGI well and compressor (Unit AGI), and an acid gas flare (Unit 23). During normal operations, acid gas exiting the ATU is routed to the AGI well for disposal resulting in no emissions to the atmosphere. During AGI SSM/M events, acid gas is rerouted to the acid gas flare for disposal, which produces SO_2 emissions.

[9] AQB Title V Operating Permit No. P095-R4, Table 102.A.

C.4.2.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. DCP did not request a future utilization adjustment for AGP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the ATS at AGP.

NMED estimated baseline actual SO_2 emissions for the ATS at AGP by averaging 2016-2021 emissions reported by DCP pursuant to 20.2.73 NMAC.[10] These emissions are summarized below.

Unit No.	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	2020 Emissions (tons)	2021 Emissions (tons)	Average Emissions (ton/yr)
23	17.96	0.04	109.96	3.25	0.00	0.03	27.8
SSM	NR (1)	0.31	NR (1)	3.36	NR (1)	NR (1)	
Malfunction	5.80	7.45	8.53	6.46	3.48	NR (1)	

(1) NR = None Reported

DCP only reports total SSM and total malfunction emissions, which include AGI SSM/M emissions from the acid gas flare associated with the ATS. Because NMED was unable to determine what portion of total SSM and total malfunction emissions were attributable to AGI SSM/M events, NMED conservatively assumed that 100 percent of total SSM and total malfunction emissions were AGI SSM/M emissions.

C.4.2.4 Technical Feasibility of Available Controls

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at AGP:

- A flare, SRU or TO are technically feasible options. However, compared to an AGI well, which is currently used as the primary control device for the ATS at AGP, a flare, SRU or TO is an inferior control. An ATS with a flare, SRU or TO will produce SO_2 emissions during normal operations and during SSM/M events. Conversely, an ATS with an AGI well will produce SO_2 emissions only during AGI SSM/M events. Therefore, NMED did not evaluate these options.
- While improved flare design might reduce emissions somewhat during AGI SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events. Therefore, NMED did not evaluate this option.
- Adding backup, redundant compression to the ATS is a technically feasible option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events.

[10] NMED was in receipt of DCP's reported 2022 emissions at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis.

C.4.2.5 Four-Factor Analysis

In order to determine what control measures are necessary at AGP to make reasonable progress, NMED conducted a FFA of the only technically feasible control option for the ATS, i.e., adding redundant compression to reduce AGI SSM/M flaring emissions. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[11]

C.4.2.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of SO_2 emissions reduced, of adding redundant compression to the ATS at AGP. Because DCP did not evaluate the ATS and therefore did not provide a source-specific cost estimate for adding redundant compression, NMED utilized cost estimates for adding redundant compression provided by other natural gas processing facilities in New Mexico to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[12]

NMED's cost effectiveness value for adding redundant compression to the ATS at AGP is provided below. NMED believes this value was calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed calculations and supporting documentation for NMED's cost estimate are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
ATS	Redundant Compression	$403,619	25.0	$16,000

NMED notes the following with respect to its determination of cost effectiveness for adding redundant compression to the ATS at AGP:

- DCP did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- Cost estimates for adding redundant compression provided by other natural gas processing facilities in New Mexico ranged from approximately $4.1M to $14.5M (2023$). NMED did not have sufficient information to determine which of the available estimates best represents the cost of adding redundant compression at AGP, so NMED conservatively used the lowest estimate in its calculations.

C.4.2.5.2 Compliance Time

Based on several recently completed projects, NMED believes a reasonable compliance time for adding redundant compression is 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.

---

[11] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[12] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

C.4.2.5.3 Remaining Useful Life

There is limited information about the useful life of EMD units, but research suggests the useful life is generally at least 25 years for units used in natural gas compression service. However, since in this case the unit would be used in acid gas service, NMED believes the useful life would not be longer than 20 years.

C.4.2.5.4 Energy and Non-Air Quality Impacts

NMED anticipates no energy or non-air quality impacts from adding redundant compression.

C.4.2.5.5 Summary

NMED performed a FFA for the only technically feasible control option for the ATS at AGP, i.e., adding redundant compression to reduce AGI SSM/M flaring emissions. The four statutory factors are discussed in Sections C.4.2.5.1 through C.4.2.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
ATS	Redundant Compression	$16,000	2-3	20	None

C.4.2.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[13]

[13] EPA, Responses to Comments on Protection of Visibility: Amendments to Requirements for State Plans (December 2016) at 186 ("While the CAA lists the four reasonable progress factors, it is silent as to whether states or the EPA may consider other, additional factors. This final rule neither requires nor prohibits states from considering visibility when making reasonable progress determinations."). *See also* EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) at 28 ("Section 169A(g)(1) of the CAA lists four factors that must be taken into consideration in determining reasonable progress … The visibility benefit of an emission reduction measure is not listed as a required factor, but neither the CAA nor the Regional Haze Rule prohibits a state from considering visibility benefits when it determines what emission control measures are required for a source to make reasonable progress at a Class I Area. Therefore, a state **may** consider the visibility benefits of potential control measures when determining what is necessary to make reasonable progress.")(emphasis added).

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. Because the estimated cost effectiveness of redundant compression exceeds this threshold, NMED determined that reasonable progress does not require adding redundant compression to the ATS at AGP.

C.4.3 DCP Operating Company – Eunice Gas Plant

Eunice Gas Plant (EGP) is a former natural gas processing facility located 7 miles northwest of Eunice in Lea County, New Mexico at latitude 32° 30' 31", longitude -103° 17' 08". It was owned and operated by DCP Operating Company, LP (DCP), and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Section C.2 in 2019. However, DCP subsequently entered into a Settlement Agreement and Stipulated Final Compliance Order (SASFCO) with NMED on September 10, 2021, which required DCP to permanently cease operations at EGP within 60 days and decommission the plant by removing process chemicals, including catalysts, and cleaning process vessels and piping within 270 days.[14] As required by the SASFCO, DCP shut down EGP on June 6, 2021, and submitted an administrative permit revision closing NSR Permit No. 0044-M11R1 and voluntarily discontinuing Title V Operating Permit No. P086-R2 on November 3, 2021.[15]

NMED originally selected EGP's five combustion turbines (Units 17A, 18A, 19A, 25A, and 26A) for an analysis of potential control measures for NO_X in the second planning period. NMED also elected to evaluate the ATS at EGP (comprising Units Amine-01, 31, 111, and 113) for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). However, because EGP has since been shut down and decommissioned pursuant to the SASFCO, NMED did not perform a FFA of potential control measures for any of these units. EPA guidance provides that a state may forgo a full FFA if a source is already "effectively controlled" and the state can demonstrate why a FFA would not result in new controls and would therefore be a futile exercise.[16] NMED considers it self-evident that a FFA of potential control measures for retired units at a facility that has been shut down and decommissioned would be futile. There is no more effective control than retirement, which reduces emissions by 100 percent, and the decommissioning of EGP makes it impossible to add new controls. Therefore, NMED has determined that these units are effectively controlled by virtue of their retirement due to the shutdown of EGP, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

Based on when EGP was shut down, the emissions reductions resulting from the retirement of the affected units were realized during the second planning period. Therefore, NMED estimated the NO_X emissions reductions resulting from the retirement of EGP Units 17A, 18A, 19A, 25A, and 26A and the SO_2 emissions reductions resulting from the retirement of the units comprising the ATS by averaging

[14] The SASFCO resolved alleged violations set forth in two Administrative Compliance Orders contested by DCP and docketed as AQB 20-46 (CO) and ABQ 20-64 (CO).

[15] DCP re-authorized certain equipment located at EGP but not part of the gas plant and not subject to the SASFCO, including the compressor station known as the Amanda Booster Station and the liquids stabilization and loading/unloading facilities known as the Eunice Treater, under two separate Oil and Gas General Construction Permits (GCP-O&G 9441 and 9442).

[16] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021) at 5.

2016-2020 emissions reported by DCP pursuant to 20.2.73 NMAC. These emissions are summarized below.

Pollutant	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	2020 Emissions (tons)	Average Emissions (ton/yr)
NO_X	424.6	407.2	407.2	182.7	186.3	321.6
SO_2	1417.9	1371.7	1706.8	1252.0	1216.0	1392.9

C.4.4 DCP Operating Company – Linam Ranch Gas Plant

Resources used in NMED's FFA for the Linam Ranch Gas Plant (LRGP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for DCP Operating Company, LP (DCP) and submitted to NMED on or about 11/1/19.
- Additional information provided by DCP on 12/16/19, 3/3/20, 8/28/23, 1/23/24, 1/25/24, and 2/5/24.
- A detailed discussion between DCP and NMED on 7/12/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA's Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP Region (March 23, 2020).
- FFAs developed for similar facilities in New Mexico and other states.

C.4.4.1 Facility Description

LRGP is a natural gas processing facility located 7 miles west of Hobbs in Lea County, New Mexico at latitude 32° 41' 43", longitude -103° 17' 07". It is owned and operated by DCP and currently operates under Title V Operating Permit No. P094-R3, which expires on December 18, 2025. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 72.7 miles.

The function of the facility is to remove hydrogen sulfide, water and carbon dioxide from field natural gas and separate natural gas liquids (NGL) from the field natural gas stream. The facility is authorized for continuous operation, and its total potential to emit is 973.5 tons per year of NO_X and 87.1 tons per year of SO_2.[17]

[17] AQB Title V Operating Permit No. P094-R3, Table 102.A.

C.4.4.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at LRGP:[18]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
6	2SLB RICE	Clark TLA-6	1974 or before	2,000 hp
7	2SLB RICE	Clark TLA-6	1974 or before	2,000 hp
8 (1)	2SLB RICE	Clark HBA-6	1951	1,267 hp
9 (1)	2SLB RICE	Clark HBA-6	1951	1,267 hp
10	2SLB RICE	Clark HBA-6	1951	1,267 hp
11	2SLB RICE	Clark HBA-6	1951	1,267 hp
29	Turbine	Solar Taurus T-70	1995	10,702 hp
30	Turbine	Solar Taurus T-70	1995	9,900 hp
31	Turbine	Solar Centaur T-4700	1995	4,700 hp
32B	Turbine	Solar Centaur T-4000	1979	3,961 hp

(1) In a detailed discussion with NMED on 7/12/23, DCP indicated that Units 8 and 9 are not operational. In its 8/28/23 submittal, DCP indicated that these units (and Units 6, 7, 10, and 11) will "either be replaced with different technology or retrofitted with appropriate equipment for compliance with §20.2.50 NMAC." In its 1/16/24 submittal, DCP reiterated that it does not plan to retire Units 8 and 9 and will either replace them or add controls as necessary. Therefore, NMED conducted a FFA for these units using operating data for identical Units 10 and 11 as a surrogate.

NMED also elected to evaluate the ATS at LRGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at LRGP consists of an ATU (Unit AM-10), AGI well (Unit AGI), two electric AGI well compressors (Units AGI-C1 and AGI-C2), and two acid gas flares (Units 2 and AGI Flare). During normal operations, acid gas exiting the ATU is routed to the AGI well for disposal resulting in no emissions to the atmosphere. During AGI SSM/M events, acid gas is rerouted to one of the flares for disposal, which produces SO_2 emissions. AGI SSM/M flaring emissions are minimized via the second, redundant AGI well compressor, which provides compression when the primary AGI well compressor fails or is taken out of service for maintenance, allowing for continued use of the AGI well when flaring would otherwise be required.

C.4.4.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. DCP did not request a future utilization adjustment for LRGP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at LRGP.

For the emissions units at LRGP requiring a FFA of potential control measures for NO_X ("NO_X units"), NMED calculated baseline actual emissions by multiplying representative annual operating hours by the NO_X emission rates reported in DCP's most recent periodic emissions test report(s).[19,] Because the NO_X

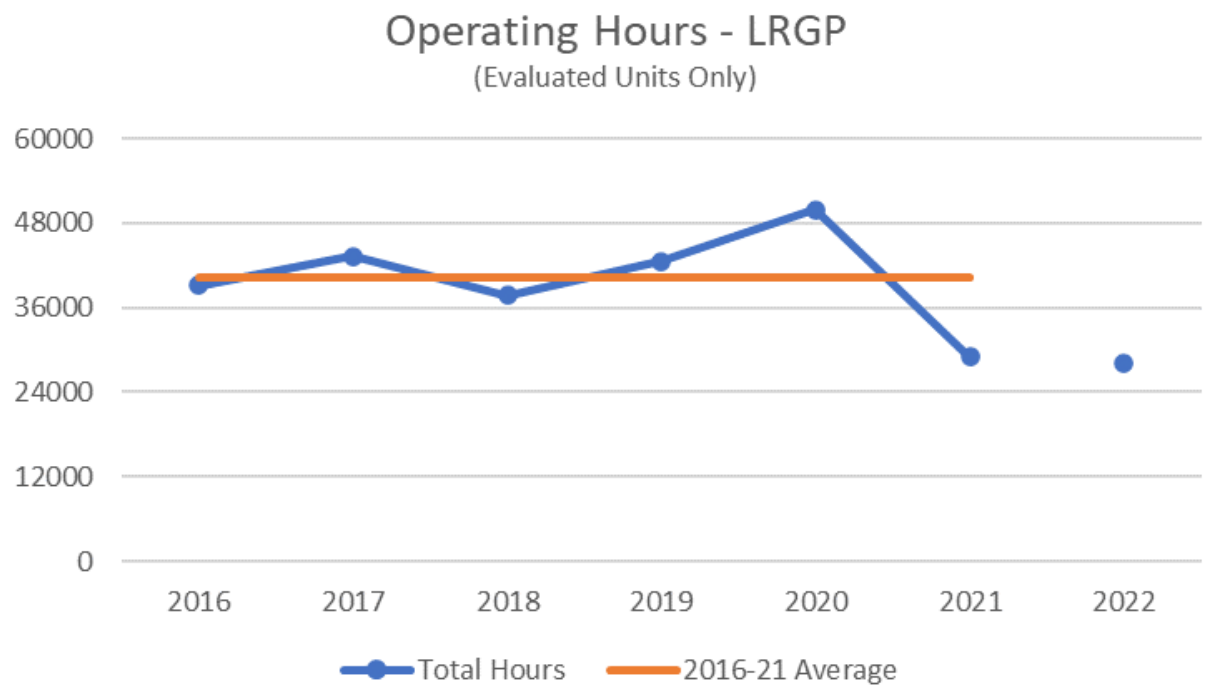
[18] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.
[19] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

units at LRGP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[20] Furthermore, because DCP is in the process of upgrading Unit 32B with DLN for compliance with 20.2.50 NMAC, NMED assumed DLN has already been installed on this unit and adjusted its emission rate to account for the anticipated effect of DLN. Reported and adjusted emission rates for the NO_X units at LRGP are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
6	2/15/23	25.5	43%	58.7
7	2/14/23	35.9	62%	58.1
8	NA [(1)]	---	---	18.1 [(2)]
9	NA [(1)]	---	---	18.1 [(2)]
10	2/15/23	19.1	71%	26.8
11	11/28/22	7.9	85%	9.3
29	2/13/23	1.0	86%	1.1
30	2/13/23	2.3	100%	2.3
31	2/14/23	3.0	100%	3.0
32B	10/11/22	15.4	95%	3.8 [(3)]

[(1)] NA = Not Available

[(2)] The average adjusted emissions of identical Units 10 and 11 were used as a surrogate for Units 8 and 9, as NMED was unable to locate a recent emissions test report for these units.



[(3)] Assumes 77% control efficiency for DLN, calculated as follows: (106.4 ppm - 25 ppm) / 106.4 ppm, where 106.4 ppm is the current actual emission rate and 25 ppm is the expected post-control emission rate after DLN is installed.

To determine representative annual operating hours for the NO_X units at LRGP, NMED analyzed 2016-2021 operating hours reported by DCP pursuant to 20.2.73 NMAC. NMED was in receipt of DCP's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the NO_X units at LRGP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
6	356	683	1449	1075	2441	833	691
7	229	594	2140	1748	2498	514	524
8	0	264	0	0	0	0	0
9	0	284	0	0	0	0	0
10	4385	3886	83	1081	2723	3516	3162
11	6213	4471	718	4607	7492	6723	6597
29	8653	7635	8388	8721	8726	8760	8657
30	8393	8559	7951	8395	8523	186	188
31	8569	8513	8351	8760	8760	8426	8372

[20] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
32B	2350	8374	8642	8162	8747	0	0

As shown above, year-over-year operating hours for the NO_X units at LRGP have been fairly consistent in recent years, although somewhat higher variability was observed in 2020-2021. However, this increased variability was firmly centered around the 2016-2021 average so its effect on the average was negligible, and there was no discernible impact from the pandemic in 2020. Furthermore, in a detailed discussion with NMED on 7/12/23, DCP indicated that it does not expect future utilization of the NO_X units at LRGP to change appreciably. Therefore, NMED determined that 2016-2021 average operating hours are representative for these units.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the NO_X units at LRGP are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
6	58.7	1140	33.5
7	58.1	1287	37.4
8	18.1	3825 (1)	34.5
9	18.1	3825 (1)	34.5
10	26.8	2612	35.0
11	9.3	5037	23.4
29	1.1	8481	4.7
30	2.3	7001	7.9

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
31	3.0	8563	12.8
32B	3.8	6046	11.5

(1) Units 8 and 9 have not operated since 2017, skewing their 2016-2021 average operating hours. Therefore, the average 2016-2021 average operating hours of identical Units 10 and 11 were used as a surrogate for these units.

C.4.4.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at LRGP:

- SCR, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by DCP based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 0.5 g/hp-hr.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.3 g/hp-hr or 0.5 g/hp-hr depending on the unit, consistent with the emission standards for new natural gas-fired spark ignition engines in 20.2.50 NMAC.[21]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, DCP did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at LRGP:

- WSI, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by DCP based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- DLN is a technically feasible option and is already installed or in the process of being installed on all of the CT at LRGP. As a result, DLN is not evaluated further.
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected, in the case of Units 29, 30, and 31, to achieve a NO_X emission rate of 15 ppm, consistent with the emission standards for new natural

[21] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent replacements for Units 6 and 7 would be subject to the NO_X standard for new lean burn engines ≥1,875 bhp (0.3 g/bhp-hr), while equivalent replacements for Units 8, 9, 10, and 11 would be subject to the NO_X standard for new lean burn engines >500 and <1,875 bhp (0.5 g/bhp-hr).

gas-fired combustion turbines in 20.2.50 NMAC.[22] In the case of Unit 32B, replacement is expected to achieve a NO_X emission rate of 25 ppm, consistent with manufacturer specifications for similar, new CT equipped with DLN.

- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, DCP did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at LRGP:

- While a flare, SRU, or TO are technically feasible options, the use of an AGI well with redundant compression is an optimal approach to reducing emissions from ATS because emissions are only produced during AGI SSM/M events. Therefore, NMED did not evaluate these options.
- While improved flare design might reduce emissions somewhat during AGI SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events. Therefore, NMED did not evaluate this option.

C.4.4.5 Four-Factor Analysis

In order to determine what control measures are necessary at LRGP to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the NO_X units identified in section C.4.4.2 above. NMED did not conduct a FFA of potential control measures for SO_2 for LRGP's ATS because the most effective control available – an AGI well with redundant compression – is already being utilized at LRGP. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[23]

C.4.4.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.4.4 above. NMED utilized source-specific cost estimates provided by DCP in its calculations whenever possible. In cases where DCP failed to provide source-specific cost estimates or NMED found estimates provided by DCP to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs.

[22] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for Units 29, 30 and 31 would be subject to the NO_X standard for new CT ≥4,000 and <15,900 bhp (15 ppm).

[23] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[24]

NMED's cost effectiveness values for all technically feasible controls for the NO_X units at LRGP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the NO_X units at LRGP and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
6	LEC	$475,935	32.2	$15,000
	Replacement	$732,267	32.7	$22,000
	Electrification	$1,169,893	33.5	$35,000
7	LEC	$475,935	36.0	$13,000
	Replacement	$732,267	36.5	$20,000
	Electrification	$1,169,893	37.4	$31,000
8	LEC	$475,935	31.9	$15,000
	Replacement	$463,891	31.9	$15,000
	Electrification	$833,188	34.5	$24,000
9	LEC	$475,935	31.9	$15,000
	Replacement	$463,891	31.9	$15,000
	Electrification	$833,188	34.5	$24,000
10	LEC	$475,935	33.2	$14,000
	Replacement	$463,891	33.2	$14,000
	Electrification	$833,188	35.0	$24,000
11	LEC	$475,935	19.8	$24,000
	Replacement	$463,891	19.8	$23,000
	Electrification	$833,188	23.4	$36,000
29	SCR	$464,471	3.7	$124,000
	Replacement	$2,936,040	-9.3 (1)	-$315,000 (1)
	Electrification	$5,167,169	4.7	$1,106,000
30	SCR	$442,122	6.4	$70,000
	Replacement	$2,716,015	-2.0 (1)	-$1,373,000 (1)
	Electrification	$4,798,769	7.9	$604,000
31	SCR	$281,318	10.3	$27,000
	Replacement	$1,289,421	2.6	$501,000
	Electrification	$2,410,142	12.8	$188,000
32B	SCR	$272,682	9.2	$30,000
	Replacement	$1,086,680	0	N/A (2)

[24]The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
	Electrification	$2,070,681	11.5	$181,000

(1) Negative estimated reductions and cost effectiveness are an artifact of NMED's methods for calculating these values and do not accurately represent the cost effectiveness of the control or its expected emissions impact. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and were not considered further.

(2) Because estimated reductions are zero, and division by zero is undefined, cost effectiveness cannot be calculated for replacement of this unit.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the NO_X units at LRGP:

- DCP did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- In DCP's 8/28/23 submittal, DCP stated that significant electricity infrastructure upgrades, with an estimated capital cost of $28M, would be necessary to support electrification. That submittal also included the estimated Total Capital Costs ($) and Additional Electric Demand ($/yr) associated with electrification. NMED accounted for these costs in its determination of cost effectiveness.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, consistent with the SCR evaluations provided in DCP's initial FFA.
- DCP recently upgraded Units 29, 30, and 31 with DLN to comply with 20.2.50 NMAC. Therefore, NMED's SCR and replacement evaluations for these units considered the incremental emissions reductions that would be achieved by adding SCR to these units or replacing them with new natural gas-fired CT. DCP is also in the advanced stages of upgrading Unit 32B with DLN to comply with 20.2.50 NMAC. Therefore, NMED's base case assumes DLN has already been installed on this unit and its SCR and replacement evaluations – like its evaluations for Units 29, 30, and 31 – considered the incremental emissions reductions that would be achieved by adding SCR to this unit or replacing it with a new natural gas-fired CT.
- DCP, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of the 2SLB RICE or CT units at LRGP with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement RICE or CT[25] along with information provided by other companies with similar units. NMED determined that the most applicable cost metrics ($ per hp basis) were provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of these metrics is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.

[25] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

C.4.4.5.2 Compliance Time

DCP did not identify any technically feasible control options for the 2SLB RICE at LRGP in its initial FFA submittal,[26] so it did not provide estimated compliance times for any of the control options NMED has determined are technically feasible. NMED's general assessment of compliance times provided in Section C.3.1 are believed to be reasonably accurate.

DCP indicated it would take 13 months to implement DLN on the CT at LRGP, and approximately 9 months to implement SCR. These estimates include a 25 percent contingency factor to account for unforeseen circumstances or setbacks associated with installation of the controls. NMED believes that even with the contingency factor these timeframes are very optimistic based on information provided by other facilities. NMED believes the general compliance times for DLN and SCR provided in Section C.3.4 are more reasonable. NMED also believes the general compliance time for replacement – which DCP did not assess in its initial FFA or follow-up submittals – provided in Section C.3.4 is reasonably accurate.

In its 8/28/23 submittal, DCP estimated that electrification would take 12-14 years. That estimate is based on the following project development timeline: 5 years for construction approval, 3 years to source the electrical equipment, and 4-6 years to complete construction. NMED disagrees with this estimate based on information provided by other facilities and the implementation time of electrification projects at other facilities. NMED believes the general compliance time for electrification, provided in Section C.3.4, is more reasonable but recognizes several more years could be required considering the relative complexity.

C.4.4.5.3 Remaining Useful Life

Despite the advanced age of the 2SLB RICE at LRGP (~50 to 70 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

Manufacturers of new RICE and CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new RICE and CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE or CT is 30 years.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

There is limited information about the useful life of electric compression equipment, but research suggests the useful life is at least 25 years.

[26] DCP implicitly acknowledged the technical feasibility of LEC by providing indicative pricing for LEC retrofits in its 8/28/23 submittal. Prior to that, DCP had maintained that the engines at LRGP were incapable of being retrofit with LEC due to their age.

C.4.4.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE and CT is provided in Sections C.3.1 and C.3.4, respectively.

C.4.4.5.5 Summary

NMED performed a FFA for all technically feasible control options for the NO_X units listed in Section C.4.4.2 above. The four statutory factors are discussed in Sections C.4.4.5.1 through C.4.4.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
6	LEC	$15,000	2-3	20	None
	Replacement	$22,000	3-4	30	None
	Electrification	$35,000	4-6	25	None
7	LEC	$13,000	2-3	20	None
	Replacement	$20,000	3-4	30	None
	Electrification	$31,000	4-6	25	None
8	LEC	$15,000	2-3	20	None
	Replacement	$15,000	3-4	30	None
	Electrification	$24,000	4-6	25	None
9	LEC	$15,000	2-3	20	None
	Replacement	$15,000	3-4	30	None
	Electrification	$24,000	4-6	25	None
10	LEC	$14,000	2-3	20	None
	Replacement	$14,000	3-4	30	None
	Electrification	$24,000	4-6	25	None
11	LEC	$24,000	2-3	20	None
	Replacement	$23,000	3-4	30	None
	Electrification	$36,000	4-6	25	None
29	SCR	$124,000	3-4	20	None
	Replacement	-$315,000	3-4	30	None
	Electrification	$1,106,000	4-6	25	None
30	SCR	$70,000	3-4	20	None
	Replacement	-$11,373,000	3-4	30	None
	Electrification	$604,000	4-6	25	None
31	SCR	$27,000	3-4	20	None
	Replacement	$501,000	3-4	30	None
	Electrification	$188,000	4-6	25	None
32B	SCR	$30,000	3-4	20	None
	Replacement	N/A	3-4	30	None
	Electrification	$181,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.4.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[27]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA did not identify any cost-effective controls for LRGP Units 6, 7, 8, 9, 10, 11, 29, 30, 31, or 32B. Therefore, NMED determined that reasonable progress does not require new controls on any of these units.

As noted above, NMED did not conduct a FFA of potential control measures for LRGP's ATS. Because the most effective control available – an AGI well with redundant compression – is already being utilized at LRGP, NMED determined that reasonable progress does not require new controls for the ATS. Because redundant compression was added to LRGP's AGI well before the start of the second planning period, the resulting emissions reductions were realized during the first planning period. Therefore, NMED did not estimate these reductions.

C.4.5 El Paso Natural Gas Company – Blanco Compressor Station A

Resources used in NMED's FFA for Blanco Compressor Station A (BCSA) include, but are not limited to, the following:

- The initial FFA completed by Alliant Environmental, LLC for El Paso Natural Gas Company, LLC (EPNG), a subsidiary of Kinder Morgan, Inc. (Kinder Morgan), and submitted to NMED on or about 11/1/19.
- Additional information provided by EPNG or Kinder Morgan on 2/14/20, 2/23/20, 9/9/20, 10/9/20, 2/23/21, and 5/26/23.
- The revised FFA submitted to NMED on 6/5/23.

[27] See *supra* note 13.

- Detailed discussions between EPNG and NMED, most recently on 5/3/23.
- EPNG's proposed Part 50 Alternative Compliance Plan (ACP), submitted on 6/13/23 and updated on 8/8/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020).
- FFAs developed for similar facilities in New Mexico and other states.

C.4.5.1 Facility Description

BCSA is a natural gas compressor station located 0.1 miles north of Bloomfield in San Juan County, New Mexico at latitude 36° 43' 42", longitude -107° 57' 21". It is owned and operated by EPNG and currently operates under Title V Operating Permit No. P048-R4, which expires on September 18, 2025. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 39.8 miles.

The function of the facility is to compress natural gas for the purpose of transportation to another facility or a major transportation pipeline. The facility is authorized for continuous operation, and its total potential to emit is 1344 tons per year of NO_X and 0.3 tons per year of SO_2.[28]

C.4.5.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at BCSA. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[29]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
A01	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A02	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A03	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A04	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A05	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A06	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A07	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A08	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A09	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A10	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp

[28] AQB Title V Operating Permit No. P048-R4, Table 301.A.

[29] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
A11	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A12	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A13	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp
A14	2SLB RICE	Cooper Bessemer GMV10-TF	<August 1953 (1)	943 hp

(1) According to EPNG's most recent Title V permit application, the date of manufacture of Units A01 through A14 is unknown but they were all constructed/reconstructed in August 1953. The date of manufacture necessarily precedes the construction/reconstruction date.

C.4.5.3 Projected Actual Emissions

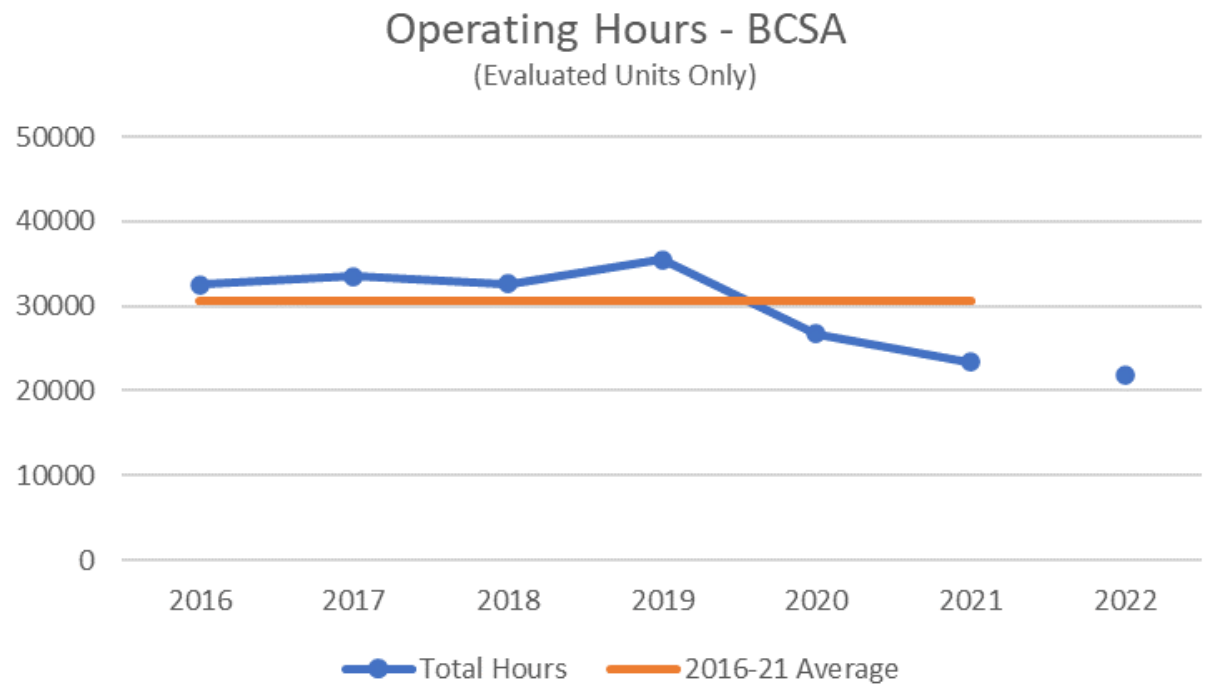
Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. EPNG initially requested a future utilization adjustment for BCSA, but later opted not to apply one in its own projected actual emissions calculations.[30] Therefore, NMED did not apply a future utilization adjustment, and projected actual emissions equal baseline actual emissions for the emissions units at BCSA.

NMED calculated baseline actual emissions for the emissions units at BCSA by multiplying representative annual operating hours by the NO_X emission rates reported in EPNG's most recent periodic emissions test report(s).[31,] Because the emissions units at BCSA operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[32] Reported and adjusted emission rates for the emissions units at BCSA are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @100% load)
A01	NA (1)	---	---	11.6 (2)
A02	3/28/23	7.8	79%	9.9
A03	3/28/23	7.1	84%	8.4
A04	4/19/22	1.4	61%	2.9
A05	NA (1)	---	---	11.6 (2)
A06	NA (1)	---	---	11.6 (2)
A07	NA (1)	---	---	11.6 (2)
A08	NA (1)	---	---	11.6 (2)
A09	4/19/22	10.8	89%	12.1
A10	NA (1)	---	---	11.6 (2)
A11	3/29/23	13.8	76%	18.1
A12	NA (1)	---	---	11.6 (2)
A13	3/29/23	16.3	90%	18.1
A14	NA (1)	---	---	11.6 (2)

(1) NA = Not Available

(2) The average adjusted emissions of Units A02, A03, A04, A09, A11, and A13 were used as a surrogate for Units A01, A05, A06, A07, A08, A10, A12, and A14, as NMED was unable to locate a recent emissions test report for these units.



[30] See EPNG's 6/5/23 revised FFA submittal.

[31] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[32] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

To determine representative annual operating hours for the emissions units at BCSA, NMED analyzed 2016-2021 operating hours reported by EPNG pursuant to 20.2.73 NMAC. NMED was in receipt of EPNG's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at BCSA are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
A01	6728	5123	579	3787	2500	0	0
A02	2	14	4	2199	5652	2	2669
A03	5012	5953	3182	5182	225	108	134
A04	99	2	2	511	5055	7980	5243
A05	281	5	9	3	0	1	2
A06	56	5567	2155	2	0	1	1817
A07	5964	6666	1371	3691	2547	1946	1371
A08	1	1	1	2	0	0	0
A09	2499	183	866	3141	2144	5007	4931
A10	1	1	6	2	0	1	0
A11	4404	3239	7450	6581	7642	7076	4897
A12	1	2	3560	3	0	218	0
A13	7490	6827	6108	7130	998	1033	720
A14	1	1	7312	3259	0	1	0

As shown above, operating hours at BCSA were fairly consistent from 2016-2019, then started dropping in 2020. It is unclear whether this was related to the pandemic, or if the lower operating hours observed in 2020-2021 represent future operating conditions better than the higher operating hours observed in 2016-2019. However, NMED notes that EPNG used the highest operating hours from 2015-2019, when total operating hours were considerably higher than they were in 2020-2021, in its own projected actual emissions calculations.[33] Therefore, NMED determined that 2016-2021 average operating hours are representative for the emissions units at BCSA.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at BCSA are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
A01	11.6	3120	18.1
A02	9.9	1312	6.5
A03	8.4	3277	13.8
A04	2.9	2275	3.2
A05	11.6	50	0.3
A06	11.6	1297	7.5
A07	11.6	3698	21.4
A08	11.6	1	0.005
A09	12.1	2307	14.0
A10	11.6	2	0.011
A11	18.1	6065	54.8
A12	11.6	631	3.7
A13	18.1	4931	44.6
A14	11.6	1762	10.2

C.4.5.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at BCSA:

- SCR, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by EPNG based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option. In this case, EPNG indicated that three LEC configurations dubbed LEC1, LEC2, and LEC3 are available that would achieve vendor-quoted, not-to-exceed NO_X emission rates of 3.0 g/bhp-hr, 1.0 g/bhp-hr, and 0.5 g/bhp-hr, respectively.[34]

[33] See EPNG's 6/5/23 revised FFA submittal.

[34] Hoerbiger Engineering Services budgetary estimate included in EPNG's 2/14/20 submittal.

- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.5 g/hp-hr, consistent with the emissions standards for new natural gas-fired spark ignition lean burn engines in 20.2.50 NMAC.[35]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). EPNG's initial FFA submittal evaluated a scenario involving the retirement of five units in conjunction with LEC upgrades to the remaining nine units, and its proposed ACP incorporated emission reductions achieved by retiring seven units. Considering that EPNG's proposed ACP was disapproved by NMED and EPNG always has the option of retiring a unit, this option was not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

C.4.5.5 Four-Factor Analysis

In order to determine what control measures are necessary at BCSA to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.5.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[36]

C.4.5.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.5.4 above. NMED utilized source-specific cost estimates provided by EPNG in its calculations whenever possible. In cases where EPNG failed to provide source-specific cost estimates or NMED found estimates provided by EPNG to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[37]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at BCSA are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at BCSA and supporting documentation for NMED's cost estimates are provided in Appendix D.

---

[35] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent replacements for the 2SLB RICE at BCSA would be subject to the NO_X standard for new lean burn engines >500 and <1,875 bhp (0.5 g/bhp-hr).

[36] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[37] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
A01	LEC1	$396,254	8.3	$48,000
	LEC2	$625,478	14.8	$42,000
	LEC3	$589,702	16.4	$36,000
	Replacement	$380,474	16.4	$23,000
A02	LEC1	$396,254	2.4	$164,000
	LEC2	$625,478	5.1	$122,000
	LEC3	$589,702	5.8	$101,000
	Replacement	$380,474	5.8	$65,000
A03	LEC1	$396,254	3.6	$111,000
	LEC2	$625,478	10.4	$60,000
	LEC3	$589,702	12.1	$49,000
	Replacement	$380,474	12.1	$31,000
A04	LEC1	$396,254	-3.8 (2)	-$103,000 (2)
	LEC2	$625,478	0.9	$711,000
	LEC3	$589,702	2.1	$286,000
	Replacement	$380,474	2.1	$185,000
A05	LEC1	$396,254	0.1	$2,975,000
	LEC2	$625,478	0.2	$2,641,000
	LEC3	$589,702	0.3	$2,245,000
	Replacement	$380,474	0.3	$1,448,000

	LEC3	$589,702	12.8	$46,000
	Replacement	$380,474	12.8	$30,000
A10	LEC1	$396,254	0.005	$80,854,000
	LEC2	$625,478	0.009	$71,793,000
	LEC3	$589,702	0.010	$61,014,000
	Replacement	$380,474	0.010	$39,366,000
A11	LEC1	$396,254	35.9	$11,000

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
	LEC2	$625,478	48.5	$13,000
	LEC3	$589,702	51.7	$11,000
	Replacement	$380,474	51.7	$7,000
A12	LEC1	$396,254	1.7	$235,000
	LEC2	$625,478	3.0	$209,000
	LEC3	$589,702	3.3	$177,000
	Replacement	$380,474	3.3	$114,000
A13	LEC1	$396,254	29.2	$14,000
	LEC2	$625,478	39.5	$16,000
	LEC3	$589,702	42.1	$14,000
	Replacement	$380,474	42.1	$9,000
A14	LEC1	$396,254	4.7	$84,000
	LEC2	$625,478	8.4	$75,000
	LEC3	$589,702	9.3	$63,000
	Replacement	$380,474	9.3	$41,000
All Units	Electrification [1]	$3,916,630	198.1	$20,000

[1] Electrification was evaluated at the station level instead of unit by unit for EPNG's facilities.
[2] Negative estimated reductions and cost effectiveness are an artifact of NMED's methods for calculating these values and do not accurately represent the cost effectiveness of the control or its expected emissions impact. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and are excluded from further consideration.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at BCSA:

- EPNG provided a company-specific cost of capital (8.53 percent) in its 2/23/20 submittal.
- The calculated cost effectiveness of each LEC configuration is based on a Total Capital Cost (TCC) estimate provided by a vendor.
- EPNG provided a Total Capital Investment (TCI) cost metric of $3,227/hp (2020$) for the installation of new, replacement RICE at BCSA. The cost metric was developed by Kinder Morgan's Cost Estimating Group based on its extensive industry experience. NMED reviewed several publicly available resources along with information provided by other companies with similar units that could be used to estimate the TCI of a replacement RICE, and determined that the Kinder Morgan metric was reasonable. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- On 2/14/20, EPNG provided a $1,469/hp (2020$) all-in TCC metric for electrification. On 9/9/20, EPNG provided an alternate cost estimate developed using "the [Kinder Morgan] Cost Estimating Group's Developmental Cost Estimating Tool." The alternate estimate applied an unusual and insufficiently documented methodology that involved a base cost estimate for replacement RICE that was adjusted using EMD-specific costs and RICE-specific costs. Using detailed cost information provided by other facilities, NMED developed a TCC metric of $2,084/hp (2023$) for replacement with EMD. Costs associated with requisite substation and utility line upgrades were estimated separately and added to TCC to estimate TCI for electrification.

C.4.5.5.2 Compliance Time

EPNG estimated that LEC retrofits could be completed in 1-3 years after the issuance of a revised permit by NMED. This estimate is based, in part, on EPNG's assertion that the units could not be simultaneously retrofitted because the facility must maintain a minimum active compression capacity to maintain pressure within the transmission pipeline. Based on information provided by other facilities and other resources, NMED believes this timeframe is reasonable.

EPNG did not provide an estimate of the time necessary to replace the units at BCSA. NMED believes the general compliance times for replacement with like-kind natural gas-fired engines or EMD provided in Section C.3.1 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

C.4.5.5.3 Remaining Useful Life

Despite the advanced age of the units at BCSA (~70 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

Manufacturers of new RICE will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new RICE are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.5.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE is provided in Section C.3.1.

C.4.5.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.5.2 above. The four statutory factors are discussed in Sections C.4.5.5.1 through C.4.5.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
A01	LEC1	$48,000	1-3	20	None
	LEC2	$42,000	1-3	20	None
	LEC3	$36,000	1-3	20	None
	Replacement	$23,000	3-4	30	None
A02	LEC1	$164,000	1-3	20	None
	LEC2	$122,000	1-3	20	None
	LEC3	$101,000	1-3	20	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [1]
	Replacement	$65,000	3-4	30	None
A03	LEC1	$111,000	1-3	20	None
	LEC2	$60,000	1-3	20	None
	LEC3	$49,000	1-3	20	None
	Replacement	$31,000	3-4	30	None
A04	LEC1	-$103,000	1-3	20	None
	LEC2	$711,000	1-3	20	None
	LEC3	$286,000	1-3	20	None
	Replacement	$185,000	3-4	30	None
A05	LEC1	$2,975,000	1-3	20	None
	LEC2	$2,641,000	1-3	20	None
	LEC3	$2,245,000	1-3	20	None
	Replacement	$1,448,000	3-4	30	None
A06	LEC1	$114,000	1-3	20	None
	LEC2	$101,000	1-3	20	None
	LEC3	$86,000	1-3	20	None
	Replacement	$56,000	3-4	30	None
A07	LEC1	$40,000	1-3	20	None
	LEC2	$36,000	1-3	20	None
	LEC3	$30,000	1-3	20	None
	Replacement	$20,000	3-4	30	None
A08	LEC1	$177,879,000	1-3	20	None
	LEC2	$157,945,000	1-3	20	None
	LEC3	$134,231,000	1-3	20	None
	Replacement	$86,605,000	3-4	30	None
A09	LEC1	$58,000	1-3	20	None
	LEC2	$54,000	1-3	20	None
	LEC3	$46,000	1-3	20	None
	Replacement	$30,000	3-4	30	None
A10	LEC1	$80,854,000	1-3	20	None
	LEC2	$71,793,000	1-3	20	None
	LEC3	$61,014,000	1-3	20	None
	Replacement	$39,366,000	3-4	30	None
A11	LEC1	$11,000	1-3	20	None
	LEC2	$13,000	1-3	20	None
	LEC3	$11,000	1-3	20	None
	Replacement	$7,000	3-4	30	None
A12	LEC1	$235,000	1-3	20	None
	LEC2	$209,000	1-3	20	None
	LEC3	$177,000	1-3	20	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
	Replacement	$114,000	3-4	30	None
A13	LEC1	$14,000	1-3	20	None
	LEC2	$16,000	1-3	20	None
	LEC3	$14,000	1-3	20	None
	Replacement	$9,000	3-4	30	None
A14	LEC1	$84,000	1-3	20	None
	LEC2	$75,000	1-3	20	None
	LEC3	$63,000	1-3	20	None
	Replacement	$41,000	3-4	30	None
All Units	Electrification	$20,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.5.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[38]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for BCSA Units A11 and A13. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

[38] See *supra* note 13.

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
A11	Replacement	51.7
A13	Replacement	42.1

NMED did not identify any cost-effective controls for BCSA Units A01, A02, A03, A04, A05, A06, A07, A08, A09, A10, A12, or A14. Therefore, NMED determined that reasonable progress does not require new controls on any of these units.

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at BCSA during the second planning period will be approximately 93.8 ton/yr of NO_X.

C.4.6 El Paso Natural Gas Company – Pecos River Compressor Station

Resources used in NMED's FFA for Pecos River Compressor Station (PRCS) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for El Paso Natural Gas Company, LLC (EPNG), a subsidiary of Kinder Morgan, Inc. (Kinder Morgan), and submitted to NMED on or about 11/1/19.
- Additional information provided by EPNG or Kinder Morgan on 2/14/20, 2/23/20, 9/9/20, 10/9/20, 2/23/21, and 5/26/2023.
- Detailed discussions between EPNG and NMED, most recently on 5/3/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.6.1 Facility Description

PRCS is a natural gas compressor station located approximately 11.5 miles south-southeast of Malaga in Eddy County, New Mexico at latitude 32° 03' 49", longitude -104° 01' 06". It is owned and operated by EPNG and currently operates under Title V Operating Permit No. P129-R4, which expires on March 4, 2026. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 22.1 miles.

The function of the facility is to compress natural gas and deliver the compressed gas to a pipeline for mainline transportation. The facility is authorized for continuous operation, and its total potential to emit is 697.7 tons per year of NO_X and 5.6 tons per year of SO_2.[39]

[39] AQB Title V Operating Permit No. P129-R4, Table 102.A.

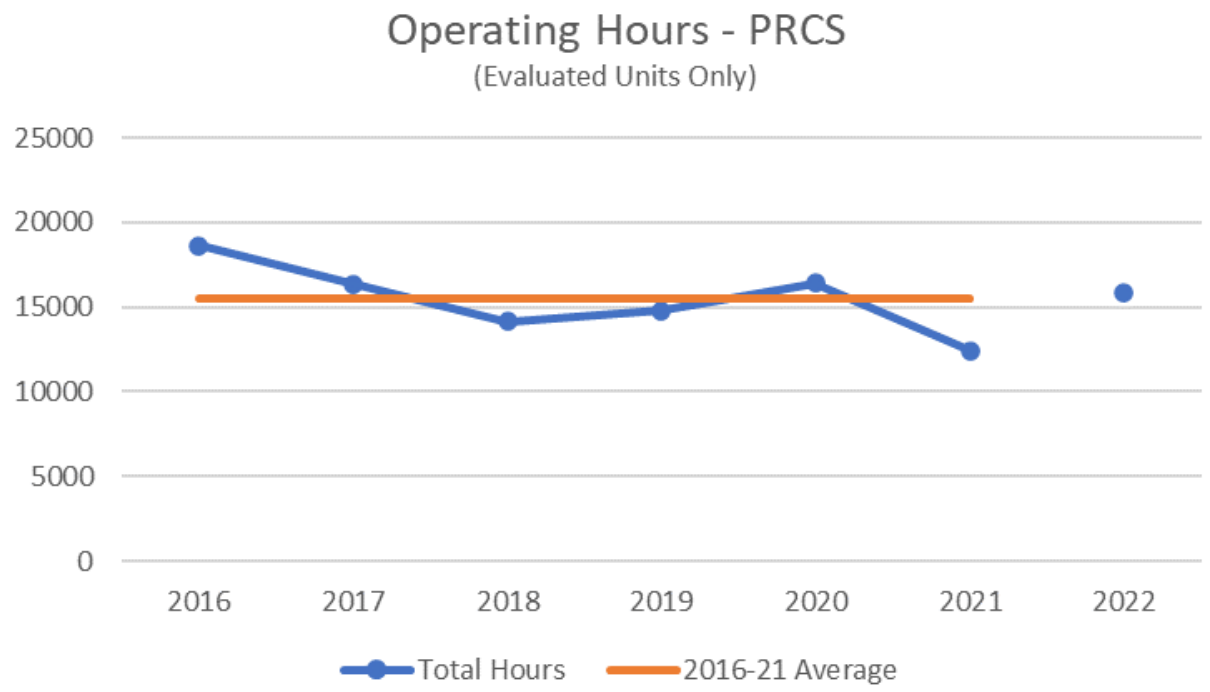
C.4.6.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at PRCS. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[40]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
A-01	Turbine	General Electric M3712-R, Frame 3	1953	7,150 hp
A-02	Turbine	General Electric M3712-R, Frame 3	1953	7,150 hp
A-03	Turbine	General Electric M3712-R, Frame 3	1953	7,150 hp

C.4.6.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. EPNG did not request a future utilization adjustment for PRCS. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at PRCS.



NMED calculated baseline actual emissions for the emissions units at PRCS by multiplying representative annual operating hours by the NO_X emission rates reported in EPNG's most recent periodic emissions test report(s).[41,] Because the emissions units at PRCS operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[42] Reported and adjusted emission rates for the emissions units at PRCS are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr at 100% load)
A-01	6/20/23	22.4	57%	39.5
A-02	6/8/22	25.3	70%	36.4
A-03	6/20/23	24.4	60%	40.5

To determine representative annual operating hours for the emissions units at PRCS, NMED analyzed 2016-2021 operating hours reported by EPNG pursuant to 20.2.73 NMAC. NMED was in receipt of EPNG's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at PRCS are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

[40] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.
[41] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.
[42] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
A-01	4982	754	5323	2700	4737	2820	6998
A-02	7166	7916	3813	6738	7344	5293	3827
A-03	6501	7693	5031	5356	4333	4305	5069

As shown above, PRCS' year-over-year operating hours have been fairly consistent in recent years, although somewhat higher variability was observed in 2016 and 2021. However, this increased variability was firmly centered around the 2016-2021 average so its effect on the average is negligible, and there was no discernible impact from the pandemic in 2020. Therefore, NMED determined that 2016-2021 average operating hours are representative for the emissions units at PRCS.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at PRCS are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
A-01	39.5	3553	70.1
A-02	36.4	6378	116.0
A-03	40.5	5537	112.2

C.4.6.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at PRCS:

- SNCR and NSCR are not technically feasible options.
- Neither WSI nor DLN is available for the make and model of CT at PRCS and thus are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by EPNG based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.[43]
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 15 ppm, consistent with the emissions standards for new natural gas-fired combustion turbines in 20.2.50 NMAC.[44]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, EPNG did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and other pollutants).

C.4.6.5 Four-Factor Analysis

In order to determine what control measures are necessary at PRCS to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.6.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[45]

C.4.6.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.6.4 above. NMED utilized source-specific cost estimates provided by EPNG in its calculations whenever possible. In cases where EPNG failed to provide source-specific cost estimates or NMED found estimates provided by EPNG to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[46]

---

[43] EPNG assumed a NOX control efficiency of 70% in the SCR evaluations provided in its initial FFA and 2/14/20 follow-up submittal. While NMED disagrees with this assumption, NMED notes that in its own evaluation, SCR remains cost effective for Units A-02 and A-03 even if the control efficiency is reduced to 70%.

[44] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for the CT at PRCS would be subject to the NO_X standard for new CT ≥4,000 and <15,900 bhp (15 ppm).

[45] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[46] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

NMED's cost effectiveness values for all technically feasible controls for the emissions units at PRCS are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at PRCS and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
A-01	SCR	$752,125	56.1	$13,000
	Replacement	$2,250,734	58.9	$38,000
A-02	SCR	$769,297	92.8	$8,000
	Replacement	$2,250,734	100.0	$23,000
A-03	SCR	$765,788	89.8	$9,000
	Replacement	$2,250,734	94.2	$24,000
All Units	Electrification [(1)]	$8,363,225	298.3	$28,000

[(1)] Electrification was evaluated at the station level instead of unit by unit for EPNG's facilities.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at PRCS:

- EPNG provided a company-specific cost of capital (8.53 percent) in its 2/23/20 submittal.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC) and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. In addition to TCC, NMED included EPNG's $3,275,000 estimate (2024$) for turbine housing reconfiguration in the Total Capital Investment (TCI) of SCR.[47] An SCR retrofit factor of 1 (average difficulty) was applied, consistent with the revised SCR evaluations provided in EPNG's 2/14/20 submittal.
- EPNG provided a TCI cost metric of $2,418/hp (2020$) for the installation of new, replacement CT at PRCS. The cost metric was developed by Kinder Morgan's Cost Estimating Group based on its extensive industry experience. NMED reviewed several publicly available resources along with information provided by other companies with similar units that could be used to estimate the TCI of a replacement CT, and determined that the Kinder Morgan metric was reasonable. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- On 2/14/20, EPNG provided a $1,469/hp ($2020) all-in TCC metric for electrification. On 9/9/20, EPNG provided an alternate cost estimate developed using "the [Kinder Morgan Cost Estimating Group's Developmental Cost Estimating Tool." The alternate estimate applied an unusual and insufficiently documented methodology that involved a base cost estimate for replacement CT that was adjusted using EMD-specific costs and CT-specific costs. Using detailed cost information provided by other facilities, NMED developed a TCC metric of $2,084/hp (2023$) for replacement with EMD. Costs associated with requisite substation and utility line upgrades were estimated separately and added to TCC to estimate TCI for electrification.

[47] EPNG's initial FFA submittal included $2,500,000 (2019$) to modify the exhaust system ducting and the building that houses the turbines to facilitate installation of SCR module and reagent storage systems. NMED adjusted this for inflation using the Chemical Engineering Plant Cost Index.

C.4.6.5.2 Compliance Time

EPNG estimated that SCR upgrades, including necessary building modifications and SCR control equipment installation, would take approximately 3 years. This estimate is consistent with NMED's general assessment of compliance times and thus believed to be reasonably accurate.

EPNG did not provide an estimate of the time necessary to replace the units at PRCS. NMED believes the general compliance times for replacement with like-kind natural gas-fired CT or EMD provided in Section C.3.4 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

C.4.6.5.3 Remaining Useful Life

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.6.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT is provided in Section C.3.4.

C.4.6.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.6.2 above. The four statutory factors are discussed in Sections C.4.6.5.1 through C.4.6.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
A-01	SCR	$13,000	3	20	None
	Replacement	$38,000	3-4	30	None
A-02	SCR	$8,000	3	20	None
	Replacement	$23,000	3-4	30	None
A-03	SCR	$9,000	3	20	None
	Replacement	$24,000	3-4	30	None
All Units	Electrification	$28,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.6.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[48]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for PRCS Units A-02 and A-03. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
A-02	SCR	92.8
A-03	SCR	89.8

NMED's FFA did not identify any cost-effective controls for PRCS Unit A-01. Therefore, NMED determined that reasonable progress does not require new controls on this unit.

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at PRCS during the second planning period will be approximately 182.6 ton/yr of NO_X.

C.4.7 El Paso Natural Gas Company – Washington Ranch Storage Facility

Resources used in NMED's FFA for Washington Ranch Storage Facility (WRSF) include, but are not limited to, the following:

[48] See *supra* note 13.

- The FFA completed by Trinity Consultants for El Paso Natural Gas Company, LLC (EPNG), a subsidiary of Kinder Morgan, Inc. (Kinder Morgan), and submitted to NMED on or about 11/1/19.
- Additional information provided by EPNG or Kinder Morgan on 2/14/20, 2/23/20, 9/9/20, 10/9/20, 2/23/21, and 5/26/23.
- Detailed discussions between EPNG and NMED, most recently on 5/3/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.7.1 Facility Description

WRSF is a natural gas storage facility located 9.1 miles southwest of Whites City in Eddy County, New Mexico at latitude 32° 04' 54", longitude -104° 29' 04". It is owned and operated by EPNG and currently operates under Title V Operating Permit No. P064-R4M2, which expires on December 30, 2025. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 3.4 miles.

The function of the facility is to compress and inject natural gas into underground storage wells and to withdraw the gas for delivery into the pipeline. The facility is authorized for continuous operation, and its total potential to emit is 243.6 tons per year of NO_X and 4.8 tons per year of SO_2.[49]

C.4.7.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at WRSF. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[50]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	2SLB RICE	Cooper Bessemer 12Q155HC2	<June 1982 (1)	4,500 hp
2	2SLB RICE	Cooper Bessemer 12Q155HC2	<June 1982 (1)	4,500 hp

(1) According to EPNG's most recent Title V permit application, the date of manufacture of Units 1 and 2 is unknown but both were constructed/ reconstructed in June 1982. The date of manufacture necessarily precedes the construction/reconstruction date.

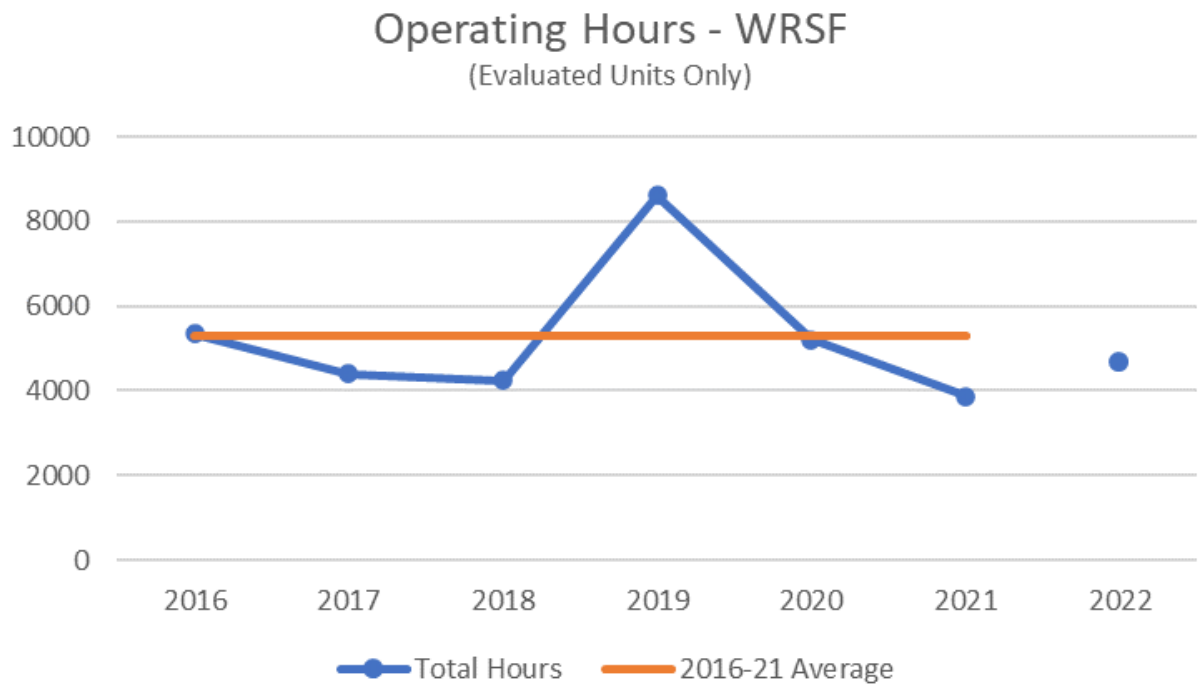
[49] AQB Title V Operating Permit No. P064-R4M2, Table 102.A.

[50] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

C.4.7.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. EPNG did not request a future utilization adjustment for WRSF. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at WRSF.

NMED calculated baseline actual emissions for the emissions units at WRSF by multiplying representative annual operating hours by the NO_X emission rates reported in EPNG's most recent periodic emissions test report(s).[51,] Because the emissions units at WRSF operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[52] Reported and adjusted emission rates for the emissions units at WRSF are summarized below.



Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr at 100% load)
1	5/26/23	6.8	94%	7.3
2	5/26/23	3.9	93%	4.2

To determine representative annual operating hours for the emissions units at WRSF, NMED analyzed 2016-2021 operating hours reported by EPNG pursuant to 20.2.73 NMAC. NMED was in receipt of EPNG's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at WRSF are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
1	2847	2183	2195	4461	2564	1798	2362
2	2502	2212	2054	4153	2647	2076	2323

[51] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[52] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

As shown above, WRSF's year-over-year operating hours have been fairly consistent in recent years save for a transient spike in 2019, and there was no discernible impact from the pandemic in 2020. Therefore, NMED determined that 2016-2021 average operating hours are representative for the emissions units at WRSF.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at WRSF are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
1	7.3	2675	9.7
2	4.2	2607	5.5

C.4.7.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at WRSF:

- SCR, SNCR, and NSCR are not technically feasible options.
- GCP is technically feasible and is currently utilized by EPNG based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option and is already installed on both units, resulting in controlled NO_X emission rates of 0.5 and 0.8 g/hp-hr, respectively. As a result, LEC is not evaluated further.

- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.3 g/hp-hr, consistent with the emissions standards for new natural gas-fired spark ignition lean burn engines in 20.2.50 NMAC.[53]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, EPNG did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and other pollutants).

C.4.7.5 Four-Factor Analysis

In order to determine what control measures are necessary at WRSF to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.7.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[54]

C.4.7.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.7.4 above. NMED utilized source-specific cost estimates provided by EPNG in its calculations whenever possible. In cases where EPNG failed to provide source-specific cost estimates or NMED found estimates provided by EPNG to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[55]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at WRSF are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at WRSF and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
1	Replacement	$1,815,624	5.8	$316,000
2	Replacement	$1,815,624	1.6	$1,136,000

[53] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent replacements for the 2SLB RICE at WRSF would be subject to the NO_X standard for new lean burn engines ≥1,875 bhp (0.3 g/bhp-hr).
[54] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).
[55] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
All Units	Electrification [(1)]	$3,636,702	15.2	$239,000

[(1)] Electrification was evaluated at the station level instead of unit by unit for EPNG's facilities.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at WRSF:

- EPNG provided a company-specific cost of capital (8.53 percent) in its 2/23/20 submittal.
- EPNG provided a Total Capital Investment (TCI) cost metric of $3,227/hp (2020$) for the installation of new, replacement RICE at WRSF. The cost metric was developed by Kinder Morgan's Cost Estimating Group based on its extensive industry experience. NMED reviewed several publicly available resources along with information provided by other companies with similar units that could be used to estimate the TCI of a replacement RICE, and determined that the Kinder Morgan metric was reasonable. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- On 2/14/20, EPNG provided a $1,469/hp ($2020) all-in TCC metric for electrification. On 9/9/20, EPNG provided an alternate cost estimate developed using "the [Kinder Morgan] Cost Estimating Group's Developmental Cost Estimating Tool." The alternate estimate applied an unusual and insufficiently documented methodology that involved a base cost estimate for replacement RICE that was adjusted using EMD-specific costs and RICE-specific costs. Using detailed cost information provided by other facilities, NMED developed a TCC metric of $2,084/hp (2023$) for replacement with EMD. Costs associated with requisite substation and utility line upgrades were estimated separately and added to TCC to estimate TCI for electrification.

C.4.7.5.2 Compliance Time

EPNG did not provide an estimate of the time necessary to replace the units at WRSF. NMED believes the general compliance times for replacement with like-kind natural gas-fired engines or EMD provided in Section C.3.1 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

C.4.7.5.3 Remaining Useful Life

Manufacturers of new RICE will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new RICE are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.7.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE is provided in Section C.3.1.

C.4.7.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.7.2 above. The four statutory factors are discussed in Sections C.4.7.5.1 through C.4.7.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	Replacement	$316,000	3-4	30	None
2	Replacement	$1,136,000	3-4	30	None
All Units	Electrification	$239,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.7.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[56]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA did not identify any cost-effective controls for WRSF Units 1 and 2. Therefore, NMED determined that reasonable progress does not require new controls on either of these units.

C.4.8 Enterprise Field Services – Blanco C&D Compressor Station

Resources used in NMED's FFA for Blanco C & D Compressor Station (BCDCS) include, but are not limited to, the following:

[56] See *supra* note 13.

- The FFA completed by Trinity Consultants for Enterprise Field Services, LLC (Enterprise) and submitted to NMED on 11/14/19.
- Additional information provided by Enterprise on 2/14/20, 2/26/20, 5/19/20, 6/2/20, 9/8/20, 10/1/20, 3/4/21, 8/30/23, and 9/20/24.
- Detailed discussions between Enterprise and NMED on 8/28/20 and 7/13/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.8.1 Facility Description

BCDCS is a natural gas compressor station located 2 miles northeast of Bloomfield in San Juan County, New Mexico at latitude 36° 43' 57", longitude -107° 57' 42". It is owned by Enterprise and operated by Enterprise Products Operating, LLC, and currently operates under Title V Operating Permit No. P218-R3, which expires on October 28, 2025. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 40 miles.

The function of the facility is to compress natural gas for the purpose of transportation to another facility or a major transportation pipeline. The facility is authorized for continuous operation, and its total potential to emit is 1332.6 tons per year of NO_X and 4.0 tons per year of SO_2.[57]

C.4.8.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at BCDCS. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[58]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
T-C01	Turbine	General Electric 5221W	<June 1989 (1)	22,280 hp
T-C02	Turbine	General Electric 5221W	<June 1989 (1)	22,280 hp
T-D01	Turbine	General Electric M5322B	<October 1987 (1)	32,550 hp

(1) According to Enterprise's most recent Title V permit application, the date of manufacture of Units T-C01, T-C02, and T-D01 is unknown but Units T-C01 and T-C02 were constructed/reconstructed prior to June 1989 and Unit T-D01 was constructed/reconstructed prior to October 1987. The date of manufacture necessarily precedes the construction/reconstruction date.

[57] AQB Title V Operating Permit No. P218-R3, Table 401.A.

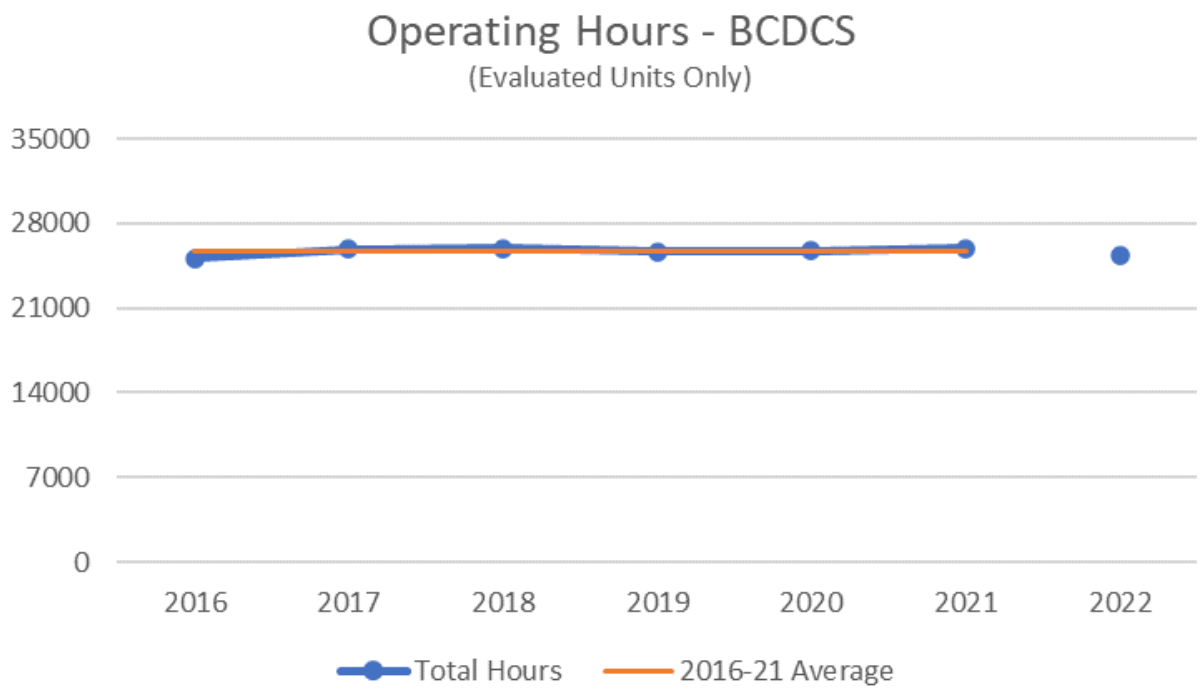
[58] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

C.4.8.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Enterprise did not request a future utilization adjustment for BCDCS. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at BCDCS.

NMED calculated baseline actual emissions for the emissions units at BCDCS by multiplying representative annual operating hours by the NO_X emission rates reported in Enterprise's most recent periodic emissions test report(s).[59,] Because the emissions units at BCDCS operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[60,61] Reported and adjusted emission rates for the emissions units at BCDCS are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
T-C01	10/1/19	65.2	---	65.2
T-C02	10/1/19	66.6	---	66.6
T-D01	10/5/22	66.6	55%	121.1



To determine representative annual operating hours for the emissions units at BCDCS, NMED analyzed 2016-2021 operating hours reported by Enterprise pursuant to 20.2.73 NMAC. NMED was in receipt of Enterprise's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at BCDCS are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
T-C01	8591	8603	8635	8357	8444	8663	8458
T-C02	8505	8644	8692	8760	8634	8663	8442
T-D01	8003	8617	8651	8558	8652	8628	8442

[59] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[60] NMED lacked sufficient test data to adjust emission rates for Units T-C01 and T-C02. Therefore, unadjusted rates were used for these units.

[61] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

As shown above, BCDCS' year-over-year operating hours have been very consistent in recent years, with no discernible impact from the pandemic in 2020. Furthermore, in a detailed discussion with NMED on 7/13/23, Enterprise indicated that it does not expect future utilization of the emissions units at BCDCS to change and that it intends to utilize its assets. Therefore, NMED determined that 2016-2021 average operating hours are representative for these units.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at BCDCS are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
T-C01	65.2	8549	278.9
T-C02	66.6	8650	288.0
T-D01	121.1	8518	515.7

C.4.8.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at BCDCS:

- SNCR and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Enterprise based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)

- DLN is a technically feasible option for Unit T-D01 (DLN technology is not available for GE 5221W turbines comprising Units T-C01 and T-C02) and is expected to achieve a vendor-quoted NO_X emission rate of 35 ppm.[62]
- WSI is a technically feasible option expected to achieve a NO_X emission rate of 42 ppm.[63]
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 9 ppm, consistent with the emission standards for new natural gas-fired combustion turbines in 20.2.50 NMAC.[64]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Enterprise did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

C.4.8.5 Four-Factor Analysis

In order to determine what control measures are necessary at BCDCS to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.8.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[65]

C.4.8.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.8.4 above. NMED utilized source-specific cost estimates provided by Enterprise in its calculations whenever possible. In cases where Enterprise failed to provide source-specific cost estimates or NMED found estimates provided by Enterprise to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[66]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at BCDCS are summarized below. NMED believes these values were calculated using the most representative

[62] Per Enterprise's 8/30/23 submittal.
[63] The target emission rate for WSI is based on information contained in "Cost Analysis of NOx Control Alternatives for Stationary Gas Turbines" (US Department of Energy, 1999).
[64] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for the CT at BCDCS would be subject to the NO_X standard for new CT ≥15,900 bhp (9 ppm).
[65] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).
[66] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at BCDCS and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
T-C01	WSI	$987,001	84.8	$12,000
	SCR	$1,227,378	223.1	$6,000
	Replacement	$8,033,866	237.3	$34,000
	Electrification	$9,798,421	278.9	$35,000
T-C02	WSI	$987,001	114.5	$9,000
	SCR	$1,229,972	230.4	$5,000
	Replacement	$8,033,866	250.8	$32,000
	Electrification	$9,851,325	288.0	$34,000
T-D01	DLN	$862,295	282.3	$3,000
	WSI	$987,001	235.6	$4,000
	SCR	$1,745,604	412.6	$4,000
	Replacement	$11,711,815	455.7	$26,000
	Electrification	$14,315,018	515.7	$28,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at BCDCS:

- Enterprise provided a company-specific cost of capital (10.5 percent) in its 8/30/23 submittal.
- Enterprise estimated the Total Capital Investment (TCI) for DLN using the capital cost factors for gas absorbers in EPA Control Cost Manual Section 5.2, Chapter 1, Table 1.3. Chapter 1 of Section 5.2 of the Control Cost Manual pertains to post-combustion controls for acid gases and is not applicable to pre-combustion controls for NO_X, such as DLN. Therefore, NMED disregarded Enterprise's estimate and utilized the underlying vendor quote provided by Enterprise in its 8/30/23 submittal.
- Enterprise failed to provide supporting documentation for its capital and operating cost estimates for WSI. Therefore, NMED developed its own estimates using cost data for similar-sized turbines provided by the U.S. Department of Energy.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. Enterprise asserted that limited physical space precludes the option of installing SCR and provided an aerial image with measurement overlays to support this assertion. However, the image provided suggests there is physical space for SCR if building modifications are made. To account for the additional capital costs needed to create space, NMED applied an SCR retrofit factor of 1.1 (above average difficulty) in its analysis.
- Enterprise, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of their CT units with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with

information that could be used to estimate the TCI of a replacement CT[67] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.

- Enterprise estimated the TCI for electrification using the capital cost factors for gas absorbers in EPA Control Cost Manual Section 5.2, Chapter 1, Table 1.3. Chapter 1 of Section 5.2 of the Control Cost Manual pertains to post-combustion controls for acid gases and is not applicable to replacement with EMD. Therefore, NMED applied a Total Capital Cost (TCC) metric of $2,084/hp (2023$), which it developed using detailed cost information provided by other facilities, to calculate TCC. The TCI calculated by NMED assumes no costs associated with substation or utility line upgrades because of lack of information. NMED understands that this assumption likely underestimates costs given that Enterprise indicated utility infrastructure upgrades would be needed to support electrification at BCDCS.

C.4.8.5.2 Compliance Time

Enterprise indicated it would take 3-4 years to implement WSI or DLN on the CT at BCDCS. Based on information provided by other facilities and other resources, NMED believes these timeframes are reasonable.

Enterprise did not provide information regarding the time necessary to implement SCR or to replace their CT units with new, functionally equivalent natural gas-fired units. NMED believes the general compliance times for SCR and replacement provided in Section C.3.4 are reasonably accurate.

In its 8/30/23 submittal, Enterprise estimated that electrification would take 5-8 years based on the slow completion of electric utility infrastructure work in the region and anticipated development delays. NMED disagrees with this estimate based on information provided by other facilities and the implementation time of electrification projects at other facilities. NMED believes the general compliance time for electrification, provided in Section C.3.4, is more reasonable but recognizes several more years could be required considering the relative complexity.

C.4.8.5.3 Remaining Useful Life

Despite the age of the units at BCDCS, owners and operators of gas compression equipment in New Mexico have indicated that similar CT would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for DLN. WSI is an exception as Enterprise indicated this control has a useful life of 15 years.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

[67] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.8.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT is provided in Section C.3.4.

C.4.8.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.8.2 above. The four statutory factors are discussed in Sections C.4.8.5.1 through C.4.8.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
T-C01	WSI	$12,000	3-4	15	None
	SCR	$6,000	3-4	20	None
	Replacement	$34,000	3-4	30	None
	Electrification	$35,000	4-6	25	None
T-C02	WSI	$9,000	3-4	15	None
	SCR	$5,000	3-4	20	None
	Replacement	$32,000	3-4	30	None
	Electrification	$34,000	4-6	25	None
T-D01	DLN	$3,000	3-4	20	None
	WSI	$4,000	3-4	15	None
	SCR	$4,000	3-4	20	None
	Replacement	$26,000	3-4	30	None
	Electrification	$28,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.8.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze

Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[68]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for BCDCS Units T-C01, T-C02, and T-D01. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
T-C01	SCR	223.1
T-C02	SCR	230.4
T-D01	SCR	412.6

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
T-C02	WSI	Less stringent than SCR
T-D01	DLN	Less stringent than SCR
T-D01	WSI	Less stringent than SCR

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at BCDCS during the second planning period will be approximately 866.1 ton/yr of NO_X.

C.4.9 Enterprise Field Services - Chaco Gas Plant

Resources used in NMED's FFA for Chaco Gas Plant (CGP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Enterprise Field Services, LLC (Enterprise) and submitted to NMED on 11/14/19.
- Additional information provided by Enterprise on 2/24/20, 9/8/20, 10/1/20, 3/4/21, 3/12/21, 8/30/23, and 9/20/24.
- Detailed discussions between Enterprise and NMED on 8/28/20 and 7/13/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.

[68] See *supra* note 13.

- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.9.1 Facility Description

CGP is a natural gas processing facility located 14 miles southwest of Bloomfield in San Juan County, New Mexico at latitude 36° 29' 00", longitude -108° 07' 13". It is owned by Enterprise and operated by Enterprise Products Operating, LLC, and currently operates under Title V Operating Permit No. P116-R3, which expires on November 13, 2025. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 49.8 miles.

The function of the facility is to receive field natural gas, process the gas through removal of water, then extract/separate natural gas liquids (NGL) through a cryogenic process. Recovered NGL are then treated to remove carbon dioxide and hydrogen sulfide, and then delivered to a pipeline for transport to fractionation facilities downstream. The facility is authorized for continuous operation, and its total potential to emit is 2608.6 tons per year of NO_X and 91.8 tons per year of SO_2.[69]

C.4.9.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at CGP:[70]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
12	2SLB RICE	Clark TLA-10	1966	3,400 hp
13	2SLB RICE	Clark TLA-10	1966	3,400 hp
14	2SLB RICE	Clark TLA-10	1966	3,400 hp
17	Turbine	General Electric Frame 5	1970	19,500 hp
18	Turbine	General Electric Frame 5	1971	19,500 hp
35	Turbine	Solar Mars T-15000	1996	15,000 hp
36	Turbine	Solar Mars T-15000	1996	15,000 hp
37	Turbine	Solar Mars T-15000	1996	15,000 hp

NMED also elected to evaluate the ATS at CGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at CGP consists of an ATU (Unit AM-01), TO (Unit 46), and emergency flare (Unit 44). During normal operations, acid gas exiting the ATU

[69] AQB Title V Operating Permit No. P116-R3, Table 102.A.

[70] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

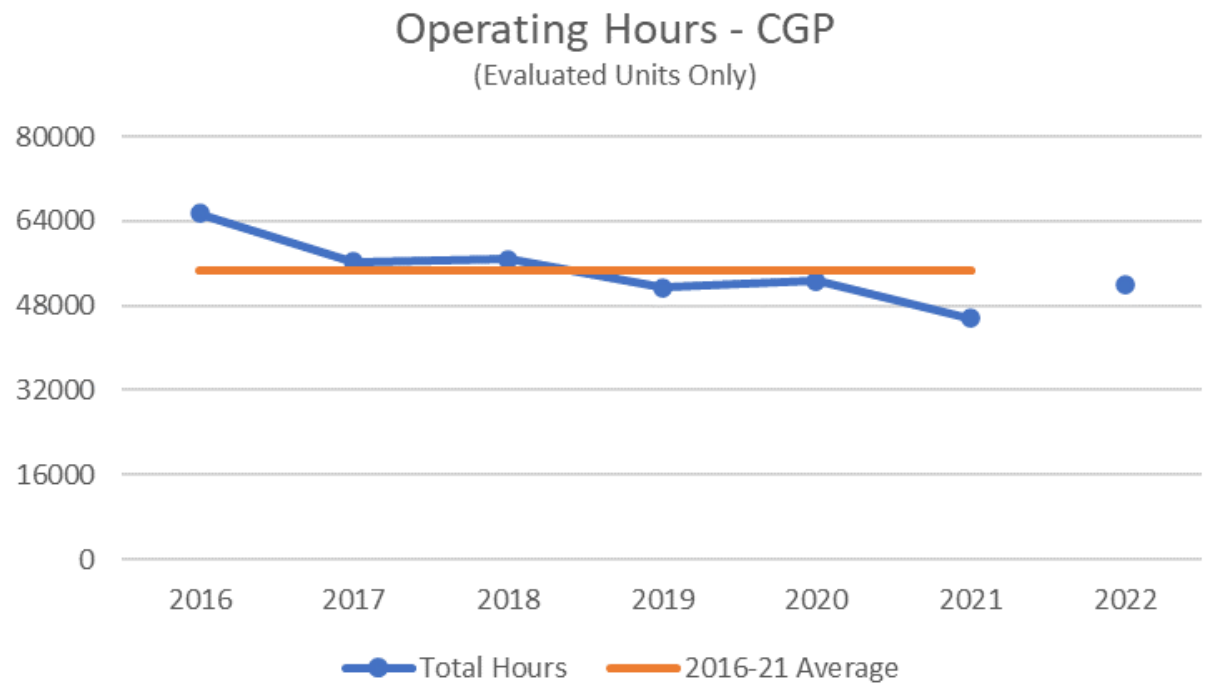
is routed to the TO for disposal. During TO SSM/M events, acid gas is rerouted to the emergency flare for disposal.

C.4.9.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Enterprise did not request a future utilization adjustment for CGP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at CGP.

For the emissions units at CGP requiring a FFA of potential control measures for NO_X ("NO_X units"), NMED calculated baseline actual emissions by multiplying representative annual operating hours by the NO_X emission rates reported in Enterprise's most recent periodic emissions test report(s).[71,] Because the NO_X units at CGP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[72] Reported and adjusted emission rates for the NO_X units at CGP are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
12	8/15/22	27.48	96%	28.63
13	6/22/22	15.33	97%	15.80
14	8/16/22	37.39	98%	38.15
17	8/9/22	17.02	97%	17.55
18	8/9/22	18.38	98%	18.76
35	8/2/22	25.43	97%	26.22
36	8/10/22	29.29	97%	30.20
37	8/10/22	28.49	96%	29.68



To determine representative annual operating hours for the NO_X units at CGP, NMED analyzed 2016-2021 operating hours reported by Enterprise pursuant to 20.2.73 NMAC. NMED was in receipt of Enterprise's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the NO_X units at CGP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
12	7765	8052	7076	6047	6985	1260	6021
13	7815	8171	4871	4313	2793	3756	5850
14	7941	4699	8433	6555	7755	5881	5572

[71] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[72] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
17	8701	8471	8647	8533	8734	8430	8548
18	8680	8531	8518	8682	8715	8665	8393
35	8623	7519	6789	8179	7951	5817	4114
36	8418	4627	4769	3789	6534	8622	8396
37	7497	6240	7703	5391	3202	3187	5206

As shown above, year-over-year operating hours for the NO_X units at CGP have been fairly consistent in recent years, although somewhat higher variability was observed in 2016 and 2021. However, this increased variability was firmly centered around the 2016-2021 average so its effect on the average was negligible, and there was no discernible impact from the pandemic in 2020. Furthermore, in a detailed discussion with NMED on 7/13/23, Enterprise indicated that it does not expect future utilization of the NO_X units at CGP to change and that it intends to utilize its assets. Therefore, NMED determined that 2016-2021 average operating hours are representative for these units.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the NO_X units at CGP are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
12	28.63	6198	88.7
13	15.8	5287	41.8
14	38.15	6877	131.2
17	17.55	8586	75.3

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
18	18.76	8632	80.9
35	26.22	7480	98.0
36	30.20	6127	92.5
37	29.68	5537	82.2

C.4.9.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at CGP:

- SCR, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Enterprise based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted, not-to-exceed NO_X emission rate of 0.5 g/hp-hr.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.3 g/hp-hr, consistent with the emissions standards for new natural gas-fired spark ignition lean burn engines in 20.2.50 NMAC.[73]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Enterprise has not indicated that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and other pollutants).

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at CGP:

- SNCR and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Enterprise based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- DLN is a technically feasible option for Units 35, 36, and 37 (DLN technology is not available for the GE Frame 5 turbines comprising Units 17 and 18) expected to achieve a vendor-quoted NO_X emission rate of 9 ppm.[74]

[73] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent replacements for the 2SLB RICE at CGP would be subject to the NO_X standard for new lean burn engines ≥1,875 bhp (0.3 g/bhp-hr).

[74] Per Enterprise's 9/20/24 submittal, which included a letter from Solar Turbines stating that Solar offers SoLoNOx (DLN) upgrades to 9 ppm NOx for the Mars 100 turbines at CGP and 15 ppm for the Centaur 40 turbines at South Carlsbad Compressor Station.

- WSI is a technically feasible option for Units 17 and 18 (WSI is not available for the Solar Mars turbines comprising Units 35, 36, and 37) expected to achieve a NO_X emission rate of 42 ppm.[75]
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 9 ppm or 15 ppm depending on the unit, consistent with the emissions standards for new natural gas-fired combustion turbines in 20.2.50 NMAC. [76]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Enterprise did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and other pollutants).

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at CGP:

- A flare is a technically feasible option. However, if used as the primary control device, a flare is inferior to all other forms of disposal because most of the H_2S in the acid gas stream (typically 98% or more) is converted to SO_2 and emitted into the atmosphere. Therefore, NMED did not evaluate this option.
- A SRU is a technically feasible option. However, no facility with an ATS evaluated by NMED currently uses a SRU. Many, and possibly all gas processing plants in New Mexico that previously used a SRU have decommissioned them in recent years due to operational concerns and/or compliance issues, some of which resulted in enforcement actions against the facility due to significant excess SO_2 emissions. NMED supports and encourages the transition away from SRUs towards more effective forms of acid gas disposal, such as AGI wells. In addition, NMED is confident that the cost effectiveness of a SRU would exceed its $10,000/ton cost effectiveness threshold, for the same reason it believes an AGI well would exceed the threshold (see explanation below). Therefore, NMED did not evaluate this option.
- A TO is a technically feasible option and is currently used as the primary control device for the ATS at CGP. Therefore, NMED did not evaluate this option.
- The technical feasibility of an AGI well is extremely dependent on the geologic characteristics of the potential well site. Therefore, absent a detailed geologic study, NMED is unable to determine whether an AGI well is technically feasible at CGP. However, even assuming an AGI well is technically feasible, NMED believes it has sufficient information to conclude that it would not be cost effective without performing a full FFA. Gas produced from the San Juan Basin in northwest New Mexico is primarily "sweet" gas containing relatively little H_2S. As a result, the primary purpose of the ATS at CGP is to remove CO_2 from recovered NGL, although small quantities of H_2S are also removed. Given the small quantities of H_2S removed by the ATS, SO_2 emissions from

[75] The target emission rate for WSI is based on information contained "Cost Analysis of NOx Control Alternatives for Stationary Gas Turbines" (US Department of Energy, 1999).

[76] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for Units 17 and 18 would be subject to the NO_X standard for new CT ≥15,900 bhp (9 ppm), while equivalent replacements for Units 35, 36, and 37 would be subject to the NO_X standard for new CT ≥4,000 and <15,900 bhp (15 ppm).

the TO average just 3.6 tons per year.[77] Hence, the potential emissions reductions from installing an AGI well are extremely limited. Considering that the capital costs for an AGI well, two compressors (primary and backup), and related piping can easily exceed $10 million, NMED is confident, given the potential for just a few tons of emissions reductions, that the cost effectiveness of an AGI well would greatly exceed its $10,000/ton cost effectiveness threshold. Therefore, NMED did not evaluate this option.

- While improved flare design might reduce emissions somewhat during TO SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during TO SSM/M events. Therefore, NMED did not evaluate this option.

C.4.9.5 Four-Factor Analysis

In order to determine what control measures are necessary at CGP to make reasonable progress, NMED conducted a FFA of potential control measures for the NO_X units identified in section C.4.9.2 above. NMED did not conduct a FFA of potential control measures for SO_2 for CGP's ATS because alternatives to the existing TO are either inferior, not cost effective, or both. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[78]

C.4.9.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.9.4 above. NMED utilized source-specific cost estimates provided by Enterprise in its calculations whenever possible. In cases where Enterprise failed to provide source-specific cost estimates or NMED found estimates provided by Enterprise to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[79]

NMED's cost effectiveness values for all technically feasible controls for the NO_X units at CGP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the NO_X units at CGP and supporting documentation for NMED's cost estimates are provided in Appendix D.

[77] Based on 2016-2022 emission inventory data.

[78] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[79] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
12	LEC	$946,197	77.1	$12,000
	Replacement	$1,625,013	81.7	$20,000
	Electrification	$1,307,009	88.7	$15,000
13	LEC	$946,197	31.9	$30,000
	Replacement	$1,625,013	35.8	$45,000
	Electrification	$1,234,069	41.8	$30,000
14	LEC	$946,197	118.3	$8,000
	Replacement	$1,625,013	123.5	$13,000
	Electrification	$1,361,441	131.2	$10,000
17	WSI	$987,001	-21.5 (1)	-$46,000 (1)
	SCR	$1,152,663	60.3	$19,000
	Replacement	$7,127,287	54.6	$131,000
	Electrification	$8,592,884	75.3	$114,000
18	WSI	$987,001	-18.1 (1)	-$55,000 (1)
	SCR	$1,166,729	64.8	$18,000
	Replacement	$7,127,287	59.7	$119,000
	Electrification	$8,613,931	80.9	$106,000
35	DLN	$1,033,311	90.4	$11,000
	SCR	$868,469	78.4	$11,000
	Replacement	$5,515,722	85.3	$65,000
	Electrification	$6,219,119	98.0	$63,000
36	DLN	$1,033,311	86.1	$12,000
	SCR	$858,488	74.0	$12,000
	Replacement	$5,515,722	81.8	$67,000
	Electrification	$5,741,137	92.5	$62,000
37	DLN	$1,033,311	76.1	$13,000
	SCR	$852,857	65.7	$13,000
	Replacement	$5,515,722	72.1	$77,000
	Electrification	$5,532,789	82.2	$67,000

(1) Negative estimated reductions and cost effectiveness are an artifact of NMED's methods for calculating these values and do not accurately represent the cost effectiveness of the control or its expected emissions impact. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost effective on their face and are excluded from further consideration.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the NO_X units at CGP:

- Enterprise provided a company-specific cost of capital (10.5 percent) in its 8/30/23 submittal.
- In its 11/14/19 FFA, Enterprise stated that the 2SLB RICE at CGP are currently equipped with LEC. Based on Enterprise's most recent periodic emissions test reports, controlled NO_X emissions from these units range from approximately 2.1 to 5.1 g/hp-hr. However, DCP provided NMED with a vendor cost estimate to retrofit similar 1970s vintage Clark TLA series 2SLB RICE with LEC capable of achieving 0.5 g/hp-hr. Therefore, NMED believes LEC upgrades are feasible for CGP's

RICE. To estimate the costs, NMED used a Total Capital Investment (TCI) metric of $1,525/hp (2021$) developed from the vendor cost estimate provided by DCP.

- The TCI and Incremental Annual Costs for DLN retrofit of Units 35, 36 and 37 were provided by a vendor, Solar Turbines.
- Enterprise failed to provide supporting documentation for its capital and operating cost estimates for WSI. Therefore, NMED developed its own estimates using cost data for similar-sized turbines provided by the U.S. Department of Energy.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. Enterprise asserted that limited physical space precludes the option of installing SCR and provided an aerial image with measurement overlays to support this assertion. However, the image provided suggests there is physical space for SCR if building modifications are made. To account for the additional capital costs needed to create space, NMED applied an SCR retrofit factor of 1.1 (above average difficulty) in its analysis.
- Enterprise, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of their RICE and CT units with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement RICE or CT[80] along with information provided by other companies with similar units. NMED determined that the most applicable cost metrics ($ per hp basis) were provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of these metrics is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- Enterprise estimated the TCI for electrification using the capital cost factors for gas absorbers in EPA Control Cost Manual Section 5.2, Chapter 1, Table 1.3. Chapter 1 of Section 5.2 of the Control Cost Manual pertains to post-combustion controls for acid gases and is not applicable to replacement with EMD. Therefore, NMED applied a Total Capital Cost (TCC) metric of $2,084/hp (2023$), which it developed using detailed cost information provided by other facilities, to calculate TCC. The TCI calculated by NMED assumes no costs associated with substation or utility line upgrades because of lack of information. NMED understands that this assumption likely underestimates costs given that Enterprise indicated utility infrastructure upgrades would be needed to support electrification at CGP.

C.4.9.5.2 Compliance Time

Enterprise did not identify any technically feasible control options for the 2SLB RICE at CGP (other than those already implemented) in its FFA submittal, so it did not provide estimated compliance times for any of the control options NMED has determined are technically feasible. NMED's general assessment of compliance times provided in Section C.3.1 are believed to be reasonably accurate.

Enterprise indicated it would take approximately 3-4 years to implement DLN on CT Units 17 and 18 and approximately 3-4 years to implement WSI on CT Units 35, 36, and 37. Based on information provided by other facilities and other resources, NMED believes these timeframes are reasonable.

[80] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

Enterprise did not provide information regarding the time necessary to implement SCR on their CT units or to replace their RICE and CT units with new, functionally equivalent natural gas-fired units. NMED believes the general compliance times for these control options provided in Sections C.3.1 and C.3.4 are reasonably accurate.

In 8/30/23 correspondence, Enterprise estimated that electrification would take 5-8 years based on the slow completion of electric utility infrastructure work in the region and expected development delays. NMED disagrees with this estimate based on information provided by other facilities and the implementation time of electrification projects at other facilities. NMED believes the general compliance time for electrification, provided in Sections C.3.1 and C.3.4, is more reasonable but recognizes several more years could be required considering the relative complexity.

C.4.9.5.3 Remaining Useful Life

Despite the advanced age of the units at CGP (~30 to 60 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE and CT would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC and DLN. WSI is an exception as Enterprise indicated this control has a useful life of 15 years.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

Manufacturers of new CT and RICE will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT and RICE are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE and replacement CT is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.9.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE and CT is provided in Sections C.3.1 and C.3.4, respectively.

C.4.9.5.5 Summary

NMED performed a FFA for all technically feasible control options for the NO_X units listed in Section C.4.9.2 above. The four statutory factors are discussed in Sections C.4.9.5.1 through C.4.9.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts (1)
12	LEC	$12,000	2-3	20	None
	Replacement	$20,000	3-4	30	None
	Electrification	$15,000	4-6	25	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts (1)
13	LEC	$30,000	2-3	20	None
	Replacement	$45,000	3-4	30	None
	Electrification	$30,000	4-6	25	None
14	LEC	$8,000	2-3	20	None
	Replacement	$13,000	3-4	30	None
	Electrification	$10,000	4-6	25	None
17	WSI	-$46,000	3-4	15	None
	SCR	$19,000	3-4	20	None
	Replacement	$131,000	3-4	30	None
	Electrification	$114,000	4-6	25	None
18	WSI	-$55,000	3-4	15	None
	SCR	$18,000	3-4	20	None
	Replacement	$119,000	3-4	30	None
	Electrification	$106,000	4-6	25	None
35	DLN	$11,000	3-4	20	None
	SCR	$11,000	3-4	20	None
	Replacement	$65,000	3-4	30	None
	Electrification	$63,000	4-6	25	None
36	DLN	$12,000	3-4	20	None
	SCR	$12,000	3-4	20	None
	Replacement	$67,000	3-4	30	None
	Electrification	$62,000	4-6	25	None
37	DLN	$13,000	3-4	20	None
	SCR	$13,000	3-4	20	None
	Replacement	$77,000	3-4	30	None
	Electrification	$67,000	4-6	25	None

(1) Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.9.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze

Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[81]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For NO_X units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For NO_X units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for CGP Unit 14. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
14	LEC	118.3

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
14	Electrification	Categorically excluded

NMED's FFA did not identify any cost-effective controls for CGP Units 12, 13, 17, 18, 35, 36, or 37. Therefore, NMED determined that reasonable progress does not require new controls on any of these units.

As noted above, NMED did not conduct a FFA of potential control measures for CGP's ATS. Because the alternatives to the existing TO are either inferior, presumptively not cost effective, or both, NMED determined that reasonable progress does not require new controls for the ATS.

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at CGP during the second planning period will be approximately 118.3 ton/yr of NO_X.

C.4.10 Enterprise Field Services – South Carlsbad Compressor Station

Resources used in NMED's FFA for South Carlsbad Compressor Station (SCCS) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Enterprise Field Services, LLC (Enterprise) and submitted to NMED on 10/30/19.

[81] See *supra* note 13.

- Additional information provided by Enterprise on 2/13/20, 2/26/20, 3/17/20, 9/8/20, 10/1/20, 3/4/21, 3/12/21, 8/30/23, and 9/20/24.
- Detailed discussions between Enterprise and NMED on 8/28/20 and 7/13/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.10.1 Facility Description

SCCS is a natural gas compressor station located 2.8 miles northwest of Loving in Eddy County, New Mexico at latitude 32° 18' 56", longitude -104° 08' 12". It is owned by Enterprise and operated by Enterprise Products Operating, LLC, and currently operates under Title V Operating Permit No. P130-R4, which expires on June 9, 2028. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 16.2 miles.

The function of the facility is to compress gas to direct to a pipeline for transport. The facility is authorized for continuous operation, and its total potential to emit is 211.3 tons per year of NO_X and 17.0 tons per year of SO_2.[82]

C.4.10.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at SCCS. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[83]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	Turbine	Solar Centaur T-4702	1973	4,328 hp
2	Turbine	Solar Centaur T-4702	1979	4,328 hp

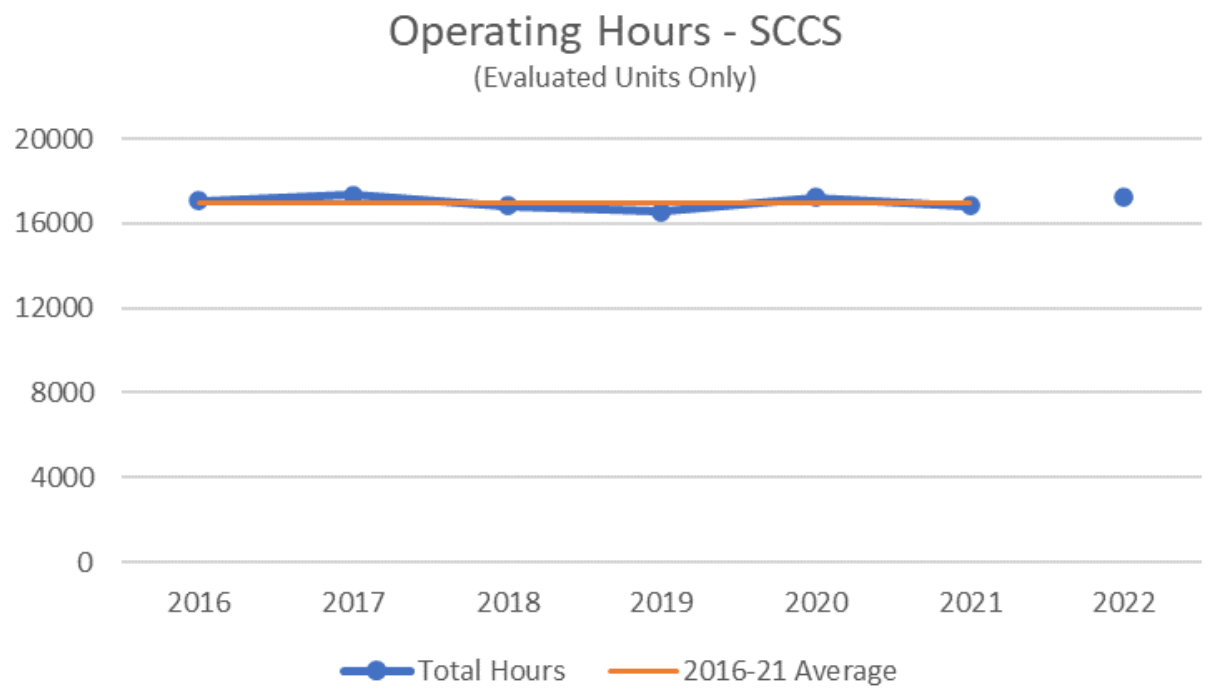
C.4.10.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Enterprise did not request a future utilization adjustment for SCCS. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at SCCS.

[82] AQB Title V Operating Permit No. P130-R4, Table 102.A.

[83] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

NMED calculated baseline actual emissions for the emissions units at SCCS by multiplying representative annual operating hours by the NO_X emission rates reported in Enterprise's most recent periodic emissions test report(s).[84,] Because the emissions units at SCCS operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[85] Reported and adjusted emission rates for the emissions units at SCCS are summarized below.



Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
1	5/17/23	17.6	97%	18.1
2	5/17/23	18.2	100%	18.2

To determine representative annual operating hours for the emissions units at SCCS, NMED analyzed 2016-2021 operating hours reported by Enterprise pursuant to 20.2.73 NMAC. NMED was in receipt of Enterprise's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at SCCS are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
1	8543	8747	8418	8407	8610	8420	8603
2	8544	8611	8415	8171	8639	8424	8634

[84] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[85] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

As shown above, SCCS' year-over-year operating hours have been very consistent in recent years, with no discernible impact from the pandemic in 2020. Furthermore, in a detailed discussion with NMED on 7/13/23, Enterprise indicated that it does not expect future utilization of the emissions units at SCCS to change and that it intends to utilize its assets. Therefore, NMED determined that 2016-2021 average operating hours are representative for these units.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at SCCS are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
1	18.1	8524	77.2
2	18.2	8467	76.9

C.4.10.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at SCCS:

- SNCR and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Enterprise based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- DLN is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 15 ppm.

- WSI is not a technically feasible option. The manufacturer, Solar Turbines, does not support the technology.
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 15 ppm, consistent with the emissions standards for new natural gas-fired combustion turbines in 20.2.50 NMAC.[86]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Enterprise did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

C.4.10.5 Four-Factor Analysis

In order to determine what control measures are necessary at SCCS to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.10.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[87]

C.4.10.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.10.4 above. NMED utilized source-specific cost estimates provided by Enterprise in its calculations whenever possible. In cases where Enterprise failed to provide source-specific cost estimates or NMED found estimates provided by Enterprise to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[88]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at SCCS are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at SCCS and supporting documentation for NMED's cost estimates are provided in Appendix D.

---

[86] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for the CT at SCCS would be subject to the NO_X standard for new CT ≥4,000 and <15,900 bhp (15 ppm).

[87] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[88] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
1	DLN	$263,725	68.0	$4,000
	SCR	$400,268	61.8	$6,000
	Replacement	$1,594,731	68.0	$23,000
	Electrification	$1,900,878	77.2	$25,000
2	DLN	$263,725	67.7	$4,000
	SCR	$400,118	61.5	$7,000
	Replacement	$1,594,731	67.7	$24,000
	Electrification	$1,895,085	76.9	$25,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at SCCS:

- Enterprise provided a company-specific cost of capital (10.5 percent) in its 8/30/23 submittal.
- Enterprise estimated the Total Capital Investment (TCI) for DLN using the capital cost factors for gas absorbers in EPA Control Cost Manual Section 5.2, Chapter 1, Table 1.3. Chapter 1 of Section 5.2 of the Control Cost Manual pertains to post-combustion controls for acid gases and is not applicable to pre-combustion controls for NO_X, such as DLN. Therefore, NMED disregarded Enterprise's estimate and utilized the underlying vendor quote provided by Enterprise in its 8/30/23 submittal. Because this quote specifically excluded installation costs, NMED added installation costs equal to 15 percent of Total Capital Costs (TCC) to its TCI estimate.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. Enterprise asserted that limited physical space precludes the option of installing SCR and provided an aerial image with measurement overlays to support this assertion. However, the image provided suggests there is physical space for SCR if building modifications are made. To account for the additional capital costs needed to create space, NMED applied an SCR retrofit factor of 1.1 (above average difficulty) in its analysis.
- Enterprise, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of their CT units with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement CT[89] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- Enterprise estimated the TCI for electrification using the capital cost factors for gas absorbers in EPA Control Cost Manual Section 5.2, Chapter 1, Table 1.3. Chapter 1 of Section 5.2 of the Control Cost Manual pertains to post-combustion controls for acid gases and is not applicable to replacement with EMD. Therefore, NMED applied a TCC metric of $2,084/hp (2023$), which it developed using detailed cost information provided by other facilities. The Total Capital

[89] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

Investment calculated by NMED assumes no costs associated with substation or utility line upgrades because of lack of information. NMED understands that this assumption likely underestimates costs given that Enterprise indicated utility infrastructure upgrades would be needed to support electrification at SCCS.

C.4.10.5.2 Compliance Time

Enterprise indicated it would take 3-4 years to implement DLN on the CT at SCCS. Based on information provided by other facilities and other resources, NMED believes this timeframe is reasonable.

Enterprise did not provide information regarding the time necessary to implement SCR or to replace their CT units with new, functionally equivalent natural gas-fired units. NMED believes the general compliance times for SCR and replacement provided in Section C.3.4 are reasonably accurate.

In 8/30/23 correspondence, Enterprise estimated that electrification would take 5-8 years based on the slow completion of electric utility infrastructure work in the region and expected development delays. NMED disagrees with this estimate based on information provided by other facilities and the implementation time of electrification projects at other facilities. NMED believes the general compliance time for electrification, provided in Section C.3.4, is more reasonable but recognizes several more years could be required considering the relative complexity.

C.4.10.5.3 Remaining Useful Life

Enterprise indicated that the expected useful life of DLN is 20 years. This is consistent with information provided by similar facilities and FFAs completed in other states.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.10.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT is provided in Section C.3.4.

C.4.10.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.10.2 above. The four statutory factors are discussed in Sections C.4.10.5.1 through C.4.10.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	DLN	$4,000	3-4	20	None
	SCR	$6,000	3-4	20	None
	Replacement	$23,000	3-4	30	None
	Electrification	$25,000	4-6	25	None
2	DLN	$4,000	3-4	20	None
	SCR	$7,000	3-4	20	None
	Replacement	$24,000	3-4	30	None
	Electrification	$25,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration

C.4.10.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[90]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for SCCS Units 1 and 2. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	DLN	68.0
2	DLN	67.7

[90] See *supra* note 13.

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
1	SCR	Less stringent than DLN
2	SCR	Less stringent than DLN

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at SCCS during the second planning period will be approximately 135.7 ton/yr of NO_X.

C.4.11 ET Gathering & Processing – Jal #3 Gas Plant

Jal #3 Gas Plant (JGP) is a natural gas processing facility located 4 miles north-northeast of Jal in Lea County, New Mexico at latitude 32° 10' 25", longitude -103° 10' 27". It is owned and operated by ET Gathering & Processing LLC – formerly ETC Texas Pipeline LTD (ETC) – and currently operates under Title V Operating Permit No. P090-R3M1, which expired on March 27, 2024.[91] The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 70 miles.

JGP was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Section C.2 in 2019. NMED originally selected two 2SLB RICE (Units 4A and 5A) at JGP for an analysis of potential control measures for NO_X in the second planning period. NMED also elected to evaluate the ATS at JGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). At the time, the ATS consisted of gas treating and cryo processing facilities (Units Existing Treater and New Treater), a SRU (Unit SRU) with TO (Unit 9S), an AGI well with two electric compressors, and a treatment flare (Unit 9F). However, due to recent changes at JGP, NMED did not need to perform an analysis for any of these units.

ETC entered into a Settlement Agreement and Stipulated Final Compliance Order (SASFCO) with NMED on August 30, 2021, requiring ETC to shut down JGP's SRU within 60 days. ETC subsequently shut down the SRU on October 8, 2021, and submitted an administrative permit revision shortly thereafter removing it and the associated thermal oxidizer from JGP's NSR permit. ETC then decided to shut down JGP's existing gas treating and cryo processing facilities and install a new ATU (Unit Amine-2). As part of the project, ETC removed 10 compressor engines, including Units 4A and 5A, and installed a tertiary electric compressor for the AGI well to provide backup, redundant compression for the AGI well at all times (before ETC added the third compressor, the two existing compressors could both get overloaded at the same time causing acid gas to be rerouted to treatment flare 9F). These changes are reflected in JGP's current NSR permit (No. 1092-M10R3), and ETC's pending renewal application for Title V Operating Permit No. P090-R3M1 requests that they be incorporated into the facility's Title V permit as well.

EPA guidance provides that a state may forgo a full FFA if a source is already "effectively controlled" and the state can demonstrate why a FFA would not result in new controls and would therefore be a futile

[91] ETC submitted a timely application to renew Title V Operating Permit No. P090-R3M1 in March 2023. At the time of preparation of this technical support document, NMED had not taken final action on the application. Pursuant to 20.2.70.201 NMAC, a Title V source may continue to operate after its operating permit expires if it has submitted a timely renewal application and meets other requirements.

exercise.[92] NMED considers it self-evident that a FFA of potential control measures for retired units at a facility that has been shut down would be futile. There is no more effective control than retirement, which reduces emissions by 100 percent. Therefore, NMED has determined that Units 4A and 5A are effectively controlled by virtue of their retirement due to the shutdown of JGP's former gas treating and cryo processing facilities, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

Regarding the ATS, with the removal of the SRU and TO, all acid gas is now routed to the AGI well for disposal, resulting in no emissions to the atmosphere during normal operations. Flaring emissions are only produced during AGI SSM/M events, which are minimized via the new tertiary, redundant AGI well compressor. As discussed in Section C.3.6, the use of an AGI well with redundant compression is an optimal approach to reducing emissions from an ATS. Because JGP now utilizes this approach, NMED determined that reasonable progress does not require new controls for the ATS.

Based on when ETC shut down JGP's old gas treating and cryo processing facilities, shut down the SRU and TO, and added redundant compression to the AGI well, the emissions reductions resulting from the retirement of the affected units were realized during the second planning period. Therefore, NMED estimated the NO_X emissions reductions resulting from the retirement of Units 4A and 5A and the SO_2 emissions reductions resulting from the shutdown of the SRU and TO by averaging 2016-2020 emissions reported by DCP pursuant to 20.2.73 NMAC.[93] These emissions are summarized below.

Pollutant	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	2020 Emissions (tons)	2021 Emissions (tons)	Average Emissions (ton/yr)
NO_X	33.1	31.8	6.7	18.9	49.4	10.7	25.1
SO_2	143.6	111.3	423.8	208.6	17.9	21.2	154.4

C.4.12 Transwestern Pipeline Company – Mountainair Compressor Station No. 7

Resources used in NMED's FFA for Mountainair Compressor Station No. 7 (MCS) include, but are not limited to, the following:

- The FFA completed by GHD Services, Inc. for Transwestern Pipeline Company, LLC (TWP) and submitted to NMED on 10/30/19.
- Additional information provided by TWP on 01/23/20, 9/10/20, 3/25/21, and 8/11/23.
- Detailed discussions between TWP and NMED on 7/11/23 and 7/21/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).

[92] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021) at 5.

[93] NMED did not have sufficient information to estimate the SO_2 reductions resulting from the addition of redundant compression to JGP's AGI well.

- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.12.1 Facility Description

MCS is a natural gas compressor station located 12 miles south-southwest of Mountainair in Torrance County, New Mexico at latitude 34° 20' 29", longitude -106° 17' 51". It is owned and operated by TWP and currently operates under Title V Operating Permit No. P153-R4, which expires on October 14, 2025. The shortest distance to the boundary of the nearest Class I Area, Bosque del Apache Wilderness Area, is approximately 50 miles.

The facility services a natural gas pipeline system, removing small amounts of entrained liquid from the gas stream before directing it back into the pipeline at a higher pressure. The facility is authorized for continuous operation, and its total potential to emit is 2263.5 tons per year of NO_X.[94]

C.4.12.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at MCS. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[95]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
701	4SLB RICE	Cooper Bessemer LSV-16SG	<1960 (1)	4,500 hp
702	4SLB RICE	Cooper Bessemer LSV-16SG	<1960 (1)	4,500 hp
703	4SLB RICE	Cooper Bessemer LSV-16SG	<1967 (1)	4,500 hp
721	4SRB RICE	Ingersoll Rand PSVG-6	<1960 (1)	335 hp
722	4SRB RICE	Ingersoll Rand PSVG-6	<1960 (1)	335 hp

(1) TWP's most recent Title V permit application does not provide the date of manufacture for any of the units at MCS but does indicate that Units 701, 702, 721, and 722 were constructed/reconstructed in 1960 and Unit 703 was constructed/reconstructed in 1967. The date of manufacture necessarily precedes the construction/reconstruction date.

C.4.12.3 Projected Actual Emissions

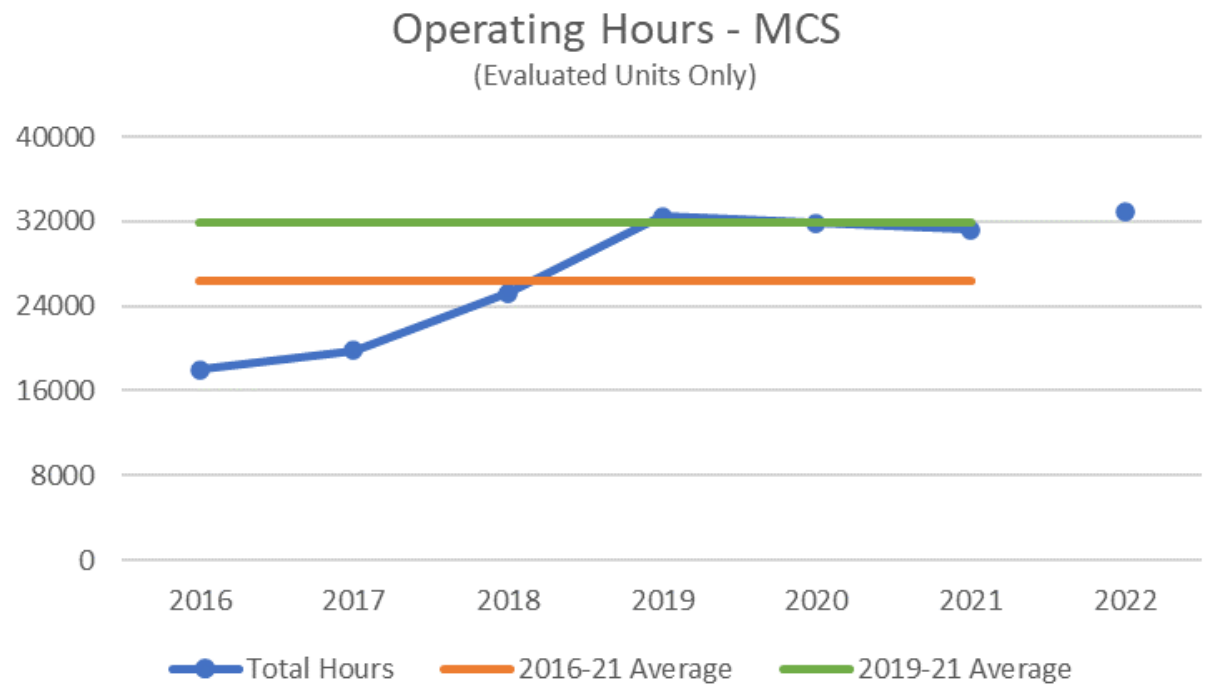
Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. TWP did not request a future utilization adjustment for MCS. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at MCS.

NMED calculated baseline actual emissions for the emissions units at MCS by multiplying representative annual operating hours by the NO_X emission rates reported in TWP's most recent periodic emissions test

[94] AQB Title V Operating Permit No. P153-R4, Table 102.A.

[95] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

report(s).[96,] Because the emissions units at MCS operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[97] Reported and adjusted emission rates for the emissions units at MCS are summarized below.



Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr at 100% load)
701	11/8/22	88.9	87%	102.5
702	11/8/22	103.2	88%	116.8
703	11/8/22	95.7	88%	108.4
721	11/8/22	14.1	59%	23.8
722	11/9/22	3.7	58%	6.3

To determine representative annual operating hours for the emissions units at MCS, NMED analyzed 2016-2021 operating hours reported by TWP pursuant to 20.2.73 NMAC. NMED was in receipt of TWP's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at MCS are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
701	1535	2278	5188	7084	7296	7553	8347
702	3116	3046	4615	8491	7572	7607	7352
703	4586	5713	6697	8189	8208	7312	8400
721	3932	2606	4408	1475	1180	28	6034
722	4860	6157	4356	7294	7609	8710	2742

[96] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[97] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

As shown above, MCP's operating hours increased steadily from 2016-2019, then stabilized in 2019 and have been very consistent for the past few years. At a meeting with NMED on 7/11/23, TWP indicated that the recent increase in utilization is due to higher gas volumes and that it expects demand and utilization to remain high "for the foreseeable future." Therefore, NMED determined that 2019-2021 average operating hours are representative for Units 701, 702, and 703. Units 721 and 722 are primary generators (the facility is not connected to an electric utility); per TWP they do not operate simultaneously but one is always in operation. Therefore, they effectively operate as a system, and NMED evaluated them collectively by assuming full time system operation and averaging their emissions.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at MCS are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
701	102.5	7311	374.4
702	116.8	7980	460.7
703	108.4	7903	428.2
721 & 722	15.1	8760	66.0

C.4.12.4 Technical Feasibility of Available Controls

The following determinations were made regarding the technical feasibility of identified control options for the 4SLB RICE at MCS:

- SNCR and NSCR are not technically feasible options for the same reasons those controls are not feasible for 2SLB RICE.

- GCP is a technically feasible option and is currently utilized by TWP based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 2.5 g/hp-hr.
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected to reduce facility-wide NO_X emissions by 1,284.5 ton/yr, a 97 percent reduction. More information on the replacement scenario evaluated by TWP is provided in Section C.4.12.5.1 below.
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, TWP did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and other pollutants).

The following determinations were made regarding the technical feasibility of identified control options for the 4SRB RICE at MCS:

- SCR is not a technically feasible option because the chemical reactions will not occur in an environment with excess oxygen.
- SNCR is not a technically feasible option because the exhaust temperature of the units is too low.
- Electrification is not a technically feasible option because the units are used to generate electricity for the facility.
- NSCR is a technically feasible option and is already installed on both units. As a result, NSCR is not evaluated further.
- GCP is a technically feasible option and is currently utilized by TWP based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 2.5 g/hp-hr.
- Unit replacement is a technically feasible option expected to reduce facility-wide NO_X emissions by 1,284.5 ton/yr, a 97 percent reduction. More information on the replacement scenario evaluated by TWP is provided in Section C.4.12.5.1 below.
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, TWP did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.

C.4.12.5 Four-Factor Analysis

In order to determine what control measures are necessary at MCS to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.12.2 above. States are required to consider four statutory factors – cost of compliance, time

necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[98]

C.4.12.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.12.4 above. NMED utilized source-specific cost estimates provided by TWP in its calculations whenever possible. In cases where TWP failed to provide source-specific cost estimates or NMED found estimates provided by TWP to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[99]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at MCS are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at MCS and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
701	LEC	$752,925	284.0	$3,000
	SCR	$357,254	299.7	$1,000
702	LEC	$752,925	362.8	$2,000
	SCR	$371,922	368.5	$1,000
703	LEC	$752,925	330.2	$2,000
	SCR	$349,859	342.5	$1,000
721	LEC	$56,051	48.1	$1,000
722	LEC	$56,051	9.8	$6,000
All Units	Replacement	$3,384,865	1284.5	$3,000
	Electrification	$9,341,163	1329.5	$7,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at MCS:

- The bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor. TWP indicated that the prime rate is appropriate for the purposes of NMED's analysis in its 8/11/23 submittal.

[98] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[99] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

- The Total Capital Investment (TCI) of a 2SLB RICE LEC retrofit was provided by TWP based on a detailed cost estimate provided by a vendor. NMED estimated the TCI of a 4SRB RICE LEC retrofit using the 2SLB estimate scaled by engine power rating.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, which appears to be consistent with the SCR evaluations provided in TWP's initial FFA.
- TWP indicated that replacing the 2SLB RICE with CT would be preferable to replacing them with new RICE. Therefore, instead of evaluating replacing Units 701, 702, and 703 with like-kind units, NMED evaluated replacing them with two functionally equivalent CT using detailed capital and O&M cost information provided by TWP. TWP indicated that this would also require replacing Units 721 and 722 with microturbine generators to meet the new demand and reliability requirements associated with the installation of CT but did not provide any cost information for new generators. Therefore, NMED estimated these costs using EPA's Catalog of CHP Technologies, Section 5. Technology Characterization – Microturbines (March 2015).
- TWP provided detailed capital and O&M cost information for the electrification of Units 701, 702, and 703. TWP indicated that electrifying MCS would also require a new substation and at least 8 miles of new transmission line to connect to the local utility but did not provide any cost information for these upgrades due to its inability to obtain estimates from the utility. Therefore, NMED estimated these costs using information provided by other facilities.

C.4.12.5.2 Compliance Time

TWP indicated it would take 2-5 years to implement LEC or SCR at the facility. This estimate is consistent with NMED's general assessment of compliance times and thus believed to be reasonably accurate.

TWP did not provide information regarding the time necessary to replace their RICE units with CT as described above. NMED believes the general compliance time for replacement, provided in Section C.3.4, is reasonable but recognizes additional time could be required considering the inability of the facility to take Units 701, 702, and 703 out of service for the replacement,[100] and thus the need to build new facilities and infrastructure within the station and switch over operation once construction is complete.

TWP did not provide information regarding the time necessary for electrification. NMED believes the general compliance time for electrification, provided in Section C.3.4, is reasonable but recognizes several more years could be required considering the inability of the facility to take the existing units out of service for the replacement and the relative complexity of the needed utility upgrades.

C.4.12.5.3 Remaining Useful Life

Despite the advanced age of the units at MCS (~50 to 60 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

[100] In its 8/11/23 submittal, TWP indicated that current firm shipping contracts require full utilization of compression horsepower at MCS.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.12.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 4SLB RICE and 4SRB RICE is provided in Sections C.3.2 and C.3.3, respectively.

C.4.12.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.12.2 above. The four statutory factors are discussed in Sections C.4.12.5.1 through C.4.12.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
701	LEC	$3,000	2-5	20	None
	SCR	$1,000	2-5	20	None
702	LEC	$2,000	2-5	20	None
	SCR	$1,000	2-5	20	None
703	LEC	$2,000	2-5	20	None
	SCR	$1,000	2-5	20	None
721	LEC	$1,000	2-5	20	None
722	LEC	$6,000	2-5	20	None
All Units	Replacement	$3,000	3-4	30	None
	Electrification	$7,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.12.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze

Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[101]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for MCS Units 701, 702, 703, 721, and 722. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
701	Replacement	362.0
702	Replacement	445.1
703	Replacement	413.7
721	Replacement	50.3
722	Replacement	13.4

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
701	LEC	Less stringent than replacement
701	SCR	Less stringent than replacement
701	Electrification	Categorically excluded
702	LEC	Less stringent than replacement
702	SCR	Less stringent than replacement
702	Electrification	Categorically excluded
703	LEC	Less stringent than replacement
703	SCR	Less stringent than replacement
703	Electrification	Categorically excluded
721	LEC	Less stringent than replacement
722	LEC	Less stringent than replacement

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at MCS during the second planning period will be approximately 1,284.5 ton/yr of NO_X.

[101] See *supra* note 13.

C.4.13 Transwestern Pipeline Company – Roswell Compressor Station No. 9

Resources used in NMED's FFA for Roswell Compressor Station No. 9 (RCS) include, but are not limited to, the following:

- The FFA completed by GHD Services, Inc. for Transwestern Pipeline Company, LLC (TWP) and submitted to NMED on 10/30/19.
- Additional information provided by TWP on 01/23/20, 09/10/20, 3/25/21, and 8/11/23.
- Detailed discussions between TWP and NMED on 7/11/23 and 7/21/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.13.1 Facility Description

RCS is a natural gas compressor station located 5 miles north of Roswell in Chaves County, New Mexico at latitude 33° 30' 37", longitude -104° 31' 08". It is owned and operated by TWP and currently operates under Title V Operating Permit No. P154-R4, which expired on September 28, 2023.[102] The shortest distance to the boundary of the nearest Class I Area, Salt Creek Wilderness Area, is approximately 5.6 miles. Notably, Salt Creek Wilderness Area is the only Class I Area in New Mexico projected to be above the URP glidepath in 2028 and for which a robust demonstration is required.[103]

The facility services a natural gas pipeline system, removing small amounts of entrained liquid from the gas stream before directing it back into the pipeline at a higher pressure. The facility is authorized for continuous operation, and its total potential to emit is 1122.5 tons per year of NO_X and 0.8 tons per year of SO_2.[104]

C.4.13.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at RCS. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[105]

---

[102] Transwestern Pipeline Company, LLC submitted a timely application to renew Title V Operating Permit No. P154-R4 in September 2022. At the time of preparation of this technical support document, NMED had not taken final action on the application. Pursuant to 20.2.70.201 NMAC, a Title V source may continue to operate after its operating permit expires if it has submitted a timely renewal application and meets other requirements.

[103] See Chapter 10, Progress, Degradation, and URP Glidepath Checks for Class I Areas in New Mexico, for NMED's robust demonstration for Salt Creek Wilderness Area.

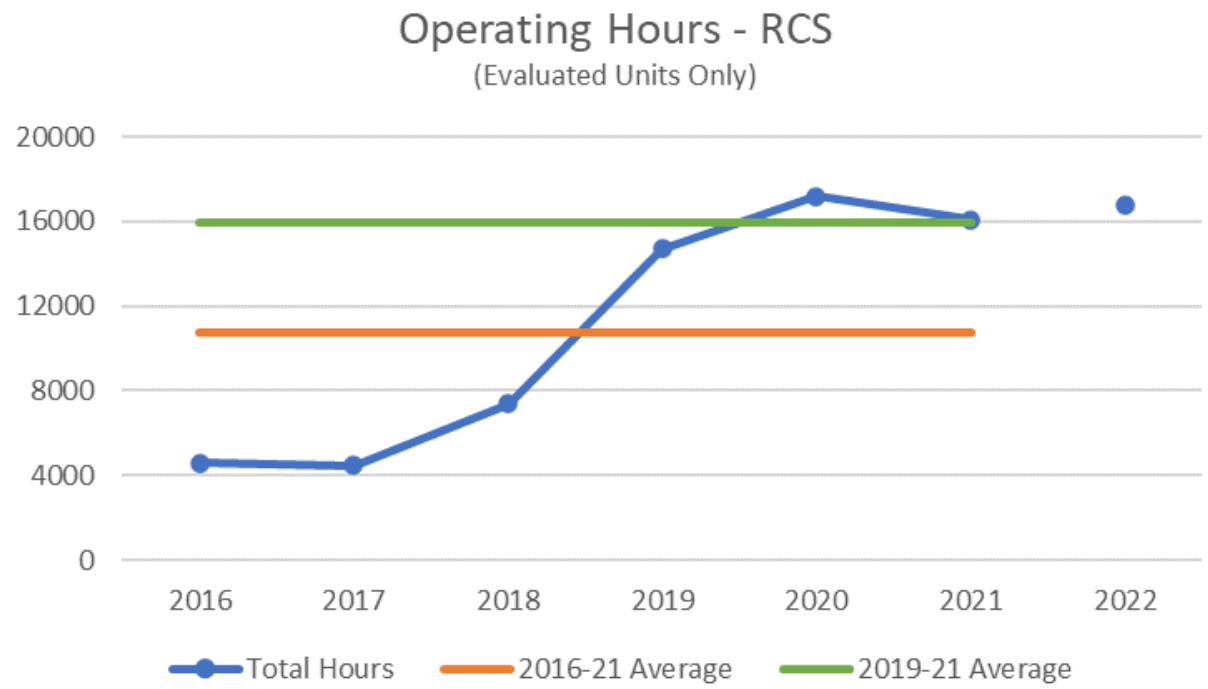
[104] AQB Title V Operating Permit No. P154-R4, Table 102.A.

[105] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
903	4SLB RICE	Cooper Bessemer LSV-16SSG	1959	4,500 hp
904	4SLB RICE	Cooper Bessemer LSV-16SSG	1959	4,500 hp

C.4.13.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. TWP did not request a future utilization adjustment for RCS. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at RCS.



NMED calculated baseline actual emissions for the emissions units at RCS by multiplying representative annual operating hours by the NO_X emission rates reported in TWP's most recent periodic emissions test report(s).[106,] Because the emissions units at RCS operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[107] Reported and adjusted emission rates for the emissions units at RCS are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr at 100% load)
903	2/27/23	106.1	95%	111.3
904	2/27/23	53.4	97%	54.8

To determine representative annual operating hours for the emissions units at RCS, NMED analyzed 2016-2021 operating hours reported by TWP pursuant to 20.2.73 NMAC. NMED was in receipt of TWP's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the emissions units at RCS are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
903	3607	3220	6343	8079	8696	8217	8303
904	971	1231	1049	6652	8490	7843	8476

[106] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.
[107] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

As shown above, RCS's operating hours increased steadily from 2016-2019, then remained fairly consistent from 2019-2021. At a meeting with NMED on 7/11/23, TWP indicated that the recent increase in utilization is due to higher gas volumes and that it expects demand and utilization to remain high "for the foreseeable future." Therefore, NMED determined that 2019-2021 average operating hours are representative for the emissions units at RCS.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at RCS are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
903	111.3	8331	463.7
904	54.8	7662	210.0

C.4.13.4 Technical Feasibility of Available Controls

The following determinations were made regarding the technical feasibility of identified control options for the 4SLB RICE at RCS:

- SNCR and NSCR are not technically feasible options for the same reasons those controls are not feasible for 2SLB RICE.
- GCP is a technically feasible option and is currently utilized by TWP based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 2.5 g/hp-hr.

- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected to reduce facility-wide NO_X emissions by 644.6 ton/yr, a 96 percent reduction. More information on the replacement scenario evaluated by TWP is provided in Section C.4.13.5.1 below.
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, TWP did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

C.4.13.5 Four-Factor Analysis

In order to determine what control measures are necessary at RCS to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.13.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[108]

C.4.13.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.13.4 above. NMED utilized source-specific cost estimates provided by TWP in its calculations whenever possible. In cases where TWP failed to provide source-specific cost estimates or NMED found estimates provided by TWP to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[109]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at RCS are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at RCS and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
903	LEC	$693,810	360.3	$2,000
	SCR	$339,730	370.9	$1,000
904	LEC	$693,810	115.0	$6,000

[108] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[109] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
	SCR	$306,279	168.0	$2,000
All Units	Replacement	$2,231,087	644.6	$3,000
	Electrification	$6,272,562	673.7	$9,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at RCS:

- The bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor. TWP indicated that the prime rate is appropriate for the purposes of NMED's analysis in its 8/11/23 submittal.
- The Total Capital Investment (TCI) of a LEC retrofit was provided by TWP based on a detailed cost estimate provided by a vendor.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, which appears to be consistent with the SCR evaluations provided in TWP's initial FFA.
- TWP indicated that replacing the 4SLB RICE with CT would be preferable to replacing them with new RICE. Therefore, instead of evaluating replacing Units 903 and 904 with like-kind units, NMED evaluated replacing them with a functionally equivalent CT using detailed capital and O&M cost information provided by TWP.
- TWP provided detailed capital and O&M cost information for the electrification of Units 903 and 904. TWP indicated that electrifying RCS would also require substation and transmission line upgrades but did not provide any cost information for these upgrades due to its inability to obtain estimates from the utility. Therefore, NMED estimated these costs using information provided by other facilities.

C.4.13.5.2 Compliance Time

TWP indicated it would take 2-5 years to implement LEC or SCR at the facility. This estimate is consistent with NMED's general assessment of compliance times and thus believed to be reasonably accurate.

TWP did not provide information regarding the time necessary to replace their RICE units with a CT as described above. NMED believes the general compliance time for replacement, provided in Section C.3.4, is reasonable but recognizes additional time could be required considering the inability of the facility to take Units 903 and 904 out of service for the replacement,[110] and thus the need to build new facilities and infrastructure within the station and switch over operation once construction is complete.

TWP did not provide information regarding the time necessary for electrification. NMED believes the general compliance time for electrification, provided in Section C.3.4, is reasonable but recognizes several more years could be required considering the inability of the facility to take the existing units out of service for the replacement and the relative complexity of the needed utility upgrades.

[110] In its 8/11/23 submittal, TWP indicated that current firm shipping contracts require full utilization of compression horsepower at RCS.

C.4.13.5.3 Remaining Useful Life

Despite the advanced age of the units at RCS (~60 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.13.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 4SLB RICE is provided in Section C.3.2.

C.4.13.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.13.2 above. The four statutory factors are discussed in Sections C.4.13.5.1 through C.4.13.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
903	LEC	$2,000	2-5	20	None
	SCR	$1,000	2-5	20	None
904	LEC	$6,000	2-5	20	None
	SCR	$2,000	2-5	20	None
All Units	Replacement	$3,000	3-4	30	None
	Electrification	$9,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.13.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making

reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[111]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for RCS Units 903 and 904. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
903	Replacement	443.7
904	Replacement	201.0

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
903	LEC	Less stringent than replacement
903	SCR	Less stringent than replacement
903	Electrification	Categorically excluded
904	LEC	Less stringent than replacement
904	SCR	Less stringent than replacement
904	Electrification	Categorically excluded

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at RCS during the second planning period will be approximately 644.7 ton/yr of NO_X.

C.4.14 Harvest Four Corners – Kutz Canyon Processing Plant

Resources used in NMED's FFA for Kutz Canyon Processing Plant (KCPP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Harvest Four Corners, LLC (Harvest) and submitted to NMED on or about 11/1/19.

[111] See *supra* note 13.

- Additional information provided by Harvest on 12/13/19, 3/2/20, 10/23/20, 2/26/21, 8/28/23, 2/22/24, and 3/27/24.
- Detailed discussions between Harvest and NMED, most recently on 7/11/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.14.1 Facility Description

KCPP is a natural gas processing facility located approximately 3.5 miles south of Bloomfield in San Juan County, New Mexico at latitude 36° 40' 11", longitude -107° 57' 42". It is owned and operated by Harvest and currently operates under Title V Operating Permit No. P097-R4, which expires on January 3, 2028. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 43.2 miles.

The function of the facility is to remove ethane and heavier hydrocarbons from natural gas through refrigerating lean oil absorption and cryogenic processes. The facility is authorized for continuous operation, and its total potential to emit is 603.3 tons per year of NO_X and 1.4 tons per year of SO_2.[112]

C.4.14.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at KCPP. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[113]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	Turbine	Solar Centaur 40	7/1/1975	3,692 hp
2	Turbine	Solar Centaur 40	7/1/1975	3,692 hp
3	Turbine	Solar Centaur 40	7/1/1975	3,692 hp
4	Turbine	Solar Centaur 40	7/1/1975	3,692 hp
5	Turbine	Solar Centaur 40	10/1/1975	3,692 hp
6	Turbine	Solar Centaur 40	10/1/1975	3,692 hp
16	4SRB RICE	Clark HRA-8	<1973	723 hp
17	4SRB RICE	Clark HRA-8	<1973	723 hp
18	4SRB RICE	Clark HRA-8	<1973	723 hp

[112] AQB Title V Operating Permit No. P097-R4, Table 102.A.

[113] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
19	Turbine	Solar Centaur 40	6/1/1981	2,907 hp
20	Turbine	Solar Centaur 40	7/1/1981	2,907 hp

After it submitted its FFA in November 2019, Harvest retired Units 16, 17 and 18 and removed them from KCPP's NSR permit. Therefore, NMED did not evaluate these units.

C.4.14.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Harvest did not request a future utilization adjustment for KCPP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at KCPP.

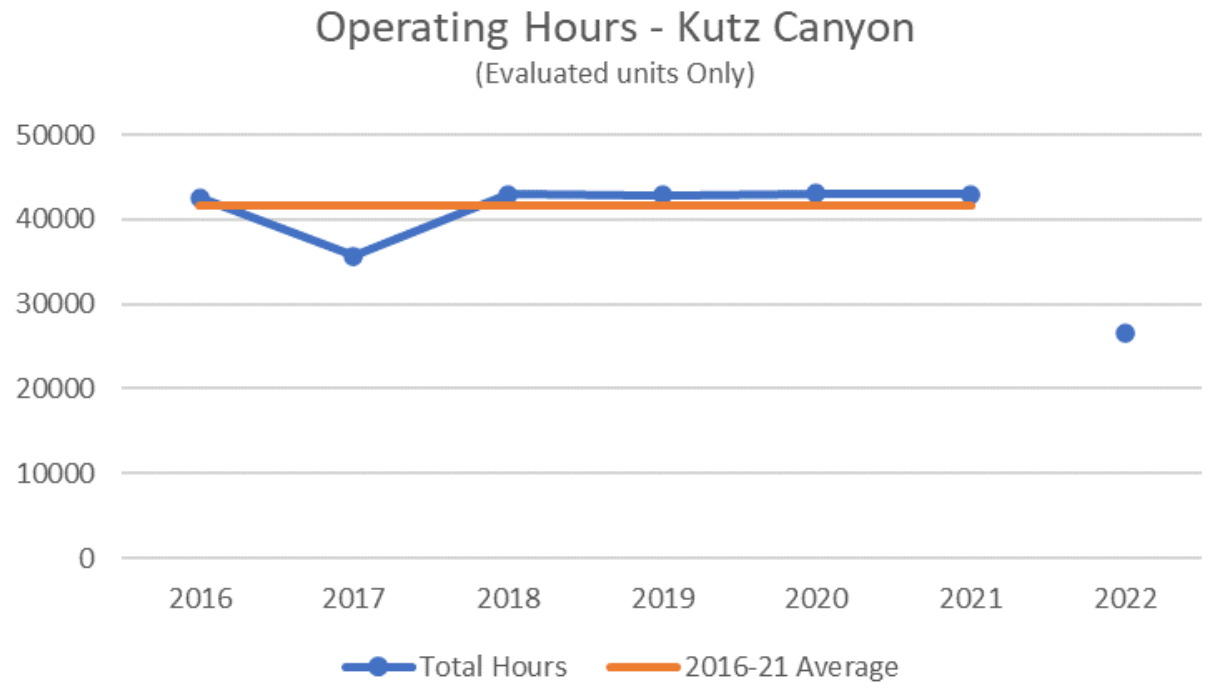
NMED calculated baseline actual emissions for the emissions units at KCPP by multiplying representative annual operating hours by the NO_X emission rates reported in Harvest's most recent periodic emissions test report(s).[114,] Because the emissions units at KCPP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[115] Reported and adjusted emission rates for the emissions units at KCPP are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
1	6/20/23	13.36	80%	16.7
2	6/20/23	14.15	80%	17.7
3	6/22/23	9.80	78%	12.6
4	NA (1)	---	---	14.1 (2)
5	5/26/22	11.66	98%	11.9
6	5/26/22	11.53	98%	11.8
19	6/22/23	4.56	9%	15.6 (3)
20	6/22/23	4.04	10%	15.6 (3)

(1) NA = Not Available

(2) The average adjusted emissions of identical Units 1-3 and 5-6 were used as a surrogate for Unit 4, as NMED was unable to locate a recent emissions test report for this unit.

(3) The most recent testing of Units 19 and 20 was conducted at very low load. Therefore, instead of adjusting reported emissions to 100 percent load based on an assumed linear relationship between emissions and load, NMED used a surrogate emission factor based on the heat input capacity (MMBtu/hr) of these units and a vendor-provided emission rate expressed in lb/MMBtu.



To determine representative annual operating hours for the emissions units at KCPP, NMED analyzed 2016-2021 operating hours reported by Harvest pursuant to 20.2.73 NMAC. NMED was in receipt of Harvest's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-

[114] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[115] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

2021 operating hours for the emissions units at KCPP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
1	5616	6784	8418	7711	6724	6389	7096
2	5228	5131	5550	6020	5048	5271	7858
3	6360	5910	2937	3917	5882	6042	2975
4	694	649	927	0	0	0	0
5	7479	718	8368	8298	8606	8076	0
6	8397	7752	8020	8128	8581	8463	0
19	2639	3774	6989	6513	4943	4016	4504
20	6172	5009	1777	2265	3333	4748	4257

As shown above, KCPP's year-over-year operating hours have been very consistent in recent years, with no discernible impact from the pandemic in 2020. 2017 was an anomaly due to a roughly 90 percent drop in operating hours for Unit 5. However, NMED suspects this may have been a reporting error, and in any event, operating hours for Unit 5 rebounded the following year and have remained steady ever since. Therefore, NMED determined that 2016-2021 average operating hours are representative for the emissions units at KCPP.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at KCPP are summarized below.

Unit No.	Adjusted Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual Emissions (ton/yr)
1	16.7	6940	58.0
2	17.7	5375	47.5
3	12.6	5175	32.5
4	14.1	6257 [(1)]	46.1
5	11.9	6924	41.2
6	11.8	8224	48.4
19	15.6	4812	37.6
20	15.6	3884	30.3

[(1)] Unit 4 has not operated since 2018, skewing its 2016-21 average operating hours. Therefore, the average 2016-21 average operating hours of identical Units 1, 2, 3, 5, and 6 were used as a surrogate for Unit 4.

C.4.14.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at KCPP:

- WSI, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Harvest based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- DLN is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 25 ppm.
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option. Because a DLN retrofit option is available for the make and model of CT comprising the existing units, it is assumed that DLN would be available on equivalent replacements. Therefore, replacement is expected to achieve a NO_X emission rate of 25 ppm, consistent with manufacturer specifications for similar, new CT equipped with DLN.
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Harvest did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

C.4.14.5 Four-Factor Analysis

In order to determine what control measures are necessary at KCPP to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.14.2 above. States are required to consider four statutory factors – cost of compliance, time

necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[116]

C.4.14.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.14.4 above. NMED utilized source-specific cost estimates provided by Harvest in its calculations whenever possible. In cases where Harvest failed to provide source-specific cost estimates or NMED found estimates provided by Harvest to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[117]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at KCPP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at KCPP and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
1	SCR	$294,770	46.4	$6,000
	DLN	$235,465	41.3	$6,000
	Replacement	$1,109,121	41.3	$27,000
2	SCR	$290,003	38.0	$8,000
	DLN	$228,625	33.4	$7,000
	Replacement	$1,109,121	33.4	$33,000
3	SCR	$287,133	26.0	$11,000
	DLN	$228,625	20.5	$11,000
	Replacement	$1,109,121	20.5	$54,000
4	SCR	$292,031	36.9	$8,000
	DLN	$228,625	29.0	$8,000
	Replacement	$1,109,121	29.0	$38,000
5	SCR	$292,033	33.0	$9,000
	DLN	$228,625	24.9	$9,000
	Replacement	$1,109,121	24.9	$45,000
6	SCR	$295,792	38.7	$8,000
	DLN	$228,625	14.7	$16,000

[116] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[117] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
	Replacement	$1,109,121	14.7	$76,000
19	SCR	$246,303	30.1	$8,000
	DLN	$234,892	23.7	$10,000
	Replacement	$885,804	23.7	$37,000
20	SCR	$243,698	24.3	$10,000
	DLN	$229,425	19.1	$12,000
	Replacement	$885,804	19.1	$46,000
All Units	Electrification	$6,094,068	341.6	$18,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at KCPP:

- Harvest provided a company-specific cost of capital (7.5 percent) in its 8/28/23 submittal.
- Harvest provided an estimate of the Total Capital Investment (TCI) and Incremental Annual O&M Costs (OMC) associated with electrification in its 10/23/20 submittal. That estimate included approximately $20M for a new electric substation.
- According to Harvest, the TCI and Incremental Annual Costs for DLN were based on information provided by a vendor, Solar Turbines.
- Harvest asserted there is insufficient space to accommodate SCR at KCPP. However, Harvest did not provide sufficient documentation in support of this assertion, so NMED evaluated the cost effectiveness of SCR. The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, due to a lack of information from Harvest supporting a higher retrofit factor.
- Harvest, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of the CT units at KCPP with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement CT[118] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.

C.4.14.5.2 Compliance Time

Harvest indicated it would take 2-3 years to implement DLN on the CT at KCPP. Based on information provided by other facilities and other resources, NMED believes this timeframe is reasonable.

[118] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Combustion Turbines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

Harvest did not provide an estimate of the time necessary to implement SCR. NMED believes the general compliance time provided in Section C.3.4 is reasonable.

Harvest also did not provide an estimate of the time necessary to replace the CT at KCPP. NMED believes the general compliance times for replacement with new, functionally equivalent natural gas-fired CT or EMD provided in Section C.3.4 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

C.4.14.5.3 Remaining Useful Life

Despite the advanced age of the CT at KCPP (~40 to 50 years), owners and operators of gas compression equipment in New Mexico have indicated that similar CT would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for DLN.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.14.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT is provided in Section C.3.4.

C.4.14.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.14.2 above. The four statutory factors are discussed in Sections C.4.14.5.1 through C.4.14.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	SCR	$6,000	3-4	20	None
	DLN	$6,000	2-3	20	None
	Replacement	$27,000	3-4	30	None
2	SCR	$8,000	3-4	20	None
	DLN	$7,000	2-3	20	None
	Replacement	$33,000	3-4	30	None
3	SCR	$11,000	3-4	20	None
	DLN	$11,000	2-3	20	None
	Replacement	$54,000	3-4	30	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
4	SCR	$8,000	3-4	20	None
	DLN	$8,000	2-3	20	None
	Replacement	$38,000	3-4	30	None
5	SCR	$9,000	3-4	20	None
	DLN	$9,000	2-3	20	None
	Replacement	$45,000	3-4	30	None
6	SCR	$8,000	3-4	20	None
	DLN	$16,000	2-3	20	None
	Replacement	$76,000	3-4	30	None
19	SCR	$8,000	3-4	20	None
	DLN	$10,000	2-3	20	None
	Replacement	$37,000	3-4	30	None
20	SCR	$10,000	3-4	20	None
	DLN	$12,000	2-3	20	None
	Replacement	$46,000	3-4	30	None
All Units	Electrification	$18,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.14.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[119]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

[119] See *supra* note 13.

NMED's FFA identified cost effective controls for KCPP Units 1, 2, 4, 5, 6, 19, and 20. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	SCR	46.4
2	SCR	38.0
4	SCR	36.9
5	SCR	33.0
6	SCR	38.7
19	SCR	30.1
20	SCR	24.3

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
1	DLN	Less stringent than SCR
2	DLN	Less stringent than SCR
4	DLN	Less stringent than SCR
5	DLN	Less stringent than SCR
19	DLN	Less stringent than SCR

NMED's FFA did not identify any cost-effective controls for KCPP Unit 3. Therefore, NMED determined that reasonable progress does not require new controls on this unit. As noted above, NMED did not conduct a FFA of potential control measures for Units 16, 17, and 18 because they have been permanently shut down and removed from KCPP's NSR permit. However, based on when they were retired, the resulting emissions reductions were realized during the second planning period. Therefore, NMED estimated the NO_X emissions reductions resulting from the retirement of these units by averaging 2016-2020 emissions reported by Harvest pursuant to 20.2.73 NMAC. These emissions are summarized below.

Unit No.	Estimated NO_X Reductions (ton/yr)
16	93.6
17	62.7
18	89.1

Combining expected reductions from the controls NMED has determined are necessary to make reasonable progress and reductions resulting from recent retirements, NMED estimates the total emissions reductions at KCPP during the second planning period will be approximately 492.8 ton/yr of NO_X.

C.4.15 Hilcorp Energy Company – San Juan Basin Gas Plant

Resources used in NMED's FFA for San Juan Basin Gas Plant (SJBGP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Harvest Four Corners, LLC (Harvest) and submitted to NMED on or about 11/1/19.
- Additional information provided by Harvest on 12/13/19, 3/2/20, 10/23/20, and 2/26/21.
- Additional information provided by successor owner Hilcorp Energy Company (Hilcorp) on 7/31/2023.[120]
- A detailed discussion between Hilcorp and NMED on 6/2/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.15.1 Facility Description

SJBGP is a natural gas processing facility located approximately 2 miles northeast of Bloomfield in San Juan County, New Mexico at latitude 36° 43' 57", longitude -107° 57' 59". It is owned and operated by Hilcorp and currently operates under Title V Operating Permit No. P124-R4, which expires on March 10, 2028. The shortest distance to the boundary of the nearest Class I Area, Mesa Verde National Park, is approximately 39.6 miles.

The function of the facility is to extract and process natural gas liquids and residue gas products from field gas. The facility is authorized for continuous operation, and its total potential to emit is 1050.1 tons per year of NO_X and 18.3 tons per year of SO_2.[121]

C.4.15.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at SJBGP:[122]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	Turbine	Rolls Royce Avon 1535	1985/1986 (1)	15,000 hp
2	Turbine	Rolls Royce Avon 1535	1985/1986 (1)	15,000 hp
3	Turbine	Rolls Royce Avon 1535	1985/1986 (1)	15,000 hp
4	Turbine	Solar Centaur T4501	1986	3,735 hp
5	Turbine	Solar Centaur T4501	1986	3,735 hp
6	Turbine	Solar Centaur T4501	1986	3,735 hp

[120] SJBGP underwent a change of ownership, from Harvest Four Corners, LLC to Hilcorp Energy Company, in 2021.
[121] AQB Title V Operating Permit No. P124-R4, Table 102.A.
[122] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
7	Turbine	Solar Centaur T4501	1986	3,735 hp

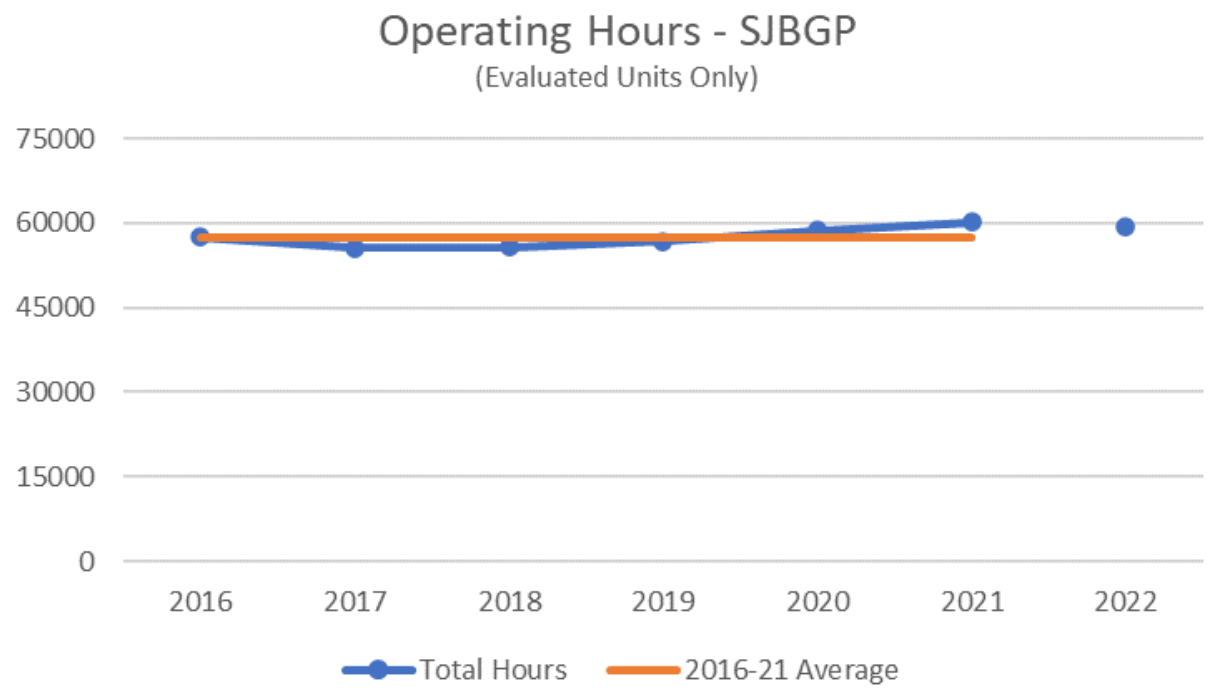
(1) Units 1, 2 and 3 may be any one of four unique turbines. Up to three of these turbines operate at any time, with the fourth held in maintenance reserve. One of these turbines was manufactured in 1985, and the rest in 1986.

NMED also elected to evaluate the ATS at SJBGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at SJBGP consists of an ATU (Unit Amine Unit), TO (Unit 15), and two flares (Units 9 and 16). During normal operations, acid gas exiting the ATU is routed to the TO for disposal. During TO SSM/M events, acid gas is rerouted to the backup flare system for disposal.[123]

C.4.15.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Hilcorp did not request a future utilization adjustment for SJBGP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at SJBGP.

For the emissions units at SJBGP requiring a FFA of potential control measures for NO_X ("NO_X units"), NMED calculated baseline actual emissions by multiplying representative annual operating hours by the NO_X emission rates reported in Hilcorp's most recent periodic emissions test report(s).[124,] Because the NO_X units at SJBGP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[125] Reported and adjusted emission rates for the NO_X units at SJBGP are summarized below.



Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
1	6/7/22	18.7	94%	19.8
2	6/7/22	19.8	93%	21.2
3	6/7/22	18.4	94%	19.4
4	6/8/22	13.6	98%	13.9
5	6/8/22	12.7	93%	13.7
6	6/8/22	14.4	95%	15.2
7	6/8/22	13.3	92%	14.4

To determine representative annual operating hours for the NO_X units at SJBGP, NMED analyzed 2016-2021 operating hours reported by Hilcorp pursuant to 20.2.73 NMAC. NMED was in receipt of Hilcorp's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal

[123] When acid gas from the ATU is rerouted to the flare system, Unit 16 is used and Unit 9 remains closed until Unit 16 reaches its maximum flow, at which point Unit 16 is closed and the gas rerouted to Unit 9.
[124] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.
[125] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the NO_X units at SJBGP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
1	8289	8427	8555	8312	8494	8507	8436
2	8164	8623	8517	8544	8571	8654	8315
3	8318	8622	8572	8556	8575	8680	8489
4	7877	7770	7328	7931	8575	8561	8445
5	8273	6904	8155	8201	8139	8670	8551
6	8468	7038	7782	7595	8678	8543	8397
7	8215	8231	6789	7687	7710	8651	8625

As shown above, year-over-year operating hours for the NO_X units at SJBGP have been very consistent in recent years, with no discernible impact from the pandemic in 2020. Therefore, NMED determined that 2016-2021 average operating hours are representative for these units.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the NO_X units at SJBGP are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
1	19.8	8431	83.6
2	21.2	8512	90.4

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
3	19.4	8554	83.1
4	13.9	8007	55.6
5	13.7	8057	55.0
6	15.2	8017	60.9
7	14.4	7881	56.8

C.4.15.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at SJBGP:

- SNCR and NSCR are not technically feasible options.
- WSI is not available for Rolls Royce or Solar turbines and thus is not a technically feasible option.
- GCP is a technically feasible option and is currently utilized by Hilcorp based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- DLN is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 25 ppm. [126]
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.[127]
- Unit replacement is a technically feasible option expected, in the case of Units 1, 2 and 3, to achieve a NO_X emission rate of 15 ppm, consistent with the emission standards for new natural gas-fired combustion turbines in 20.2.50 NMAC.[128] In the case of Units 4, 5, 6, and 7, because a DLN retrofit option is available for the make and model of CT comprising the existing units, it is assumed that DLN would be available on equivalent replacements. Therefore, replacement is expected to achieve a NO_X emission rate of 25 ppm, consistent with manufacturer specifications for similar, new CT equipped with DLN.
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Hilcorp has not indicated that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option for Units 1, 2 and 3 that would result in a 100 percent reduction of NO_X (and all other pollutants). Electrification is not a feasible option for Units 4, 5, 6, and 7 because they are used to generate electricity for the facility.

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at SJBGP:

[126] Hilcorp's 7/14/23 submittal indicated that DLN upgrades for the Rolls Royce Avon turbines (Units 1-3) would not be available until 2025.

[127] Hilcorp assumed a NOX control efficiency of 65-75% in the SCR evaluations provided in its initial FFA. While NMED disagrees with this assumption, NMED notes that in its own evaluation, SCR remains cost effective for Units 2 and 4-7 even if the control efficiency is reduced to 75%.

[128] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for Units 1, 2 and 3 would be subject to the NO_X standard for new CT ≥4,000 and <15,900 bhp (15 ppm).

- A flare is a technically feasible option. However, if used as the primary control device, a flare is inferior to all other forms of disposal because most of the H_2S in the acid gas stream (typically 98% or more) is converted to SO_2 and emitted into the atmosphere. Therefore, NMED did not evaluate this option.
- A SRU is a technically feasible option. However, no facility with an ATS evaluated by NMED currently uses a SRU. Many, and possibly all gas processing plants in New Mexico that previously used a SRU have decommissioned them in recent years due to operational concerns and/or compliance issues, some of which resulted in enforcement actions against the facility due to significant excess SO_2 emissions. NMED supports and encourages the transition away from SRUs towards more effective forms of acid gas disposal, such as AGI wells. In addition, NMED is confident that the cost effectiveness of a SRU would exceed its $10,000/ton cost effectiveness threshold, for the same reason it believes an AGI well would exceed the threshold (see explanation below). Therefore, NMED did not evaluate this option.
- A TO is a technically feasible option and is currently used as the primary control device for the ATS at SJBGP. Therefore, NMED did not evaluate this option.
- The technical feasibility of an AGI well is extremely dependent on the geologic characteristics of the potential well site. Therefore, absent a detailed geologic study, NMED is unable to determine whether an AGI well is technically feasible at SJBGP. However, even assuming an AGI well is technically feasible, NMED believes it has sufficient information to conclude that it would not be cost effective without performing a full FFA. Gas produced from the San Juan Basin in northwest New Mexico is primarily "sweet" gas containing relatively little H_2S. As a result, the primary purpose of the ATS at SJBGP is to remove CO_2 from recovered NGL, although small quantities of H_2S are also removed. Given the small quantities of H_2S removed by the ATS, SO_2 emissions from the TO average just 0.1 tons per year.[129] Hence, the potential emissions reductions from installing an AGI well are extremely limited. Considering that the capital costs for an AGI well, two compressors (primary and backup), and related piping can easily exceed $10 million, NMED is confident, given the potential for less than a ton of emissions reductions, that the cost effectiveness of an AGI well would greatly exceed its $10,000/ton cost effectiveness threshold. Therefore, NMED did not evaluate this option.
- While improved flare design might reduce emissions somewhat during TO SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during TO SSM/M events. Therefore, NMED did not evaluate this option.

C.4.15.5 Four-Factor Analysis

In order to determine what control measures are necessary at SJBGP to make reasonable progress, NMED conducted a FFA of potential control measures for the NO_X units identified in section C.4.15.2 above. NMED did not conduct a FFA of potential control measures for SO_2 for SJBGP's ATS because alternatives to the existing TO are either inferior, not cost effective, or both. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air

[129] Based on 2016-2022 emission inventory data.

quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[130]

C.4.15.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.15.4 above. NMED utilized source-specific cost estimates provided by Hilcorp in its calculations whenever possible. In cases where Hilcorp failed to provide source-specific cost estimates or NMED found estimates provided by Hilcorp to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[131]

NMED's cost effectiveness values for all technically feasible controls for the NO_X units at SJBGP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the NO_X units at SJBGP and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
1	DLN	$831,415	2.4	$351,000
	SCR	$687,435	66.9	$10,000
	Replacement	$4,325,174	34.9	$124,000
2	DLN	$831,415	3.5	$237,000
	SCR	$689,106	72.3	$10,000
	Replacement	$4,325,174	38.3	$113,000
3	DLN	$831,415	-0.2 (1)	-$4,990,000 (1)
	SCR	$688,251	66.5	$10,000
	Replacement	$4,325,174	33.2	$130,000
4	DLN	$349,891	38.1	$9,000
	SCR	$231,225	44.5	$5,000
	Replacement	$1,134,203	38.1	$30,000
5	DLN	$349,891	37.7	$9,000
	SCR	$231,200	44.0	$5,000
	Replacement	$1,134,203	37.7	$30,000
6	DLN	$349,891	43.2	$8,000
	SCR	$232,091	48.7	$5,000

[130] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[131] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
	Replacement	$1,134,203	43.2	$26,000
7	DLN	$349,891	40.2	$9,000
	SCR	$231,249	45.5	$5,000
	Replacement	$1,134,203	40.2	$28,000
All Units	Electrification	$15,122,088	485.6	$31,000

(1) Negative estimated reductions and cost effectiveness are an artifact of NMED's methods for calculating these values and do not accurately represent the cost effectiveness of the control or its expected emissions impact. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and are excluded from further consideration.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the NO_X units at SJBGP:

- Hilcorp did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, consistent with the SCR evaluations provided in Hilcorp's initial FFA.
- Hilcorp indicated that significant upgrades to the electric utility infrastructure would be needed to support electrification; this assertion was supported by a letter from the City of Farmington Electric Utility System. Hilcorp also provided a detailed cost estimate for the capital costs associated with replacing Units 1-3, which provide compression, with EMD units. NMED's electrification evaluation includes these costs as well as estimated substation and transmission line costs. NMED's evaluation also conservatively assumes that providing line power to electrify Units 1-3 would obviate the need for Units 4-7, which currently provide power for the facility, and that they would be retired if the facility electrified Units 1-3.
- Hilcorp, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of the CT units at SJGP with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement CT[132] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.

C.4.15.5.2 Compliance Time

Hilcorp indicated it would take 2-3 years to implement DLN or SCR on Units 4, 5, 6, and 7. Based on information provided by other facilities and other resources, NMED believes these timeframes are reasonable.

[132] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

Hilcorp did not provide an estimate of the time necessary to implement DLN or SCR on Units 1, 2, and 3. NMED's general assessment of compliance times provided in Section C.3.4 is believed to be reasonably accurate.

Hilcorp also did not provide an estimate of the time necessary to replace the CT at SJBGP. NMED believes the general compliance times for replacement with new, functionally equivalent natural gas-fired CT or EMD provided in Section C.3.4 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

C.4.15.5.3 Remaining Useful Life

Despite the age of the units at SJBGP (~40 years), owners and operators of gas compression equipment in New Mexico have indicated that similar CT would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for DLN.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.15.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT is provided in Section C.3.4.

C.4.15.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.15.2 above. The four statutory factors are discussed in Sections C.4.15.5.1 through C.4.15.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	DLN	$351,000	2-3	20	None
	SCR	$10,000	3-4	20	None
	Replacement	$124,000	3-4	30	None
2	DLN	$237,000	2-3	20	None
	SCR	$10,000	3-4	20	None
	Replacement	$113,000	3-4	30	None
3	DLN	-$4,990,000	2-3	20	None
	SCR	$10,000	3-4	20	None

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
	Replacement	$130,000	3-4	30	None
4	DLN	$9,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$30,000	3-4	30	None
5	DLN	$9,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$30,000	3-4	30	None
6	DLN	$8,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$26,000	3-4	30	None
7	DLN	$9,000	2-3	20	None
	SCR	$5,000	2-3	20	None
	Replacement	$28,000	3-4	30	None
All Units	Electrification	$31,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.15.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[133]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

[133] See *supra* note 13.

NMED's FFA identified cost-effective controls for SJBGP Units 1, 2, 3, 4, 5, 6, and 7. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	SCR	66.9
2	SCR	72.3
3	SCR	66.5
4	SCR	44.5
5	SCR	44.0
6	SCR	48.7
7	SCR	45.5

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
4	DLN	Less stringent than SCR
5	DLN	Less stringent than SCR
6	DLN	Less stringent than SCR
7	DLN	Less stringent than SCR

As noted above, NMED did not conduct a FFA of potential control measures for SJBGP's ATS. Because the alternatives to the existing TO are either inferior, presumptively not cost effective, or both, NMED determined that reasonable progress does not require new controls for the ATS.

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at SJBGP during the second planning period will be approximately 388.4 ton/yr of NO_X.

C.4.16 IACX Roswell – Bitter Lake Compressor Station

Resources used in NMED's FFA for Bitter Lake Compressor Station (BLCS) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for IACX Roswell, LLC (IACX) and submitted to NMED on or about 11/1/19.
- Additional information provided by IACX on 1/29/20, 11/4/20 and 1/5/21.
- A detailed discussion between IACX and NMED on 7/7/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA's Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020).
- FFAs developed for similar facilities in New Mexico and other states.

C.4.16.1 Facility Description

BLCS is a natural gas compressor station located 13.3 miles northeast of Roswell in Chaves County, New Mexico at latitude 33° 33' 11", longitude -104° 23' 27". It is owned and operated by IACX and is currently authorized as a synthetic minor source under New Source Review Permit No. 0274-M8. The facility previously operated as a major source under Title V Operating Permit No. P047-R3, which was cancelled at IACX's request on March 13, 2020. The shortest distance to the boundary of the nearest Class I Area, Salt Creek Wilderness Area, is approximately 1.1 miles. Notably, Salt Creek Wilderness Area is the only Class I Area in New Mexico projected to be above the URP glidepath in 2028 and for which a robust demonstration is required.[134]

The function of the facility is to gather casinghead gas from multiple wells and compress the gas using natural gas-fired compressor engines. The facility is authorized for continuous operation, and its total potential to emit is 79.6 tons per year of NO_X and 1.5 tons per year of SO_2.[135]

C.4.16.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at BLCS. No units met NMED's criteria for requiring an evaluation of potential control measures for SO_2.[136]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
C-891	2SLB RICE	Cooper Bessemer GMVH-10C	4/7/1981	2,250 hp
C-893	2SLB RICE	Cooper Bessemer GMVH-10C	4/7/1981	2,250 hp

C.4.16.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. IACX did not request a future utilization adjustment for BLCS. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at BLCS.

NMED calculated baseline actual emissions for the emissions units at BLCS by multiplying representative annual operating hours by the NO_X emission rates reported in IACX's most recent periodic emissions test report(s).[137,] Because the emissions units at BLCS operate at varying loads, NMED conservatively

[134] See Chapter 10, Progress, Degradation, and URP Glidepath Checks for Class I Areas in New Mexico, for NMED's robust demonstration for Salt Creek Wilderness Area.

[135] AQB New Source Review Permit No. 0274-M8, Table 102.A.

[136] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

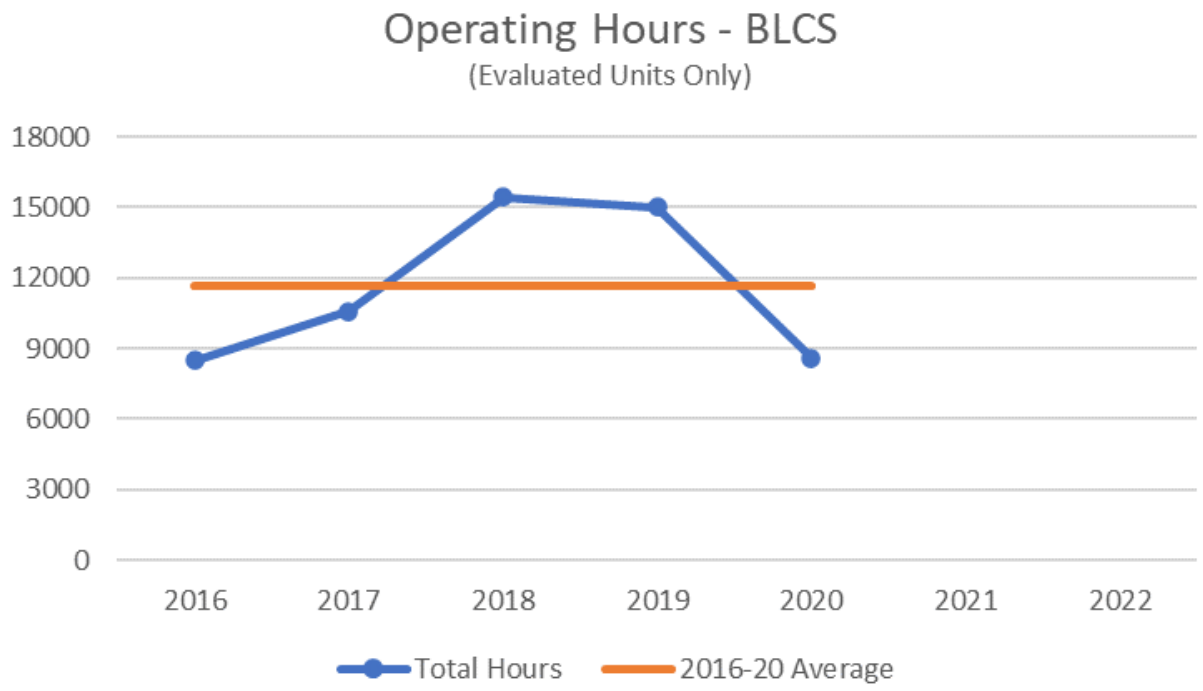
[137] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

adjusted reported emission rates to 100 percent load to represent worst-case emissions.[138] Reported and adjusted emission rates for the emissions units at BLCS are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
C-891	11/15/22	2.22	42%	5.2
C-893	NA (1)	---	---	5.2 (2)

(1) NA = Not Available

(2) The average adjusted emissions of identical Unit C-891 were used as a surrogate for Unit C-893, as NMED was unable to locate a recent emissions test report for this unit.



At IACX's request, NMED cancelled the Title V operating permit for BLCS on March 13, 2020, after IACX re-permitted the facility under a general construction permit for oil and gas facilities.[139] As a result, IACX is no longer required to submit an annual emission inventory, which includes operating hours. 2020 was the last year IACX submitted such an inventory to NMED.[140] Therefore, to determine representative annual operating hours for the emissions units at BLCS, NMED analyzed 2016-2020 operating hours reported by IACX pursuant to 20.2.73 NMAC. 2016-2020 operating hours for the emissions units at BLCS are summarized and plotted below.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours
C-891	6638	8571	7530	7601	1042
C-893	1851	1998	7922	7411	7557

[138] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

[139] IACX subsequently re-permitted BLCS again under a New Source Review permit due to the facility being located within three miles of a Class I Area and thus ineligible for a general construction permit for oil and gas facilities.

[140] Only major sources are required to submit emissions inventories annually. Minor sources are only required to do so every three years. 2020 was the last triennial inventory year for New Mexico.

As shown above, BLCS' year-over-year operating hours have risen and fallen in recent years, with no obvious pattern and no discernible impact from the pandemic in 2020. Therefore, NMED determined that 2016-2020 average operating hours are representative for the emissions units at BLCS.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at BLCS are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
C-891	5.2	6276	16.4
C-893	5.2	5348	14.0

C.4.16.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at BLCS:

- SCR, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by IACX based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- Units C-891 and C-893 are already equipped with LEC. However, IACX indicated that some LEC upgrades are technically feasible for these units. These upgrades are expected to achieve a vendor-quoted NO_X emission rate of 2.0 g/hp-hr.

- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.3 g/hp-hr, consistent with the emission standards for new natural gas-fired spark ignition engines in 20.2.50 NMAC.[141].
- Unit retirement is a technically feasible option and would result in a 100 percent reduction of NO_X (and all other pollutants). However, IACX has not indicated that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

C.4.16.5 Four-Factor Analysis

In order to determine what control measures are necessary at BLCS to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.16.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[142]

C.4.16.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.16.4 above. NMED utilized source-specific cost estimates provided by IACX in its calculations whenever possible. In cases where IACX failed to provide source-specific cost estimates or NMED found estimates provided by IACX to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[143]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at BLCS are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at BLCS and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
C-891	LEC	$129,808	-14.9 (1)	-$9,000 (1)
	Replacement	$823,801	11.7	$70,000

[141] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent replacements for the 2SLB RICE at BLCS would be subject to the NO_X standard for new lean burn engines ≥1,875 bhp (0.3 g/bhp-hr).
[142] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).
[143] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
C-893	LEC	$129,808	-12.7 (1)	-$10,000 (1)
	Replacement	$823,801	10.0	$82,000
All Units	Electrification	$1,408,011	30.4	$46,000

(1) Negative estimated reductions and cost effectiveness are an artifact of NMED's methods for calculating these values and do not accurately represent the cost effectiveness of the control or its expected emissions impact. Negative values are an indication that the emission rate associated with the control is greater than the current emission rate of the unit in question, which means the control would not be expected to reduce emissions. Controls that would not reduce emissions are not cost-effective on their face and are excluded from further consideration.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at BLCS:

- IACX did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- IACX, like most of the companies required to submit a FFA, did not provide information regarding the Total Capital Investment (TCI) associated with the replacement of the 2SLB RICE units at BLCS with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement RICE[144] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- IACX did not provide information regarding the costs associated with electrification. Therefore, NMED applied a Total Capital Cost (TCC) metric of $2,084/hp (2023$), which it developed using detailed cost information provided by other facilities, to calculate TCC. The TCI calculated by NMED assumes no costs associated with substation or utility line upgrades because of lack of information. NMED understands that this assumption likely underestimates costs given that IACX indicated utility infrastructure upgrades would be needed to support electrification at BLCS.

C.4.16.5.2 Compliance Time

IACX indicated it would take 2 years to implement LEC upgrades on the 2SLB RICE units at BLCS. Based on information provided by other facilities and other resources, NMED believes this timeframe is reasonable.

IACX did not provide an estimate of the time necessary to replace the 2SLB RICE units at BLCS. NMED believes the general compliance times for replacement with like-kind natural gas-fired engines or EMD provided in Section C.3.1 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

[144] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

C.4.16.5.3 Remaining Useful Life

Despite the age of the 2SLB RICE at BLCS (~40 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

Manufacturers of new RICE will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new RICE are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.16.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE is provided in Section C.3.1.

C.4.16.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.16.2 above. The four statutory factors are discussed in Sections C.4.16.5.1 through C.4.16.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
C-891	LEC	-$9,000	2	20	None
	Replacement	$70,000	3-4	30	None
C-893	LEC	-$10,000	2	20	None
	Replacement	$82,000	3-4	30	None
All Units	Electrification	$46,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.16.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze

Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[145]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA did not identify any cost-effective controls for BLCS Units C-891 or C-893. Therefore, NMED determined that reasonable progress does not require new controls on either of these units.

C.4.17 Oxy USA WTP Limited Partnership – Indian Basin Gas Plant

Resources used in NMED's FFA for Indian Basin Gas Plant (IBGP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Oxy USA WTP Limited Partnership (Oxy) and submitted to NMED on 10/31/19.
- Additional information provided by Oxy on 2/13/20, 10/21/20, 7/21/23, and 8/14/23.
- Detailed discussions between Oxy and NMED on 7/6/23 and 4/24/24.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA's Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP Region (March 23, 2020).
- FFAs developed for similar facilities in New Mexico and other states.

C.4.17.1 Facility Description

IBGP is a natural gas processing facility located 14.5 miles west of Carlsbad in Eddy County, New Mexico at latitude 32° 27' 50", longitude -104° 34' 27". It is owned and operated by Oxy and currently operates under Title V Operating Permit No. P103-R3, which expires on November 1, 2024.[146] The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 21.2 miles.

[145] See *supra* note 13.

[146] Oxy submitted a timely application to renew Title V Operating Permit No. P103-R3 on October 12, 2023. At the time of preparation of this technical support document, NMED had not taken final action on the application.

The function of the facility is to remove hydrogen sulfide, carbon dioxide, condensate and water from raw natural gas to make commercial natural gas. The facility also extracts natural gas products (propane and butane) from natural gas. The facility is authorized for continuous operation, and its total potential to emit is 363.0 tons per year of NO_X and 87.1 tons per year of SO_2.[147]

C.4.17.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at IBGP:[148]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
ES-06/07	Turbine	Solar Centaur 40	1980	4,000 hp
ES-08/09	Turbine	Solar Centaur 40	1980	4,000 hp
ES-10/11	Turbine	Solar Centaur 40	1980	4,700 hp

NMED also elected to evaluate the ATS at IBGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at IBGP consists of an ATU (Unit AU-01), AGI well (Unit AGI), electric AGI well compressor (Unit AG-COM), and an acid gas flare (Unit ES-50). During normal operations, acid gas exiting the ATUs is routed to the AGI well for disposal resulting in no emissions to the atmosphere. During AGI SSM/M events, acid gas is rerouted to the acid gas flare for disposal, which produces SO_2 emissions.

C.4.17.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Oxy did not request a future utilization adjustment for IBGP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at IBGP.

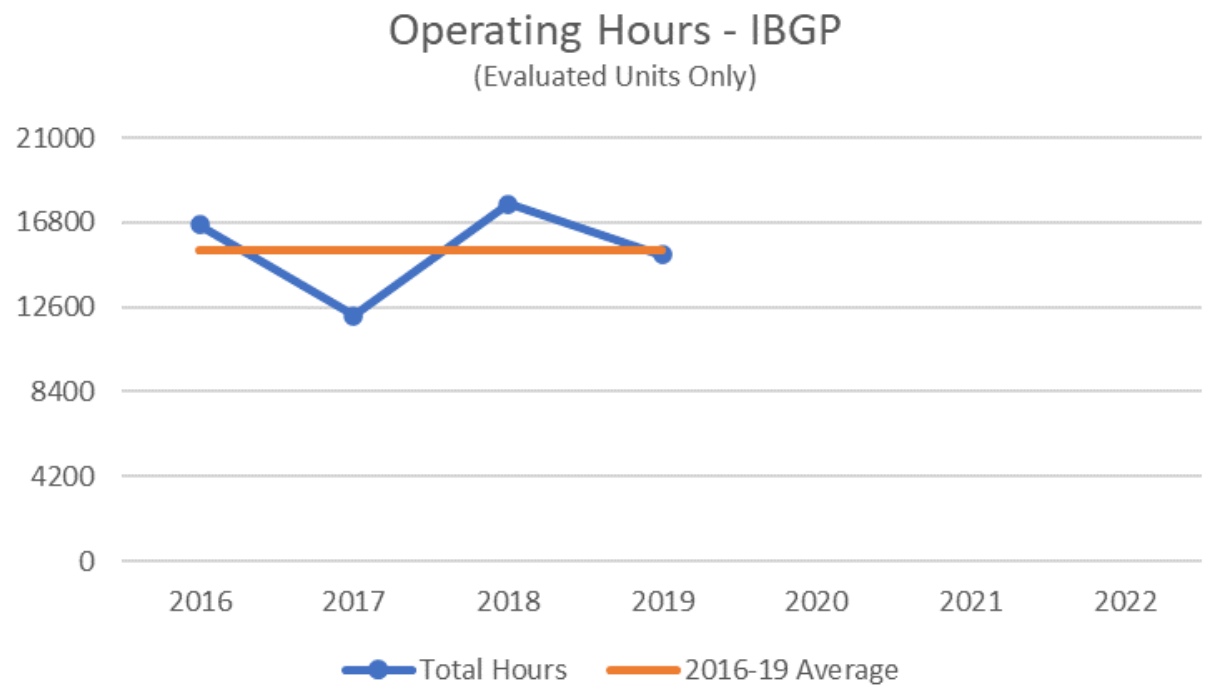
For the emissions units at IBGP requiring a FFA of potential control measures for NO_X ("NO_X units"), NMED calculated baseline actual emissions by multiplying representative annual operating hours by the NO_X emission rates reported in Oxy's most recent periodic emissions test report(s).[149,] Because the NO_X units at IBGP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[150] Reported and adjusted emission rates for the NO_X units at IBGP are summarized below.

[147] AQB Title V Operating Permit No. P103-R3, Table 102.A.

[148] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

[149] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[150] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.



Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
ES-06/07	2/12/19	14.8	100%	14.8
ES-08/09	NA [1]	---	---	15.4 [2]
ES-10/11	2/12/19	9.8	99%	9.9

[1] NA = Not Available

[2] The average adjusted emissions of identical Unit ES-06/07 were used as a surrogate for Unit ES-08/09, as NMED was unable to locate a recent emissions test report for this unit.

To determine representative annual operating hours for the NO_X units at IBGP, NMED analyzed 2016-2019 operating hours reported by Oxy pursuant to 20.2.73 NMAC (the facility has been idled since June 2020, and 2019 was its last full year of operation). 2016-2019 operating hours for the NO_X units at IBGP are summarized and plotted below.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours
ES-06/07	8664	6051	7340	4651
ES-08/09	8014	6135	6604	4853
ES-10/11	0	0	3772	5685

As shown above, year-over-year operating hours for the NO_X units at IBGP varied somewhat randomly with no discernable trend during the period 2016-2019. Therefore, NMED determined that 2016-2019 average operating hours are representative for Units ES-06/07 and ES-08/09. Unit ES-10/11 did not operate in 2016 or 2017, and NMED did not think 2018-2019 operating hours were necessarily representative of future operations due to the limited sample size. Furthermore, in a detailed discussion between Oxy and NMED on 4/24/24, Oxy suggested that utilization could increase if the plant is ever

restarted. Therefore, NMED determined that 8,760 hours is representative for Unit ES-10/11, consistent with what Oxy assumed in its initial FFA submittal.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the NO_X units at IBGP are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
ES-06/07	14.8	6677	49.3
ES-08/09	14.8	6402	47.3
ES-10/11	9.9	8760	43.4

NMED estimated baseline actual SO_2 emissions for the ATS at IBGP by averaging 2016-2019 emissions reported by Oxy pursuant to 20.2.73 NMAC. These emissions are summarized below.

Unit No.	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	Average Emissions (ton/yr)
ES-50	8.2	7.4	8.1	5.9	24.6
ES-50 SSM	41.9	8.0	17.6	1.2	

C.4.17.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at IBGP:

- WSI, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Oxy based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- DLN is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 25 ppm.
- SCR is a technically feasible option expected to achieve an average NO_X control efficiency of 80 percent.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 15 ppm, consistent with the emission standards for new natural gas-fired combustion turbines in 20.2.50 NMAC.[151]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Oxy did not indicate that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

[151] 20.2.50 NMAC contains varying emission standards for new natural gas-fired stationary combustion turbines based on rated brake horsepower. See Section 113, Table 3. Equivalent replacements for the CT at IBGP would be subject to the NO_X standard for new CT ≥4,000 and <15,900 bhp (15 ppm).

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at IBGP:

- A flare, SRU or TO are technically feasible options. However, compared to an AGI well, which is currently used as the primary control device for the ATS at IBGP, a flare, SRU or TO is an inferior control. An ATS with a flare, SRU or TO will produce SO_2 emissions during normal operations and during SSM/M events. Conversely, an ATS with an AGI well will produce SO_2 emissions only during AGI SSM/M events. Therefore, NMED did not evaluate these options.
- While improved flare design might reduce emissions somewhat during AGI SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events. Therefore, NMED did not evaluate this option.
- Adding backup, redundant compression to the ATS is a technically feasible option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events.

C.4.17.5 Four-Factor Analysis

In order to determine what control measures are necessary at IBGP to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the NO_X units identified in section C.4.17.2 above. NMED also conducted a FFA of the only technically feasible control option for the ATS, i.e., adding redundant compression to reduce AGI SSM/M flaring emissions. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[152]

C.4.17.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X or SO_2 emissions reduced, of each technically feasible control option identified in section C.4.17.4 above. NMED utilized source-specific cost estimates provided by Oxy in its calculations whenever possible. In cases where Oxy failed to provide source-specific cost estimates or NMED found estimates provided by Oxy to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[153]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at IBGP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed calculations and supporting documentation for NMED's cost estimates are provided in Appendix D.

---

[152] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[153] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
ES-06/07	DLN	$313,173	36.5	$9,000
	SCR	$458,400	39.5	$12,000
	Replacement	$1,137,517	41.6	$27,000
ES-08/09	DLN	$313,173	35.0	$9,000
	SCR	$457,457	37.8	$12,000
	Replacement	$1,137,517	39.9	$28,000
ES-10/11	DLN	$289,862	29.0	$10,000
	SCR	$462,198	34.8	$13,000
	Replacement	$1,333,590	34.8	$38,000
All CT	Electrification	$4,394,819	140.1	$31,000
ATS	Redundant Compression	$562,019	22.1	$25,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at IBGP:

- Oxy did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, due to a lack of information from Oxy supporting a higher retrofit factor. Oxy indicated that there is insufficient power available to support SCR but did not provide a cost estimate for necessary utility infrastructure upgrades. As a result, NMED included $5M for these upgrades in its cost estimate. NMED believes this value likely underestimates the cost based on information provided by other facilities.
- Oxy, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of their CT units with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement CT[154] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- Oxy did not provide information regarding the costs associated with electrification. Therefore, NMED applied a Total Capital Cost (TCC) metric of $2,084/hp (2023$), which it developed using detailed cost information provided by other facilities, to calculate TCC. NMED also included $5M for utility infrastructure upgrades based on Oxy's assertion that there is insufficient power to support SCR. NMED believes this value likely underestimates the cost based on information provided by other facilities.

[154] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

- Cost estimates for adding redundant compression provided by other natural gas processing facilities in New Mexico ranged from approximately $4.1M to $9.1M (2023$), significantly less than Oxy's undocumented estimate of $14.5M (2023$). Therefore, NMED disregarded Oxy's estimate. NMED did not have sufficient information to determine which of the available estimates from other facilities best represents the cost of adding redundant compression at IBGP, so NMED conservatively used the lowest estimate in its calculations.

C.4.17.5.2 Compliance Time

Oxy indicated it would take 4-5 years to implement DLN on the CT at IBGP. NMED disagrees with this estimate based on information provided by other facilities and believes the general compliance time provided in Section C.3.4 is more reasonable.

Oxy did not provide an estimate of the time necessary to implement SCR. NMED believes the general compliance time provided in Section C.3.4 is reasonable.

Oxy did not provide an estimate of the time necessary to replace the units at IBGP. NMED believes the general compliance times for replacement with like-kind natural gas-fired CT or EMD provided in Section C.3.4 are reasonable but recognizes that in the case of EMD several more years could be required considering the relative complexity.

Oxy indicated it would take approximately 5 years to implement redundant compression on the ATS at IBGP. Based on several recently completed projects, NMED believes a more reasonable compliance time for adding redundant compression is 2-3 years. This does not account for any facility-specific challenges that would prolong implementation.

C.4.17.5.3 Remaining Useful Life

Oxy indicated that the expected useful life of DLN is 20 years. This is consistent with information provided by similar facilities and FFAs completed in other states.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

There is limited information about the useful life of electric compression equipment, but research suggests the useful life is at least 25 years. For EMD used in acid gas service (i.e., AGI well compressors), NMED believes the useful life would not be longer than 20 years.

C.4.17.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT is provided in Section C.3.4.

NMED anticipates no energy or non-air quality impacts from adding redundant compression to the ATS at IBGP.

C.4.17.5.5 Summary

NMED performed a FFA for all technically feasible control options for the emissions units listed in Section C.4.17.2 above. The four statutory factors are discussed in Sections C.4.17.5.1 through C.4.17.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
ES-06/07	DLN	$9,000	2-3	20	None
	SCR	$12,000	3-4	20	None
	Replacement	$27,000	3-4	30	None
ES-08/09	DLN	$9,000	2-3	20	None
	SCR	$12,000	3-4	20	None
	Replacement	$28,000	3-4	30	None
ES-10/11	DLN	$10,000	2-3	20	None
	SCR	$13,000	3-4	20	None
	Replacement	$38,000	3-4	30	None
All CT	Electrification	$31,000	4-6	25	None
ATS	Redundant Compression	$25,000	2-3	20	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.17.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[155]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For NO_X units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For NO_X units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the

[155] See *supra* note 13.

categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for IBGP Units ES-06/07, ES-08/09 and ES-10/11. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
ES-06/07	DLN	36.5
ES-08/09	DLN	35.0
ES-10/11	DLN	29.0

NMED's FFA did not identify any cost-effective controls for the ATS at IBGP. Therefore, NMED determined that reasonable progress does not require new controls for the ATS.

Based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at IBGP during the second planning period will be approximately 100.5 ton/yr of NO_X.

C.4.18 Public Service Company of New Mexico – San Juan Generating Station

San Juan Generating Station (SJGS) is a former 1,800 MW coal-fired electric power plant located 3 miles north of Waterflow in San Juan County, New Mexico at latitude 36° 48' 07", longitude -108° 26' 20". It is owned by Public Service Company of New Mexico (PNM),[156] and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Section C.2 in 2019. However, PNM subsequently shut down SJGS on or about November 1, 2022, and submitted an administrative permit revision closing NSR Permit No. 0063-M12R3 and voluntarily discontinuing Title V Operating Permit No. P062-R4M1 on December 27, 2022. PNM's demolition and remediation plan for the facility was approved by the San Juan County Commission on March 7, 2023, and demolition was initiated on July 10, 2023. The plant's stacks are scheduled to be demolished in the second quarter of 2024, and the majority of the remaining work is expected to be completed by the end of 2025.

NMED originally selected SJGS' two coal-fired boilers (Units S301/E301 and S304/E304) for an analysis of potential control measures for NO_X and SO_2 in the second planning period. However, because SJGS has since been shut down and demolition is underway, NMED did not perform a FFA of potential control measures for these units. EPA guidance provides that a state may forgo a full FFA if a source is already "effectively controlled" and the state can demonstrate why a FFA would not result in new controls and would therefore be a futile exercise.[157] NMED considers it self-evident that a FFA of potential control measures for retired units at a facility that has been shut down and is in the process of being demolished would be futile. There is no more effective control than retirement, which reduces emissions by 100

[156] PNM shared ownership of SJGS' four coal-fired units with the City of Anaheim, California; City of Farmington, New Mexico; Los Alamos County, New Mexico; M-S-R Public Power Authority; Southern California Public Power Authority; Tri-State Generation and Transmission Association, Inc.; Tucson Electric Power Company; and Utah Associated Municipal Power Systems.

[157] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021) at 5.

percent, and the demolition of SJGS will make it impossible to add new controls. Therefore, NMED has determined that Units S301/E301 and S304/E304 are effectively controlled by virtue of their retirement due to the shutdown of SJGS, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

Based on when SJGS was shut down, the emissions reductions resulting from the retirement of the affected units were realized during the second planning period. Therefore, NMED estimated the NO_X and SO_2 emissions reductions resulting from the retirement of Units S301/E301 and S304/E304 by averaging 2016-2021 emissions reported by PNM pursuant to 20.2.73 NMAC. These emissions are summarized below.

Pollutant	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	2020 Emissions (tons)	2021 Emissions (tons)	Average Emissions (ton/yr)
NO_X	7,165.4	7,594.2	6,403.0	6,478.0	6,772.5	6,629.3	7,007.4
SO_2	1,722.5	1,799.8	1,246.6	1,453.3	1,355.2	936.3	1,558.5

C.4.19 Targa Midstream Services – Eunice Gas Processing Plant

Resources used in NMED's FFA for Eunice Gas Processing Plant (EGPP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Targa Midstream Services, LLC (Targa) and submitted to NMED on or about 11/1/19.
- Additional information provided by Targa on 12/13/19, 2/17/20, 3/12/20, 11/20/20, 2/16/21, 8/4/23, and 3/14/24.
- A detailed discussion between Targa and NMED on 6/8/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.19.1 Facility Description

EGPP is a natural gas processing facility located one mile southeast of Eunice in Lea County, New Mexico at latitude 32° 25' 28", longitude -103° 08' 50". It is owned by Versado Gas Processors, LLC and operated by Targa, and currently operates under Title V Operating Permit No. P109-R3M1, which expires on

November 29, 2024.[158] The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 73.5 miles.

The function of the facility is to receive field natural gas, perform dehydration and removal of carbon dioxide and hydrogen sulfide, and separate natural gas liquids. The facility is authorized for continuous operation, and its total potential to emit is 2606.0 tons per year of NO_X and 482.0 tons per year of SO_2.[159]

C.4.19.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at EGPP:[160]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
B-01	Boiler	Wickes Type A	<1972	100 MMBTU/hr
B-02	Boiler	Wickes Type A	<1972	100 MMBTU/hr
C-01	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-02	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-03	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-04	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-05	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-06	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-07	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-08 (1)	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-09 (1)	2SLB RICE	Clark BA-6	<1972	1,200 hp
C-10 (1)	2SLB RICE	Clark HBA-8	<1972	1,600 hp
C-11 (1)	2SLB RICE	Clark HBA-8	<1972	1,600 hp
C-12 (1)	2SLB RICE	Clark HBA-8	<1972	1,600 hp
C-13 (1)	2SLB RICE	Clark HBA-T-8	<1972	2,050 hp

(1) Targa's November 2019 FFA indicated that Unit C-08 was inoperable and had been permanently shut down, and its 8/4/23 submittal indicated that Units C-09, C-10, C-11, C-12, and C-13 had also been permanently shut down. Targa has since removed these units from EGPP's NSR and Title V permits. Therefore, NMED did not evaluate them.

NMED also elected to evaluate the ATS at EGPP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at EGPP consists of an ATU (Unit AM-01), AGI well (Unit AGI), two electric AGI well compressors (Units AGI-C1 and AGI-C2), and an acid gas flare (Unit F-01). During normal operations, acid gas exiting the ATU is routed to the AGI well for disposal resulting in no emissions to the atmosphere. During AGI SSM/M events, acid gas is rerouted to the acid gas flare for disposal, which produces SO_2 emissions. AGI SSM/M flaring emissions are minimized via the second, redundant AGI well compressor, which provides compression when the

[158] Targa submitted a timely application to renew Title V Operating Permit No. P109-R3M1 on November 28, 2023. At the time of preparation of this technical support document, NMED had not taken final action on the application.
[159] AQB Title V Operating Permit No. P109-R3M1, Table 102.A.
[160] See Chapter 6, Selection of Sources for Control Measures Analysis, for a detailed discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

primary AGI well compressor fails or is taken out of service for maintenance, allowing for continued use of the AGI well when flaring would otherwise be required.

C.4.19.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Targa did not request a future utilization adjustment for EGPP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at EGPP.[161]

For the emissions units at EGPP requiring a FFA of potential control measures for NO_X ("NO_X units"), NMED calculated baseline actual emissions by multiplying representative annual operating hours by the NO_X emission rates reported in Targa's most recent periodic emissions test report(s).[162,] Because the engines at EGPP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[163] Reported and adjusted emission rates for the NO_X units at EGPP are summarized below.

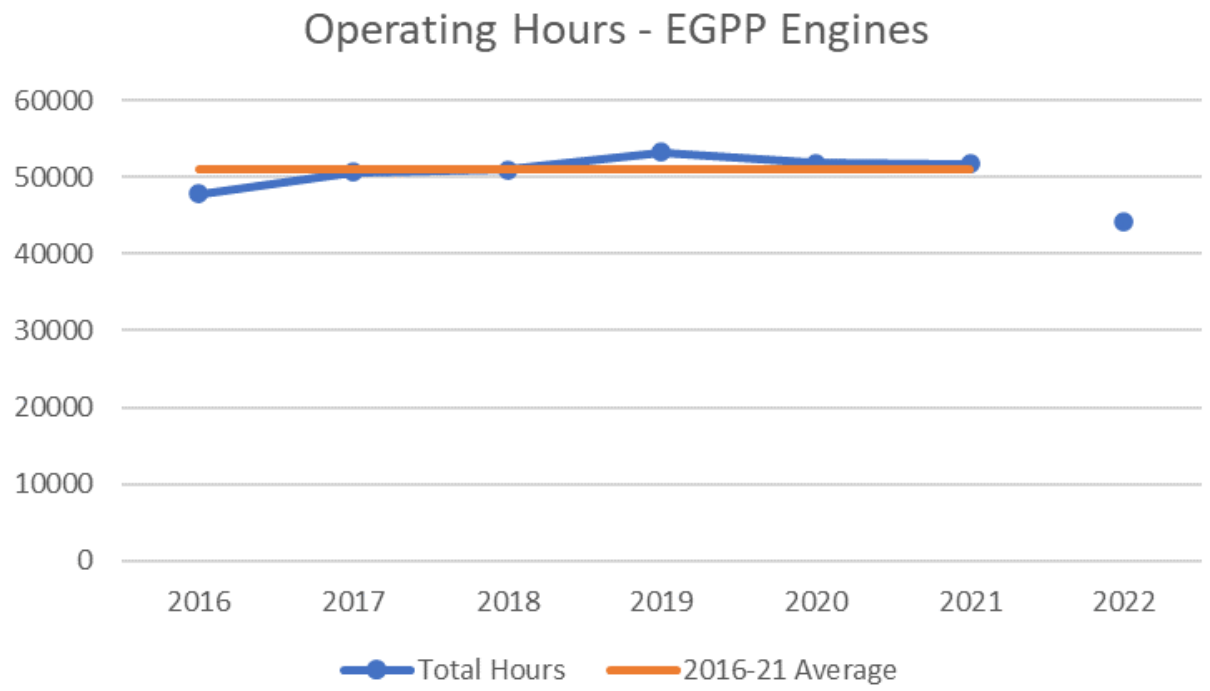
Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
B-01	NA [(1)]	---	---	6.0 [(2)]
B-02	NA [(1)]	---	---	6.0 [(2)]
C-01	7/18/23	52.8	96%	55.0
C-02	NA [(1)]	---	---	50.0 [(3)]
C-03	7/18/23	44.2	96%	46.1
C-04	7/18/23	50.1	96%	52.1
C-05	7/18/23	49.7	96%	51.8
C-06	7/18/23	43.0	96%	44.7
C-07	NA [(1)]	---	---	50.0 [(3)]

[(1)] NA = Not Available

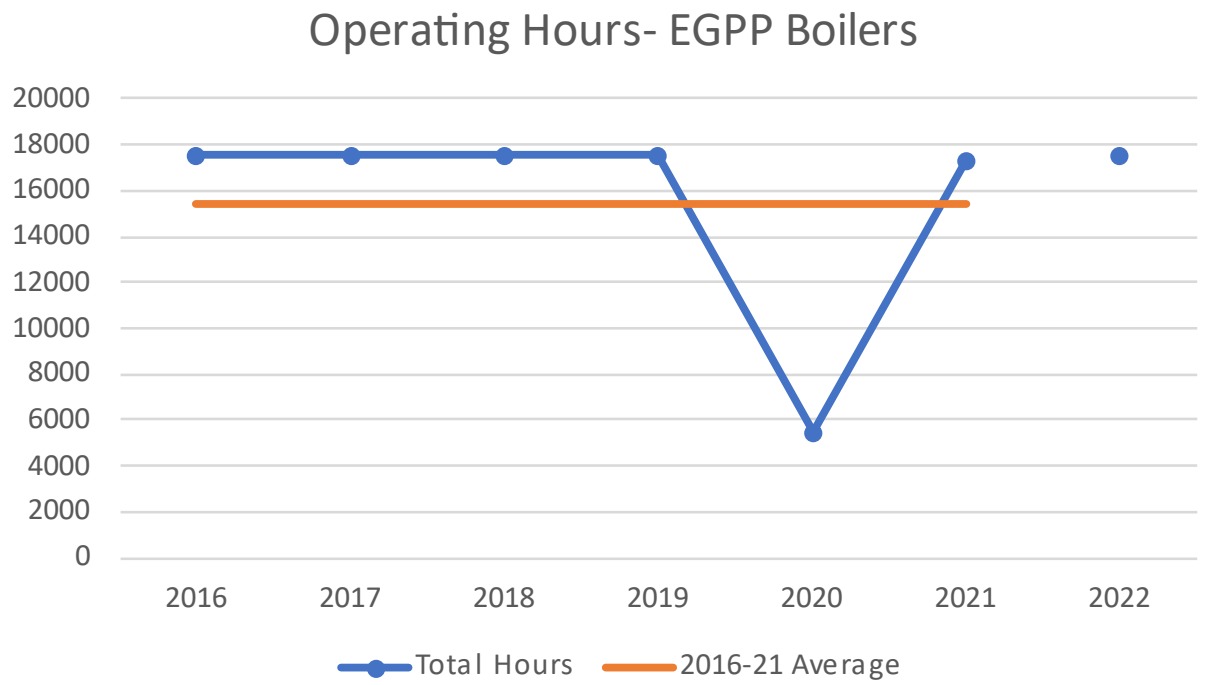
[(2)] EGPP's Title V operating permit does not require periodic testing of Units B-01 and B-02. NMED estimated the emissions of these units based on their heat input capacity (MMBtu/hr) and an emission rate (lb/MMBtu) provided by a vendor.

[(3)] The average adjusted emissions of Units C-01, C-03, C-04, C-05, and C-06 were used as a surrogate for Units C-02 and C-07, as NMED was unable to locate a recent emissions test report for these units.

To determine representative annual operating hours for the NO_X units at EGPP, NMED analyzed 2016-2021 operating hours reported by Targa pursuant to 20.2.73 NMAC. NMED was in receipt of Targa's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021



[161] Projected actual emissions for Units C-09, C-10, C-11, C-12, and C-13 are zero. However, NMED still calculated baseline actual emissions for these units for purposes of estimating the NOx emissions reductions resulting from their retirement.



[162] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

[163] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

operating hours for the NO_X units at EGPP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
B-01	8760	8760	8760	8760	2738	8642	8760
B-02	8760	8760	8760	8760	2738	8657	8760
C-01	8009	6882	7276	7652	7168	6537	6314
C-02	4271	7840	7580	8368	6537	6306	7725
C-03	7275	6742	6798	7176	8016	7538	7345
C-04	5996	7604	7237	6927	8021	7971	5392
C-05	7684	7168	7931	7499	8107	8010	5900
C-06	8123	6656	6133	7572	7078	7956	5926
C-07	6476	7690	7961	8029	6880	7386	5480

As shown above, year-over-year operating hours for EGPP's engines have been very consistent in recent years, and there was no discernible impact from the pandemic in 2020. Therefore, NMED determined that 2016-2021 average operating hours are representative for these units.[164] Year-over-year operating hours for EGPP's boilers have also been very consistent in recent years. With the exception of 2020, which was an anomaly for unknown reasons,[165] both boilers have consistently seen full time (or nearly full time) utilization. Therefore, NMED determined that 8,760 hr/yr is representative for these units.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the NO_X units at EGPP are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
B-01	6.0	8760	26.1
B-02	6.0	8760	26.1
C-01	55.0	7254	199.3
C-02	50.0	6817	170.3
C-03	46.1	7258	167.2
C-04	52.1	7293	190.2
C-05	51.8	7733	200.3

[164] Retired Units C-09, C-10, C-11, and C-12 were standby units limited to operating 500 hr/yr. Therefore, NMED determined that 500 hr/yr is representative for these units. NMED determined that 2016-2019 average operating hours are representative for retired Unit C-13, since 2019 was the last year of operation for this unit.

[165] The lack of a similar drop in operating hours for EGPP's engines in 2020 suggests that the pandemic may not be the cause of that year's boiler utilization anomaly.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
C-06	44.7	7253	162.3
C-07	50.0	7404	184.9

C.4.19.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at EGPP:

- SCR, SNCR, and NSCR are not technically feasible options.
- GCP is a technically feasible option and is currently utilized by Targa based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 3 g/hp-hr. [166]
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.5 g/hp/hr, consistent with the emissions standards for new natural gas-fired spark ignition lean burn engines in 20.2.50 NMAC.[167]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Harvest did not indicate that it intends to permanently retire any additional engines, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

As indicated in Section C.3.5, the following determinations were made regarding the technical feasibility of identified control options for the boilers at EGPP:

- SNCR is not a technically feasible option, in this case, because the exhaust temperature of the boilers is too low.
- GCP is a technically feasible option and is currently utilized by Targa based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- SCR is a technically feasible option with an expected NO_X control efficiency of 90 percent.
- FGR is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 30 ppm.
- LNB is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 9 ppm.
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 9 ppm.

[166] Targa's initial FFA submittal in 2019 specified that 2.0 g/hp-hr was achievable according to a vendor. However, in its June 2023 FFA update, an email from Siemens Energy indicated that the appropriate target NO_X rate for LEC modifications of the RICE is 3.0 g/hp-hr.

[167] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent for the 2SLB RICE at EGPP would be subject to the NO_X standard for new lean burn engines >500 and <1,875 bhp (0.5 g/bhp-hr).

- Unit retirement is a technically feasible option. However, Targa did not indicate that it intends to permanently retire any of the affected boiler units, so this option is not evaluated further.

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at EGPP:

- While a flare, SRU, or TO are technically feasible options, the use of an AGI well with redundant compression is an optimal approach to reducing emissions from ATS because emissions are only produced during AGI SSM/M events. Therefore, NMED did not evaluate these options.
- While improved flare design might reduce emissions somewhat during AGI SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events. Therefore, NMED did not evaluate this option.

C.4.19.5 Four-Factor Analysis

In order to determine what control measures are necessary at EGPP to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the NO_X units identified in section C.4.19.2 above. NMED did not conduct a FFA of potential control measures for SO_2 for EGPP's ATS because the most effective control available – an AGI well with redundant compression – is already being utilized at EGPP. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[168]

C.4.19.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.19.4 above. NMED utilized source-specific cost estimates provided by Targa in its calculations whenever possible. In cases where Targa failed to provide source-specific cost estimates or NMED found estimates provided by Targa to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[169]

NMED's cost effectiveness values for all technically feasible controls for the NO_X units at EGPP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the NO_X units at EGPP and supporting documentation for NMED's cost estimates are provided in Appendix D.

---

[168] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[169] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
B-01	FGR	$44,384	17.4	$3,000
	LNB	$80,201	23.5	$3,000
	SCR	$399,366	23.5	$17,000
	Replacement	$182,670	23.5	$8,000
B-02	FGR	$44,384	17.4	$3,000
	LNB	$80,201	23.5	$3,000
	SCR	$399,366	23.5	$17,000
	Replacement	$182,670	23.5	$8,000
C-01	LEC	$321,408	170.5	$2,000
	Replacement	$439,360	194.5	$2,000
C-02	LEC	$321,408	143.2	$2,000
	Replacement	$439,360	165.7	$3,000
C-03	LEC	$321,408	138.4	$2,000
	Replacement	$439,360	162.4	$3,000
C-04	LEC	$321,408	161.2	$2,000
	Replacement	$439,360	185.3	$2,000
C-05	LEC	$321,408	169.6	$2,000
	Replacement	$439,360	195.2	$2,000
C-06	LEC	$321,408	133.5	$2,000
	Replacement	$439,360	157.5	$3,000
C-07	LEC	$321,408	155.5	$2,000
	Replacement	$439,360	180.0	$2,000
C-01, C-02, C-03 [(1)]	Electrification	$950,592	536.8	$2,000
C-04, C-05, C-06 [(1)]	Electrification	$853,596	552.8	$2,000
C-07 and C-13 [(1)]	Electrification	$929,628	367.6	$3,000

[(1)] For purposes of its electrification analysis, Targa grouped certain RICE to reasonably match the capacity of one 3,250 hp EMD unit. Targa grouped Unit C-07 with Unit C-13 even though C-13 has been permanently retired.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the NO_X units at EGPP:

- Targa did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- In its 2019 FFA submittal, Targa indicated that the addition of "turbochargers or externally driven blowers" would be necessary to accommodate LEC. Targa also indicated that it would have to significantly upgrade EGPP's electrical substation to operate blowers associated with LEC. Targa used these requirements to justify including $8.4M for substation upgrades and $164,000 per engine per year in additional electricity costs for 400 hp electric blowers in the updated LEC cost evaluation provided in its 8/4/23 submittal. These costs were omitted from NMED's evaluation for several reasons. First, no other FFA submitted to NMED references the need for an external

blower as part of a LEC retrofit on a 2SLB RICE. Every other FFA references the potential (or actual) need for a turbocharger – which is powered by the engine's exhaust and thus does not have a significant electric demand – as part of a LEC retrofit on a 2SLB RICE, including engines identical or nearly identical to the ones at EGPP. Second, the vendor quote Targa utilized in the updated LEC cost evaluation provided in its 8/4/23 submittal provides two "turnkey" cost estimates for LEC, one for units already equipped with turbochargers and one for units not equipped with turbochargers. The quote states that "a non-turbocharged unit would require a turbocharger" and other equipment/modifications to achieve the target emission rate of 3 g/bhp-hr. In its updated cost evaluation, Targa indicated that EGPP's engines are not turbocharged and used the higher vendor cost estimate for non-turbocharged units. Hence, Targa's own evaluation is premised on the addition of turbochargers, not blowers, to accommodate LEC. Finally, Targa did not state, or provide any details supporting, the idea that adding turbochargers, as opposed to blowers, would necessitate upgrades to EGPP's substation.

- The Total Capital Costs (TCC), Direct Annual Costs (DAC) and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, due to a lack of information from Targa supporting a higher retrofit factor.
- In its 8/4/23 submittal, Targa indicated that $8.4M in substation upgrades would be necessary to support electrification at EGPP. NMED accounted for these costs in its determination of cost effectiveness. However, Targa's estimate did not include costs associated with distribution line upgrades. Therefore, NMED's Total Capital Investment (TCI) for electrification may be underestimated.
- In its 8/4/23 submittal, Targa indicated that electrification would result in approximately $3.6M in annual O&M costs for electricity and engine maintenance. NMED believes these costs are exaggerated based on calculations performed using the electricity rate provided by Targa ($0.053/kW-h) and reasonable assumptions regarding incremental maintenance costs for EMD. Furthermore, Targa failed to account for fuel savings associated with the shutdown of the existing natural gas-fired engines in its estimate of annual O&M costs. Therefore, NMED replaced Targa's estimate with its own estimate based on engineering judgement.
- Targa, like most of the companies required to submit a FFA, did not provide information regarding the TCI associated with the replacement of the 2SLB RICE units at EGPP with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement RICE[170] along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.
- Targa similarly did not provide information regarding the TCI associated with replacement of the boilers at EGPP with new boilers. Therefore, NMED used information provided by ERG for the replacement of a similar boiler at another facility to estimate these costs.

[170] This includes, but is not limited to, the U.S. EPA's Combined Heat and Power Catalog of Technologies (Reciprocating engines) and the U.S. Energy Information Agency's *Cost and Performance Characteristics of New Generating Technologies* in the 2023 Annual Energy Outlook.

C.4.19.5.2 Compliance Time

In its 2019 FFA submittal, Targa indicated it would take 7 years to implement LEC on the 2SLB RICE at EGPP. In its 2/17/20 submittal, Targa clarified that this estimate was based on the time necessary to install LEC on all 2SLB RICE at its Eunice, Monument and Saunders Gas Plants. NMED's FFA is specific to EGPP and does not consider the time necessary for compliance at other facilities when evaluating this factor. NMED's general assessment of the compliance time for LEC provided in Section C.3.1 is believed to be reasonably accurate.

Targa did not indicate how many years it would take to replace the 2SLB RICE at EGPP with new, functionally equivalent natural gas-fired units. NMED believes the general compliance times for like-kind replacement, provided in Section C.3.1, is reasonable.

In its 11/20/20 submittal, Targa estimated it would take 7-8 years to budget, design, procure, and construct all the equipment necessary to electrify the 2SLB RICE units at EGPP. NMED disagrees with this estimate based on information provided by other facilities and the implementation time of electrification projects at other facilities. NMED believes the general compliance time for electrification, provided in Section C.3.1, is more reasonable but recognizes several more years could be required considering the relative complexity.

Targa indicated it would take 5 years to implement FGR on the boilers at EGPP. NMED's general assessment of compliance time provided in Section C.3.5 is more reasonable. Targa did not indicate a timeline to implement LNB or replace the boilers. NMED's general assessment of compliance times provided in Sections C.3.5 is believed to be reasonably accurate.

Targa did not provide an estimate of the time necessary to implement SCR on the boilers at EGPP. NMED believes the general compliance time provided in Section C.3.5 is reasonable.

C.4.19.5.3 Remaining Useful Life

Despite the advanced age of the 2SLB RICE units at EGPP (>50 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

Manufacturers of new RICE will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new RICE are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE is 30 years. The estimated useful life of a replacement boiler is also 30 years based on the same reasoning.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

A vendor evaluation was provided that identified the useful life of FGR and LNB to be 30 years. Thirty years is thus the estimated remaining useful life for FGR and LNB.

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years.

C.4.19.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE and boilers at EGPP is provided in Sections C.3.1 and C.3.5, respectively.

C.4.19.5.5 Summary

NMED performed a FFA for all technically feasible control options for the NO_X units listed in Section C.4.19.2 above. The four statutory factors are discussed in Sections C.4.19.5.1 through C.4.19.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
B-01	FGR	$3,000	2-3	30	None
	LNB	$3,000	2-3	30	None
	SCR	$17,000	2-3	30	None
	Replacement	$8,000	3-4	30	None
B-02	FGR	$3,000	2-3	30	None
	LNB	$3,000	2-3	30	None
	SCR	$17,000	2-3	30	None
	Replacement	$8,000	3-4	30	None
C-01	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-02	LEC	$2,000	2-3	20	None
	Replacement	$3,000	3-4	30	None
C-03	LEC	$2,000	2-3	20	None
	Replacement	$3,000	3-4	30	None
C-04	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-05	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-06	LEC	$2,000	2-3	20	None
	Replacement	$3,000	3-4	30	None
C-07	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-01, C-02, C-03	Electrification	$2,000	4-6	25	None
C-04, C-05, C-06	Electrification	$2,000	4-6	25	None
C-07 and C-13	Electrification	$3,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.19.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[171]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For NO_X units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For NO_X units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost effective controls for EGPP Units B-01, B-02, C-01, C-02, C-03, C-04, C-05, C-06, and C-07. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
B-01	LNB	23.5
B-02	LNB	23.5
C-01	Replacement	194.5
C-02	Replacement	165.7
C-03	Replacement	162.4
C-04	Replacement	185.3
C-05	Replacement	195.2
C-06	Replacement	157.5
C-07	Replacement	180.0

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
B-01	FGR	Less stringent than LNB
B-01	Replacement	Same stringency as LNB but less cost-effective

[171] See *supra* note 13.

Unit No.	Control Measure	Reason
B-02	FGR	Less stringent than LNB
B-02	Replacement	Same stringency as LNB but less cost-effective
C-01	LEC	Less stringent than replacement
C-01	Electrification	Categorically excluded
C-02	LEC	Less stringent than replacement
C-02	Electrification	Categorically excluded
C-03	LEC	Less stringent than replacement
C-03	Electrification	Categorically excluded
C-04	LEC	Less stringent than replacement
C-04	Electrification	Categorically excluded
C-05	LEC	Less stringent than replacement
C-05	Electrification	Categorically excluded
C-06	LEC	Less stringent than replacement
C-06	Electrification	Categorically excluded
C-07	LEC	Less stringent than replacement
C-07	Electrification	Categorically excluded

As noted above, NMED did not conduct a FFA of potential control measures for Units C-08, C-09, C-10, C-11, C-12, and C-13 because they have been permanently shut down and removed from EGPP's NSR permit. However, based on when they were retired, the resulting emissions reductions were realized during the second planning period. Therefore, NMED estimated the NO_X emissions reductions resulting from the retirement of these units by averaging 2016-2019 emissions reported by Harvest pursuant to 20.2.73 NMAC.[172] These emissions are summarized below.

Unit No.	Estimated NO_X Reductions (ton/yr)
C-08	144.0
C-09	32.7
C-10	18.9
C-11	30.2
C-12	40.6
C-13	225.6

NMED also did not conduct a FFA of potential control measures for EGPP's ATS. Because the most effective control available – an AGI well with redundant compression – is already being utilized at EGPP, NMED determined that reasonable progress does not require new controls on the ATS. However, based on when redundant compression was added to the AGI well, the resulting emissions reductions were realized during the second planning period. Therefore, NMED estimated the SO_2 reductions resulting from the addition of redundant compression to the AGI well using reported AGI SSM/M flaring emissions for acid gas flare F-01.

[172] NMED estimated the emissions reductions resulting from the retirement of Unit C-08 by averaging 2016-2018 emissions reported by Harvest, as it was shut down a year earlier than the other units.

Unit No.	Estimated SO_2 Reductions (ton/yr)
F-01	308.2 [(1)]

[(1)] Estimated reductions represent the difference between AGI SSM/M emissions from F-01 prior to installation of the backup compressor (416.7 ton/yr) and after (108.5 ton/yr).

Combining expected reductions from the controls NMED has determined are necessary to make reasonable progress and reductions resulting from recent retirements and the addition of redundant compression to the AGI well, NMED estimates the total emissions reductions at EGPP during the second planning period will be approximately 1,779.6 ton/yr of NO_X and 308.2 ton/yr of SO_2.

C.4.20 Targa Midstream Services – Monument Gas Plant

Resources used in NMED's FFA for Monument Gas Plant (MGP) include, but are not limited to, the following:

- The FFA completed by Trinity Consultants for Targa Midstream Services, LLC (Targa) and submitted to NMED on or about 11/1/19.
- Additional information provided by Targa on 12/13/19, 2/17/20, 3/12/20, 11/20/20, 2/16/21, and 8/4/23.
- A detailed discussion between Targa and NMED on 6/8/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- Memorandum from Ramboll to WRAP Oil and Gas Working Group - Additional Reasonable Control Strategies for Oil and Gas Emission Sources in the WESTAR-WRAP region (March 23, 2020)
- FFAs developed for similar facilities in New Mexico and other states.

C.4.20.1 Facility Description

MGP is a natural gas processing facility located 2.8 miles west of Monument in Lea County, New Mexico at latitude 32° 36' 38", longitude -103° 18' 44". It is owned by Versado Gas Processors, LLC and operated by Targa, and currently operates under Title V Operating Permit No. P110-R3M1, which expires on April 12, 2025. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 68.2 miles.

The function of the facility is to process natural gas through inlet separation, an amine system for acid gas removal (carbon dioxide and hydrogen sulfide), dehydration for water removal, and the separation of methane from natural gas liquids. The facility is authorized for continuous operation, and its total potential to emit is 1012.8 tons per year of NO_X and 372.9 tons per year of SO_2.[173]

[173] AQB Title V Operating Permit No. P110-R3M1, Table 102.A.

C.4.20.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at MGP.[174]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
C-01	2SLB RICE	Clark RA-8	<1956 (1)	800 hp
C-02	2SLB RICE	Clark RA-8	<1956 (1)	800 hp
C-04	2SLB RICE	Clark RA-6	<1956 (1)	600 hp
C-05	2SLB RICE	Clark RA-6	<1956 (1)	600 hp
C-06	2SLB RICE	Clark RA-6	<1956 (1)	600 hp
C-24	2SLB RICE	Clark HRA-8	<1696 (1)	880 hp
C-28	2SLB RICE	Cooper Bessemer GMVA-8	<1977 (1)	1,100 hp

(1) Targa's most recent Title V permit application does not provide a date of manufacture for Units C-01 through C-28, but indicates they were all constructed/reconstructed in 1956 (C-01 through C-06), 1969 (C-24), or 1977 (C-28). The date of manufacture necessarily precedes the construction/reconstruction date.

NMED also elected to evaluate the ATS at MGP for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). The ATS at MGP consists of an ATU (Unit AM-01), AGI well (Unit AGI), two electric AGI well compressors (Units AGI-C1 and AGI-C2), and an acid gas flare (Unit F-03). During normal operations, acid gas exiting the ATU is routed to the AGI well for disposal resulting in no emissions to the atmosphere. During AGI SSM/M events, acid gas is rerouted to the acid gas flare for disposal, which produces SO_2 emissions. AGI SSM/M flaring emissions are minimized via the second, redundant AGI well compressor, which provides compression when the primary AGI well compressor fails or is taken out of service for maintenance, allowing for continued use of the AGI well when flaring would otherwise be required.

C.4.20.3 Projected Actual Emissions

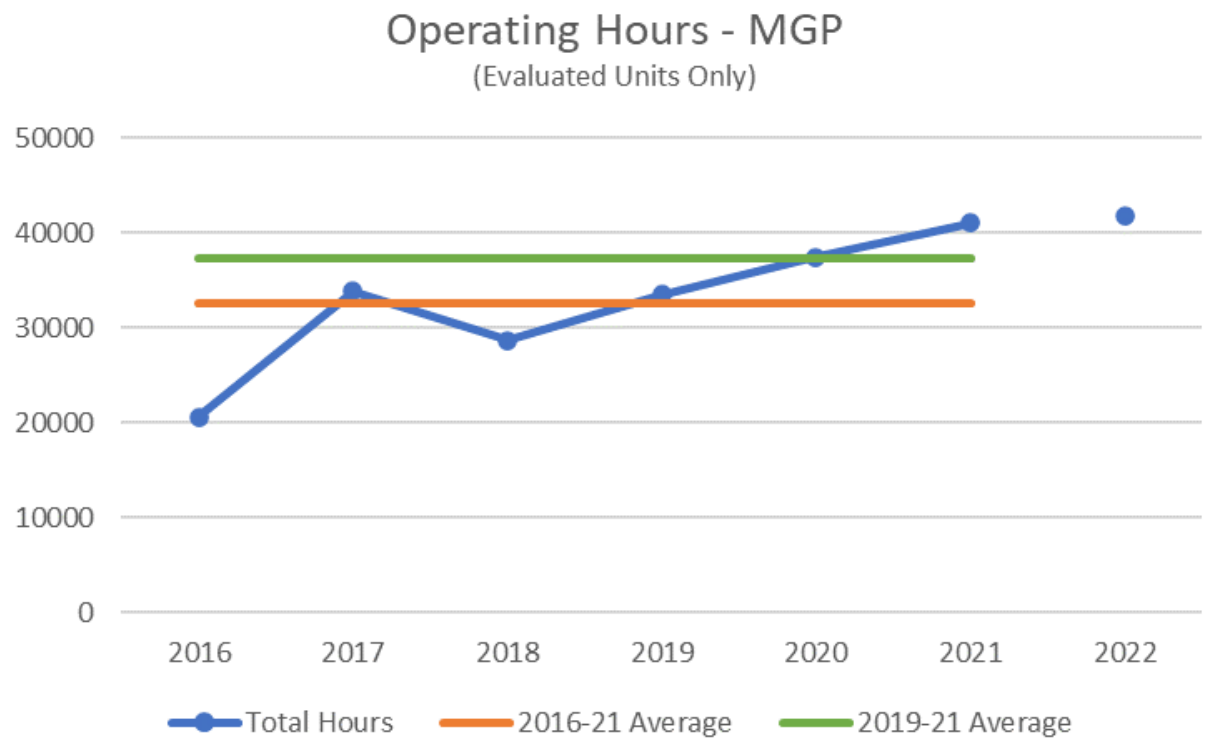
Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Targa did not request a future utilization adjustment for MGP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at MGP.

For the emissions units at MGP requiring a FFA of potential control measures for NO_X ("NO_X units"), NMED calculated baseline actual emissions by multiplying representative annual operating hours by the NO_X emission rates reported in Targa's most recent periodic emissions test report(s).[175,] Because the NO_X units at MGP operate at varying loads, NMED conservatively adjusted reported emission rates to 100

[174] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.
[175] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.

percent load to represent worst-case emissions.[176] Reported and adjusted emission rates for the NO_X units at MGP are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr @ 100% load)
C-01	NA (1)	---	---	28.5 (2)
C-02	6/14/23	27.4	96%	28.5
C-04	NA (1)	---	---	24.0 (2)
C-05	6/14/23	22.1	92%	24.0
C-06	6/14/23	9.3	96%	9.7
C-24	6/15/23	37.6	94%	40.0
C-28	6/16/23	15.8	92%	17.2



(1) NA = Not Available

(2) The adjusted emissions of Unit C-02 were used as a surrogate for identical Unit C-01, as NMED was unable to locate a recent emissions test report for this unit. The adjusted emissions of Unit C-05 were used as a surrogate for identical Unit C-04 for the same reason.

To determine representative annual operating hours for the NO_X units at MGP, NMED analyzed 2016-2021 operating hours reported by Targa pursuant to 20.2.73 NMAC. NMED was in receipt of Targa's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-2021 operating hours for the NO_X units at MGP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
C-01	2357	6257	2965	4813	2388	648	0
C-02	4069	4689	4217	5609	4992	6630	8604
C-04	990	3285	3912	3525	600	756	0
C-05	3938	4730	4342	7255	8760	8550	8540
C-06	2035	6553	3879	3641	8590	8244	8488
C-24	6610	6541	8501	8683	8478	8511	8421
C-28	573	1798	841	0	3624	7719	7749

[176] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

As shown above, MGP's operating hours have increased steadily in recent years, with preliminary 2022 data suggesting utilization plateaued in 2021. Therefore, NMED determined that 2019-2021 average operating hours are representative for the NO_X units at MGP.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the NO_X units at MGP are summarized below.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
C-01	28.5	2616	37.3
C-02	28.5	5744	82.0
C-04	24.0	1627	19.5
C-05	24.0	8188	98.3
C-06	9.7	6825	33.1
C-24	40.0	8557	171.1
C-28	17.2	3781	32.5

C.4.20.4 Technical Feasibility of Available Controls

As indicated in Section C.3.1, the following determinations were made regarding the technical feasibility of identified control options for the 2SLB RICE at MGP:

- SCR, SNCR, and NSCR are not technically feasible options.

- GCP is a technically feasible option and is currently utilized by Targa based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- LEC is a technically feasible option expected to achieve a vendor-quoted NO_X emission rate of 3.0 g/hp-hr.[177]
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 0.5 g/hp-hr, consistent with the emissions standards for new natural gas-fired spark ignition lean burn engines in 20.2.50 NMAC. [178]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Targa has not indicated that it intends to permanently retire any of the affected units, so this option is not evaluated further.
- Electrification is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants).

As indicated in Section C.3.6, the following determinations were made regarding the technical feasibility of identified control options for the ATS at MGP:

- While a flare, SRU, or TO are technically feasible options, the use of an AGI well with redundant compression is an optimal approach to reducing emissions from ATS because emissions are only produced during AGI SSM/M events. Therefore, NMED did not evaluate these options.
- While improved flare design might reduce emissions somewhat during AGI SSM/M events, the potential marginal improvement in combustion efficiency – perhaps 1 to 2 percentage points – from the most optimized flare is not anticipated to be a cost-effective option for reducing SO_2 emissions from acid gas flaring during AGI SSM/M events. Therefore, NMED did not evaluate this option.

C.4.20.5 Four-Factor Analysis

In order to determine what control measures are necessary at MGP to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the NO_X units identified in section C.4.20.2 above. NMED did not conduct a FFA of potential control measures for SO_2 for MGP's ATS because the most effective control available – an AGI well with redundant compression – is already being utilized at MGP. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[179]

C.4.20.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.20.4 above.

---

[177] Targa's initial FFA submittal in 2019 indicated that 2.0 g/hp-hr was achievable, according to a vendor. However, in its June 2023 FFA update, an email from Siemens Energy indicated that the appropriate target NO_X emission rate for LEC modifications of the RICE at MGP is 3.0 g/hp-hr.

[178] 20.2.50 NMAC contains varying emission standards for new natural gas-fired spark ignition engines based on engine type and rated brake horsepower. See Section 113, Table 2. Equivalent replacements for the 2SLB RICE at MGP would be subject to the NO_X standard for new lean burn engines >500 and <1,875 bhp (0.5 g/bhp-hr).

[179] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

NMED utilized source-specific cost estimates provided by Targa in its calculations whenever possible. In cases where Targa failed to provide source-specific cost estimates or NMED found estimates provided by Targa to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[180]

NMED's cost effectiveness values for all technically feasible controls for the NO_X units at MGP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the NO_X units at MGP and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
C-01	LEC	$321,408	30.4	$11,000
	Replacement	$292,907	36.2	$8,000
C-02	LEC	$321,408	66.8	$5,000
	Replacement	$292,907	79.4	$4,000
C-04	LEC	$321,408	16.3	$20,000
	Replacement	$219,680	19.0	$12,000
C-05	LEC	$321,408	82.1	$4,000
	Replacement	$219,680	95.6	$2,000
C-06	LEC	$321,408	19.5	$16,000
	Replacement	$219,680	30.8	$7,000
C-24	LEC	$321,408	146.2	$2,000
	Replacement	$322,198	167.0	$2,000
C-28	LEC	$266,171	18.7	$14,000
	Replacement	$402,747	30.2	$13,000
C-01, C-02 (1)	Electrification	$770,731	119.3	$6,000
C-04, C-05, C-06 (1)	Electrification	$839,974	150.9	$6,000
C-24	Electrification	$742,765	171.1	$4,000
C-28	Electrification	$1,085,102	32.5	$33,000

(1) For purposes of its electrification analysis, Targa grouped certain RICE to reasonably match the capacity of one 1,750 hp EMD unit.

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the NO_X units at MGP:

[180] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

- Targa did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.
- In its 2019 FFA submittal, Targa indicated that the addition of "turbochargers or externally driven blowers" would be necessary to accommodate LEC. Targa also indicated that it would have to significantly upgrade MGP's electrical substation to operate blowers associated with LEC. Targa used these requirements to justify including $6.3M for substation upgrades and $164,000 per engine per year in additional electricity costs for 400 hp electric blowers in the updated LEC cost evaluation provided in its 8/4/23 submittal. These costs were omitted from NMED's evaluation for several reasons. First, no other FFA submitted to NMED references the need for an external blower as part of a LEC retrofit on a 2SLB RICE. Every other FFA references the potential (or actual) need for a turbocharger – which is powered by the engine's exhaust and thus does not have a significant electric demand – as part of a LEC retrofit on a 2SLB RICE, including engines identical or nearly identical to the ones at MGP. Second, the vendor quote Targa utilized in the updated LEC cost evaluation provided in its 8/4/23 submittal provides two "turnkey" cost estimates for LEC, one for units already equipped with turbochargers and one for units not equipped with turbochargers. The quote states that "a non-turbocharged unit would require a turbocharger" and other equipment/modifications to achieve the target emission rate of 3 g/bhp-hr. In its updated cost evaluation Targa indicated that, with the exception of Unit C-28, MGP's engines are not turbocharged and used the higher vendor cost estimate for non-turbocharged units (Targa used the lower vendor cost estimate for turbocharged units for Unit C-28). Hence, Targa's own evaluation is premised on the addition of turbochargers, not blowers, to accommodate LEC. Finally, Targa did not state, or provide any details supporting, the idea that adding turbochargers, as opposed to blowers, would necessitate upgrades to MGP's substation.
- In its 8/4/23 submittal, Targa indicated that $6.3M in substation upgrades would be necessary to support electrification at MGP. NMED accounted for these costs in its determinations of cost effectiveness. However, Targa's estimate did not include any costs associated with distribution line upgrades. Therefore, NMED's Total Capital Investment (TCI) estimates for electrification may be underestimated.
- In its 8/4/23 submittal, Targa indicated that electrification would result in approximately $2M in annual O&M costs for electricity and engine/compressor maintenance. NMED believes these costs are exaggerated based on calculations performed using the electricity rate provided by Targa ($0.053/kW-h) and reasonable assumptions regarding incremental maintenance costs for EMD. Furthermore, Targa failed to account for fuel savings associated with the shutdown of the existing natural gas-fired engines in its estimate of annual O&M costs. Therefore, NMED substituted its own estimate of annual O&M costs based on engineering judgement.
- Targa, like most of the companies required to submit a FFA, did not provide information regarding the Total Capital Investment (TCI) associated with the replacement of the 2SLB RICE at MGP with new, functionally equivalent natural gas-fired units. NMED reviewed several publicly available resources with information that could be used to estimate the TCI of a replacement RICE along with information provided by other companies with similar units. NMED determined that the most applicable cost metric ($ per hp basis) was provided by El Paso Natural Gas Company in support of their FFA submittals. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy.

C.4.20.5.2 Compliance Time

In its 2019 FFA submittal, Targa indicated it would take 7 years to implement LEC on the 2SLB RICE at MGP. In its 2/17/20 submittal, Targa clarified that this estimate was based on the time necessary to install LEC on all 2SLB RICE at its Eunice, Monument and Saunders Gas Plants. NMED's FFA is specific to MGP and does not consider the time necessary for compliance at other facilities when evaluating this factor. NMED's general assessment of the compliance time for LEC provided in Section C.3.1 is believed to be reasonably accurate.

Targa did not indicate how many years it would take to replace the 2SLB RICE units at MGP with new, functionally equivalent natural gas-fired units. NMED believes the general compliance time for like-kind replacement, provided in Section C.3.1, is reasonable.

In its 11/20/20 submittal, Targa estimated it would take 7-8 years to budget, design, procure, and construct all the equipment necessary to electrify the 2SLB RICE units at MGP. NMED disagrees with this estimate based on information provided by other facilities and the implementation time of electrification projects at other facilities. NMED believes the general compliance time for electrification, provided in Section C.3.1, is more reasonable but recognizes several more years could be required considering the relative complexity.

C.4.20.5.3 Remaining Useful Life

Despite the advanced age of the units at MGP (~50 to 70 years), owners and operators of gas compression equipment in New Mexico have indicated that similar RICE would last at least 20 more years with proper maintenance. Twenty years is thus the estimated remaining useful life for LEC.

Manufacturers of new RICE will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new RICE are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement RICE is 30 years.

There is limited information about the useful life of EMD units, but research suggests the useful life is at least 25 years.

C.4.20.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for 2SLB RICE at MGP is provided in Section C.3.1.

C.4.20.5.5 Summary

NMED performed a FFA for all technically feasible control options for the NO_X units listed in Section C.4.20.2 above. The four statutory factors are discussed in Sections C.4.20.5.1 through C.4.20.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
C-01	LEC	$11,000	2-3	20	None
	Replacement	$8,000	3-4	30	None
C-02	LEC	$5,000	2-3	20	None
	Replacement	$4,000	3-4	30	None
C-04	LEC	$20,000	2-3	20	None
	Replacement	$12,000	3-4	30	None
C-05	LEC	$4,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-06	LEC	$16,000	2-3	20	None
	Replacement	$7,000	3-4	30	None
C-24	LEC	$2,000	2-3	20	None
	Replacement	$2,000	3-4	30	None
C-28	LEC	$14,000	2-3	20	None
	Replacement	$13,000	3-4	30	None
C-01, C-02	Electrification	$6,000	4-6	25	None
C-04, C-05, C-06	Electrification	$6,000	4-6	25	None
C-24	Electrification	$4,000	4-6	25	None
C-28	Electrification	$33,000	4-6	25	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.20.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[181]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For NO_X units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For NO_X units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective

[181] See *supra* note 13.

control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost-effective controls for MGP Units C-01, C-02, C-04, C-05, C-06, and C-24. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following cost-effective controls are necessary to make reasonable progress:

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
C-01	Replacement	36.2
C-02	Replacement	79.4
C-05	Replacement	95.6
C-06	Replacement	30.8
C-24	Replacement	167.0

NMED rejected the following cost-effective controls for the reason(s) stated:

Unit No.	Control Measure	Reason
C-01	Electrification	Categorically excluded
C-02	LEC	Less stringent than replacement
C-02	Electrification	Categorically excluded
C-04	Electrification	Categorically excluded
C-05	LEC	Less stringent than replacement
C-05	Electrification	Categorically excluded
C-06	Electrification	Categorically excluded
C-24	LEC	Less stringent than replacement
C-24	Electrification	Categorically excluded

NMED's FFA did not identify any cost-effective controls for MGP Unit C-28. Therefore, NMED determined that reasonable progress does not require new controls on this unit.

As noted above, NMED did not conduct a FFA of potential control measures for MGP's ATS. Because the most effective control available – an AGI well with redundant compression – is already being utilized at MGP, NMED determined that reasonable progress does not require new controls for the ATS. However, based on when redundant compression was added to the AGI well, the resulting emissions reductions were realized during the second planning period. Therefore, NMED estimated the SO_2 reductions resulting from the addition of redundant compression to the AGI well using reported AGI SSM/M flaring emissions for acid gas flare F-03. These reductions are summarized below.

Unit No.	Estimated SO_2 Reductions (ton/yr)
F-03	112.2[(1)]

[(1)] Estimated reductions represent the difference between AGI SSM/M emissions from F-03 prior to installation of the backup compressor (125.4 ton/yr) and after (13.2 ton/yr).

Combining expected reductions from the controls NMED has determined are necessary to make reasonable progress and reductions resulting from the addition of redundant compression to the AGI

well, NMED estimates the total emissions reductions at MGP during the second planning period will be approximately 409.0 ton/yr of NO_X and 112.2 ton/yr of SO_2.

C.4.21 Targa Midstream Services – Saunders Gas Plant

Saunders Gas Plant (SGP) is a former natural gas processing facility located 15 miles northwest of Lovington in Lea County, New Mexico at latitude 33° 03' 26", longitude -103° 36' 27". It is owned by Versado Gas Processors, LLC and operated by Targa Midstream Services, LLC (Targa), and previously operated under Title V Operating Permit No. P111-R3. The shortest distance to the boundary of the nearest Class I Area, Salt Creek Wilderness Area, is approximately 56.4 miles. Notably, Salt Creek Wilderness Area is the only Class I Area in New Mexico projected to be above the URP glidepath in 2028 and for which a robust demonstration is required.[182]

SGP was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Section C.2 in 2019. NMED originally selected nine 2SLB RICE (Units C-01, C-02, C-03, C-04, C-05, C-06, C-07, C-08, and C-09) and three 4SRB RICE (Units G-01, G-02 and G-03) for an analysis of potential control measures for NO_X in the second planning period. NMED also elected to evaluate the ATS at SGP (comprising Units A-01, F-01, F-03, and I-01) for potential control measures for SO_2 due to the potential for significant emissions, during normal operations and/or SSM/M events, from some of the controls commonly used to dispose of ATS acid gas streams (e.g., flares). However, Targa idled the facility in 2021, and later informed NMED that it had decided to permanently shut down gas plant operations, remove all equipment selected for analysis in the second planning period from SGP's permits, and re-permit the few remaining sources under an Oil and Gas General Construction Permit. On May 30, 2024, Targa submitted an administrative permit revision removing Units C-01, C-02, C-03, C-04, C-05, C-06, C-07, C-08, C-09, G-01, G-02, G-03, A-01, F-01, F-03, and I-01 from NSR Permit No. 0315-M4R2 and Title V Permit No. P111-R3, and voluntarily discontinuing the Title V.

Because Targa has shut down gas plant operations at SGP, removed all of the units selected for analysis in the second planning period from SGP's NSR and Title V permits, and discontinued the Title V, NMED did not perform a FFA of potential control measures for any of these units. EPA guidance provides that a state may forgo a full FFA if a source is already "effectively controlled" and the state can demonstrate why a FFA would not result in new controls and would therefore be a futile exercise.[183] NMED considers it self-evident that a FFA of potential control measures for retired units at a facility that has been shut down would be futile. There is no more effective control than retirement, which reduces emissions by 100 percent. Therefore, NMED has determined that Units C-01, C-02, C-03, C-04, C-05, C-06, C-07, C-08, C-09, G-01, G-02, G-03, A-01, F-01, F-03, and I-01 are effectively controlled by virtue of their retirement due to the shutdown of gas plant operations at SGP, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

Based on when SGP was shut down, the emissions reductions resulting from the retirement of the affected units were realized during the second planning period. Therefore, NMED estimated the NO_X emissions reductions resulting from the retirement of SGP Units C-01, C-02, C-03, C-04, C-05, C-06, C-07,

[182] See Chapter 10, Progress, Degradation, and URP Glidepath Checks for Class I Areas in New Mexico, for NMED's robust demonstration for Salt Creek Wilderness Area.

[183] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021) at 5.

C-08, C-09, G-01, G-02, and G-03 and the SO_2 emissions reductions resulting from the retirement of the units comprising the ATS by averaging 2016-2020 emissions reported by Targa pursuant to 20.2.73 NMAC. These emissions are summarized below.

Pollutant	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	2020 Emissions (tons)	Average Emissions (ton/yr)
NO_X	599.0	636.6	696.3	713.8	514.0	632.0
SO_2	385.6	561.0	247.3	226.6	3.7	284.8

C.4.22 Tri-State Generation & Transmission Association – Prewitt Escalante Generating Station

Prewitt Escalante Generating Station (PEGS) is a former 268 MW coal-fired electric power plant located 4 miles north of Prewitt in McKinley County, New Mexico at latitude 35° 24' 57", longitude -108° 04' 58". It is owned by Tri-State Generation and Transmission Association, Inc. (Tri-State), and was one of 23 facilities selected for an analysis of potential control measures when NMED performed the source screening described in Section C.2 in 2019. However, Tri-State subsequently shut down PEGS on August 31, 2020, and NMED voluntarily discontinued its Title V permit (Permit No. P012-R3) as of September 28, 2020.

Tri-State's shutdown of PEGS occurred in two phases. Phase 1, completed on August 31, 2020, included the permanent shutdown of the main coal-fired boiler, associated coal and limestone handling equipment, and cooling tower after all existing coal stored at the site was combusted. Phase 2, completed on January 28, 2021, included the transfer of ownership and operation of the auxiliary boiler and water treatment plant to McKinley Paper Company's Prewitt Mill. All previously shutdown or transferred equipment was subsequently removed from PEGS' NSR permit (Permit No. 0285-M5); the only remaining emissions units include the plant heating boiler, gasoline tank, fire pump engine, and fugitive sources associated with final site restoration. According to Tri-State, these units "will allow the continued decommissioning of PEGS until total facility closure."[184] Tri-State's timeline to fully decommission the plant is unknown.

NMED originally selected the main boiler for an analysis of potential control measures for NO_X and SO_2 in the second planning period, and the auxiliary boiler and plant heating boiler for an analysis of potential control measures for NO_X. However, because PEGS has since been shut down and is in the process of being decommissioned, NMED did not perform a FFA of potential control measures for any of these units. With regard to the main boiler, EPA guidance provides that a state may forgo a full FFA if a source is already "effectively controlled" and the state can demonstrate why a FFA would not result in new controls and would therefore be a futile exercise.[185] NMED considers it self-evident that a FFA of potential control measures for a retired unit at a facility that has been shut down and is the process of being decommissioned would be futile. There is no more effective control than retirement, which reduces emissions by 100 percent, and the decommissioning of PEGS will make it impossible to add new controls. Therefore, NMED has determined that the main boiler is effectively controlled by virtue of its

[184] Air Quality Permit #0285-M4-R2 Significant Revision Application (February 10, 2021).
[185] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021) at 5.

retirement due to the shutdown of PEGS, and that a FFA could only result in the conclusion that no further controls are necessary to make reasonable progress.

With regard to the auxiliary boiler, McKinley Paper Company's Prewitt Mill is a minor source and thus exempt from analysis in the second planning period. As described in Section C.2, NMED limited its tier one source screening to Title V facilities and only selected a subset of those for analysis. As such, the transfer of the auxiliary boiler to Prewitt Mill removed it from consideration during the second planning period, although it could be selected for analysis in a future planning period as NMED expands the universe of sources evaluated beyond just Title V facilities.

Finally, with regard to the plant heating boiler, NMED believes it has sufficient information to conclude that there are no cost-effective controls without performing a full FFA. The plant heating boiler is currently limited to 4,350 hours of operation per calendar year to ensure that pipes and other equipment don't freeze in the winter months but has averaged just 2,204 hours of operation per year since PEGS shut down, resulting in 11.6 tons per year of NO_X emissions on average.[186] This suggests that, based on a maximum achievable control efficiency of approximately 90%, the potential emissions reductions from new controls are about 10 tons per year at best. Furthermore, the annualized costs of any new controls would be grossly inflated given that their remaining useful life would be limited to the relatively short time likely required to finish decommissioning the plant. High annualized costs coupled with low expected emissions reductions yield high cost effectiveness values, and based its experience and FFAs conducted for other facilities, NMED is confident that the cost effectiveness of any new controls for PEGS' plant heating boiler would greatly exceed its $10,000/ton cost effectiveness threshold.[187] Therefore, NMED has determined that reasonable progress does not require new controls on this unit.

Based on when PEGS was shut down, the emissions reductions resulting from the retirement of the main boiler were realized during the second planning period. Therefore, NMED estimated the NO_X and SO_2 emissions reductions resulting from the retirement of the main boiler by averaging 2016-2019 emissions reported by Tri-State pursuant to 20.2.73 NMAC. These emissions are summarized below.

Pollutant	2016 Emissions (tons)	2017 Emissions (tons)	2018 Emissions (tons)	2019 Emissions (tons)	Average Emissions (ton/yr)
NO_X	2,436.7	2,124.8	2,441.9	2,250.2	2,313.4

C.4.23 Xcel Energy – Cunningham Station Power Plant

Resources used in NMED's FFA for Cunningham Station Power Plant (CSPP) include, but are not limited to, the following:

[186] Based on 2020 and 2021 emission inventory data. PEGS transitioned to a minor source when shutdown and transferred equipment was removed from its NSR permit in 2021. Therefore, it was no longer required to submit an annual emission inventory starting in 2022.

[187] This conclusion is supported by Tri-State's initial FFA for PEGS, which estimated cost effectiveness values ranging from $19,410 to $33,653/ton (2019$) for plant heating boiler NO_X controls. The FFA was completed prior to the decision to shut down the plant and therefore assumed a remaining useful life of 20 to 30 years for all controls.

- The FFA completed by Trinity Consultants for Xcel Energy (Xcel) and submitted to NMED on or about 11/1/19.
- Additional information provided by Xcel on 2/14/20, 11/2/20, 1/25/21, and 7/18/23.
- A detailed discussion between Xcel and NMED on 6/22/23.
- NMED's archive of files and documentation related to the facility, including but not limited to permits, emissions test reports, and operating hours and other emission inventory data.
- U.S. EPA Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019) and Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period (July 8, 2021).
- FFAs developed for similar facilities in New Mexico and other states.

C.4.23.1 Facility Description

CSPP is a 487 MW electric power plant located 12.5 miles west of Hobbs in Lea County, New Mexico at latitude 32° 42' 44", longitude -103° 21' 13". It is owned and operated by Southwestern Public Service Company, a subsidiary of Xcel, and currently operates under Title V Operating Permit No. P080-R4, which expires on April 9, 2026. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 69.4 miles.

The function of the facility is to provide commercial electric power using boilers and turbines fueled with natural gas. The facility is authorized for continuous operation,[188] and its total potential to emit is 4072.5 tons per year of NO_X and 155.8 tons per year of SO_2.[189]

C.4.23.2 Evaluated Units

NMED determined that a FFA of potential control measures for NO_X was required for the following emissions units at CSPP:[190]

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	Boiler	Combustion Engineering 9752	<1957 (1)	82 MW
2	Boiler	Combustion Engineering 19813	<1965 (1)	234 MW
3	Turbine	Westinghouse 501D5	<1997 (1)	115 MW
4	Turbine	Westinghouse 501D5	<1997 (1)	115 MW

(1) Xcel's most recent Title V permit application does not provide a date of manufacture for any of the units at CSPP, but indicates that Units 1 and 2 were constructed/reconstructed in 1957 and 1965, respectively, and Units 3 and 4 were constructed/reconstructed in 1997. The date of manufacture necessarily precedes the construction/reconstruction date.

NMED also determined that a FFA of potential control measures for SO_2 was required for CSPP Units 3 and 4. However, due to the high volumetric flow rate and very low SO_2 concentration of CT exhaust, no technically or economically feasible SO_2 controls exist for these units. CT SO_2 emissions are a function of the sulfur content of the fuel gas. As a result, limiting the fuel sulfur content is the only practicable means of reducing CT SO_2 emissions. CSPP Units 3 and 4 are already subject to fuel total sulfur content

[188] The boilers at CSPP may operate on a continuous basis, but the turbines are subject to annual limits on operating hours and the number of startup and shutdown cycles.
[189] AQB Title V Operating Permit No. P080-R4, Table 102.A.
[190] See Chapter 6, Selection of Sources for Control Measures Analysis, for a discussion of NMED's two-tiered process for selecting sources and emissions units requiring a FFA of potential control measures for NO_X and/or SO_2.

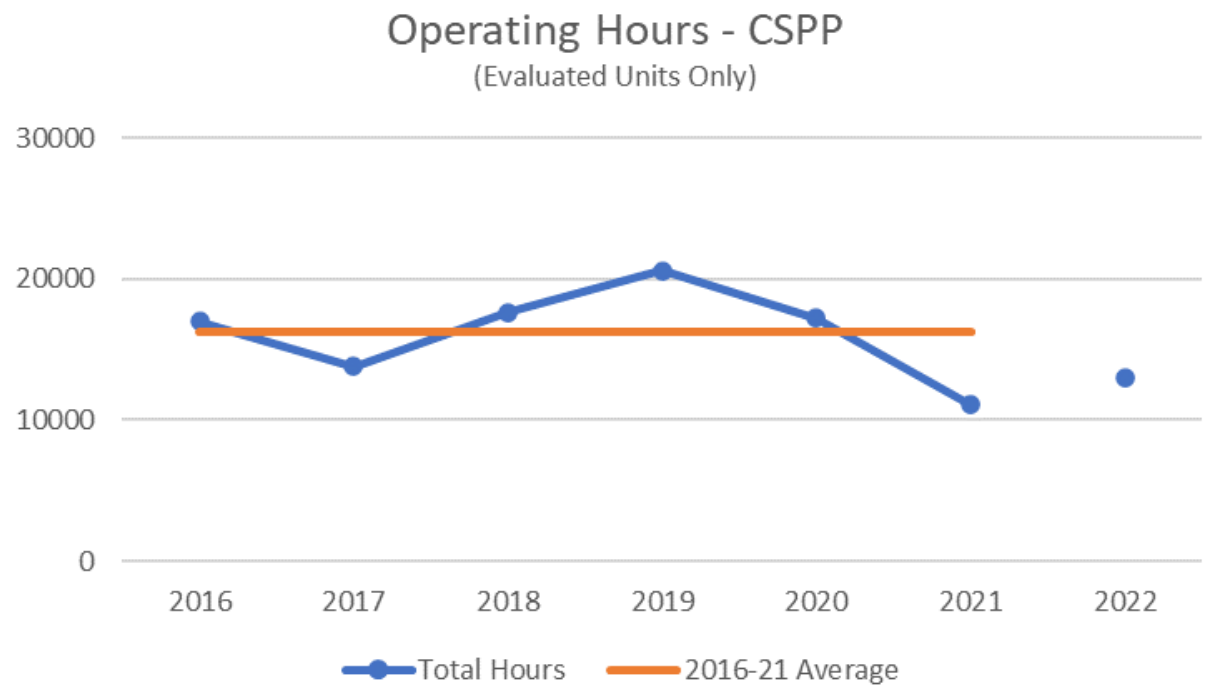
limits representing best available control technology (BACT) and emit less than one ton of SO_2 per year on average.[191] Therefore, NMED did not evaluate Units 3 and 4 for potential control measures for SO_2, only NO_X.

C.4.23.3 Projected Actual Emissions

Projected actual emissions represent estimated 2028 emissions absent any additional controls. NMED estimated projected actual emissions by applying a future utilization adjustment to baseline (i.e., current) actual emissions if the owner requested this adjustment. Xcel did not request a future utilization adjustment for CSPP. Therefore, NMED did not apply one, and projected actual emissions equal baseline actual emissions for the emissions units at CSPP.

NMED calculated baseline actual emissions for the emissions units at CSPP by multiplying representative annual operating hours by the NO_X emission rates reported in Xcel's most recent periodic emissions test report(s).[192,] Because the emissions units at CSPP operate at varying loads, NMED conservatively adjusted reported emission rates to 100 percent load to represent worst-case emissions.[193] Reported and adjusted emission rates for the emissions units at CSPP are summarized below.

Unit No.	Test Date	Reported NO_X Emissions (lb/hr)	Load During Test (%)	Adjusted NO_X Emissions (lb/hr at 100% load)
1	NA [(1)]	---	---	120.7 [(3)]
2	12/28/21	0.154	NP [(2)]	300.5
3	6/29/23	0.057	NP [(2)]	79.8 [(4)]
4	7/19/23	0.048	NP [(2)]	67.2 [(4)]



[(1)] NA = Not Available
[(2)] NP = Not Provided
[(3)] The reported emission rate (in lb/MMBtu) of Unit 2 was used as a surrogate for Unit 1, as NMED was unable to locate a recent emissions test report for this unit.
[(4)] Assumed the reported emission rates of Units 3 and 4 are representative of emissions at 100 percent load, as load was not provided in the emissions test reports for these units.

To determine representative annual operating hours for the emissions units at CSPP, NMED analyzed 2016-21 operating hours reported by Xcel pursuant to 20.2.73 NMAC. NMED was in receipt of Xcel's reported 2022 operating hours at the time of its analysis, but the data were still undergoing internal QA/QC checks and had not been certified yet, so NMED excluded them from its analysis. 2016-21 operating hours for the emissions units at CSPP are summarized and plotted below; reported 2022 operating hours are included for informational purposes only.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
1	4506	4336	6373	6927	6295	1379	728
2	8040	6833	4887	4717	4621	5578	7061

[191] Based on 2016-2022 emission inventory data.
[192] Emissions test reports were obtained from NMED's Air Quality Bureau Compliance Reporting System.
[193] NMED assumed a linear relationship between emissions and load for purposes of this adjustment. NMED recognizes that this relationship is likely not always linear but generally lacks sufficient information to characterize it for individual emissions units.

Unit No.	2016 Hours	2017 Hours	2018 Hours	2019 Hours	2020 Hours	2021 Hours	2022 Hours
3	1597	996	2168	4066	3358	2003	1869
4	2848	1611	4217	4870	2963	2120	3368

As shown above, CSPP's year-over-year operating hours have risen and fallen in recent years, with no obvious pattern and no discernible impact from the pandemic in 2020. Therefore, NMED determined that 2016-2021 average operating hours are representative for the emissions units at CSPP.

Adjusted emissions rates, representative annual operating hours, and baseline actual emissions for the emissions units at CSPP are summarized below.

Unit No.	Adjusted Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual Emissions (ton/yr)
1	120.7	4969	300.0
2	300.5	5779	868.2
3	79.8	2365	94.4
4	67.2	3105	104.3

C.4.23.4 Technical Feasibility of Available Controls

As indicated in Section C.3.4, the following determinations were made regarding the technical feasibility of identified control options for the CT at CSPP:

- DLN and SNCR are not technically feasible options.[194]
- GCP is a technically feasible option and is currently utilized by Xcel based on its compliance with the operating, maintenance, and testing requirements in its Title V permit. As a result, GCP is not evaluated further. (This determination is consistent with FFA completed in other states.)
- Water injection is a technically feasible option expected, according to the manufacturer, to reduce the concentration of NO_X in the exhaust by approximately 4.0 ppm.
- SCR is a technically feasible option expected to achieve a NO_X control efficiency of 90 percent.[195]
- Unit replacement is a technically feasible option expected to achieve a NO_X emission rate of 9.0 ppm, consistent with the emissions standards for new natural gas-fired turbines in 20.2.50 NMAC.[196]
- Unit retirement is a technically feasible option that would result in a 100 percent reduction of NO_X (and all other pollutants). However, Xcel did not indicate that it intends to permanently retire the units, which are currently scheduled to shut down in 2040, earlier than their current retirement date, so this option was not evaluated further.

Regarding the boilers at CSPP, in a detailed discussion with NMED on 6/22/23, Xcel indicated that Units 1 and 2 were scheduled to be shut down by 12/31/25 and 12/31/28, respectively. However, the New Mexico Public Regulation Commission (PRC) issued an order on 10/19/23 adopting a Certification of Stipulation requiring Xcel to retire Unit 1 by 12/31/23,[197] and another order on 5/30/24 approving Xcel's request to extend the service life of Unit 2 from 2025 to 2027 and retire it in 2027.[198] Therefore, neither unit is expected to operate beyond the end of the second planning period (Unit 1 appears to be shut down already based on EPA Clean Air Markets Program data), which would preclude the installation of new controls. However, because the current retirement schedule is not a federally enforceable requirement, NMED evaluated SCR, which is the only technically feasible control option for the boilers at CSPP,[199] as a backstop in case their retirement dates slip and one or both units continue to operate beyond the end of the second planning period.

---

[194] A version of DLN is already installed on the CT at CSPP which results in NO_X emissions in the 15 to 25 ppm range. According to the manufacturer, improved DLN (with lower NO_X) is not available.

[195] Xcel assumed a NO_X control efficiency of 80% for Units 1 and 2 and 65% for Units 3 and 4 in the SCR evaluations provided in its initial FFA. While NMED disagrees with these assumptions, NMED notes that in its own evaluation, SCR remains cost effective for Units 1 and 2 even if the control efficiency is reduced to 80%.

[196] Part 50 does not apply to CSPP, but the emissions standard for new NG-fired CT >15,900 hp is believed to be a reasonable surrogate for equivalent replacements for Units 3 and 4.

[197] New Mexico Public Regulation Commission, In the Matter of Southwestern Public Service Company's Application For: (1) Revision of Its Retail Rates Under Advice Notice No. 312; (2) Authority to Abandon Its Plant X Unit 1, Plant X Unit 2, and Cunningham Unit 1 Generating Stations and Amend the Abandonment Date of Tolk Generating Station; and (3) Other Associated Relief, Docket No. 22-00286-UT.

[198] New Mexico Public Regulation Commission, In the Matter of Southwestern Public Service Company's Application Requesting: (1) Issuance of a Certificate of Public Convenience and Necessity to Construct and Operate Solar Generation and Battery Storage Projects and Associated Facilities; (2) Authorization of Related Ratemaking Principles Including Accrual of an Allowance for Funds Used During Construction; (3) Authorization to Abandon the Cunningham Unit 2 Generating Facility; and (4) Other Associated Relief, Docket No. 23-00252-UT.

[199] LNB and FGR are not technically feasible control options for CSPP's boilers for reasons described in Xcel's November 2019 FFA, while SNCR is not a technically feasible option because the exhaust temperature of the boilers is too low.

C.4.23.5 Four-Factor Analysis

In order to determine what control measures are necessary at CSPP to make reasonable progress, NMED conducted a FFA of potential control measures for NO_X for the emissions units identified in section C.4.23.2 above. States are required to consider four statutory factors – cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts, and remaining useful life of the source – in determining reasonable progress.[200]

C.4.23.5.1 Cost of Compliance

To characterize this factor, NMED calculated the cost effectiveness, expressed in terms of cost per ton of NO_X emissions reduced, of each technically feasible control option identified in section C.4.23.4 above. NMED utilized source-specific cost estimates provided by Xcel in its calculations whenever possible. In cases where Xcel failed to provide source-specific cost estimates or NMED found estimates provided by Xcel to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs. EPA's Control Cost Manual uses real prices, not nominal prices, for estimation of capital costs and other costs. Therefore, NMED adjusted prices not already in 2024 dollars for inflation using the Chemical Engineering Plant Cost Index.[201]

NMED's cost effectiveness values for all technically feasible controls for the emissions units at CSPP are summarized below. NMED believes these values were calculated using the most representative information available and in a manner consistent with EPA-approved methodology. Detailed cost effectiveness calculations for the emissions units at CSPP and supporting documentation for NMED's cost estimates are provided in Appendix D.

Unit No.	Control Option	Total Annualized Cost (2024$)	Estimated NO_X Reductions (ton/yr)	Cost Effectiveness (2024$/ton)
1	SCR	$1,990,564	270.0	$7,000
2	SCR	$3,960,964	781.4	$5,000
3	WI	$829,976	23.9	$35,000
	SCR	$3,063,838	84.9	$36,000
	Replacement	$9,621,782	40.7	$237,000
4	WI	$829,976	32.0	$26,000
	SCR	$3,126,244	93.9	$33,000
	Replacement	$10,043,871	32.2	$312,000

NMED notes the following with respect to its determination of cost effectiveness for the technically feasible control options for the emissions units at CSPP:

- Xcel did not provide a company-specific cost of capital, so the bank prime rate (7.5 percent as of December 2024) was used to determine the appropriate capital recovery factor.

[200] CAA Section 169A(g)(1). *See also* 40 CFR 51.308(f)(2)(i).

[201] The Chemical Engineering Plant Cost Index is widely used for adjusting plant construction costs from one period to another. It is a composite index based on sub-indexes for equipment, construction labor, buildings, and engineering and supervision.

- The Total Capital Costs (TCC), Direct Annual Costs (DAC), and Indirect Annual Costs (OAC) of SCR were calculated using EPA's SCR Tool. An SCR retrofit factor of 1 (average difficulty) was applied, consistent with the SCR evaluations provided in Xcel's initial FFA.
- The Total Capital Investment (TCI) of water injection is based on a vendor estimate provided by Xcel that includes equipment, installation, labor, contingency, overhead and other capital costs. The Incremental annual O&M Costs (OMC) of water injection were also provided by Xcel.
- The TCI and OMC for replacement with new, functionally equivalent natural gas-fired units was determined using information available from the U.S. Department of Energy,[202] scaled by power rating. NMED recognizes that its OMC estimates do not account for existing O&M costs that would be displaced by replacement. However, cost effectiveness for replacement is far in excess of NMED's $10,000/ton cost effectiveness threshold based on TCI alone, so NMED did not attempt to refine its OMC estimates.

C.4.23.5.2 Compliance Time

Xcel indicated it would take 18 months to implement water injection on the CT at CSPP. NMED believes this is a reasonable timeframe.

Xcel indicated it would take 30 months to implement SCR on the CT at CSPP. This estimate is less than NMED's general assessment of compliance times and thus believed to be reasonably accurate.

Xcel did not provide information regarding the time necessary to replace the CT at CSPP with new, functionally equivalent fossil fuel-powered units. NMED believes the general compliance time for replacement, provided in Section C.3.4, is reasonable.

C.4.23.5.3 Remaining Useful Life

Consistent with generally accepted EPA methodology and NMED's experience, the useful life of SCR is estimated to be 20 years for CT and 30 years for the boilers.

Xcel indicated WI has a useful life of 15 years. This is consistent with other FFA.

Manufacturers of new CT will guarantee their equipment for at least 30 years if the unit is properly maintained and operated. Energy performance contracts for new CT are routinely 20 to 25 years, with extensions beyond 30 years. Therefore, it is estimated that the useful life of a replacement CT is 30 years.

C.4.23.5.4 Energy and Non-Air Quality Impacts

NMED's general assessment of the energy and non-air quality impacts associated with technically feasible controls for CT and boilers is provided in Sections C.3.4 and C.3.5, respectively.

[202,7] U.S. Energy Information Administration's (EIA) Annual Energy Outlook 2023 (AEO2023) Assumptions document - Electricity Market Module

C.4.23.5.5 Summary

NMED performed a FFA for all technically feasible control options for NO_X for the units listed in Section C.4.23.2 above. The four statutory factors are discussed in Sections C.4.23.5.1 through C.4.23.5.4 and are summarized below.

Unit No.	Control Measure	Cost Effectiveness (2024$/ton)	Compliance Time (yr)	Remaining Useful Life (yr)	Significant Energy & Non-Air Quality Impacts [(1)]
1	SCR	$7,000	2.5	20	None
2	SCR	$5,000	2.5	20	None
3	WI	$35,000	1.5	15	None
	SCR	$36,000	2.5	20	None
	Replacement	$237,000	3-4	30	None
4	WI	$26,000	1.5	15	None
	SCR	$33,000	2.5	20	None
	Replacement	$312,000	3-4	30	None

[(1)] Significant energy and non-air quality impacts are those strongly influencing NMED's decision about the control measure under consideration.

C.4.23.6 Reasonable Progress Control Determinations

Cost effectiveness was the predominant factor in NMED's decision-making regarding control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations. For example, remaining useful life was used to calculate annualized costs, which in turn were used to calculate cost effectiveness, and thus was fully subsumed into the cost of compliance whereas compliance time, which is more important at the next step (determining reasonable deadlines for installing selected controls), was not a major consideration in selecting which controls are necessary to make reasonable progress in the first instance. NMED did not consider visibility impacts when making reasonable progress control determinations; EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making such determinations.[203]

As discussed in Chapter 7, Four Factor Analysis and Control Measures, NMED selected a cost effectiveness threshold of $10,000/ton for its reasonable progress control determinations based on an analysis of incremental NO_X reductions at increasing cost effectiveness levels. For emissions units with only one NO_X control below the $10,000/ton cost effectiveness threshold, NMED determined that that control is necessary to make reasonable progress. For emissions units with multiple NO_X controls below the $10,000/ton cost effectiveness threshold, NMED determined that the most stringent cost-effective control is necessary to make reasonable progress. The sole exception to these general rules is the categorical exclusion of electrification as the reasonable progress control. This exception is explained in greater detail in Chapter 7.

NMED's FFA identified cost effective controls for CSPP Units 1 and 2. Based on its analysis of the four statutory factors and the decision-making criteria described above, NMED determined that the following

[203] See *supra* note 13.

cost-effective controls are necessary to make reasonable progress **should either unit operate beyond the end of the second planning period** (if Xcel retires Units 1 and 2 on schedule, no controls are necessary to make reasonable progress):[204]

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	SCR	270.0
2	SCR	781.4

NMED's FFA did not identify any cost effective controls for CSPP Units 3 or 4. Therefore, NMED determined that reasonable progress does not require new controls on either of these units.

If Xcel retires Units 1 and 2 on schedule, NMED estimates the total emissions reductions at CSPP during the second planning period will be approximately 1,168.2 ton/yr of NO_X. If their retirement dates slip and both units continue to operate beyond the end of the second planning period, then based on the expected reductions from the controls NMED has determined are necessary to make reasonable progress, NMED estimates the total emissions reductions at CSPP during the second planning period will be approximately 1,051.4 ton/yr of NO_X.

[204] As noted above, the PRC recently issued an order adopting a Certification of Stipulation requiring Xcel to retire Unit 1 by 12/31/23, and another one approving Xcel's request to extend the service life of Unit 2 from 2025 to 2027 and retire it in 2027. Therefore, neither unit is expected to operate beyond the end of the second planning period.

Appendix D: Four-Factor Analyses Supporting Documentation

D.1 Davis Gas Processing

Supporting documentation for Davis Gas Processing is provided below. Facility-specific documentation is provided first, followed by documentation pertaining to multiple facilities and/or the owner/operator. The following documents are included in this section (in reading order):

- Denton Gas Plant:
    - Administrative Permit Revision (2/2/2022)
    - Permit Closure Letter (3/1/2022)

Dear Program Manager,

On behalf of Davis Gas Processing, Inc., "DGP", Environmental Operational Solutions, LLC, is submitting the attached Permitting Administrative Multi-Form for the Denton Gas Plant. Section 2-D of this form has been completed (see Attachment A) as the Denton Gas Plant was permanently shut down on December 1, 2021. The facility is being cleaned and equipment will be demoed and salvaged beginning in March of 2022. DGP is taking this action to request NMED cancel both the site's New Source Review "NSR" Construction Permit No. 0065-M8 along with this site's Title V Operating Permit No. P079-R3. Please note that DGP currently has a Title V permit renewal that was submitted to NMED on May 7, 2021, and is currently being worked by NMED permit engineer Urshula Bajracharya. This renewal project should also be cancelled.

Copies of the site's construction permit and Title V permit are included in Attachments B and C.

If you have any questions or concerns regarding this submittal, please feel free to contact me directly at (713) 983-0112 or via email at elena.hofmann@eosolutions.net.

Sincerely,

Elena L. Hofmann
President

Ref: **Air Quality Operating Permit Application No.** P079R3M1
Denton Gas Plant
NSR Permit No. 0065M8R1
Agency Interest No. 568 - PRT20220001
AIRS No: 35-025-0007

Dear David Freeman:

The Air Quality Bureau (AQB) is in receipt of Davis Gas Processing's January 27, 2022, request to voluntarily discontinue the Denton Gas Plant Title V Operating Permit No. P079R3 pursuant to 20.2.70.400.I NMAC. On February 4, 2022, the AQB received Davis Gas Processing's request to close the New Source Review permit 0065M8 for the facility located in Lea County, New Mexico at latitude and longitude decimal degrees: 33.043869, -103.169989. In that request, the AQB was notified the plant was permanently shut down on December 1, 2021. The request to close the NSR permit was effective upon receipt per 20.2.72.219.A(3) NMAC.

With the closure of the NSR permit, the actions required to reduce the potential to emit of this facility to below Major Source thresholds have been met. Therefore, the Department has voluntarily discontinued Title V Operating Permit No. P079R3 for the Denton Gas Plant as of February 4, 2022, and this facility will be removed from the list of major Title V sources in New Mexico. Lastly, the application received May 11, 2021, for the renewal P079R4 has been identified as withdrawn.

If you have any questions, please call Clayton Hengst in Santa Fe at (505) 629-7684.

Sincerely,

Elizabeth Kuehn

LIST OF TABLES

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis 1-2

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across with United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).* This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).* The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed DCP Operating Company, LP (DCP), that its Artesia Gas Plant (Artesia) was identified as one of the sources possibly contributing to regional haze at nearby Class I areas.

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. The NMED's July 18, 2019 notification letter to DCP specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility

subject to the analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Emergency Wet Gas Flare (Unit 22)	642.9	7.5	No*	4918.4	49.9	No*
Emergency Acid Gas Flare (Unit 23)	10.4	2.4	No*	2001.0	328.2	No*
Malfunction Flaring (Unit M1)	642.9	10.0	No*	4918.4	10.0	No*

* Pursuant to NMED Guidance received on 9/23/2019, the Four Factor Analysis is to be completed for steady state sources of emissions only; as such, emissions from SSM/M activities are not subject to a Four Factor Analysis.

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED[1], this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC).

At Artesia Gas Plant, there are potentially three (3) units which could be subject to this four-factor analysis based on SO_2 emissions (shown in Table 1). There are no units at the facility which would be subject to this analysis based on NO_X emissions. Units 22, 23 and M1 all have SO_2 emissions greater than 10 lb/hr and 5 tpy; however, these emissions are the result of either startup, shutdown, maintenance (SSM) or malfunction (M). Based on guidance received from the NMED on 9/23/2019; the four-factor analysis is to be completed for steady state sources of emissions only, which excludes emissions units associated with non-steady state/irregular emissions such as SSM/M flare sources. As such, the analysis will not be completed for any of the units at the Artesia facility.

[1] NMED 2021 Regional Haze Planning Website ("Links to other information"). https://www.env.nm.gov/air-quality/reg-haze/

2. SUMMARY & CONCLUSIONS

Based on a comprehensive review of the units at Artesia, DCP has determined that due to the non-steady state nature of the emissions at this facility, i.e., intermittent nature of the emissions associated with SSM/M flaring, a four-factor analysis is not required. The costs of compliance, time necessary for compliance, energy and non-air quality environmental impacts and remaining useful life elements of a Four Factor Analysis are thus inapplicable.

3. SUPPORTING DOCUMENTATION

There is no applicable supporting documentation.

Re: Request for additional Information on the Four-Factor Analysis Report
Regional Haze Program
Artesia Gas Plant
DCP Operating Company, LP

Mr. Singleton,

DCP Operating Company, LP (DCP) is in receipt of the New Mexico Environment Department's (NMED's) January 7, 2020, "*Request for Additional Information for Four-Factor Analyses under the Regional Haze Program*" ("Request for Additional Information" or supplemental information request), which requests various and specific supplemental information, technical discussions, analyses, and data, including possible supplemental "Four-Factor Analyses," for multiple sources with respect to DCP's Artesia natural gas processing plant in Eddy County, New Mexico. In the time afforded, and given the objections below, this letter provides DCP's responses to the January 2020 Request for Additional Information (in **blue** font, below).

NMED's January 7, 2020, Request for Additional Information, including potential Four-Factor Analyses, does not state a timeline by when the operator is to provide responsive information, and only states qualitatively to submit responses "as soon as possible." DCP notes that NMED's initial request for Four-Factor Analyses dated July 18, 2019, afforded approximately three and a half months to fulfill NMED's request for responses and analyses, requested by November 1, 2019. Given the level of information expected in NMED's initial request, DCP believes three and a half months was impracticably short, but DCP fulfilled the request to the best of the company's ability. With respect to the January 2020 Request for Additional Information, DCP received a phone call from NMED on February 10, 2020, expecting a response to the supplemental information request and possible Four-Factor Analyses by February 14, 2020, five weeks from NMED's letter of January 7, 2020. February 14, 2020, is unrealistic and unreasonable for the responses requested by NMED. DCP will provide what information it reasonably can by March 3, 2020, and will otherwise provide follow-on requested information when it is reasonable to do so given what is being requested by the agency.

As this is an administrative proceeding with an administrative record, for the record DCP must note any objections it has to the NMED request. DCP states the following objections for the record in relation to NMED's request for Regional Haze-related information and analyses, and preserves its rights related thereto notwithstanding DCP's providing information requested by NMED.

- DCP has limited resources available to respond to NMED's initial, and now supplemental information request; DCP does not have resources available to be dedicated full time to responding to NMED requests analyses, technical discussions, and responding to requests for information. DCP has expended resources, where practicable, to have third party support with respect to the company's responses to NMED's requests for assessments and information, but that support is not always practicable or available, and there are limitations on DCP's use of such third party support. DCP is providing the responses herein, to the agency's supplemental request for information, to the best of the company's ability, in the time afforded, given the limitations of its resources.

- NMED's amount of time afforded to respond to the agency's Request for Additional Information, potentially including Four-Factor Analyses, is impracticably short, unrealistic and unreasonable for a number of the requested items, and affects DCP's ability to respond to the various requests.

- DCP objects to NMED's Request for Additional Information to the extent the requests are for assessments, discussion, information, data that are not presently available and in the possession of the source, in this case DCP. It is within NMED's authority to request information presently available and in the possession of a source operator, but it is beyond the agency's authority to require a source to create or generate information or data that does not presently exist or is not in the possession of the source, or to require a source to expend monies/resources to create or generate such information or data.

- DCP objects to vague, ambiguous or undefined terms in the Request for Additional Information, and objects to the extent the request require DCP to engage in speculation in order to attempt to respond to an agency's stated question or request.

- DCP objects NMED's requests for assessments or analyses that directly or indirectly result in or would relate to "redefining the source," being a properly-authorized, operating, and permitted emissions source. The federal Regional Haze regulation contemplates emissions control technologies that might be cost-effectively retrofitted on a source; redefining a properly-authorized, permitted and operating source is not a retrofit control technology, and is beyond the authority of the Regional Haze rule to consider as a Reasonable Progress measure.

- DCP objects to the fact that NMED has not provided, as part of this administrative process, the cost-effectiveness threshold for control technologies for the Regional Haze Reasonable Progress rulemaking.

- DCP objects to the agency's fundamental threshold for requesting 4-Factor Analyses from sources in the State, *i.e*., Q/d of 5, as this is unreasonably stringent and requiring resource expenditures for assessments of sources that would not effectively contribute to visibility improvement in Class I areas. The State of Colorado applied a Q/d of 20 as its screening criteria, which assumed an estimated associated deciview improvement of 0.3; a Q/d of 5 would provide, presumably, one-quarter of the assumed visibility improvement, so requiring screening of sources at that level that would provide potentially, *e.g*., 0.07 deciview improvement.

Preserving the objections noted, above, DCP responds to the agency's January 7, 2020, Request for Additional Information as follows (NMED Jan. 7, 2020, requests re-stated in black font, and DCP responses provided in blue font).

a. Provide a description of each flare, the design and type, and its purpose.

Unit No. SSM (22), Emergency Wet Gas Flare, serves as both emergency/SSM flare and a process flare to Artesia's wet gas service. The Emergency wet gas flare will flare pilot, purge, and blanket gas from TK-C (condensate storage tank) during steady state operations and any gas flow to the flare that results from startup, shutdown, maintenance, malfunction (SSM&M) and other emergency events.

Unit No. SSM (23), Acid Gas Flare, serves as emergency/SSM&M flare to Artesia's acid gas service. The Acid gas flare will flare pilot, purge, assist gas and any acid gas flow to the flare that results from SSM&M and emergency events.

Please reference *Attachment A – Flare Emission Calculation*.

b. List and describe the reasons that trigger each type of flaring event.

Steady state emission from the Emergency Wet Gas Flare and Acid Gas Flare are represented in the *Attachment A – Flare Emission Calculation*.

Other flaring events include permit authorized planned SSM flaring events and unplanned flaring events. Planned SSM emission flaring events are triggered by routine maintenance at frequency recommended by the manufacturer. Allowable emission limit as included in the facility's air permit represent maximum amount of emission that can occur during all planned maintenance activities and startup/shutdown events that is anticipated pre and post-maintenance. However, these planned maintenance events do not occur at the same frequency, i.e. quarterly, annual, biennial, every five year and etc, therefore, actual emission that occur at the facility differs each year as represented in DCP's process and SSM flaring four factor analysis report submitted on December 16, 2019.

Unplanned flaring events are triggered through various unforeseeable reasons such as equipment malfunction, power loss, and etc. Excess emission resulting from these event are reported to NMED pursuant to NMAC 20.2.7.110. DCP operates emission equipment in a manner consistent with good air pollutant control practices for minimizing emission.

c. Discuss potential alternative control options or operational changes that could reduce NO_X and/or SO_2 flaring emissions, including:

i. infrastructure that allows re-routing or recirculating the gas within the facility or outside of the facility until an SSM event is over;

Artesia's current infrastructure supports nat. gas re-routing, and off-loading when feasible under certain circumstances, each of which serve to reduce flaring emissions. Artesia has the ability, when necessary, to close the nat. gas inlet to the facility, which significantly limits or prevents flaring at the facility. Artesia also coordinates with the producers, either prior to a planned event, or when feasible during an unplanned event, to temporarily re-route nat. gas to other facilities if practicable or to shut in nat. gas for a finite period, to reduce the volume of nat. gas potentially subjected to flaring at the facility. Under certain circumstances DCP can, and does, utilize producer temporary off-load capabilities, or DCP capability to temporarily re-route gas when practicable and feasible, to minimize the volume of nat. gas potentially subjected to flaring at the facility. DCP believes that these capabilities and measures, taken together, serve to prevent flaring at the Artesia facility or to mitigate the duration of a flaring event or the volume

of material subjected to flaring. DCP is not aware of another technically feasible option to appreciably further reduce flaring events or volumes at the facility.

ii. sulfur absorbent technology used to remove sulfur from pipelines and other auxiliary equipment to reduce inlet or plant flaring SO_2 emissions;

The Artesia nat. gas processing plant receives, and is designed to receive, high hydrogen sulfide ("H2S") concentration natural gas, referred to as "sour" nat. gas. Given the high H2S concentration received by the Artesia plant, an amine treatment system is the most effective and the only technology that is technically feasible to remove sulfur and treat the sour gas stream of this volume and concentration.

Other sulfur absorbent technology, such as pipeline additive injection, commonly referred to as hydrogen sulfide scavenger, is utilized only non-sour gas systems, meaning on what are known as "sweet" gas streams, in order to treat very small amounts of hydrogen sulfide that might exist in a sweet gas stream to meet a certain specification, and are not suitable or effective for treating the sour gas stream processed at Artesia Plant; they would not meaningfully reduce the concentration of H2S that would recognizably affect the amount of sulfur received by the Artesia plant.

iii. Gas Capture Plans with facilities located downstream and upstream similar to those required for producers to better synchronize upstream and downstream services with the facility;

DCP objects to the use of an ambiguous or undefined term with respect to a midstream nat. gas processing plant facility, and to the extent this question requires speculation. A Gas Capture Plan is a New Mexico Oil Conservation Division ("NMOCD") requirement for producer entities, for the producer's production development, to ensure communication between the producer entity and gatherer in order to improve communication and planning future nat. gas takeaway capacity, in order to mitigate the potential for a producer entity having to flare what would be stranded gas at its well production facility if there weren't nat. gas takeaway. DCP as a midstream entity does confer with producers about the producer's Gas Capture Plans. The concept, however, has no applicability to a midstream nat. gas processing plant as such a facility, for example the Artesia plant, is by definition designed to receive and process the producer's nat. gas; DCP's Artesia gas plant does not flare nat. gas due to lacking capacity, for example, so the concept is not applicable to a midstream gas processing plant.

iv. use of remote capture equipment;

DCP objects to the use of an ambiguous or undefined term with respect to a midstream nat. gas processing plant facility, and to the extent this question requires speculation. Remote capture equipment, as DCP understands it from NM agency materials, is a concept that relates to and provides capability at a producer wellhead and relates to wellhead volumes of nat. gas and nat. gas products (liquids) at the producer wellhead. The same concept does not have applicability to a midstream nat. gas processing facility, and the type of technology is not applicable at the scale of a nat. gas processing facility; a midstream nat. gas processing plant, by definition, is removing nat. gas products (liquids) from the inlet material, which is one of its functions.

v. better infrastructure planning and changes to existing infrastructure that connects the downstream and upstream operations to DCP facilities to ensure that there is adequate processing capacity to move produced gas to market.

DCP objects to the use of ambiguous or undefined terms, and to the extent this question requires speculation. As described in the prior responses, DCP's Artesia nat. gas plant processing capacity appropriately and adequately manages relevant producer nat. gas production; the plant does not flare nat. gas due to lacking capacity.

Note that flaring at an up or downstream facility to avoid flaring at the Artesia Gas Plant is not considered to be an actual reduction in flared emissions rates under the four-factor analysis.

d. For any technically feasible solutions, provide a four-factor analysis. For additional information regarding potential alternative controls to flaring see the New Mexico Methane Strategy website: https://www.env.nm.gov/new-mexico-methane-strategy/methane-advisory-panel/.

Considering the above requests, DCP is not aware of any additional flaring technology or relevant operational changes that are technically feasible.

e. Please explain the discrepancy between the SSM SO_2 emissions provided in the supplemental flaring analysis (0.0 tons) and NMED's 2016 inventory (17.96 tons).

The referenced SSM SO2 emission amount only refers to authorized emission and does not include excess emission resulting from unforeseeable events. Table 2 of the December 16, 2019 submitted response is titled "Artesia 2016 EIQ Reported **Process** Flaring and **SSM** Flaring Emission".

If you have any questions or concerns, please feel free to contact me directly by phone at 432-215-8514 or via email at hshong@dcpmidstream.com.

Sincerely,

Sam Hong
Environmental Engineer

DCP OPERATING COMPANY, LP

Respondent.

SETTLEMENT AGREEMENT AND STIPULATED FINAL COMPLIANCE ORDER

This Settlement Agreement and Stipulated Final Compliance Order ("Final Order") is entered into between the Environmental Protection Division ("Division") of the New Mexico Environment Department ("Department" or "NMED") and Respondent, DCP Operating Company, LP and relevant affiliates thereof, ("DCP") (collectively, the "Parties") to resolve alleged statutory, regulatory, and permit violations by DCP. The Department alleges violations of the New Mexico Air Quality Control Act ("AQCA"), NMSA 1978, Sections 74-2-1 to -17; the Air Quality Control Regulations ("Regulations") at Title 20, Chapter 2 NMAC, and various Air Quality Permits ("Permits") as identified below.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

I. BACKGROUND

A. PARTIES

1. The Division is an organizational unit of the Department and has been delegated the authority by the Secretary of the Department to issue compliance orders under the AQCA. NMSA 1978, § 74-2-12.A (2006). The Air Quality Bureau ("Bureau") is an organizational unit of the Division.

2. DCP is a limited partnership doing business in New Mexico at the following facilities: Burton Flats Compressor Station, Fitz Compressor Station, Lovington Booster Station, Lynch Booster Station, Monument Booster Station, Sand Dunes Compressor Station, South Hat Compressor Station, West Turkey Track Compressor Station, Artesia Gas Plant, Eunice Gas Plant, Linam Ranch Gas Plant and Zia II Gas Plant (collectively, the "Facilities"). DCP owns and operates the Facilities, located in Lea and Eddy Counties, New Mexico. At all times relevant to this Final Order, DCP owned and operated the Facilities.

B. HISTORY AND ALLEGED VIOLATIONS

The alleged violations are set forth in the two Compliance Orders and are summarized below.

Burton Flats Compressor Station

3. Since April 15, 2014, Burton Flats has been authorized to operate under NSR Permit 0612-M5.

4. The following table from NSR permit 0612-M5, Condition A106 lists the Facility emission units and their allowable emission limits. *See* 40 CFR Part 50; 40 CFR Part 60, Subparts A and JJJJ; 40 CFR Part 63, Subparts A and ZZZZ; 20.2.72.210.A and B(1) NMAC.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 1: Burton Flats, Table 106.A, Allowable Emissions

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)
1	2.8	12.2	2.8	12.2	1.4	6.1
2	2.8	12.2	2.8	12.2	1.4	6.1
3	2.8	12.2	2.8	12.2	1.4	6.1
4	2.8	12.2	2.8	12.2	1.4	6.1
5	2.8	12.2	2.8	12.2	1.4	6.1
6	2.8	12.2	2.8	12.2	1.4	6.1
7	3.6	15.8	3.6	15.8	1.8	7.9
TK-1[4]	- [2]	-	-	-	*[3]	4.9
TK-2	-	-	-	-	*	4.9
LOAD	-	-	-	-	*	0.87

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
2 Total Particulate matter (TSP) is estimated to equal PM10 and PM2.5. These emissions include condensable PM emissions.
3 For Title V facilities, the Title V annual fee assessments are based on the sum of allowable tons per year emission limits in Sections A106 and A107.
4 F-100R represents routine flaring from tank flash, amine, pilot, dehydrator.

5. The following table from NSR Permit 0612 M5, Condition A.107 - "Facility: Allowable Startup, Shutdown, and Maintenance and Malfunction Emissions," lists the facility-wide startup, shutdown, maintenance ("SSM"), and malfunction emission limits:

Table 2: Burton Flats, Table 107.A, Allowable SSM & M Units, Activities, and Emission Limits

Unit No.	Description	VOC (tpy)
SSM Facility Wide	Compressor & Associated Piping Blowdowns during Routine and Predictable Startup, Shutdown, Maintenance (SSM), and/or Malfunctions	10

(This authorization does not include VOC combustion emissions.)

6. Between December 29, 2017 and June 30, 2019, DCP reported ten (10) excess emission events and asserted affirmative defenses as provided in 20.2.7 NMAC.

7. The Bureau issued Notice of Violation ("NOV") DCP-0251-1801 for four of these alleged violations on December 7, 2018.

8. The Division alleges that DCP violated NSR permits 0612-M5, Condition A106.A and A107.A, by exceeding the permitted allowable emission limits of the emergency blowdown

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

vent during ten (10) excess emission events. These events resulted in a total of eighty-nine (89) alleged violations ("Burton Flats Violations").

9. The Division alleges that the Burton Flats Violations resulted in the unlawful emission of 63,437 pounds of volatile organic compounds ("VOC") and hydrogen sulfide ("H_2S")

10. The Division maintains that DCP's reported excess emission events at Burton Flats Compressor Station do not qualify for affirmative defenses under the New Mexico Air Quality Control Act and the NMED Air Quality Bureau Civil Penalty Policy and are therefore subject to penalties. DCP maintains that its affirmative defense claims are valid.

Fitz Compressor Station

11. Between June 21, 2012 and October 3, 2019, the Fitz Compressor Station was authorized to operate under NSR permit 0832-M2. Since October 4, 2019, the Fitz Compressor Station has been authorized to operate under GCP-O&G Permit number 0832-M3.

12. The following table from NSR Permit 0832-M2, Condition A.106 – "Facility: Allowable Emissions," lists the emission units and their allowable emission limits. *See* 40 CFR Part 50; 40 CFR Part 63, Subparts A and ZZZZ; and 20.2.72.210.A and B(1) NMAC:

Table 3: Fitz, Table 106.A, Allowable Emissions

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (tpy)
1	4.2	18.5	5.0	21.9	< [3]	2.5	1.1
2	4.2	18.5	5.0	21.9	< [3]	2.5	1.1

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

15. Between January 1, 2018 and June 30, 2019, DCP reported eighty-six (86)[1] excess emission events and asserted affirmative defenses as provided in 20.2.7 NMAC.

16. The Bureau issued two NOVs for fifty-one of these alleged violations: DCP-0263-1801 on December 14, 2018, and DCP-0263-1802 on March 18, 2019.

17. The Division alleges that DCP violated NSR Permit 0832-M2, Conditions A106.A and A107.A and NSR Permit 0832-M3, Oil and Gas GCP Application Table 2B, by venting emissions in excess of the permitted allowable emission limits for the vent during eighty-six (86) excess emission events. These events resulted in a total of one thousand one hundred and eighty (1,180) alleged violations ("Fitz Violations").

18. The Division alleges that the Fitz Violations resulted in the unlawful emission of 822,823.15 pounds of VOC and H_2S.

19. The Division maintains that the Fitz Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and DCP is therefore subject to penalties for those violations. DCP maintains that its affirmative defense claims are valid.

Lovington Booster Station

20. Between June 2, 2006 and April 23, 2019, the Lovington Booster Station was authorized to operate under NSR Permit 0423-M7.

21. The following table from NSR Permit 0423-M7, "Table 2.1, Allowable Emissions," lists the emission units and their allowable emission limits. Malfunction and SSM emissions are not listed separately.

[1] Revised Compliance Order No. AQB-20-46 stated that 51 excess emission events were reported and included in the two NOVs, and an additional 45 excess emission events were reported and not included in NOVs. DCP's Answer identified that ten of the additional 45 events were included in one of the NOVs, resulting in 35 excess emission reports not included in the two NOVs.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 6: Lovington, Table 2.1, Allowable Emissions

Unit No.	PM_{10} (pph)	PM_{10} (tpy)	SO_2 (pph)	SO_2 (tpy)	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	H_2S (pph)	H_2S (tpy)

Flare			3226.4	96.8	37.6	1.2	204.4	6.4	510.5	15.4	35.1	1.1
TK-5	-	-	-	-	-	-	-	-	3.8	16.5	-	-

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO2
2 "-" indicates that in accordance with the application, no emissions of this pollutant are expected
3 "- -" indicates that emissions are less than 0.5 pph or 0.5 tpy and emission limits are not required for this permit

22. Between November 27, 2018 and April 26, 2019, DCP reported ten (10) excess emission events and asserted affirmative defenses as provided by 20.2.7 NMAC.

23. The Division alleges that DCP violated NSR Permit 0423-M7, Table 2.1, by flaring emissions from the unit Flare in excess of its permitted allowable emission limits during ten (10) excess emission events. These events resulted in a total of one hundred and sixty (160) alleged violations ("Lovington Violations").

24. The Division alleges that the Lovington Violations resulted in the unlawful emission of 21,499.33 pounds of carbon monoxide ("CO"), sulfur dioxide ("SO_2"), nitrogen oxide ("NO_x"), H_2S, and VOC.

25. The Division maintains that nine (9) of the ten (10) excess emissions events underlying the Lovington Violations do not qualify for affirmative defenses under the New Mexico Air Quality Control Act or the Penalty Policy, and therefore DCP is subject to penalties for one hundred and fifty-five (155) of the Lovington Violations. DCP maintains that its affirmative defense claims are valid.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Lynch Booster Station

26. Since July 29, 2015, the Lynch Booster Station has been authorized to operate under NSR Permit 0609-M7.

27. The following table from NSR Permit 0609-M7, Condition A.106 – "Facility: Allowable Emissions," lists the emission units and their allowable emission limits. *See* 40 CFR Part 50; 40 CFR Part 63, Subparts A and ZZZZ; and 20.2.72.210.A and B(1) NMAC:

Table 7: Lynch, Table 106.A: Allowable Emissions

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
2 "-" indicates the application represented emissions of this pollutant are not expected
3 "<" indicates the application represented uncontrolled emissions are less than 1.0 pph or 1.0 tpy for this pollutant. Allowable limits are not imposed on this level of emissions, except for flares and pollutants with controls.
4 "*" indicates hourly emission limits are not appropriate for this operating situation

28. The following table from NSR Permit 0609-M7, Condition A.107 – "Facility: Allowable Startup, Shutdown, and Maintenance and Malfunction Emissions," lists the facility-wide SSM and malfunction emission limits:

Table 8: Lynch, Table 107.A: Allowable SSM and Malfunction Units, Activities, and Emission Limits

Unit No.	Description	VOC (tpy)
SSM/M	[1]Venting of Gas Due to SSM and	10

[1]This authorization does not include VOC combustion emissions.

29. Between February 12, 2018 and June 30, 2019, DCP reported forty-five (45) excess emission events and asserted affirmative defenses as provided by 20.2.7 NMAC.

30. Two NOVs were issued for eleven of these alleged violations: DCP-0641-1802 on November 1, 2018, and DCP-0641-1803 on December 7, 2019.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

31. The Division alleges that DCP violated NSR Permit 0609-M7, Conditions A106.A and A107.A, by exceeding the permitted allowable emission limits of the vent during forty-five (45) excess emission events. These events resulted in a total of three hundred and eighty-one (381) alleged violations ("Lynch Violations"). exceeding permitted allowable emissions by 279,693.69 pounds of VOC and NO_X.

32. The Division alleges that the Lynch Violations resulted in the unlawful emission of 279,693.69 pounds of VOC and NO_x.

33. The Division maintains that forty-four (44) of the forty-five (45) excess emissions events underlying the Lynch Violations do not qualify for affirmative defenses under the New Mexico Air Quality Control Act or the Penalty Policy, and therefore DCP is subject to penalties for three hundred and eighty (380) of the Lynch Violations. DCP maintains that its affirmative defense claims are valid.

Monument Booster Station

34. Between August 6, 2014 and October 16, 2018, the Monument Booster Station was authorized to operate under NSR Permit 0123-M6R2. Since October 16, 2018, the Monument Booster Station has been authorized to operate under NSR Permit 0123-M6R3.

35. The following table from NSR Permit 0123-M6R2, Condition A.106 – "Facility: Allowable Emissions," lists the emission units and their allowable emission limits. *See* 40 CFR Part 50; 40 CFR Part 63, Subparts A and ZZZZ; and 20.2.72.210.A and B(1) NMAC:

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
2 "-" indicates the application represented emissions of this pollutant are not expected
3 "*" indicates hourly emission limits are not appropriate for this operating situation

37. The following table from NSR Permit 0123-M6R2 and M6R3, Condition A.107 – "Facility: Allowable SSM and Malfunction Emissions," lists the SSM and malfunction emission limits:

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 11: Monument, Table 107.A, Allowable SSM and Malfunction Units, Activities, and Emission Limits

Unit No.	Description	VOC (tpy)	H_2S (tpy)
SSM from Units 3-4	Compressor & Associated Piping Blowdowns during Routine and Predictable Startup, Shutdown, and/or Maintenance (SSM); and Malfunction emissions.	3.9	0.22

(This authorization does not include VOC combustion emissions)

38. Between September 1, 2018 and June 30, 2019, DCP reported twenty-one (21) excess emissions events and asserted affirmative defense claims as provided by 20.2.7 NMAC.

39. The Division alleges that DCP violated NSR Permits 0123-M6R2 and -M6R3, Conditions A106.A and A107.A, by exceeding the permitted allowable emission limits from the unit Flare during twenty-one (21) excess emission events. These events resulted in a total of two hundred and forty-nine (249) alleged violations ("Monument Violations").

40. The Division alleges that the Monument Violations resulted in the unlawful emission of 4,756 pounds of CO, SO_2, VOC and NOx.

41. The Division maintains that twenty (20) of the twenty-one (21) excess emissions events underlying the Monument Violations do not qualify as emergencies, startup, shutdown, or malfunctions under the Act or the Penalty Policy, and therefore DCP is subject to penalties for two hundred and thirty-three (233) of the Monument Violations. DCP maintains that its affirmative defense claims are valid.

Sand Dunes Compressor Station

42. From October 24, 2006 to January 24, 2019, the Sand Dunes Compressor Station was authorized to operate under NSR Permit 1201-M6.

43. Since January 25, 2019, the Sand Dunes Compressor Station has been authorized to operate under NSR Permit 1201-M7R4.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

44. The following table from NSR Permit 1201-M6, Table 2.1 lists the emission units and their allowable emission limits. Malfunction and SSM are not listed separately. *See* 20.2.72.210 NMAC, paragraphs A and B.1.

Table 12: Sand Dunes, Table 2.1, Allowable Emissions

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)
1	4.4	19.3	4.4	19.3	1.8	7.7

3 "*" indicates hourly emission limits are not appropriate for this operation

46. The following table from NSR Permit 1201-M7R4, Condition A.107 – "Facility: Allowable SSM and Malfunction Emissions," lists the facility-wide SSM emission limits:

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 14: Sand Dunes, Table 107.A: Allowable SSM Units, Activities, and Emission Limits

Unit No.	Description	VOC (tpy)
SSM from F-3	[1]Emergency Blowdown	30

1 This authorization does not include VOC combustion emissions

47. Between January 2, 2018 and June 30, 2019, DCP reported forty-six (46) excess emission events and asserted affirmative defenses as provided by 20.2.7 NMAC.

48. The Bureau issued two NOVs for a portion of these alleged violations: DCP-0302-1801 on November 15, 2018, and DCP-0302-1802 on January 31, 2019.

49. The Division alleges that DCP violated NSR Permit 1201-M6 or 1201-M7R4, Tables 14 and 15, by exceeding the permitted allowable emission limits of the emergency blowdown vent during forty-six (46) excess emission events. These events resulted in a total of one hundred and twenty-five (125) alleged violations ("Sand Dunes Violations").

50. The Division alleges that the Sand Dunes Violations resulted in the unlawful emission of 228,549.52 pounds of VOC.

51. The Division maintains that thirty-eight (38) of the forty-six (46) excess emission events underlying the Sand Dunes Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and therefore DCP is subject to penalties for one-hundred seventeen (117) of the Sand Dunes Violations. DCP maintains that its affirmative defense claims are valid.

South Hat Booster Station

52. Between November 22, 2010 and August 13, 2018, South Hat Booster Station was authorized to operate under NSR Permit 1018-M7.

53. Between May 21, 2012 and January 11, 2018, South Hat Booster Station was authorized to operate under Title V Permit P044-R3.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

54. Between January 12, 2018, and August 13, 2018, South Hat Booster Station was authorized to operate under Title V Permit P044-R4. That permit was terminated on August 14, 2018.

55. Since August 14, 2018, South Hat Booster Station has been authorized to operate under GCP-O&G Permit 1018-M8.

56. The following table from Title V Permit P044-R3, Condition A.106 – "Facility: Allowable Emissions," lists the emission units, and their allowable emission limits. *See* 40 CFR Part 50; 40 CFR Part 60, Subparts A & JJJJ; 40 CFR Part 63, Subparts A & ZZZZ; 40 CFR Part 64; 20.2.70.302.A(1), (7), and (8) NMAC; and NSR Permit 1018-M7:

Table 15: South Hat, Table 106.A, Allowable Emissions

Unit No.		NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)
1		5.3	23.2	5.3	23.2	1.8	7.7
2		5.3	23.2	5.3	23.2	1.8	7.7
3		5.4	23.7	5.4	23.7	1.8.	7.8
4		5.4	23.7	5.4	23.7	1.8	7.8
5		5.3	23.2	5.3	23.2	1.8	7.7
6		5.3	23.2	5.3	23.2	1.8	7.7
7		9.8	28.642.8	9.8	42.8	3.3	14.3

TK-7		-	-	-	-	<	2.7
Load		-	-	-	-	<	1.5
Total[4]		-	211.3			<	81.8

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
2 "_" indicates the application represented emissions of this pollutant are not expected
3 "<" indicates the application represented uncontrolled emissions are less than 1.0 pph or 1.0 tpy for this pollutant. Allowable limits are not imposed on this level of emissions, except for flares and pollutants with controls.
4 Total allowables are for information and are not enforceable conditions

57. The following table from Title V Permit P044-R3, Condition A.107 – "Facility: Allowable Startup, Shutdown, and Maintenance and Malfunction Emissions," lists the facility-wide SSM and malfunction emission limits:

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 16: South Hat, Table 107.A, Allowable SSM and Malfunction Units, Activities, and Emission Limits

Unit No.	Description	VOC (tpy)
SSM from 1, 2, 3, 4, 5, 6, 7, 8	Compressor & Associated Piping Blowdowns during Routine and Predictable Startup, Shutdown, and/or Maintenance (SSM)	1.9
M1	Venting [2] of Gas due to Malfunctions.	10.0
Total [1]		11.9

1 Totals are for information only, not enforceable conditions.
2 This authorization does not include VOC combustion emissions.

58. Title V Permit P044-R4, Tables 106.A and 107.A unit emission limits are equal to Title V Permit P044-R3.

59. The following table from Oil and Gas GCP Application Table 2: "Allowable Emission Limits" lists (beginning August 14, 2018) the maximum allowable, facility-wide SSM and malfunction emission limits:

Table 17: South Hat, Table 2. Oil and Gas GCP Application, Allowable Emission Limits

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (pph)	SO_2 (tpy)
1	0.22	0.97	0.44	1.93	0.056	0.25	0.0035	0.015

TK-7	-	-	-	-	*	6.31	-	-
Load	-	-	-	-	*	0.69	-	-
Fug[3]	-	-	-	-	4.99	21.88	-	-
SSM[4]	-	-	-	-	*	50.00	-	-
Malfunction[5]	-	-	-	-	*	10.00	-	-
Total[4]	3.59	15.71	7.71	33.76	5.57	97.71	0.033	0.15

[1] Significant Figures Examples: One significant figure – 0.03, 3, 0.3. Two significant figures – 0.34, 34, 3400, 3.4
[2] Condensable PM: Include condensable particulate matter emissions in particulate matter calculations.
[3] FUG: Pursuant to condition A106 of the permit, fugitive emissions of VOC do not typically count toward Title V or PSD applicability. Thus, the total VOC emissions, including fugitive sources, may exceed 100 tpy without triggering additional permitting requirements.
[4] SSM and Malfunction: As stated in NMED's *Implementation Guidance for Permitting SSM Emissions and Excess Emissions* document (June 2012): there is no limit to the quantity of SSM emissions that can be permitted,

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

provided they are routine and predictable DCP would like to request 50 tpy of VOC and 1 tpy of HAP. In addition, pursuant to condition A107.C the permittee may select to authorize up to 10 tpy of malfunction events. DCP is requesting 10 tpy of VOC and 1 tpy of HAP associated with malfunction events in addition to the aforementioned SSM emissions limits.
"*" Denotes an hourly limit is not appropriate and is not being requested.

60. Between January 5, 2018 and June 30, 2019, DCP reported one hundred and nine (109)[2] excess emission events and asserted affirmative defenses as provided by 20.2.7 NMAC.

61. The Bureau issued two NOVs for sixty-nine (69) of these alleged violations: DCP-0665-1801 on December 14, 2018, and DP-0665-1802 and February 4, 2019.

62. The Division alleges that DCP violated Title V Permits P044-R3 and P044-R4, Conditions A106.A and A107.A, and GCP Oil and Gas Permit 1018-M8, Table 2, by exceeding its permitted allowable emission limits through a vent during one hundred and fourteen (114) excess emission events. These events resulted in a total of five hundred and ninety-seven (597) alleged violations (the "South Hat Violations").

63. The Division alleges that the South Hat Violations resulted in the unlawful emission of a total of 687,013.20 pounds of VOC.

64. The Division maintains that one hundred and three (103) of the one hundred and nine (109) excess emission events underlying the South Hat Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and DCP is therefore subject to penalties for five hundred and eighty (580) of the South Hat Violations. DCP maintains that its affirmative defense claims are valid.

[2] Revised Compliance Order No. AQB-20-46 stated that 69 excess emission events were reported and included in the two NOVs, and a total of 114 excess emission events were reported. DCP's Answer identified that five events were included in both one of the NOVs and an exhibit of excess emission reports not included in any NOV, resulting in a total of 109 excess emission reports.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

West Turkey Track Compressor Station

65. From June 28, 2013 to April 1, 2020, the West Turkey Track Compressor Station was authorized to operate under NSR Permit 2098-M4, GCP-4.

66. The following table from NSR Permit 2098-M4, GCP-4 Application Table 5: "Flares [Condition VII Line 5]," lists the emission units and their allowable emission limits:

Table 4: West Turkey Track, Table 5, Flares (abbreviated)

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)
Flare	0.03	0.15	0.19	0.81	0.03	0.14

67. Between June 3, 2018 and June 30, 2019, DCP reported twenty-seven (27) excess emission events and asserted affirmative defenses as provided by 20.2.7 NMAC.

68. The Department issued NOV DCP-413-1801 for a portion of these alleged violations on January 31, 2019.

69. The Department alleges that DCP violated GCP Oil and Gas Permit 2098-M4, Application Table 5: "Flares [Condition 7 Line 5]," by exceeding the permitted allowable emission limits for the unit Flares during twenty-seven emissions events. These events resulted in a total of two hundred and forty-two (242) alleged violations ("West Turkey Violations").

70. The Division alleges that the West Turkey Violations resulted in the unlawful emission of 49,896.50 pounds of NO_x, CO, and VOC.

71. The Division maintains that twenty-four (24) of the twenty-seven (27) excess emission events underlying the West Turkey Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and DCP is therefore subject to penalties for two hundred and eighteen (218) of the West Turkey Violations. DCP maintains that its affirmative defense claims are valid.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Artesia Gas Plant

72. Since June 27, 2017, the Artesia Gas Plant has been authorized to operate under Title V Permit P095-R3.

73. The following table from Title V Permit P095-R3, Condition A106 Facility: Allowable Emissions, lists, in part, the applicable emission units and their allowable emission limits (40 CFR 50; 40 CFR 60, Subparts A and JJJJ; 40 CFR 63, Subparts Kb and KKK; 40 CFR 63, Subparts A, HH, and ZZZZ; Paragraphs 1, 7, and 8 of 20.2.70.302.A NMAC; and NSR Permit 0434M10) (only applicable emission units listed):

Table 19: Artesia Gas Plant, Table 106.A, Allowable Emissions

Unit No.	NO_x[1] (pph)	NO_x (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (tpy)	H_2S (tpy)
23	0.09	0.38	0.47	2.06	-	-	0.04	3.9E-5

[1] Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
[2] "-" indicates the application represented emissions of this pollutant are not expected
[3] Compliance with emergency flare emission limits is demonstrated by limiting combustion to pilot and/or purge gas only.

74. The following table from Title V Permit P095-R3, Condition A107 Facility: Allowable Startup, Shutdown, and Maintenance ("SSM") and Malfunction Emissions, lists the facility-wide startup, shutdown, and maintenance, and malfunction emission limits (only applicable emission units and information listed):

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 20: Artesia Gas Plant, Table 107.A, Allowable SSM & M Units and Emission Limits

Unit No.	Description	NO_x (pph)	NO_x (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (pph)	SO_2 (tpy)	H_2S (pph)	H_2S (tpy)
SSM (23)	Flaring during routine and predictable startup, shutdown, and/or maintenance	10.4	2.4	56.6	13.2	<	<	2001.0	328.2	21.3	3.5
M	Venting of gas and combustion of gas flared due to malfunction	*	10.0	*	10.0	*	10.0	*	10.0	*	9.0

"<" Indicates that the application represented the uncontrolled mass emission rates are less than 1.0 pph or 1.0 tpy for this emissions unit and this air pollutant. The Department determined that allowable mass emission limits were not required for this unit and this pollutant.

"*" Pound per hour (pph) emission limits for SSM 23 shall apply during malfunction flaring events.

75. Between May 18, 2018 and June 14, 2018, DCP reported four (4) excess emission events at the Artesia Gas Plant and asserted affirmative defenses as provided by 20.2.7 NMAC.

76. The Bureau issued NOV DCP-0199-1801 for these alleged violations on March 18, 2019.

77. The Division alleges that DCP violated Title V Permit P095-R3, Condition A106.A by exceeding the permitted allowable emission limits of the emergency acid gas flare during four (4) excess emission events. These events resulted in a total of two hundred and sixty (260) alleged violations ("Artesia Violations").

78. The Division alleges that the Artesia Violations resulted in the unlawful emission of 99,768 pounds of NO_x, CO, SO_2, VOC and H_2S.

79. The Division maintains that the excess emissions events underlying the Artesia Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and DCP is

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

therefore subject to penalties for those violations. DCP maintains that its affirmative defense claims are valid.

Eunice Gas Plant

80. Since December 11, 2013, the Eunice Gas Plant has been authorized to operate under Title V Permit P086-R2.

81. The following table from Title V Permit P086-R2, Condition A106 Facility: Allowable Emissions, lists the emission units and their allowable emission limits (40 CFR 50; 40 CFR 60, Subpart A and GG, Kb, KKK; 40 CFR 63, Subpart A and HH, Paragraphs 1, 7, and 8 of 20.2.70.302.A NMAC; and NSR Permit 0044M10) (only applicable emission units listed):

Table 21: Eunice Gas Plant, Table 106.A, Allowable Emissions

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (pph)	SO_2 (tpy)	H_2S (pph)	H_2S (tpy)
SRU Incinerator (31)	3.6	15.8	4.0	17.7	0.2	0.87	629.7[3]	2,758	6.8	29.9
ESD Flare (112A)	0.43	1.9	2.3	10.2	-	-	0.45	0.2	4.5E-05	2.0E-04
Acid Gas Flare (113)	0.1	0.36	0.45	2.0	-	-	0.0087	0.038	8.6E-06	3.8E-05
Booster Flare (114)	0.1	0.46	0.57	2.5	-	-	0.011	0.048	1.1E-05	4.8E-05

[1] Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
[2] "-" indicates the application represented emissions of this pollutant are not expected
[3] "<" SO2 emissions shall not exceed 629.7 pounds per hour during any three-hour period.

82. The following table from Title V Permit P086-R2, A107 Facility: Allowable Startup, Shutdown, & Maintenance ("SSM") and Malfunction Emissions, lists the facility-wide startup, shutdown, and maintenance, and malfunction emission limits (only applicable emissions listed):

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 22: Eunice Gas Plant, Table 107.A, Malfunction Emission Limit

Unit No.	NO_x (pph)	NO_x (tpy)	CO	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (pph)	SO_2 (tpy)	H_2S (pph)	H_2S (tpy)
SSM-113	8.57	0.92	46.7	5.0	5.9	0.18	4233.9	128.8	52.9	1.37
Malfunction						10.0				

83. Between May 1, 2017 and August 16, 2018, DCP reported one hundred and thirty-one (131) excess emission events at the Eunice Gas Plant and asserted affirmative defenses as provided by 20.2.7 NMAC.

84. The Bureau issued four NOVs for these alleged violations: DCP-0595-1702 on January 29, 2018; DCP-0595-1801 on March 7, 2018; DCP-0595-1802 on November 19, 2018; and DCP-0595-1804 December 14, 2018.

85. The Division alleges that DCP violated Title V Permit P086-R2, Conditions A106.A and A107A, by exceeding the permitted allowable emissions of a vent or the ESD or Acid gas flares during one hundred and thirty-one (131) events. These events resulted in a total of two thousand one hundred and seventy-two (2,172) alleged violations ("Eunice Violations").

86. The Division alleges that the Eunice Violations resulted in the unlawful emission of 396,664 pounds of NO_x, CO, SO_2, VOC, and H_2S.

87. The Division maintains that one hundred and sixteen (116) of the one hundred and thirty-one (131) excess emission events underlying the Eunice Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and therefore DCP is subject to penalties for one thousand eight hundred and eighty-two (1,882) of the Eunice Violations. DCP maintains that its affirmative defense claims are valid.

Linam Ranch Gas Plant

88. Since April 28, 2014, the Linam Ranch Gas Plant has been authorized to operate under Title V Permit P094-R2.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

89. The following table from Title V Permit P094-R2, Condition 106.A, Allowable Emissions, lists the emission units and their allowable emission limits:

Table 23: Linam Ranch Gas Plant, Table 106.A, Allowable Emissions

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO (pph)	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (pph)	SO_2 (tpy)

36	5.5	24.2	9.3	40.7	0.6	2.7	<	<
37	5.5	24.2	9.3	40.7	0.6	2.7	<	<

[1] Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_x
"<" indicates the application represented uncontrolled emissions less than 1.0 pph or 1.0 tpy for this pollutant.

90. The following table from Title V Permit P094-R2, A107 Facility: Allowable Startup, Shutdown, & Maintenance ("SSM") and Malfunction Emissions, lists the facility-wide startup, shutdown, and maintenance, and malfunction emission limits (only applicable emissions listed):

Table 24: Linam Ranch Gas Plant, Table 107.A, Malfunction Emission Limit

Unit No.	NO_x[1] (pph)	NO_x[1] (tpy)	CO	CO (tpy)	VOC (pph)	VOC (tpy)	SO_2 (pph)	SO_2 (tpy)	H_2S (pph)	H_2S (tpy)
SSM 2	15.0	0.88	81.0	4.8	1.6	0.01	7,751	46.0	84.0	0.48
SSM AGI	18.0	0.71	97.0	44.0	1.90	0.00	9,301	4.1	101	0.048
Malfunction	288	10.0	1,565	10.0	3,029	10.0	9,301	10.0	101	9.0

[1] Nitrogen dioxide emissions include all oxides of nitrogen expressed as NOx
Venting of gas due to malfunctions that does not include VOC combustion emissions

91. Between May 16, 2017 and April 30, 2018, DCP reported one hundred and sixty-three (163) excess emission events and asserted affirmative defenses as provided by 20.2.7 NMAC.

92. The Bureau issued three NOVs for these alleged violations: DCP-0589-1702 on January 30, 2018; DCP-0589-1801 on March 7, 2018; and DCP-0589-1802 on September 28, 2018.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

93. The Division alleges that DCP violated Title V Permit P094-R2, Conditions A106.A and 107.A, by exceeding the permitted allowable emission limits of multiple units during one hundred and sixty-three (163) excess emission events. These events resulted in a total of four thousand one hundred and forty-four (4,144) alleged violations ("Linam Ranch Violations").

94. The Division alleges that the Linam Ranch Violations resulted in the unlawful emission of 890,678 pounds of NO_x, CO, SO_2, VOC, and H_2S.

95. The Division maintains that one hundred and thirty-five (135) of the one hundred and sixty-three (163) excess emissions events underlying the Linam Ranch Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and therefore DCP is subject to penalties for two thousand three hundred and thirty-six (2,336) of the Linam Ranch Violations. DCP maintains that its affirmative defense claims are valid.

Zia II Gas Plant

96. Between December 22, 2016 and November 22, 2017, the Zia II Gas Plant was authorized to operate under PSD Permit PSD-5217M1-R2. Since November 22, 2017, the Zia II Gas Plant has been authorized to operate under PSD Permit PSD-5217M2.

97. The following table from PSD Permits PSD-5217M1-R2 and PSD-5217M2, Condition 107.A Facility: Allowable Startup, Shutdown, & Maintenance ("SSM") Emissions, lists the facility-wide startup, shutdown, and maintenance emission limits:

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

Table 25: Zia II Plant, Table 107.A, Allowable SSM Emission Limits

Unit No.	NO_x[1] (pph) BACT	NO_x[1] (tpy)	CO (pph) BACT	CO (tpy)	VOC (pph) BACT	VOC (tpy)	SO_2 (pph) BACT	SO_2 (tpy)	H_2S (pph)	H_2S (tpy)	CO_{2e} (typ) BACT
SSM FL1	799.2	3.9	4,348.8	21.1	2,942.1	11.8	14,977.	59.9	162.9	0.7	6,518
SSM FL2	102.0	1.2	554.8	6.5	7.8	0.09	4,409.8	22.0	48.0	0.2	1,094
SSM Compressor Blowdown (CB)	-	-	-	-	358.8	0.8	-	-	-	-	15
SSM Plant Venting (PV)	-	-	-	-	1,500.0	12.0	-	-	-	-	3,355

[1] Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
[2] Pound per hour limits for NOx, CO, VOC, and SOx and the ton per year limit for CO2e are PSD BACT limits for units FL1, FL2, and SSM Compressor Blowdown and Plant Venting.
[3] Allowable SSM emission limits for FL1 and FL2 for all pollutants include pilot and purge emissions, except for CO2e which has separate emission limits for SSM and pilot and purge. Emission limits for pilot and purge appear in Table 106B.
[4] SSM for FL2 includes assist gas and acid gas (not pilot or purge).

98. Between September 6, 2017 and August 31, 2018, DCP reported two hundred and thirty-five (235) excess emission events at the Zia II Gas Plant and asserted affirmative defenses as provided by 20.2.7 NMAC.

99. The Bureau issued three NOVs for these alleged violations: DCP-32800-1801 on March 21, 2018; DCP-32800-1802 on November 16, 2018; and DCP-32800-1803 on February 20, 2019.

100. The Division alleges that DCP violated PSD Permits PSD-5217M1-R2 and -M2, Condition A107.A by exceeding the permitted allowable emission limits for multiple units during two hundred and thirty-five (235) events. These events resulted in a total of six thousand seven hundred and one (6,701) alleged violations ("Zia II Violations").

101. The Division alleges that the Zia II Violations resulted in the unlawful emission of 251,197 pounds of NO_x, CO, SO_2, VOC, and H_2S.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

102. The Division maintains that two hundred and twenty-two (222) of the two hundred and thirty-five (235) excess emissions events underlying the Zia II Violations do not qualify for affirmative defenses under the Act or the Penalty Policy, and therefore DCP is subject to penalties for six thousand and thirty (6,030) of the Zia II Violations. DCP maintains that its affirmative defense claims are valid.

C. SUMMARY OF ADMINISTRATIVE COMPLIANCE ORDERS

103. On May 13, 2020, the Division issued an Administrative Compliance Order alleging violations for the eight compressor or booster stations.

104. On June 30, 2020, the Division issued a Revised Administrative Compliance Order ("Compressor Station ACO") alleging violations for the eight compressor or booster stations superseding the May 13, 2020 Administrative Compliance Order.

105. On July 30, 2020, DCP filed its Request for Hearing and Answer to the Compressor Station ACO, denying the alleged violations and proposed civil penalty, and requesting that after a hearing, the Secretary of the Department dismiss the Compressor Station ACO with prejudice and such other relief as the Secretary deems just and appropriate. The Department docketed this matter as AQB 20-46 (CO).

106. On August 28, 2020, the Division issued an Administrative Compliance Order ("Gas Plant ACO") alleging violations for the four gas plants.

107. On September 25, 2020, DCP filed its Request for Hearing and Answer to the Gas Plant ACO, denying the alleged violations and proposed civil penalty, and requesting that after a hearing, the Secretary of the Department dismiss the Gas Plant ACO with prejudice and such other relief as the Secretary deems just and appropriate. The Department docketed this matter as AQB 20-64 (CO).

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

108. DCP identified a total of 194 excess emissions events at eight (8) compressor or booster station facilities for which a civil penalty is barred, in whole or in part, by the 1-year statute of limitations for administrative compliance orders in NMSA 1978, § 74-2-12.A(1) (2006). *See* DCP Operating Company's Request for Hearing and Answer to Revised Administrative Compliance Order, AQB 20-46 (CO), p. 18, ¶ 2.

II. COMPROMISE AND SETTLEMENT

A. GENERAL

109. Following good faith settlement negotiations to resolve this matter without further costly litigation, the Parties agree to a complete settlement of all the violations alleged in the Compressor Station ACO and the Gas Plant ACO, including DCP's affirmative defense claims, and have consented to the terms of this Final Order. DCP does not admit any of the violations alleged in the ACOs and does not waive or concede its affirmative defense claims, and the Division does not concede that DCP met its burden on the affirmative defense claims.

110. The Parties admit jurisdiction and consent to the relief specified herein.

B. CIVIL PENALTY, INJUNCTIVE RELIEF, AND COMPLIANCE ASSURANCE

111. In compromise and settlement of all of the violations alleged in the Compressor Station ACO and the Gas Plant ACO, and upon consideration of the seriousness of the alleged violations and DCP's efforts to address the causes of excess emissions at the Facilities, the Parties agree that DCP shall: (1) pay a civil penalty of $950,000 in a cash payment to the State of New Mexico; (2) permanently cease operation of its Eunice Gas Plant, with the exception of those operations identified in paragraph 112, and surrender or modify, as set forth in paragraph 116, its permits for the Eunice Gas Plant; and (3) comply with additional requirements relating to operations at its gas plant facilities, as set forth below.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

112. The requirement to cease operations of the Eunice Gas Plant does not apply to those specific operations located at the Eunice Gas Plant that are associated with the compressor station known as the "Amanda Compressor Station," and those liquids stabilization and loading/unloading facilities known as the "Eunice Treater."

Civil Penalty

113. DCP shall pay a civil penalty of $950,000.00 to the State of New Mexico within 30 calendar days after the effective date of this Final Order.

114. Payment shall be made to the ***State of New Mexico General Fund, NMED-Air Quality Bureau, 525 Camino de los Marquez, Suite 1, Santa Fe, New Mexico, 87505*** by certified or corporate check, or by wire transfer (ACH deposit). On the date that delivery of funds is initiated, notify the Air Quality Bureau Enforcement Manager by email at cindy.hollenberg@state.nm.us.

Certified or corporate checks must be sent to the following address:

New Mexico Environment Department
Air Quality Bureau
c/o Compliance and Enforcement Manager
525 Camino de los Marquez, Suite 1
Santa Fe, New Mexico 87505

Wire transfers must be made to Wells Fargo Bank as follows:

Wells Fargo Bank, N.A.
100 W Washington Street, Floor 20
Phoenix, AZ 85003

Routing Transit Number: 121000248
Deposit Account Number: 4123107799
Descriptor: NMED-AQB-C&E

115. If DCP fails to make timely and complete payment of the civil penalty pursuant to paragraphs 113 and 114, and unless the Parties agree to extend the time for payment of the civil

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

penalty, DCP shall pay a stipulated penalty of $1,500.00 per day for each day the payment is not timely or complete.

Shutdown of Eunice Gas Plant

116. Within 60 days of the effective date of this Final Order, DCP shall permanently cease operations at the Eunice Gas Plant, except as specified in paragraph 112. Within the 60-day period, DCP shall surrender its authority to continue to operate the Eunice Gas Plant under the AQCA by filing: (1) an administrative revision to the NSR permit removing the SRU and other equipment associated with the gas plant and deleting conditions relating to those units, with the exception of conditions, provisions and authority to operate relating to the Amanda Compressor Station and the Eunice Treater; and (2) an administrative modification to the Title V permit terminating the permit.

117. In addition to permanently ceasing operations at the Eunice Gas Plant as specified in paragraph 116 and complying with the requirements of paragraph 116, DCP shall decommission the Eunice Gas Plant by removing process chemicals, including catalysts, and cleaning process vessels and piping within 270 days of the effective date of this Final Order. Within 30 days of the decommission completion date, DCP shall submit a written certification to the Department that the facility was properly decommissioned in accordance with this paragraph and applicable statutes and regulations. The certification shall include the following statement, signed by DCP's responsible official:

> *I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I have no personal knowledge that the information submitted is other than true, accurate, and complete. I am aware that there are significant penalties for*

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

submitting false information, including the possibility of fines and/or revocation of air quality permits for knowingly and willfully submitting a materially false statement.

118. If DCP fails to permanently cease operations of the Eunice Gas Plant or submit the applications to surrender or modify the air quality permits issued by the Department for the Eunice Gas Plant as specified in paragraph 116 within 60 days of the effective date of this Final Order, and unless the Parties agree to extend the time by which DCP must permanently cease operations at the Eunice Gas Plant or submit the applications to surrender or modify the air quality permits issued by the Department for the Eunice Gas Plant as set forth in paragraph 116, DCP shall pay a stipulated penalty of $1,500.00 per day for each day thereafter until the date operations at the Eunice Gas Plant are permanently ceased.

119. If DCP fails to submit the written certification specified in paragraph 117 within 30 days of completing decommissioning at the Eunice Gas Plant, and unless the Parties agree to extend the time by which DCP must submit the written certification, DCP shall pay a stipulated penalty of $1,500.00 per day for each day thereafter until the date the required certification is submitted.

Compliance Assurance Requirements

120. Within 120 days from the signing of the Final Order by the Secretary of the Department, DCP shall comply with all of the requirements set forth in Appendix 1[3] at the following three facilities:

DCP Operating Company, LP, Artesia Gas Plant

DCP Operating Company, LP, Linam Ranch Gas Plant

DCP Operating Company, LP, Zia II Gas Plant

3 These requirements are based on Title V Permit P094-R3 (Linam Ranch Gas Plant), Specific Condition A206. Flares.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

To the extent that any of the requirements of Appendix 1 address emissions that are subject to requirements in existing permits for any of these facilities, the requirements of Appendix 1 shall supersede those permit requirements.

121. Within 60 days of the effective date of the Final Order, DCP shall submit applications to the Department for revision of the NSR permits for the Artesia Gas Plant and the Zia II Gas Plant to incorporate the applicable provisions set forth in Appendix 1, and to address any conflicting or duplicative provisions in the existing NSR permits.

122. The following specific compliance assurance requirements shall apply to the DCP facilities listed in Paragraph 2 for a period of two years beginning on the effective date of the Final Order:

a. In addition to the "Once per calendar year" frequency of flare inlet gas analysis required by Appendix 1, Specific Condition A206.B(2)(a), DCP shall conduct 11 additional monthly flare inlet gas analyses within the first five business days of each month to meet the standards provided in Appendix 1, Specific Condition A206.(B)(2). Results of these analyses shall be used in production of monthly flare emissions calculations per Appendix 1, Specific Condition A206.C(2)(a). This requirement shall commence on the date of the signing of this Final Order by the Secretary of the Department.

b. Within five days of the last business day of each month DCP shall compile all of the monitoring data and emissions calculations prepared for the previous month of affected facility flare operations, per the requirements of this Final order, and submit under separate NMED "Reporting Submittal Form" via electronic mail to cindy.hollenberg@state.nm.us.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

c. For any flaring event lasting longer than 3 hours continuous duration, the DCP shall prepare a root cause analysis in accordance with the requirements of 20.2.7.114 NMAC, ROOT CAUSE AND CORRECTIVE ACTION ANALYSIS, to determine the cause of the flaring event. DCP shall submit the results of any root cause analysis under this subparagraph to the Department on a monthly basis.

123. All submissions and reports required under paragraph 122 shall be submitted via email in accordance with Paragraph 108 and shall include the following statement, signed by DCP's responsible official:

> *I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I have no personal knowledge that the information submitted is other than true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fines and/or revocation of air quality permits for knowingly and willfully submitting a materially false statement.*

124. If DCP fails to submit permit applications as specified in Paragraph 121 within 60 days of this Final Order, and unless the Parties agree to extend the time by which DCP shall submit the permit applications, DCP shall pay a stipulated penalty of $1,500.00 per day for each day thereafter until the date all the required applications are submitted.

125. If DCP fails to submit the reports required in paragraph 122 of this final order within the specified timeframes, and unless the Parties agree to extend the time by which DCP shall submit a required report, DCP shall pay a stipulated penalty of 1,500.00 per day for each day thereafter until the date the required report is submitted.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

126. Within 30 days following receipt of a written demand by the Department, DCP shall make payment of any stipulated penalty that is due and payable under this Final Order. DCP shall make a cash payment of any stipulated penalty in the same manner as the civil penalty payment, as instructed in paragraph 114. DCP shall not contest or dispute in any way the amount of the stipulated penalty of $1,500.00 per day in the event that the Department brings an action against DCP to recover stipulated penalties due under paragraphs 115, 118, 119, 124 and/or 125, provided that DCP reserves the right to contest the basis for assessment of a stipulated penalty.

III. OTHER TERMS AND CONDITIONS

A. COMPLIANCE WITH OTHER LAWS AND REGULATIONS

127. Nothing in this Final Order shall relieve DCP of its obligation to comply with all applicable federal, state, and local laws and regulations.

B. RESERVATION OF RIGHTS AND DEFENSES

128. This Final Order shall not be construed to prohibit or limit the Department in any way from requiring DCP to comply with any applicable state or federal requirement not resolved herein. This Final Order shall not be construed to prohibit or limit the Department in any way from seeking any relief authorized by the AQCA for violation of any state or federal requirement applicable to DCP not resolved herein. This Final Order shall not be construed to prohibit or limit DCP in any way from raising any defense to a Department action seeking such relief.

C. MUTUAL RELEASE

129. The Parties mutually release each other from all claims that each Party raised or could have raised against the other regarding the facts and violations alleged in the NOVs, the Compressor Station ACO and the Gas Plant ACO. Such release applies only to civil liability.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

D. WAIVER OF STATE LIABILITY

130. DCP shall assume all costs and liabilities incurred in performing all obligations under this Final Order. The Department, on its own behalf and on behalf of the State of New Mexico, does not assume any liability for DCP's performance of any obligation under this Final Order.

E. EFFECTIVE DATE AND TERMINATION DATES

131. This Final Order and any modifications thereto shall be effective when the Final Order or modification has been executed by both of the Parties.

132. Except as otherwise provided in this Paragraph, the terms of this Final Order shall terminate when DCP has fulfilled the requirements of this Final Order as set forth in Paragraphs 113 through 125, provided that the requirements in paragraphs 120 and 121 shall be deemed to be satisfied when the two NSR permits have been modified to incorporate the requirements of Appendix 1 as provided by paragraph 121. The reservations of rights and defenses and the mutual release in Paragraphs 128 and 129 shall survive the execution and performance of this Final Order, and shall remain in full force and effect as an agreement between the Parties.

F. INTEGRATION

133. This Final Order merges all prior written and oral communications between the Parties concerning the subject matter of this Final Order, contains the entire agreement between the Parties, and shall not be modified without the express written agreement of the Parties.

G. BINDING EFFECT

134. This Final Order shall be binding on the Parties and their officers, directors, employees, agents, subsidiaries, successors, assigns, trustees, or receivers.

DocuSign Envelope ID: 8DE262AE-6A1D-477A-9B0B-B15278C26CC9

H. AUTHORITY OF SIGNATORIES

135. The persons executing this Final Order on behalf of DCP and the Department, respectively, represent that they have the authority to execute this Final Order on behalf of DCP and the Department.

I. SIGNATURE AND COUNTERPARTS

136. This Final Order is intended to be executed on separate pages. Faxed, emailed, electronic, or digital signatures shall constitute original signatures binding on the signing party.

137. This Final Order may be executed in multiple counterparts, each of which shall be deemed an original, but all of which shall constitute one and the same agreement.

RE: Application for an Administrative Revision
DCP Operating Company, LP; Eunice Gas Plant

Permit Programs Manager:

DCP entered into a Settlement Agreement (No. AQB 20-64 (CO)) and Stipulated Final Compliance Order (Final Order) with NMED which was signed on September 9, 2021. Per requirement 116 of the Final Order:

"Within 60 days of the effective date of this Final Order, DCP shall permanently cease operations at the Eunice Gas Plant, except as specified in paragraph 112. Within the 60-day period, DCP shall surrender its authority to continue to operate the Eunice Gas Plant under the AQCA by filing: (1) an administrative revision to the NSR permit removing the SRU and other equipment associated with the gas plant and deleting conditions relating to those units, with the exception of conditions, provisions and authority to operate relating to the Amanda Compressor Station and the Eunice Treater; and (2) an administrative modification to the Title V permit terminating the permit."

On behalf of DCP Operating Company, LP, Trinity Consultants is submitting an application for an administrative revision for the Eunice Gas Plant Facility, currently authorized to operate under NSR Permit No. 0440-M11R1 and Title V Permit No. P086R2. With this application, DCP seeks to cease operations of the entire Eunice Gas Plant facility, except for operations related to the Amanda Compressor Station and the Eunice Treater, cancel the construction permit, and voluntarily discontinue the Title V permit. GCP-O&G applications for the Amanda Compressor Station and Eunice Treater were submitted to the NMED on November 3, 2021.

The format and content of this application are consistent with the Bureau's current policy regarding administrative revision applications; it is a complete application package. Enclosed is the hard and copy of the application. Please feel free to contact me by email at aerenstein@trinityconsultants.com if you have any questions regarding this application.

Sincerely,

Adam Erenstein
Manager of Consulting Services

Ref: **Air Quality Operating Permit Application No.** P086R3M2
DCP - Eunice Gas Plant
NSR Permit No. 0044M11R2
Agency Interest No. 595 - PRT20210001
AIRS No: 350250044

Dear Samuel Keen:

The Air Quality Bureau is in receipt of DCP Operating Company LP's November 3, 2021 request to voluntarily discontinue the DCP Operating Company LP - Eunice Gas Plant Title V Operating Permit No. P086R3, pursuant to 20.2.70.400.I NMAC. An existing Title V major source may apply for a permit under 20.2.72 NMAC, to obtain federally enforceable conditions that restrict the facility's potential to emit to below Title V Major Source thresholds.

DCP entered into a Settlement Agreement (No. AQB 20-64 (CO)) and Stipulated Final Compliance Order (Final Order) with NMED which was signed on September 9, 2021. Per requirement 116 of the Final Order: "Within 60 days of the effective date of this Final Order, DCP shall permanently cease operations (effective on 11/9/2021) at the Eunice Gas Plant, except as specified in paragraph 112. Within the 60-day period, DCP shall surrender its authority to continue to operate the Eunice Gas Plant under the AQCA by filing: (1) an administrative revision (NSR 0044-M11R2) to the NSR permit removing the SRU and other equipment associated with the gas plant and deleting conditions relating to those units resulting in the closing of Eunice Gas Plant-AI-595, with the exception of conditions, provisions and authority to operate relating to the Amanda Compressor Station (GCP Oil & Gas registration-9442 approved 11/16/2021) and the Eunice Treater (GCP Oil & Gas registration-9441 approved 11/16/2021); and (2) an administrative modification to the Title V permit terminating the permit.

The Air Quality Bureau received DCP Operating Company LP's NSR Permitting actions on November 8, 2021 for Eunice Gas Plant located in Township 21S, Range 36E, Section 5 in Lea County, New Mexico. The approve mentioned permitting actions results in federally enforceable limitations to comply with the stated Settlement Agreement.

The Air Quality Bureau has verified that the actions required to reduce the potential to emit of this facility to below Major Source thresholds have been met. Therefore, the Department has cancelled Title V Operating Permit No. P085-R3 for the Eunice Gas Plant as of November 9, 2021 and DCP Operating Company LP's facility will be removed from the list of major Title V sources in New Mexico.

If you have any questions, please call Joseph Kimbrell at 505-629-2718 or Joseph.Kimbrell@State.NM.US.

Sincerely,

Elizabeth Kuehn

NMED Final Cost Evaluation
DCP Operating Company - Linam Ranch Gas Plant

Unit 29: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	77.6	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	638,337,148	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3730	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days	Number of SCR reactor chambers (n_{scr})	1
Number of days the boiler operates (t_{plant})	365	days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR	0.0425	lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0085	lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050		Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
			Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours		
Estimated SCR equipment life	20	Years*	Gas temperature at the SCR inlet (T)	650 °F
Base case fuel gas volumetric flow rate factor (Q_{fuel})				UNK ft^3/min-MMBtu/hour
Concentration of reagent as stored (C_{stored})	29	percent*		
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14	days		

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

* For industrial boilers, the typical equipment life is between 20 and 25 years.

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 29: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	78	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	659,336,566	scf/Year	
Actual Annual fuel consumption (Mactual) =		638,337,148	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.968	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8481	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	2.64	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	11.19	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	276.54	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	1	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	4	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	0	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	45.94	kW

Unit 29: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$4,008,496	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$68,400 in 2024 dollars
Indirect Annual Costs (IDAC) =	$396,102 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$464,502 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$20,042 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$2,120 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$38,962 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$7,275 in 2024 dollars
Direct Annual Cost =		$68,400 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,869 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$393,233 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$396,102 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$464,502 per year in 2024 dollars
NOx Removed =	11 tons/year
Cost Effectiveness =	$41,492 per ton of NOx removed in 2024 dollars

Unit 30: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	73.95	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	502,157,081	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3730 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.031	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0061	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024			
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI
Annual Interest Rate (i)	7.5	Percent		
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia		
Electricity ($Cost_{elect}$)	0.1000	$/kWh		
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst		
Operator Labor Rate	60.00	$/hour (including benefits)*		
Operator Hours/Day	4.00	hours/day*		

CEPCI = Chemical Engineering Plant Cost Index

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 30: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	74	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	628,323,957	scf/Year
Actual Annual fuel consumption (Mactual) =		502,157,081	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.799	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7001	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	1.82	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	6.36	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	262.38	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	1	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	2	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	0	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	43.78	kW

NMED Final Cost Evaluation
DCP Operating Company - Linam Ranch Gas Plant

Unit 30: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,884,912	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$58,181 in 2024 dollars
Indirect Annual Costs (IDAC) =	$383,971 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$442,152 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$19,425 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$1,204 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$30,650 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$6,902 in 2024 dollars
Direct Annual Cost =		$58,181 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,861 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$381,110 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$383,971 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$442,152 per year in 2024 dollars
NOx Removed =	6 tons/year
Cost Effectiveness =	$69,555 per ton of NOx removed in 2024 dollars

Unit 31: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	36.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	305,643,453	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3730 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.0813	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0163	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024			
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI
Annual Interest Rate (i)	7.5	Percent		
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia		
Electricity ($Cost_{elect}$)	0.1000	$/kWh		
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst		
Operator Labor Rate	60.00	$/hour (including benefits)*		
Operator Hours/Day	4.00	hours/day*		

CEPCI = Chemical Engineering Plant Cost Index

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 31: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	37	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	312,675,073	scf/Year
Actual Annual fuel consumption (Mactual) =		305,643,453	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.978	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8563	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	2.39	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	10.24	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	133.02	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	1	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	3	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	0	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	21.79	kW

NMED Final Cost Evaluation
DCP Operating Company - Linam Ranch Gas Plant

Unit 31: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,468,155	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$36,435 in 2024 dollars
Indirect Annual Costs (IDAC) =	$244,902 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$281,337 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,341 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$1,940 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$18,655 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,500 in 2024 dollars
Direct Annual Cost =		$36,435 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,776 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$242,126 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$244,902 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$281,337 per year in 2024 dollars
NOx Removed =	10 tons/year
Cost Effectiveness =	$27,471 per ton of NOx removed in 2024 dollars

Unit 32B: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	36.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	212,284,384	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3730	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.1046	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0209	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 32B: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	36	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	307,577,110	scf/Year	
Actual Annual fuel consumption (Mactual) =		212,284,384	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.690	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6046	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	3.03	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	9.16	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	131.97	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	1	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	4	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	1	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	21.43	kW

NMED Final Cost Evaluation
DCP Operating Company - Linam Ranch Gas Plant

Unit 32B: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,441,923	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$30,374 in 2024 dollars
Indirect Annual Costs (IDAC) =	$242,327 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$272,701 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,210 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$1,735 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$12,957 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,472 in 2024 dollars
Direct Annual Cost =		$30,374 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,775 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$239,553 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$242,327 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$272,701 per year in 2024 dollars
NOx Removed =	9 tons/year
Cost Effectiveness =	$29,767 per ton of NOx removed in 2024 dollars

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across with United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).* This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).* The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long-Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed DCP Operating Company, LP (DCP), that its Linam Ranch Gas Plant (Linam) was identified as one of the sources possibly contributing to regional haze at nearby Class I areas.

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. The NMED's July 18, 2019 notification letter to DCP specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility

subject to the analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Clark TLA-6 2SLB RICE (Unit 6)	39.29		Yes	0.010		No
Clark TLA-6 2SLB RICE (Unit 7)	39.29		Yes	0.010		No
Clark HBA-6 2SLB RICE (Unit 8)	47.49	566.08	Yes	0.0070	0.12	No
Clark HBA-6 2SLB RICE (Unit 9)	47.49		Yes	0.0070		No
Clark HBA-6 2SLB RICE (Unit 10)	47.49		Yes	0.0070		No
Clark HBA-6 2SLB RICE (Unit 11)	47.49		Yes	0.0070		No
Solar Centaur T-70 Turbine (Unit 29)	11.82	51.78	Yes	0.26	1.16	No
Solar Centaur T-70 Turbine (Unit 30)	11.26	49.32	Yes	0.25	1.10	No
Solar Centaur T-4700 Turbine (Unit 31)	26.03	114.01	Yes	0.13	0.55	No
Solar Centaur T-4000 Turbine (Unit 32B)	23.72	103.88	Yes	0.12	0.54	No
ESD Flare (Unit 4A)	14.80	0.88	No*	9301.45	4.13	No*

* Pursuant to NMED Guidance received on 9/23/2019, the Four Factor Analysis is to be completed for steady state sources of emissions only; as such, emissions from SSM/M activities are not subject to a Four Factor Analysis.

Once the applicability of the four factor analysis has been determined for process equipment and pollutants, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED[1], potentially applicable emissions reduction technologies are informed by reviewing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC). In order to determine the most relevant and current retrofit controls available, the RBLC was queried for the previous ten years. Summaries of the result of this search are provided and discussed under Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis is then conducted for those controls that are technically feasible.

[1] NMED 2021 Regional Haze Planning Website ("Links to other information"). https://www.env.nm.gov/air-quality/reg-haze/

At Linam, the six (6) natural gas-fired two-stroke lean burn engines (Units 6, 7, 8, 9, 10 & 11) and four (4) combustion turbines (Units 29, 30, 31 & 32B) are subject to this four-factor analysis based on NO_X emissions. No units are subject based on SO_2 emissions. The turbines are either Solar Centaur T-70, T-4000 or T-4700 units. Manufacture dates for these units range from 1979 to 1995. The engines are either Clark TLA-6 or HBA-6 units. Manufacture dates range from 1951 to 1974 for the engines.

2.1. NATURAL GAS-FIRED COMBUSTION TURBINES

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[2]

The treatment of the exhaust gases exiting the turbine dictate the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[3] The units at Linam are regenerative cycle turbines, which are essentially simple cycle gas turbine with an added heat exchanger.

NO_X is formed via three fundamentally different mechanisms. The principle NO_X formation mechanism, thermal NO_X, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_X forms in the highest temperature regions of the combustion chamber. The second NO_X formation mechanism, fuel NO_X, arises from the evolution and reaction of fuel bound nitrogen compounds with oxygen. The final NO_X formation mechanism, prompt NO_X, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_X is negligible in comparison to thermal and fuel NO_X. Fuel NO_X will also be negligible for Linam's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_X.

2.1.2. Potential NO_X Controls for a Combustion Turbine

There are three general methods of controlling NO_X emission from gas turbines; (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation, (2) dry controls that use

[2] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[3] Ibid.

advanced combustor design to suppress NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[4]

The retrofit control equipment that was identified for combustion turbines during a comprehensive review of the RBLC, available literature, and manufacturer's input is reported in Table 2. A more detailed table summarizing the RBLC review is provided in Appendix A. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible?	NO_X Control Efficiency
Good Combustion Practices	Yes	Base Case
Improved Combustion Technology	Yes	vendor ppm guarantee
Water/Steam Injection	No	N/A
Selective Catalytic Reduction	Yes	70%

2.1.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at Linam. However, these good combustion practices are currently in use at Linam, as required by various conditions in its Title V and NSR permits. Accordingly, no further assessment of these control practices has been included in this report.

2.1.2.2. Improved Combustion Technology

The improved combustion technology control option, commonly referred to as Dry Low NO_X (DLN) control, also seeks to reduce the combustion temperature and residence time of fuel in the combustor (thereby decreasing NO_X formation) by increasing the air-to-fuel ratio in the combustion chamber. There are several levels of improvements that can be made to the combustion chamber, which achieve this NO_X control at varying levels. Based on communications with Solar, the DLN control option involves a thorough overhaul of the combustion section of the turbine, including replacement of the air and fuel injection nozzles, modifications to or complete replacement of the combustion chamber, and replacement of the electrical control system for the unit. Solar's specific technology, SoLoNO$_X$ utilizes lean-premixed combustion technology to ensure an extremely uniform air/fuel mixture and stringently controls the combustion process to prevent undesirable emissions from forming. An overall reduction efficiency of 55% - 80% can be achieved for the turbines located at this facility

[4] Ibid.

using this technology in comparison to permitted PTE. Reduction efficiencies are dependent on, and can vary based on, existing technologies already installed on the facility's units.

Solar has performed numerous retrofits of existing turbines with SoLoNO$_X$ and, even though there are extensive overhaul and implementation costs, the technology is technically feasible. Therefore, a cost analysis will be completed to determine the cost effectiveness per ton of NO$_X$ removed.

2.1.2.3. Water/Steam Injection

Water or steam injection is a control technology for gas turbines that has been demonstrated to effectively suppress NO$_X$ emissions. Injection of steam and water has the effect of increasing the thermal mass by dilution and thereby reducing the peak temperature in the flame zone. There is an additional benefit of absorbing the latent heat of vaporization from the flame zone when water injection is utilized. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.[5]

Steam injection is not discussed as an option for these Solar turbines at Linam because Solar does not manufacture turbines with steam injection technology. Although the Solar turbines are mechanically capable of supporting water injection, Solar has stated that they do not offer water injection retrofits for any of the Centaur 40 conventional combustion line of turbines. This is primarily due to the design of the combustor housing of the conventional Centaur 40. The injectors on this style of combustor intersect directly into the combustor without using direct air flow for the direction of fuel. The style of injector needed to implement water injection technology is referred to by Solar as a Dual Lined Injector. This type of injector introduces fuel laterally into the front of a combustor and utilizes a controlled flow to disperse fuel.

Solar considers the control technique to be antiquated technology in comparison to the other control methods they have available, such as SoLoNO$_X$. Solar has retired this control option and does not recommend water injection be installed to control emissions from their turbine units. Also, Solar stated that if direct modifications are made to the turbine engine or it's supporting hardware to retrofit third party water injection control, then Solar will not uphold any existing warranty to the unit and previous maintenance work done by Solar to the turbines. Combustion turbine units are high capital value assets and this retrofit would create a high risk factor going against manufacturer's recommendation.

Furthermore, per conversations with Solar, approximately 5 gallons per minute (gpm) of de-ionized or de-mineralized water will be needed to properly implement this control. For a continuously operating turbine, this represents a total water usage of approximately 2.6 million gallons per year, per unit, without taking into consideration leaks and evaporative losses that would occur during transport. Securing the availability of such a large quantity of water will be a difficult even without factoring in the necessary de-ionization and de-mineralization treatment.

Although the Solar turbines on site have the potential to be mechanically retrofitted with water injection, the facility also does not have access to sufficient water for this technology. Additionally, based on the high mineral content of water in the Permian Basin, even when filtration techniques are implemented, DCP engineers have determined that continuous water injection poses a high risk for vibrational imbalance on rotating equipment, which may cause critical damage to the equipment and ultimately decrease the equipment life expectancy. For these reasons, DCP has deemed this control technology as technically infeasible for the turbines located at Linam.

---

[5] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust downstream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[6] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O \quad \text{(Equation 1)}$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O \quad \text{(Equation 2)}$$

A SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituent, thermal sintering, or compacting, of active sites due to high temperatures in the reactor, fouling caused by ammonia-sulfur salts and particulate matter in the gas, and erosion due to high gas velocities.[7]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[8]

In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[9] The exhaust temperature of the turbines assessed here is approximately 580 °F.

Assuming that any space limitations can be overcome, SCR is considered a technically feasible control option for the turbines located at Linam. SCR units typically achieve 65% to 90% NO_X reduction, dependent on the exhaust temperature and upstream NO_X concentration. If the NO_X concentration is already low, it can be difficult to achieve these control efficiencies.[10] A cost analysis is completed for SCR using an overall reduction efficiency of 70%.

2.2. NATURAL GAS-FIRED TWO-STROKE LEAN-BURN (2SLB) ENGINES

2.2.1. Two-Stroke Lean-Burn Engines Background

A reciprocating internal combustion engine (RICE) is a device that uses the combustion of fuel and air in an internal chamber to generate a reciprocating motion and convert heat energy into mechanical work. The units use a piston to draw air and fuel into the combustion chamber and compress it. The compressed air/fuel mixture is then ignited, generating combustion in the chamber. The energy of combustion pushes out the piston, turning

[6] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.
[7] Ibid.
[8] Ibid.

[10] Ibid.

a crankshaft and producing mechanical work. In the same cycle, the products of combustion remaining in the chamber are released and exhausted from the unit.

Natural gas-fired RICE are separated into multiple design classes, including 2-stroke lean-burn (2SLB), 4-stroke lean-burn (4SLB), and 4-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1) with exhaust oxygen levels less than 4%, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12% or more.[11]

NO_X is formed in reciprocating engines via the same three mechanisms applicable to the turbines:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Linam engines also use natural gas fuel; therefore, the formation of prompt and fuel NO_X will again be insignificant, and this analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[12]

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:[13]

(1) Operational control methods, such as adjusting the timing or other operating parameters.
(2) Combustion control techniques, for example reducing the peak flame temperature or introducing inerts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.

The PTE associated with each engine is reported in the facility's New Source Review and Title V permits, as well as summarized in Table 1 of this report.

2.2.2. Potential NO_X Controls for 2SLB Engines

Potential retrofit control options identified for 2SLB RICE were identified via comprehensive review of the RBLC and available technical literature and are summarized in Table 3. A detailed description and discussion of the technical feasibility and anticipated performance of each control is provided below.

[11] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[12] Ibid.
[13] Ibid.

Table 3. Potential Control Equipment for 2SLB RICE

Control Equipment	Technically Feasible?	NO_X Control Efficiency
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**
Clean Burn Technology	**No**	**5% - 30%**
Selective Catalytic Reduction	**No**	**N/A**
Non-Selective Catalytic Reduction	**No**	**N/A**

2.2.2.1. Good Combustion Practices and Fuel Selection

By following the same concepts from engineering knowledge, experience, and manufacturer's recommendations referenced above, good combustion practices for operation of engines can be developed and maintained. This is achieved by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection for the 2SLB engines are similar to those identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Linam and these practices are currently in use at Linam, as required by various conditions in its Title V and NSR permit authorizations. Accordingly, no further assessment of these control practices is included in this report.

2.2.2.2. Clean Burn Technology

Clean Burn Technology (CBT) is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding or enhancing an air-to-fuel ratio controller, making the unit capable of operating at more desirable ratios.

Rich-burn engines are normally designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio of 16:1, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1). A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. As noted, 2SLB engines are typically designed to operate at the high air-to-fuel ratios employed in CBT, so by design these units are in general not amenable to an increase in air-to-fuel ratio to receive significant NOx reduction benefits. The technology will also have a negative trade-off through an increase in Carbon Monoxide(CO) emissions; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease the NO_X emissions to some degree.[14]

Additionally, in order to avoid derating the engine, combustion air must be increased at constant fuel flow. To achieve this, the engine will need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel ratio controller.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at

[14] State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines, State of New Jersey Department of Environmental Protection, 2003.

lean conditions, high energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[15]

2SLB engines are mechanically capable of being retrofit with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NO_X emissions. However, based on the advanced age, type of engine, and discussion with vendor, DCP has determined that clean burn technology retrofits are physically possible yet deemed technically infeasible for the engines at Linam. The aforementioned available clean burn control technologies are incapable of being retrofit on the existing 70-year-old engines on site.

2.2.2.3. Selective Catalytic Reduction

Implementation of SCR controls for 2SLB engines follows the same process and has the same technical drawbacks as discussed in Section 2.1.2.4 of this report.

Typical concerns for SCR system in regards to ammonia slip or insufficient ammonia was not applicable to the engines at Linam. For engines that typically operate at variable loads, such as engines on gas transmission pipelines, a SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed.[16] As Linam Ranch does not typically operate with variable loads, the facility does not expect to have periods of ammonia slip or insufficient ammonia.

The characteristics of 2SLB engine exhaust streams are well understood across industry to be non-favorable conditions for the chemical reactions necessary for SCR to reduce NOx emissions effectively. This is due to undesirable processes occurring in SCR systems as lean burn engines, by design, have higher oxygen level in the exhaust system. In the SCR system of a 2SLB engine, several competitive, nonselective reactions will occur with abundant oxygen. These reactions can either produce secondary emissions or, at best, unproductively consume ammonia as complete oxidation of ammonia generates nitric oxide. For the aforementioned reasons, SCR installation on 2SLB engines requires significant understanding of the process to design, implement and maintain as this type of control system often requires retrofit upgrades/modifications to the engine's combustion system resulting in a custom type control system. Due to the aforementioned reasons, SCR systems have not been widely applied to natural gas fired 2SLB engines similar to those at Linam and application of this control technology can only be seen on very large diesel-fired stationary engines and on large combustion turbines.

Additionally, there is historical precedent that installation of SCR on 2SLB engines can result in significant technical complications, including a necessity to derate the engines and unreliable operation post-retrofit due to a back pressure drop that happens with the exhaust system putting constraints on the engines. Many times, sizing of the SCR system has to be custom designed in accordance with the allowable pressure drop in the exhaust per manufacturer specifications. Another issue using a catalyst (part of the SCR system) on a 2SLB engine is poisoning of the catalyst by lubricant because in two stroke engines, the oil is mixed with either the fuel or the air to lubricate the piston.

AP-42 Section 3.2 does list SCR as an available control technology for 2SLB engines, however, the challenges of applying this control technology on 2SLB engines are strongly asserted by RBLC not identifying SCR as a control for these specific engine models.[17]

---

[15] Ibid.
[16] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[17] Ibid.

Due to the technical barriers associated with SCR as applied to specific 2SLB engines, as described above, it has been determined that this method of NO_X control is technically infeasible for the 2SLB engines at Linam.

2.2.2.4. Non-Selective Catalytic Reduction

Non-Selective Catalytic Reduction (NSCR) is a control technique that uses residual hydrocarbons and carbon monoxide (CO) in engine exhaust as a reducing agent for NO_X. In an NSCR system, hydrocarbons and CO are oxidized by oxygen (O_2) and NO_X. The excess hydrocarbons, CO, and NO_X pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_X to N_2.[18] This technique does not require additional reagents to be injected because the unburnt hydrocarbons in the engine exhaust are used as the reductant. The chemical reactions for this process are shown in the equations below.[19]

Phase 1:
$$2CO + O_2 \rightarrow 2CO_2$$
$$2H_2 + O_2 \rightarrow 2H_2O$$
$$HC + O_2 \rightarrow CO_2 + H_2O$$

Phase 2:
$$NO_X + CO \rightarrow CO_2 + N_2$$
$$NO_X + H_2 \rightarrow H_2O + N_2$$
$$NO_X + HC \rightarrow CO_2 + H_2O + N_2$$

The reactions in Phase 1 of the chemical process above function to remove excess oxygen from the exhaust stream. This step is necessary because if the oxygen is not removed, it will react more readily with the CO and hydrocarbons than the NO_X, thus reducing the potential for NO_X removal.

Despite this oxygen removal step in the chemical process, the engine exhaust gas stream must already have low levels of excess oxygen, or the oxygen will not be fully removed in Phase 1 and the NO_X removal will not be efficient. Consequently, application of the NSCR control technique is effectively limited to engines with normal exhaust oxygen levels of 4% or less. This does not include lean-burn engines, which typically have an exhaust excess oxygen level around 8%, ranging from 4% to 17%.[20]

The exhaust oxygen levels for 2SLB engines are not sufficiently low to support the reactions described above; therefore, this technology is not a method used to control NO_X emissions from lean-burn engines. Furthermore, NSCR was not identified in the review of the RBLC as a potential control of NO_X emissions from large natural gas-fired lean-burn stationary RICE and AP-42 Section 3.2 does not list NSCR as an available control technique for 2SLB engines.[21] For these reasons, it has been determined that this method of NO_X control is infeasible for the 2SLB engines at Linam.

[21] Ibid.

DCP has evaluated the costs of implementing the technologically feasible control technologies as thoroughly as possible in the time provided to complete this assessment. These cost estimates are calculated according to the methods and recommendations in the EPA Air Pollution Control Cost Manual using quotes provided by vendors as well as default assumptions form the Cost Control Manual.[22] Cost effectiveness considerations for the turbines are discussed below, with costs summarized in Table 4.

3.1. NATURAL GAS-FIRED COMBUSTION TURBINES

Table 4. Cost Analysis Summary of Technically Feasible Control Options for Combustion Turbines at Linam

Control Equipment	Unit	Capital Cost ($)	Annual Cost ($)	Emission Reduction (tpy)	Cost Effectiveness ($/ton)[23]
SoLoNOx	29	$188,125	$605,743	29.21	$21,278.01
	30	$188,125	$618,799	25.97	$23,829.64
	31	$1,377,841	$269,048	86.78	$3,100.23
	32B	$1,377,841	$268,605	21.04	$12,764.91
SCR	29	$1,500,000	$256,678	35.81	$7,168.48
	30	$1,500,000	$254,319	33.08	$7,688.74
	31	$1,500,000	$246,027	78.07	$3,151.46
	32B	$1,500,000	$231,770	19.51	$11,880.95

[22] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

[23] Cost Effectiveness and emission reduction as shown in Table 4 are based on 2016 EI information, which reflects a conservative emission calculation approach multiplying turbine operating hours by *permitted PTE emission rate* (lb/hr). Using the actual emission testing data (NSPS KKKK) for these turbines, rather than PTE, the following table reflects what actual emission reduction would be derived from the control technologies and estimated cost effectiveness:

Control Equipment	Unit	Capital Cost ($)	Annual Cost ($)	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
SoLoNOx	29	$188,125	$605,743	0	N/A
	30	$188,125	$618,799	0	N/A
	31	$1,377,841	$269,048	31.98	$8,413.01
	32B	$1,377,841	$268,605	3.82	$70,315.54
SCR	29	$1,500,000	$256,678	13.08	$19,623.74
	30	$1,500,000	$254,319	5.99	$42,457.25
	31	$1,500,000	$246,027	39.71	$6,195.60
	32B	$1,500,000	$231,770	7.45	$31,110.07

DCP has selected to use the EPA Air Pollution Control Cost Spreadsheet for SCR to estimate the costs associated with implementing a SCR control system on the turbines at Linam. The estimate incorporates direct capital cost for equipment and vendor labor, direct annual costs (maintenance, operator costs, reagent cost, electricity cost, and catalyst cost), and indirect costs associated with DCP's internal labor, overhead and capital recovery for the project.

This cost estimate assumes that the SCR will reduce NO_X emissions with a 70% efficiency.[24] There is no historical data to support a higher control efficiency assumption. In addition, due to the age of the units and current availability of control equipment for them, it is assumed that there would be significant difficulties retrofitting each of these turbines due to initial assessment and the need of a custom engineered SCR system.

These cost estimates have been developed, and applied to the retrofit of these turbines based on two approaches: (i) in Table 4 using the 2016 Emission Inventory submittal for Linam, which is based on PTE for the turbines, so it reflects a potential or theoretical emissions reduction if the turbine were operating at its maximum permitted emissions rate, and; (ii) the Table in Footnote 23 using NSPS KKKK testing data for these turbines reflecting actual emissions for the turbines, thus reflecting actual emissions reductions that would be achieved. A copy of the EPA Air Pollution Control Cost Spreadsheet for each unit is included in Appendix B of this report. Based on actual emissions reductions, these technologies reflect a cost-effectiveness of over $5,000 per ton on the lowest-side, and generally tens of thousands of dollars per ton for these turbines.

[24] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of DCP's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

4.1. NATURAL GAS-FIRED COMBUSTION TURBINES

DCP estimates that approximately 13 months will be needed to budget, design, procure, and construct the SoLoNO$_X$ control equipment. Factors that have been considered for this anticipated timeline include time for DCP to budget and allocate funds (3 months); 6 months for unit inspection and delivery; and 3 weeks for installation. A contingency factor of 25% has also been applied to account for potential circumstances or setbacks associated with installation of this new technology.

DCP is not certain whether standard SCR technology can be found to be applied to these particular turbines at Linam given their age, design and the fact that such control system is not provided by the turbine manufacturer. It is possible that SCR technology for the turbines at Linam may need to be custom engineered and developed. DCP estimates that approximately 9 months would be needed to budget, design, procure, and construct the SCR control equipment. Factors that have been considered for this anticipated timeline include time for DCP to budget and allocate funds (3 months); and 4 months to design, deliver and install SCR technology. A contingency factor of 25% has also been applied to account for potential circumstances or setbacks associated with installation of this new technology.

This section addresses the potential energy and non-air environmental impacts that installation of the technically feasible control options pose on a source. The consideration of energy impacts involves assessing the impact of a control measure on the energy that is consumed by the source. Non-air environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

5.1. NATURAL GAS-FIRED COMBUSTION TURBINES

The implementation of SCR on the turbines at Linam would result in several energy and non-air impacts. The primary impact of this control would be a significant increase in energy consumption, which would be necessary to power the units. The estimated energy consumption for each unit is summarized in Table 5, and is based on the EPA Air Pollution Control Cost Manual.[25] The calculation for these values is included in Appendix B of this report.

Table 5. Energy Consumption Analysis Summary

Unit	Annual Energy Consumption
29	349.7 MWh/year
30	333.1 MWh/year
31	165.8 MWh/year
32B	163.1 MWh/year
Total	1011.6 MWh/year

In addition to the increased energy burden, there are several non-air environmental impacts associated with the handling and storage of the reagent used in the SCR system, typically ammonia or urea. Ammonia is a Toxic Air Pollutant (TAP) regulated under 20.2.72.502 NMAC with an occupational exposure limit (OEL) of 18 mg/m^3. In both soil and water, urea is hydrolyzed quickly to ammonia and carbon dioxide by urease, an extracellular enzyme that originates from microorganisms and plant roots.[26] Short-term inhalation exposure to high levels of ammonia in humans can cause irritation and serious burns in the mouth, lungs, and eyes. Chronic exposure to airborne ammonia can increase the risk of respiratory irritation, cough, wheezing, tightness in the chest, and impaired lung function in humans. Animal studies also suggest that exposure to high levels of ammonia in air may adversely affect other organs, such as the liver, kidney, and spleen.[27]

[25] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual
[26] U.S. EPA, EPA/635/R-10/005F, "Toxilogical Report of Urea", July 2011
[27] U.S. EPA, EPA/635/R-16/163Fc, "Toxicological Review of Ammonia Noncancer Inhalation: Executive Summary", September 2016

Unavoidable releases of ammonia could have significant and irreversible impacts on the living and physical environment affected. Storage and handling of urea or ammonia onsite would result in an increased risk to the health and safety of facility operators. Linam is a Gas Plant, which already maintains a high level of health and safety risk. DCP considers any increase to this risk unacceptable.

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system. Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.[28]

6.1. NATURAL GAS-FIRED COMBUSTION TURBINES

Based on their current age and operating efficiency, it is estimated that the remaining useful life of the turbines will be longer than the SCR units. The turbines have operated for more than 40 years without any significant deterioration in operating efficiency; therefore, this analysis of the remaining useful life of the equipment will be based on the anticipated useful life of the SoLoNO$_X$ and SCR control technologies.

The estimated useful life of the SoLoNO$_X$ control technology is 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[29]

The estimated useful life of the SCR control technology is 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[30]

7. SUMMARY & CONCLUSIONS

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input of potentially available control technologies for the natural-gas fired turbines located at Linam, DCP has determined that both SoLoNO$_X$ and SCR are technically feasible control options for the turbines. DCP notes that there are significant cost implications for each turbine at the facility with these technologies, that there are significant time and resource expenditures necessary for these technologies, and that there are significant energy and non-air impacts associated with these technologies particularly the SCR technology. DCP further notes that, considering the information reflected in this report, these control technologies are not cost-effective for the estimated reasonable progress improvement, and further notes that DCP's Linam Ranch natural gas processing plant is barely over the agency's Q/d assessment threshold of 5.5 with a Q/d of 7.6.

APPENDIX A - RBLC TABLES

RBLC Analysis for Natural Gas Fired Turbines – NO_X Control

	Control Technology	Good Combustion Technique	Improved Combustion Technology (Low-NO_X Combustors, Ultra-Low NO_X Combustors and other improved combustion technology)[a]	Water/Steam Injection[b]	Selective Catalytic Reduction (SCR)[c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. Primary combustion occurs at lower temperatures under oxygen-deficient conditions. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.	Low-NO_x burners employ multi-staged combustion to inhibit the formation of NO_X. Primary combustion occurs at lower temperatures under oxygen-deficient conditions; secondary combustion occurs in the presence of excess air. This category includes Improved Combustion Technology Lean Head End Liners for the GE turbines assessed here.	Injected water/steam acts as a heat sink, lowering combustion zone peak temperatures, resulting in a decrease in thermal NO_X.	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_X to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.
	Other Considerations	N/A	N/A	Results in a small efficiency penalty but an increase in power output. May increase CO and VOC emissions. Not available in certain models.	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.

RBLC Analysis for Natural Gas-Fired Lean-Burn RICE – NO_X Control

	Control Technology	Good Combustion Practices and Fuel Selection	Clean Burn Technology [a]	Selective Catalytic Reduction (SCR) [b,c]	Non-Selective Catalytic Reduction (NSCR) [c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.	Natural gas fueled engines that operate with a fuel-lean air/fuel ratio are capable of low NO_X emissions.	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_x to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.	This technique uses residual hydrocarbons and CO in rich-burn engine exhaust as a reducing agent for NO_x. In an NSCR, hydrocarbons and CO are oxidized by O_2 and NO_x. The excess hydrocarbons, CO, and NO_x pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_x to N_2.[b]
	Other Considerations	N/A	N/A	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.	N/A
ELIMINATE TECHNICALLY INFEASIBLE OPTIONS	RBLC Database Information	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.
	Feasibility Discussion	Technically feasible.	Technically feasible.	Technically infeasible. Site and unit-specific complications exclude SCR as a control option for the 2SLB engines at this facility.	Technically infeasible. The NSCR technique is limited to engines with normal exhaust oxygen levels of 4 percent or less. This includes 4-stroke rich-burn naturally aspirated engines and some 4-stroke rich-burn turbocharged engines. Lean-burn engines could not be retrofitted with NSCR control because of the reduced exhaust temperatures.

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	77.63	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,020	Btu/scf
What is the estimated actual annual fuel consumption?	658,580,746	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3710 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = _____ percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.152	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.046	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	484	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	78	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	666,724,528	scf/Year	
Actual Annual fuel consumption (Mactual) =		658,580,746	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.988	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8653	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	8.28	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	35.81	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	35,954	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	137.74	/hour	
Residence Time	1/V_{space}	0.01	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.14		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	261.03	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	37	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	3	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	43	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	6.6	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	50	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	3	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	11	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	1	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	500	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ =	39.92	kW
	where A = (0.1 x QB) for industrial turbines.	349683.0549	kWh/yr
		349.6830549	MWh/yr

Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$1,500,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =		$128,441 in 2018 dollars
Indirect Annual Costs (IDAC) =		$128,268 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC		$256,709 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$7,500 in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600 in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$3,756 in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$23,350 in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$6,235 in 2018 dollars
Direct Annual Cost =		$128,441 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,718 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$125,550 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$128,268 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$256,709 per year in 2018 dollars
NOx Removed =	36 tons/year
Cost Effectiveness =	$7,169 per ton of NOx removed in 2018 dollars

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	73.95	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,020	Btu/scf
What is the estimated actual annual fuel consumption?	608,459,422	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3710	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = _____ percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.15	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.046	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	484	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	74	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	635,065,475	scf/Year
Actual Annual fuel consumption (Mactual) =		608,459,422	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	0.82	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.958	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8393	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	7.88	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	33.08	tons/year
NO_x removal factor (NRF) =	EF/80 =	0.88	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	34,247	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	137.74	/hour
Residence Time	1/V_{space}	0.01	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.14	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing turbine	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ =	38.02	kW
	where A = (0.1 x QB) for industrial turbines.	333078.5449	kWh/yr
		333.0785449	MWh/yr

Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$1,500,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =		$126,082 in 2018 dollars
Indirect Annual Costs (IDAC) =		$128,268 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC		$254,350 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$7,500 in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600 in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$3,470 in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$21,573 in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$5,939 in 2018 dollars
Direct Annual Cost =		$126,082 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,718 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$125,550 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$128,268 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$254,350 per year in 2018 dollars
NOx Removed =	33 tons/year
Cost Effectiveness =	$7,690 per ton of NOx removed in 2018 dollars

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	36.80	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,020	Btu/scf
What is the estimated actual annual fuel consumption?	309,156,078	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3710 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = _____ percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.71	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.21	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	484	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	37	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	316,047,059	scf/Year
Actual Annual fuel consumption (Mactual) =		309,156,078	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	0.82	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.978	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8569	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	18.22	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	78.07	tons/year
NO_x removal factor (NRF) =	EF/80 =	0.88	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	17,043	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	115.02	/hour
Residence Time	1/V_{space}	0.01	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		
Elevation Factor (ELEVF) =	14.7 psia/P =	1.14	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing turbine	1.00	

Not applicable; factor applies only to coal-fired turbines

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	148.18	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	18	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	4	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	20	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	4.5	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	52	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	24	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,100	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ =	18.92	kW
	where A = (0.1 x QB) for industrial turbines.	165760.065	kWh/yr
		165.760065	MWh/yr

Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$1,500,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =		$117,790 in 2018 dollars
Indirect Annual Costs (IDAC) =		$128,268 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC		$246,058 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$7,500 in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600 in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$8,190 in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$10,961 in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$3,540 in 2018 dollars
Direct Annual Cost =		$117,790 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,718 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$125,550 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$128,268 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$246,058	per year in 2018 dollars
NOx Removed =	78	tons/year
Cost Effectiveness =	$3,152	per ton of NOx removed in 2018 dollars

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	36.21	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,020	Btu/scf
What is the estimated actual annual fuel consumption?	83,425,083	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3710	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = _____ percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.66	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.20	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	484	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	36	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	310,980,309	scf/Year
Actual Annual fuel consumption (Mactual) =		83,425,083	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	0.82	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.268	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	2350	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	16.60	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	19.51	tons/year
NO_x removal factor (NRF) =	EF/80 =	0.88	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	16,770	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	116.84	/hour
Residence Time	1/V_{space}	0.01	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.14	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing turbine	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	143.54	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	17	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	4	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	20	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	4.5	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	52	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	22	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,000	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ =	18.62	kW
	where A = (0.1 x QB) for industrial turbines.	163102.6609	kWh/yr
		163.1026609	MWh/yr

Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$1,500,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =		$103,533 in 2018 dollars
Indirect Annual Costs (IDAC) =		$128,268 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC		$231,801 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$7,500 in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600 in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$2,046 in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$2,958 in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$3,429 in 2018 dollars
Direct Annual Cost =		$103,533 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,718 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$125,550 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$128,268 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =		$231,801 per year in 2018 dollars
NOx Removed =		20 tons/year
Cost Effectiveness =		$11,883 per ton of NOx removed in 2018 dollars

Re: NMED Jan. 7, 2020, Request for Additional Information on the Four-Factor Analysis Report
Regional Haze Program
DCP Operating Company, LP – Linam Ranch Gas Plant

Mr. Singleton,

DCP Operating Company, LP (DCP) is in receipt of the New Mexico Environment Department's (NMED's) January 7, 2020, "*Request for Additional Information for Four-Factor Analyses under the Regional Haze Program*" ("Request for Additional Information" or supplemental information request), which requests various and specific supplemental information, technical discussions, analyses, and data, including possible supplemental "Four-Factor Analyses," for multiple sources with respect to DCP's Linam Ranch natural gas processing plant in Lea County, New Mexico. In the time afforded, and given the objections below, this letter provides DCP's responses to the January 2020 Request for Additional Information (in blue font, below).

NMED's January 7, 2020, Request for Additional Information, including potential Four-Factor Analyses, does not state a timeline by when the operator is to provide responsive information, and only states qualitatively to submit responses "as soon as possible." DCP notes that NMED's initial request for Four-Factor Analyses dated July 18, 2019, afforded approximately three and a half months to fulfill NMED's request for responses and analyses, requested by November 1, 2019. Given the level of information expected in NMED's initial request, DCP believes three and a half months was impracticably short, but DCP fulfilled the request to the best of the company's ability. With respect to the January 2020 Request for Additional Information, DCP received a phone call from NMED on February 10, 2020, expecting a response to the supplemental information request and possible Four-Factor Analyses by February 14, 2020, five weeks from NMED's letter of January 7, 2020. February 14, 2020, is unrealistic and unreasonable for the responses requested by NMED. DCP will provide what information it reasonably can by March 3, 2020, and will otherwise provide follow-on requested information when it is reasonable to do so given what is being requested by the agency.

As this is an administrative proceeding with an administrative record, for the record DCP must note any objections it has to the NMED request. DCP states the following objections for the record in relation to NMED's request for Regional Haze-related information and analyses, and preserves its rights related thereto notwithstanding DCP's providing information requested by NMED.

- DCP has limited resources available to respond to NMED's initial, and now supplemental information request; DCP does not have resources available to be dedicated full time to responding to NMED requests analyses, technical discussions, and responding to requests for information. DCP has expended resources, where practicable, to have third party support with respect to the company's responses to NMED's requests for assessments and information, but that support is not always practicable or available, and there are limitations on DCP's use of such third party support. DCP is providing the responses herein, to the agency's supplemental request for information, to the best of the company's ability, in the time afforded, given the limitations of its resources.

- NMED's amount of time afforded to respond to the agency's Request for Additional Information, potentially including Four-Factor Analyses, is impracticably short, unrealistic and unreasonable for a number of the requested items, and affects DCP's ability to respond to the various requests.

- DCP objects to NMED's Request for Additional Information to the extent the requests are for assessments, discussion, information, data that are not presently available and in the possession of the source, in this case DCP. It is within NMED's authority to request information presently available and in the possession of a source operator, but it is beyond the agency's authority to require a source to create or generate information or data that does not presently exist or is not in the possession of the source, or to require a source to expend monies/resources to create or generate such information or data.

- DCP objects to vague, ambiguous or undefined terms in the Request for Additional Information, and objects to the extent the request require DCP to engage in speculation in order to attempt to respond to an agency's stated question or request.

- DCP objects NMED's requests for assessments or analyses that directly or indirectly result in or would relate to "redefining the source," being a properly-authorized, operating, and permitted emissions source. The federal Regional Haze regulation contemplates emissions control technologies that might be cost-effectively retrofitted on a source; redefining a properly-authorized, permitted and operating source is not a retrofit control technology, and is beyond the authority of the Regional Haze rule to consider as a Reasonable Progress measure.

- DCP objects to the fact that NMED has not provided, as part of this administrative process, the cost-effectiveness threshold for control technologies for the Regional Haze Reasonable Progress rulemaking.

- DCP objects to the agency's fundamental threshold for requesting 4-Factor Analyses from sources in the State, *i.e.*, Q/d of 5, as this is unreasonably stringent and requiring resource expenditures for assessments of sources that would not effectively contribute to visibility improvement in Class I areas. The State of Colorado applied a Q/d of 20 as its screening criteria, which assumed an estimated associated deciview improvement of 0.3; a Q/d of 5 would provide, presumably, one-quarter of the assumed visibility improvement, so requiring screening of sources at that level that would provide potentially, *e.g.*, 0.07 deciview improvement.

Preserving the objections noted, above, DCP responds to the agency's January 7, 2020, Request for Additional Information as follows (NMED Jan. 7, 2020, requests re-stated in black font, and DCP responses provided in **blue** font).

Please provide the following information for the units that were evaluated in four-factor analysis for potential nitrogen oxides (NO_X) controls.

Flares

Thank you for providing the flaring supplement to the four-factor analysis for startup, shutdown, and/or maintenance (SSM) flaring emissions. The Department still requires the following information for the flares at the DCP Midstream Linam Gas Plant, Unit Numbers 2, 4A and AGI Flare.

1. Provide a description of each flare, the design and type, and its purpose.

   Unit No. 2 (Amine Acid Gas Flare) and Unit No. AGI Flare are both in service providing both emergency as well as startup, shutdown, maintenance/malfunction ("SSM&M") flare function for Linam Ranch Gas Plant's ("Linam Ranch's") acid gas service. Both flares will flare pilot, purge, assist gas and any acid gas flow to the flare that results from SSM&M and other emergency events.

   Unit No. 4A (ESD Flare) serves as an emergency/SSM&M flare and as a process flare to Linam Ranch. The ESD flare will flare pilot, purge, and emission from TEG dehydrator during steady state operations and any gas flow to the flare that results from SSM&M and other emergency events.

   Refer to *Attachment A – Process Flow Diagram and Flare Emission Calculation* as reference.

2. List and describe the reasons that trigger each type of flaring event.

   Steady-state emission from the flares are represented on *Attachment A*.

   Other flaring events include permit-authorized planned SSM flaring events and unplanned flaring events, *e.g.*, malfunction-related or emergency flaring events. Planned SSM flaring events are triggered by routine maintenance at frequencies recommended by the manufacturer or as regularly scheduled by DCP as part of planned maintenance. Allowable emission limits in the facility's air permit represent the maximum amount of emissions authorized to occur during planned maintenance activities and startup/shutdown events anticipated pre- and post-maintenance. However, these planned maintenance events do not occur at the same sequence or frequency generally reflected in a permit, *i.e*. quarterly, annually, biennially, etc., therefore, actual emissions that occur at the facility can differ each year as represented in DCP's process and SSM flaring four factor analysis report submitted on December 16, 2019.

   Unplanned flaring events are triggered for various unforeseeable, unexpected or unpredictable reasons, such as equipment malfunction, third party power loss, emergencies, *etc*. Excess emission resulting from these events, to the extent they are not reflected in the facility air permit SMM&M allotment, are reported to NMED pursuant to NMAC 20.2.7.110. DCP operates its process equipment and emission control equipment in a manner consistent with good air pollution control practices for minimizing emissions, including minimizing to the extent practicable the duration of unplanned flaring events and the volume of material subjected to such flaring.

3. Discuss potential alternative control options or operational changes that could reduce nitrogen oxides (NO_X) and/or sulfur dioxide (SO_2) flaring emissions, including:

DCP objects to this question 3 to the extent it uses ambiguous or undefined terms, requires speculation, and for the objections referenced above. Preserving those objections, DCP responds as follows.

a. infrastructure that allows re-routing or recirculating the gas within the facility or outside of the facility until an SSM event is over;

Linam Ranch's current infrastructure supports nat. gas re-routing, and off-loading when feasible under certain circumstances, each of which serve to reduce flaring emissions. Linam Ranch has the ability, when necessary, to close the nat. gas inlet to the facility, which significantly limits or prevents flaring at the facility. Linam Ranch also coordinates with the producers, either prior to a planned event, or when feasible during an unplanned event, to temporarily re-route nat. gas to other facilities if practicable or to shut in nat. gas for a finite period, to reduce the volume of nat. gas potentially subjected to flaring at the facility. Under certain circumstances DCP can, and does, utilize producer temporary off-load capabilities, or DCP capability to temporarily re-route gas when practicable and feasible, to minimize the volume of nat. gas potentially subjected to flaring at the facility. DCP believes that these capabilities and measures, taken together, serve to prevent flaring at the Linam Ranch facility or to mitigate the duration of a flaring event or the volume of material subjected to flaring. DCP is not aware of another technically feasible option to appreciably further reduce flaring events or volumes at the facility. DCP would note that with its operational practices and improvements Linam Ranch has operated within its permitted SSM&M flaring parameters in the last year, and has had minimal or no unanticipated, e.g., malfunction- or third party-related flaring events, so flaring at the facility has been positively managed.

b. sulfur absorbent technology used to remove sulfur from pipelines and other auxiliary equipment to reduce inlet or plant flaring SO_2 emissions;

The Linam Ranch nat. gas processing plant receives, and is designed to receive, high hydrogen sulfide ("H2S") concentration natural gas, referred to as "sour" nat. gas. Given the high H2S concentration received by the Linam Ranch plant, an amine treatment system is the most effective and the only technology that is technically feasible to remove sulfur and treat the sour gas stream of this volume and concentration.

Other sulfur absorbent technology, such as pipeline additive injection, commonly referred to as hydrogen sulfide scavenger, is utilized only non-sour gas systems, meaning on what are known as "sweet" gas streams, in order to treat very small amounts of hydrogen sulfide that might exist in a sweet gas stream to meet a certain specification, and are not suitable or effective for treating the sour gas stream processed at Linam Ranch; they would not meaningfully reduce the concentration of H2S that would recognizably affect the amount of sulfur received by the Linam Ranch plant.

c. Gas Capture Plans with facilities located downstream and upstream similar to those required for producers to better synchronize upstream and downstream services with the facility;

DCP objects to the use of an ambiguous or undefined term with respect to a midstream nat. gas processing plant facility, and to the extent this question requires speculation. A Gas Capture Plan is a New Mexico Oil Conservation Division ("NMOCD") requirement for producer entities, for the producer's production development, to ensure communication between the producer entity and gatherer in order to improve communication and planning future nat. gas takeaway capacity, in order to mitigate the potential for a producer entity having to flare what would be stranded gas at its well production facility if there weren't nat. gas takeaway. DCP as a midstream entity does confer with producers about the producer's Gas Capture Plans. The concept, however, has no applicability to a midstream nat. gas processing plant as such a facility, for example the Linam Ranch plant, is by definition designed to receive and process the producer's nat. gas; DCP's Linam Ranch gas plant does not flare nat. gas due to lacking capacity, for example, so the concept is not applicable to a midstream gas processing plant.

d. use of remote capture equipment;

DCP objects to the use of an ambiguous or undefined term with respect to a midstream nat. gas processing plant facility, and to the extent this question requires speculation. Remote capture equipment, as DCP understands it from NM agency materials, is a concept that relates to and provides capability at a producer wellhead and relates to wellhead volumes of nat. gas and nat. gas products (liquids) at the producer wellhead. The same concept does not have applicability to a midstream nat. gas processing facility, and the type of technology is not applicable at the scale of a nat. gas processing facility; a midstream nat. gas processing plant, by definition, is removing nat. gas products (liquids) from the inlet material, which is one of its functions.

e. better infrastructure planning and changes to existing infrastructure that connects the downstream and upstream operations to DCP facilities to ensure that there is adequate processing capacity to move produced gas to market.

DCP objects to the use of ambiguous or undefined terms, and to the extent this question requires speculation. As described in the prior responses, DCP's Linam Ranch nat. gas plant processing capacity appropriately and adequately manages relevant producer nat. gas production; the plant does not flare nat. gas due to lacking capacity.

Note that flaring at an up or downstream facility to avoid flaring at the Linam Gas Plant is not considered to be an actual reduction in flared emissions rates under the four-factor analysis.

4. For any technically feasible solutions, provide a four-factor analysis. For additional information regarding potential alternative controls to flaring see the New Mexico Methane Strategy website: https://www.env.nm.gov/new-mexico-methane-strategy/methane-advisory-panel/.

Considering the above requests, DCP is not aware of any additional flaring technology or relevant operational changes that are technically feasible.

5. DCP states in its December 16th letter that "since the sources of SSM emission originates from normal plant activities….notes that it's impractical to employ such measure in order to decrease flaring…and the facility has an existing BMP *[best management practices]* process"….DCP concludes that there are no reasonable nor technically feasible emission reduction measure for flare sources ……" Provide details of the existing BMPs employed at the facility to reduce flaring emissions.

The referenced passage, above, refers to planned/routine SSM events. Facility equipment has routine maintenance schedules in order to maintain the equipment in good working order.

Examples of existing BMPs employed at the Linam Ranch Plant to reduce flaring during planned/routine SSM events includes:

- Coordination/communication between upstream entities (producers), DCP, and downstream entities and facilities prior to and during planned outages to minimize volumes of nat. gas directed to the Linam Ranch nat. gas plant during these events.
- When practicable and feasible, DCP temporary re-routing of upstream nat. gas to other DCP facilities.
- When practicable and feasible, producer or DCP use of nat. gas off-load agreements to temporarily route upstream nat. gas to third party facilities.
- Actions at the facility to minimize the duration/number of SSM events and volume flared through:
    - Critical Spare Program to ensure necessary equipment is on site and lacking such does not delay to duration of a planned event.
    - Coordination between operation and maintenance teams to ensure efficient implementation of a planned event.
    - DCP tracks and documents all work orders for needed maintenance or repairs through an asset management software to ensure that necessary work orders are executed appropriately and on time, which reduces the likelihood of having to have an off-cycle turnaround or maintenance event and associated SSM flaring.

6. The allowable flaring emission limits for NO_X are all less than 5 tons per year (TPY) and Unit AGI Flare has a limit less than 5 tpy for SO_2 which are less that the threshold that NMED established for sources to submit a four-factor analysis. However, in 2016, actual emissions reported for each flare exceeded their allowable limits and DCP's emissions inventory for years 2014 through 2018 show that the AGI flare and amine plant flare consistently exceeded allowable limits. (See Table 1.) Please explain the discrepancy between the SSM SO_2 emissions provided in the supplemental flaring analysis and NMED's 2016 emissions inventory. As the permitted limits do not reflect actual operations at the facility, please resubmit the four-factor analysis for the flares based on actual emissions reported in 2016. (See Table 1.)

Table 1 SSM Flare Emission Rates and Limits		
Flare Unit	NO_X tpy	SO_2 tpy
Emission Limits		
2	0.51	46.0
4A	3.3	18.9
AGI Flare	0.34	4.06
Emissions reported in 2016 Emissions Inventory		
2	1.84	26.97
4A	0.09	35.86
AGI Flare	1.84	242.85
Emissions Reflected in Four-Factor Supplement Dec 16, 2019		
2	0	3.28
AGI Flare	0	0
Malfunction	0.04	9.79

The SSM SO2 emission amount described in DCP's Dec. 16, 2019, letter only refers to authorized/permitted emissions and does not include reported excess emissions resulting from unforeseeable or unplanned, *e.g.*, malfunction-related events. Table 2 of the December 16, 2019 submitted response is titled "2016 EIQ Reported **Process Flaring** and **SSM Flaring** Emission".

The reported excess emissions not included in the above table can differ from year to year and are, by nature, unforeseeable/unanticipated. These events are addressed through facility's continuous improvement efforts to reduce such events by, for example, identifying causes and addressing them through equipment investments and/or operational improvements. As a result, Linam Ranch had zero excess emission events since February 10, 2019, and recently celebrated one year without an excess emission event.

Turbines

1. Provide documentation from Solar that they do not manufacture turbines with steam injection technology and that the Centaur 40 is not capable of being retrofitted to accept this technology.

   Please reference DCP's original November 2019 four factor analysis report on this topic. The report does not indicate that the Solar Turbine is not capable of being retrofitted to accept this technology, but rather states that "[s]team injection is not discussed as an option for these Solar turbines at Linam because Solar does not manufacture turbines with steam injection technology", meaning Solar no longer offers steam injection retrofit packages because they are obsolete. Please refer to *Attachment B – Solar Wet NOx Letter*, which states that Solar does not offer Wet-NOx technology.

2. Consider and include a discussion of the technical feasibility of other types of catalytic combustion, such as XONON^{TM} developed by Catalytic Combustion Systems, Inc.

   DCP objects to the use of an ambiguous or undefined term or phrase, and to the extent this question requires speculation. DCP is not familiar with the referenced technology, and therefore cannot offer any concrete opinion on its potential technical feasibility on these

particular turbines. Given the time limitation for this request, DCP was unable to and did not initiate a discussion between DCP's engineering and operations functions with the XONON technology manufacturer with whom the agency is suggesting DCP speak. DCP has no knowledge of this technology being applied in nat. gas midstream industry service.

3. Provide more detail of the Good Combustion Practices that have been implemented on the turbines, including routine inspections, maintenance and training schedules. It is unclear if these practices are fully optimized or conform to permit conditions alone.

DCP objects to the use of an ambiguous or undefined term or phrase, and to the extent this question requires speculation. The turbines at Linam Ranch are equipped with additional monitoring hardware, which provides live data allowing monitoring of equipment health. DCP has historically used the monitoring service offered by OEM vendor, Solar, which affords strong routine inspection and maintenance practices on the turbines. DCP is in the process of transitioning the monitoring service to DCP's internal reliability group. Routine inspection and maintenance activities, such as daily visual inspection, water wash, borescope inspection, and all other interval preventive maintenance activities, are tracked through DCP's asset management/maintenance software to ensure that they are executed appropriately and timely. In addition, Solar technicians are brought in to supervise DCP's turbine technicians when performing major maintenance or overhauls.

4. Please consider and include a discussion on the feasibility of replacing the natural gas-fueled turbines with commercial electric powered turbines.

DCP objects to this request as it pre-supposes re-definition of the facility process equipment, in this case properly authorized, permitted, and operating nat. gas-fired turbines – re-defining a source is not a retrofit control technology, and is beyond the authority of the Regional Haze rule to consider as a Reasonable Progress measure. Accordingly, it is not required that DCP discuss this topic.

Without waiving objections, the replacement of the existing natural gas-fueled turbines with electric compressor motors are not technically feasible with existing infrastructure at Linam Ranch. The four turbines subject to the Four Factor Analysis (Units 29, 30, 31 and 32B) have total site rating horsepower of 28,291 HP. Accommodating nearly 30,000 HP electric motor capacity is not feasible with the present electric infrastructure at Linam Ranch, would require significant electric power supply analysis, and would, for example, potentially require construction of a new 100 MW substation.
Construction of a substation does not guarantee electricity, which would depend on generation capacity and, for example, whether or not the conductors need to be resized to handle the load. Exclusive of cost considerations, including consideration of the cost of electric power supply on a regular basis for this HP equivalent, technical feasibility would require a feasibility study by XCEL Energy, which can take longer than 18-24 Months.

Please refer to *Attachment C – Priority Power Discussion*.

5. Provide copies of vendor quotes used to determine the cost of compliance.

DCP notes that in its initial report provided a vendor estimate of expected costs for retrofitting existing turbines; this was not a vendor quote providing more accuracy with respect to costs, and it is what was available in the time provided.

Please refer to *Attachment D – SoLoNOx and SCR estimate*

Engines

1. Provide more detail of the Good Combustion Practices that have been implemented on the two-stroke lean-burn (2SLB) engines, including routine inspections, maintenance and training schedules. It is unclear if these practices are fully optimized or conform to permit conditions alone.

   DCP objects to the use of an ambiguous or undefined term or phrase, and to the extent this question requires speculation. Linam's two-stroke lean-burn (2SLB) engine's Good Combustion Practices includes routine inspection and preventative maintenance. Also, prior to every quarterly preventative maintenance, DCP use specialized tool to monitor engine running condition and check for presence of any abnormal vibration. Routine inspection and all interval PM activities are tracked through DCP's asset management and maintenance system to ensure they are implemented appropriately and in a timely manner. Inspection/Maintenance is appropriately optimized for the emission units based on DCP's long history/experience operating such engines.

2. Provide more detail on why the age of the 2SLB engines prohibits retrofitting these units with Clean Burn Technology, including a discussion on why the installation of high energy ignition systems (HEIS) is not feasible. It would be beneficial to submit detailed documentation from the vendor on why none of the CBT options is technically feasible.

   Referencing the initial four factor analysis report submitted for Linam Ranch, the report states that "*2SLB engines are mechanically capable of being retrofit with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NOX emissions. However, based on the advanced age, type of engine,* ***and discussion with vendor****, DCP has determined that clean burn technology retrofits are physically possible yet deemed technically infeasible for the engines at Linam*."

   Above statement was based on discussion with the vendor, but also with DCP's experienced asset engineers – due to the type and vintage of these particular 2SLB engines, any clean burn retrofit technology would (i) require detailed studies/evaluations of each engine for custom retrofit specific to these engines, and (ii) while hypothetically feasible, such retrofits for this type and vintage engines would be so extensive and invasive that they would be as or more uneconomical than a new engine, so the retrofit emissions control technology is deemed impracticable, otherwise infeasible, for these particular engines.
   DCP believes a retrofit control technology is infeasible and beyond the scope of the Regional Haze rule if the cost of the control technology exceeds the cost of the base authorized/permitted emissions source; with the time limitations afforded, DCP was not able to develop further analyses and details on potential CBT retrofit actions for these particular 2SLB engines.

3. The report references AP-42 Section 3.2 that identifies Selective Catalytic Reduction (SCR) as an available control technology for 2SLB engines. Provide supporting data and information for the determination that SCR systems may result in technical complications and unreliable operation. Documentation from the equipment vendor detailing the technical drawbacks to this technology and the preferred technology for NO_X would be beneficial.

   Please refer to *Attachment E – Engine SCR vendor discussion*.

   After further discussion over the phone with the vendor representative, if an SCR were applied to these 2SLB engines the vendor is not able to guarantee life of catalyst nor accurate emission reduction that SCR system would be intended to achieve. DCP's facility engineer indicates that backpressures imposed by the SCR system will result in de-rated output of the unit. Therefore, DCP deemed this technology too uncertain, and fundamentally affecting the authorized equipment, to be considered as technically feasible control technology for engines at Linam Ranch.

4. The report states that the exhaust oxygen levels for 2SLB engines are not sufficiently low to support that occur during non-selective catalytic reduction (NSCR). Has DCP Midstream verified the average exhaust oxygen levels from each stack to support this assertion?

   DCP has data reflecting exhaust oxygen levels for these engines verified by data in third party stack test reports. Please refer to *Attachment F – EU 10 & 11 Stack Test Report.* These exhaust oxygen levels reflect oxygen levels that are too high to accommodate an NSCR process. There is no requirement to verify average exhaust oxygen levels, so it is unreasonable to expect such is available.

5. Consider and include a discussion on the feasibility and cost of technology that limits engine capacity to reduce NO_X emissions.

   DCP objects to the use of an ambiguous or undefined term or phrase, and to the extent this question requires speculation. DCP objects to the extent it does not understand the retrofit technology referred to. DCP objects to this request as it may pre-suppose re-definition of the facility process equipment (*e.g.*, limiting engine capacity), in this case properly authorized, permitted, and operating nat. gas-fired engines – re-defining a source is not a retrofit control technology, and is beyond the authority of the Regional Haze rule to consider as a Reasonable Progress measure. Accordingly, it is not required that DCP discuss this topic.

6. Please consider and include a discussion on the feasibility of replacing the natural gas-fueled engines with commercial electric powered compressors.

   DCP objects to this request as it pre-supposes re-definition of the facility process equipment, in this case properly authorized, permitted, and operating nat. gas-fired engines – re-defining a source is not a retrofit control technology, and is beyond the authority of the Regional Haze rule to consider as a Reasonable Progress measure. Accordingly, it is not required that DCP discuss this topic. Without waiving objections, the Linam Ranch gas plant's existing infrastructure does not support replacement of nearly 10,000 HP natural gas-fueled engines with electric driven motors. Please refer to discussion provided on Turbine question 4.

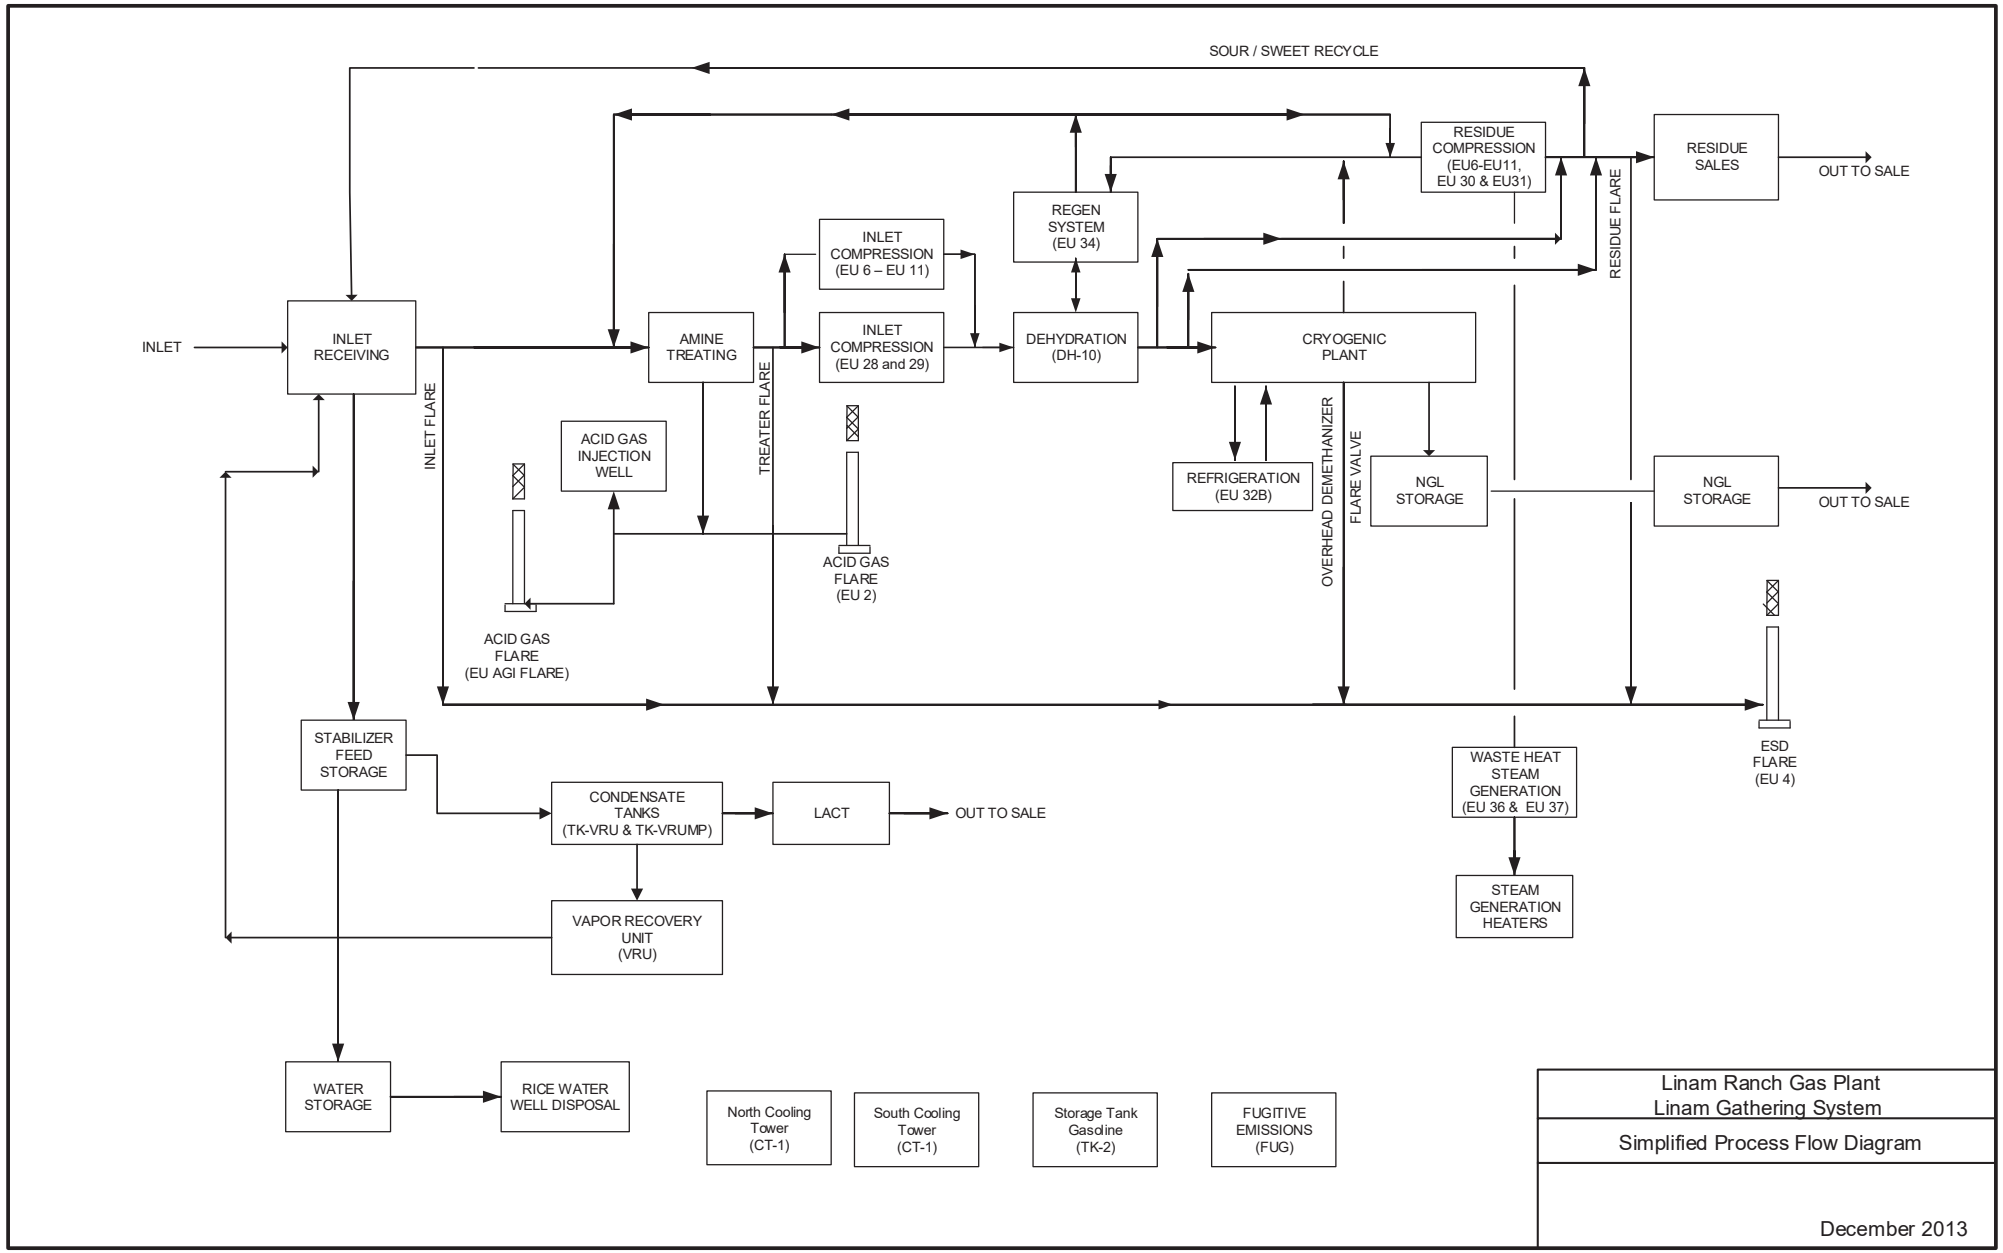
7. Provide copies of vendor quotes used to determine the cost of compliance.

   There are no vendor quotes used for the engines at Linam Ranch.

8. Provide the electronic spreadsheets used for control cost calculations.

   There are no cost calculation spreadsheets for the engines at Linam Ranch.

If you have any questions on the specific responses provided, please feel free to contact me directly by phone at 432-215-8514 or via email at hshong@dcpmidstream.com.



Sincerely,

Sam Hong
Environmental Engineer

Solar Turbines
A Caterpillar Company
Powering the Future Through Sustainable, Innovative Energy Solutions

February 18, 2020
DCP SENM
Attn: John Cook

SUBJECT: Wet Nox on SENM Solar Turbines

Dear Mr. Cook:

Thank you for your questions regarding emissions controls on the South East New Mexico turbines. Currently our emissions controls offering on our 2-shaft turbines are limited to SoLoNOx technology. In the past we have offered Wet-Nox emissions controls on our generator set packages. This technology is no longer offered as our SoLoNOx technology offers lower emissions control with a lower operational cost to our customers. Attached below are the current SoLoNOx emissions limits as well as our historical best available Wet-Nox limits.

Kenneth,
The second part to your question related to the 100 MW is a much more involved issue. Serving a load this size would require a major study on the part of XCEL to see how this load could be served. Any transmission project (regardless of size) must go through XCEL's transmission planning group to see what it would take to serve the load. In this case, the amount of load is so large, that the capacity of the lines now also come into play. Normally our rule of thumb for a 10 MW load would be 18 months to 24 months from the date the customer initiates studies. Increasing the load 10 fold will definitely stretch this out. I would like to tell you it could be done in 3 yrs but that really is going to depend on the generation capacity and whether or not the conductors need to be resized to handle the new load.

Best way to find out is to submit a request to XCEL and let them study it. The request will need a detailed load list showing all the motors, et all that add up to the 100 MW of load. Let me know if this is what you want to do and if so I will reach out to XCEL to get more information.

Thanks,

Brian

Kenneth,
See Roger's note below on the capacity of the line being 13.9 MVA. This would indicate you have room to add another 2.500 hp load without issues. However, this only addresses your feeder from the plant to the substation (the one PPM built for you). Still need to check with XCEL on their system and capabilities. I will reach out to them and see what they say.

Brian

Subject: RE: Xcel - Linam Ranch Gas Plant

Brian, we built the DCP Linam one-span feeder with 477 ACSR for this 7.2/12.47kV distribution line. That wire size can handle up to 646amps, which is about 13.9 MVA. However, it should not be loaded up to that amount, as DCP will experience voltage problems before that limit.

Adding more load truly depends on Xcel Energy's approval and ability to serve it. Attached is the PSA from James Delaney in May 2018. Unfortunately, it doesn't list how much they are approved for at the PME. Perhaps you have records of that and/or can get it from Xcel?

Thanks.

What size line was put in for the Linam Ranch Feeder from the Monument sub (12.5kV or 25kV? Expect there is plenty of capacity regardless for the additional 2,500 hp unit. I am not aware of a study done by XCEL to address the adding of this unit.

Brian

Subject: Xcel - Linam Ranch Gas Plant

Brian,

Do you have access to the "study" that was done to determine whether or not we could add the 2500 HP 4160V motor at Linam Ranch Gas Plant using the existing dedicated line from the Monument sub-station?

Was that done by Xcel or by your team?

We are getting asked by the NMED what the maximum additional delivery is to Linam on that new dedicated line. The additional 2500 HP motor at the plant could still happen – that project is "on hold" at the moment, but could be re-activated.

I would expect that we would need to pay for a completely new substation (100 MW?) located at the plant to convert all of our existing turbines/engines from fuel-powered to electric.

Best regards,

Kenneth

Hi Sam,

We have not done many SCR's through our company but the quotes we do have ranged from 850K-1,200,00 depending on what the starting emissions were to what the required target was. From what I can tell it does not looked like we have executed any of the SCR projects. The few of our customers that do have SCR's went directly to the SCR vendors.

To: Hong, Hyung S
Subject: RE: Linam Clark engines back pressure limit

Hey Sam,

Below is the rough numbers I have come up with, making a lot of assumptions…

Per engine~
Reactor Housing: $200,000
Reactor Housing Install: $75,000
Annual Run time avg cost (urea consumption, maintence): $350,000

Negative side effects:
Particulate Matter "PM" slip will be quite substantial as these are really dirty engines were trying to control
Catalyst Maintenance: because of the level of control and the nature of these engines the catalyst will mask off fairly quickly and require lots of maintenance and service.

Subject: RE: Linam Clark engines back pressure limit

Sam,

All Clarks have a direct-to-atmosphere exhaust stack (unrestricted flow).
Without measuring to confirm, my *conjecture* is that backpressure is single digit.
OF course any increase in backpressure is concomitant with a decrease in power (unwelcome); for this reason, think big…

Cc: Cook, John W <JWCook@dcpmidstream.com>
Subject: Linam Clark engines back pressure limit

Ron/Wade,

SCR vendor is wanting to know back pressure limitation on the exhaust to provide quote for correct size SCR system.

Example: a Caterpillar 3616le engine has an engine exhaust backpressure limitation of 20 inches of water. Knowing that we have to size our equipment large enough so that it doesn't restrict the exhaust flow rates and de-rate or harm the engines mechanical performance

Is this information available anywhere? I've checked through all of the old air permit applications and could not find anything other than engine parameters and emission guarantees.

I know it's a long shot but maybe on the engine operating manual or anything we can dig into?

GAS

1.0 Key Personnel

Great Plains Analytical Services:	Tyler Burns
DCP Midstream	Anthony Garcia

2.0 Sampling System

The sampling system used consisted of a Stainless steel probe, Non-porous teflon Line, coiled stainless cooler to drop out moisture from line and an Electrochemical Analyzer. Analyzers are housed in the air conditioned cab of the mobile laboratory. The sample system contains a seperate path to deliver EPA protocol gas to the port in order to allow testing of the entire system. A schematic Diagram can also be found in section 4 of this report.

3.0 Methods

EPA Method 1 or 1A

The purpose of the method is to provide guidance for the selection of sampling ports and traverse points at which sampling for air pollutants will be performed pursuant to regulations set forth in this part. This method is designed to aid in the representative measurement of pollutant emissions. This method is used for stacks with a diameter larger than 12 inches. Should the stack not meet that requirment, method 1A will be used. The applicability and principle of Method 1A are identical to Method 1 in stacks.

EPA Method 2 or 2C

This method is applicable for the determination of the average velocity and the volumetric flow rate of a gas stream.

ASTM D6522

This is the standard test method for determination of Nitrogen Oxides, Carbon Monoxide, and Oxygen concentrations in emissions from natural gas fired reciprocating engines, using portable analyzers

5.0 Summary

A Clark HBA-6 located at Linam Ranch Gas Plant and operated by DCP Midstream LP was tested for emissions of Carbon Monoxide (CO), Oxides of Nitrogen (NOx). The test was conducted by Tyler Burns with Great Plains Analytical Services, Inc. All quality assurance and quality control tests were within acceptable tolerances. This test was conducted using (3) 1 hour test runs.

2.0 Sampling System

The sampling system used consisted of a Stainless steel probe, Non-porous teflon Line, coiled stainless cooler to drop out moisture from line and Testo 350 analyzer.

3.0 Methods

EPA Method 1

The purpose of the method is to provide guidance for the selection of sampling ports and traverse points at which sampling for air pollutants will be performed pursuant to regulations set forth in this part. This method is designed to aid in the represnetative measurement of pollutant emissions. This method is used for stacks with a diameter larger than 12 inches. Should the stack not meet that requirment, method 1A will be used. The applicability and principle of Method 1A are identical to Method 1 in stacks.

EPA Method 2 & 2C

This method is applicable for the determination of the average velocity and the volumetric flow rate of a gas stream.

EPA Method 7E

This method is for measuring nitrogen oxides (Nox) in stationary sources using a continuous instrumental analyzer. Quality assurance and control requiremnents are also included in this method

EPA Method 10

This method is for measuring carbon monoxide in stationary sources using a continuous instrumental analyzer.

Re: Regional Haze
Linam Ranch Gas Plant
NMED ID 589
DCP Operating Company, LP

Dear Michael Baca,

Phillips 66 Company is submitting this document on behalf of DCP Operating Company LP (DCP), as it is an indirect subsidiary.

On July 12, 2023, representatives of DCP met with New Mexico Environmental Department (NMED) to discuss DCP plants that are of interest for the purposes of Regional Haze Planning. While the Artesia Gas Plant and Eunice Gas Plant issues were addressed during the meeting, there were outstanding questions for the Linam Ranch Gas Plant. This letter addresses those outstanding questions and follows the numbering of the July 12, 2023 NMED agenda.

Question 4.b. What plans, if any, does DCP have for retiring or replacing any of the engines or combustion turbines (CTs) at the Linam Ranch facility?

> DCP does not have any plans to retire or replace any of the combustion turbines at Linam Ranch Gas Plant. DCP has been working with turbine manufacture (Solar Turbines) to install upgrades/controls to the existing turbines to be compliant with §20.2.50 NMAC.

Turbines 28, 29, and 30 have been upgraded to be compliant with §20.2.50 NMAC.

Turbine Unit No.	NOx (ppmvd @15% O2)	Note
28	15	Solar upgrade complete
29	15	Solar upgrade complete
30	25	Solar upgrade complete
31	25	Solar upgrade expected to be complete by end of 2023
32B	<50	Future Solar upgrade to be completed by 20.2.50 NMAC timeline.

Turbine 31 is expected to be compliant with §20.2.50 NMAC by the end of 2023. Turbine 32B does not have a schedule, at this time, but will be compliant with §20.2.50 NMAC.

The six Clark engines (Unit Numbers 6-11) will either be replaced with different technology or retrofitted with appropriate equipment for compliance with §20.2.50 NMAC. DCP will ensure Units 6-11, or their replacements, will be compliant with §20.2.50 NMAC emission limitations and timelines.

Question 4.c. How does DCP plan to comply with the ozone precursor rule with respect to the applicable units at the Linam Ranch facility?

This has been addressed in the answer to Question 4.b.

Question 4.d. Is projected utilization of the units subject to Regional Haze expected to be appreciably different than historical utilization?

The utilization of the turbines and engines at Linam Ranch are not being modified due to the Regional Haze rule. There is ongoing drilling in the area that could have impacts on the utilization of Linam Ranch Gas Plant; however, the baseline actual emissions should be used for the projected 2028 modeling.

*Question 4.e. I*s DCP's cost-of-capital notably different that the current prime rate of ~8%?

With the current volatility of the current prime rate, the ~8% is a good an estimate as can be determined.

Question 4.f. Does DCP plan to provide updated cost evaluations for any of the pollution control options it evaluated in its submitted FFAs? If so, when should NMED expect to receive that information?

In 2021, Dresser-Rand provided an indicative pricing for necessary system retrofits on the Clark engines for the, at the time, proposed 20.2.50 NMAC regulations. Attached, is shown that the total indicative pricing is $3.05MM in 2021. Additionally, attached is an email in 2023 that indicates with inflation and supply chain issues that 20% should be added, resulting in $3.66MM per Clark engine as a total indicative price.

Question 5.a. Does DCP anticipate continued availability of maintenance parts for its engines and CTs (especially older engines) for 10 to 20 more years?

At this point, there is no indication of a shortage of maintenance parts for the engines and CTs. Suppliers work on a competitive market and as long as there is demand there is an expectation of supply.

Question 5.b. Estimates of maintenance costs for engines and CTs?

Maintenance to engines and CTs is completed by competitive bid process. This also is affected by the supply and demand model and can fluctuate.

Question 6. Does DCP plan to provide a cost evaluation for the replacement of its existing engines and CTs with new, like-kind engines or CTs? If so, when should NMED expect to receive that information?

A cost evaluation for the replacement of the existing engines and CTs with new, like-kind equipment is not anticipated for this planning period.

Question 7.a. Does DCP plan to provide a cost evaluation for the replacement of any of its existing engines or CTs with electric motor equivalents? If so, when should NMED expect to receive that information?

Yes, the information is provided in response to Question 7.b.

Question 7.b. Please provide documentation

Here is some background information to discuss electrical infrastructure:

- The five gas-fueled turbines at Linam Ranch represent about 40,000 HP, which would be approximately 30 MW if converted to electric.
- The Clark compression engines represents another 5 MW of combined if converted to electric.
- Note: 1 HP = 745 Watts + power factor
- Linam Ranch Gas Plant currently has four large electric motors for acid-gas injection (about 5 MW total), which includes two compressors for vapor recovery.

Linam Ranch History:

- In 2018, a “one-span” was created for the plant to
  - Providing a single, isolated source of power from the sub-station 9 miles to the south.
  - Providing higher electrical reliability than the multiple, unreliable power source which had multiple customer feeds that existed prior to 2018.
  - The project had no change in total electrical capacity but reduced flaring events due to “power blips”.
  - At a cost of $1.8MM (2018) to improve electrical reliability.

The following are future costs and impacts related to electrifying the existing gas-fueled compression at Linam Ranch Gas Plant:

- Utility – Bringing an additional 35 MW of power to the site will cost $28MM.
  - Cost: $2MM/mile for transmission-level power
  - Cost: $10MM for the substation
  - Schedule: Up to 5 years for approvals from the state of NM to begin construction
  - Schedule: Up to 3 years of supply chain delays for the electrical equipment (transformers and switchgear)
- New electric compression equipment
  - Electric compression will cost about $2,000/HP when labor and on-site electrical infrastructure downstream of the sub-station is included.
  - Total Cost is $90MM
    - Turbines: 40,000 HP x $2,000
    - Engines (2SLB): 5,000 HP x $2,000
  - Schedule: About 4 to 6 years to execute after approvals
  - Rights of Way: Existing space owned by Phillips 66 is insufficient to accommodate all the new electrical buildings and substation
    - No cost estimate has been determined for additional right of way, at this time, but will need to be added.
- Total Capital Costs of Utility + New Compression: $118MM estimated
- Operational Costs ($/year)
  - Future Electricity costs to operate the same compression: $21.46MM at $70/MWh

This addresses all the outstanding questions from the July 12, 2023 meeting that were noted.

If you have any questions or need any clarification regarding this response, please feel free to contact me at steve.torpey@p66.com or 832-765-3444.

Sincerely,

Steven R. Torpey, PE (TX)

John,
See response form Siemens on the Clarks.

The technology is still the same, but they suggested adding 20% to the attached proposal to update pricing for inflation.

That will make the cost for each Clark $3.050 MM x 120% = $3.66 MM

Best Regards,

Wolfgang Foerg, P.E.

Report Suspicious

Wolfgang,
Good morning,
I did a quick look at both your email and our files, and the budget Steve had set for you.
In all cases, the technology proposed is the same as was provided previously.
We'll still need to apply the same technology, which is probably good as it set's the table for meeting future emissions.
Unfortunately, as I'm sure you are aware, prices on almost everything has skyrocketed over the last 2.5 years.
Therefore, for planning purposes, I'd add another 20%, to the number's provided earlier.

If you wish to proceed beyond high level budget numbers everything Steve stated still applies, we'd need to make trip to location and gain some further detail.
Please let us know if you have any additional questions or require further support.

With best regards,
Kevin Davies

6-July-2021

DCP Midstream New Mexico Proposed Rule NOx, CO, VOC Reduction Estimations

Dresser-Rand Company (hereinafter, "Dresser-Rand") appreciates the opportunity to present this *indicative pricing* for necessary system retrofits on Clark HBA-6 and TLA-6 engines to achieve targeted reduced emissions levels with 20% operating margin per the proposed New Mexico pending regulations.

The scope supports 0.5 gm NOx/bhp-hr., over a load range 80-100%, Full Speed, with +/-20% NOx operating margin.

Pricing is inclusive of on and off engine modifications required. Also listed are pricing for optional items for consideration. Assumptions identified at this time are noted.

For each "Category" item in the following table, pricing given is inclusive of estimated time and cost for Project Management, Engineering, Drafting, Procurement, Hardware, Installation Supervision, Subcontractors, Field Services Commissioning, and Expenses.

Pricing is provided for a single unit type for DCP investigative analysis of regulatory compliance options. It does not reflect potential discounts which may be offered to DCP if Siemens-Energy is awarded multiple engines to retrofit in one project or up-front commitment to multiple projects.

Pricing reflects current market price conditions. It does not reflect potential year-over-year pricing increases on materials, labor, subcontractors, etc. if work is targeted to be completed in the years 2025 and following.

No actual site visits were conducted to identify or validate specific station or engine needs to verify successful scope, price and execution of such a project.

In no way is this letter to be considered an offer for services nor binding in any manner. No purchase order nor contract may be executed against this letter.

6-July-2021

Engine Unit Type = Clark TLA6 or HBA6

CATEGORY	PURPOSE & DESCRIPTION	PRICE (in $K)
NOx Emissions Reduction - Enhanced Combustion	**New Turbocharger x1**: Leaner AFR mixture, improved scavenging, reduced combustion temperature: ABB TPL-69. On engine mounted. Includes: Stand, wastegate, intake/exhaust piping, expansion joints, insulation. **Turbo L.O. Sump system**: To support additional requirements of off engine mounted turbocharger(s). Includes: LO pump, cooling and heating systems, reservoirs, platform, piping, end devices. **Aftercoolers x1:** New or updated aftercooler bundles to handle increased heat rejection of new turbocharger(s). Includes: Housing, cores, and piping. **EPCi - PCC fuel injectors**: Precision control of PCC fueling; eliminate miss-fires as source of NOx formation and engine imbalance. **HPFi - High Pressure Fuel Injection:** Improve A/F homogeneous mixture in cylinder to reduce A/F 'hot spots' and NOx formation; improve complete burn of in-cylinder A/F mixture. **iBALANCE:** Real-time Peak-Firing-Pressure monitoring, closed loop control to continuously auto-balance engine, reducing NOx formation due to imbalance; component protection; reliability in lean operation.	**$2,150**
Off Engine Modifications	**Air Intake Filters x1:** Required to accommodate increase intake air flow of new turbocharger(s).	**$50**
CO & VOC Emissions Reduction - Exhaust Aftertreatment	**Oxidation Catalyst:** Required treatment of exhaust gas to maintain or reduce CO and VOCs emissions in leaner operation. Piping included.	**$130**
Optional Items/Systems	**Silencer:** Hospital grade exhaust silencer if old silencers create too much back pressure/worn out. Base mount with tailpipe.	**$88**
	Jet Assist Air Study: Study to determine requirements for starting & sustaining turbocharger	**$22**
	iFLOW g3: Compressor health pressure, temperature, vibration monitoring.	**$160**
	O/H Parts - Severe Case: Parts new pistons, rings and cylinder liners. **DCI:** Would be part of the FS Labor to replace existing or with new parts.	**$450**
	TOTAL INDICATIVE PRICING:	**$3,050**

6-July-2021

Assumptions

Cooling System	Existing fin fan systems for main/AUX can handle increased heat rejection loads
Jet Assist System	Present system can support all engine starting scenarios and turbocharger start, as well as sustaining turbochargers during low (50-65%) load operations.
Natural Gas	Pipeline quality natural gas
Electric Power	DCP supplies necessary power for new controls subpanel
Intake Filters	Stand, mounting pad, piping is re-usable
Pre-Combustion Chambers	Engines have existing system and is working. One (1) PCC per head
Catalyst/Silencer	Existing pad for silencer stand can be re-used for base-mount combo unit
Optional Items	Not priced as separate projects. Priced to be part of base project at same time.

Comments & Clarifications

This budgetary indicative pricing is provided by Dresser-Rand with the intention of entering into further and more detailed exchanges of information, discussions, and negotiations with Purchaser, which may ultimately result in a legally binding agreement in writing with Dresser-Rand. It is not an offer to sell the products or services referred to for the prices or schedule specified herein but is an estimate only which has been provided to Purchaser as requested. This budgetary indicative pricing l is based solely on Dresser-Rand standard design practices and quality assurance procedures. Client specifications were not provided for review. Any client specifications which may apply will need to be reviewed by Dresser-Rand before compliance with these specifications can be assured within the pricing and delivery schedules as proposed.

For the avoidance of doubt, this budgetary indicative pricing shall not be considered an offer for sale, and no purchase order issued against this budgetary indicative pricing shall be accepted by Dresser-Rand.

Good afternoon, Ms. Olson.

In response to the inquiry about Linam Ranch Gas Plant- Turbine Unit No. 31 (T-4700); the turbine the emissions upgrade was completed approximately October 29, 2023 and resumed operation the next day.

Please let me know if there are any further questions.

Good afternoon, Mark.

Here is the emissions testing report for Unit 31. This has not been submitted through regular channels yet.

As for the question on Unit 32B, I am still waiting for an answer. I will forward an answer when I have it.

Steve

EMISSIONS TEST REPORT

New Mexico Environment Department Periodic Test

Report #	20240109_T02
Test Date	Jan 09, 2024

Performed For:

DCP Midstream, LP
10 Desta Drive Suite 400 West
Midland, TX 79705

Location: Linam Ranch Gas Plant, Unit 31(EU-31), Lea County, NM
Turbine: Solar T-4700, 3000724

Performed By:

Slipstream Environmental Services, LLC

Mobile Lab: Lab T
772 Airfield Lane
Sheridan, WY 82801
josh.canfield@slipstreames.com
307-760-5262

Certification:

I certify, to the best of my knowledge, the test results are accurate and representative of the emissions from this source

Amy Harrah
Slipstream Environmental Services, LLC
(281) 323-1386
amy.harrah@slipstreamtesting.com

1.0 PERFORMANCE OVERVIEW SUMMARY

Results of the emissions test are summarized in Table 1-1 and Table 1-2 below; the site conditions are tabulated in Table 2-1: Test Conditions and Operational Data. Emissions rates and factors were calculated using the methods discussed in Section 6 – Emissions Calculations.

Table 1-1: Customer and Source Summary

Kirby,

I have done some research on ID 32B. At this point the request of bid is out. There is an expectation, not guaranteed, to be completed withing the second group of the Ozone precursor rule. This would have the controls updated by the end of 2025. I am sure you were hoping for a more definitive schedule, but this is the best that I have at this time.

I hope that this helps.

Steve

Re: Four-Factor Analysis on Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring – CAA Regional Haze Program
Artesia Gas Plant,
Eunice Gas Plant,
and Linam Gas Plant
DCP Operating Company, LP

Mr. Singleton,

Enclosed you will find Four Factor Analysis of Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring for DCP's Artesia Gas Plant, Eunice Gas Plant and Linam Gas Plant.

DCP submitted the initial Four Factor Analysis without any analysis on non-steady state sources pursuant to NMED Guidance received on 9/23/2019. But we are submitting following attachment for DCP's three Regional Haze subject facilities as requested by November 14, 2019 letter from NMED,

If you have any questions or concerns, please feel free to contact me directly by phone at 432-215-8514 or via email at hshong@dcpmidstream.com.

Sincerely,

Sam Hong
Environmental Engineer
DCP Operating Company, LP

Enclosures
Attachment A – Artesia Gas Plant
Attachment B – Linam Gas Plant
Attachment C – Eunice Gas Plant

Midland Regional EHS File: 1.1.10

Attachment A:
DCP Midstream – Artesia Gas Plant
Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring applicable to Four-Factor Analysis

Table 1. Summary of Process Flaring and SSM Flaring applicable to Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Emergency Wet Gas Flare (Unit 22)	642.9	7.5	Yes	4918.4	49.9	Yes
Emergency Acid Gas Flare (Unit 23)	10.4	2.4	No	2001.0	328.2	Yes
Malfunction Flaring (Unit M1)	642.9	10.0	Yes	4918.4	10.0	Yes

Artesia Plant's facility SSM&M emission include plant turnaround, plant startup (post turnaround), condensate tank degassing during VRU downtime, gas piping degassing, pig launcher degassing, vacuum trucks, engine startup, compressor blowdown, emergency wet gas flare and acid gas flare SSM emissions. The permitted PTE are based on worst case scenario and actual year-to-year emissions vary but are significantly less than the permitted emissions based on which SSM activities were carried out during the year:

Table 2. Artesia 2016 EIQ Reported Process Flaring and SSM Flaring Emission

Unit No.	NOx	SO_2
	ton/yr	ton/yr
SSM (22)	0.57	0.31
SSM (23)	0.00	0.00
M1	2.03	7.45
Totals	**2.60**	**7.76**

NO_x emission is based on emission factor from AP-42 Table 13.5-1 (9/91) (Reformatted 1/95) and SO_2 emission is calculated based on gas analysis and an assumed 98% combustion of H_2S (conversion of H_2S to SO2 was assumed to be 100%).

Since the sources of SSM emission originates from normal plant activities, without decreasing number of causes (i.e. plant turnarounds and routine maintenance events), DCP notes that it's impractical to employ such measures in order to decrease flaring emissions. DCP further notes that Artesia plant currently has an existing BMP process and strive for continuous improvement on non-routine flare reduction.

Therefore, based on a comprehensive review of the non-steady state flaring emission sources, DCP concludes that there are no reasonable nor technically feasible emission reduction measures for flare sources subject to Four Factor Analysis at Artesia Gas Plant.

Attachment B:
DCP Midstream – Linam Gas Plant
Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring applicable to Four-Factor Analysis

Table 1. Summary of Process Flaring and SSM Flaring applicable to Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Amine Plant Flare East (Unit 2)	14.8	0.88	No	7751.21	45.59	**Yes**
ESD Flare (Unit 4A)	17.75	0.71	No	9301.45	4.13	No
AGI Flare (Unit AGI Flare)	287.65	4.33	No	2148.40	18.97	**Yes**
Malfunction (Unit Malfunction)	287.65	10	**Yes**	9301.45	10	**Yes**

Linam Plant's Unit 2 Gas Flare and AGI Flare emission include SSM emissions from the acid gas and AGI flares are calculated using the estimated maximum hourly and annual SSM flow rates routed to the respective flares. Malfunction. The permitted PTE are based on worst case scenario and actual year-to-year emissions vary but are significantly less than the permitted emissions based on which SSM activities were carried out during the year:

Table 2. 2016 EIQ Reported Process Flaring and SSM Flaring emission

Unit No.	NOx	SO_2
	ton/yr	ton/yr
Unit 2	0	3.28
AGI Flare	0	0
Malfunction	0.04	9.79

NO_x emission is based on emission factor from AP-42 Table 13.5-1 (9/91) (Reformatted 1/95) and SO_2 emission is calculated based on sulfur content of 5 gr S/100 scf.

Since the sources of SSM emission originates from normal plant activities, without decreasing number of causes (i.e. plant turnaround and routine maintenance events), DCP notes that it's impractical to employ such measures in order to decrease flaring emissions. DCP further notes that Linam plant currently has an existing BMP process and strive for continuous improvement on non-routine flare reduction.

Therefore, based on a comprehensive review of the non-steady state flaring emission sources, DCP concludes that there are no reasonable nor technically feasible emission reduction measures for flare sources subject to Four Factor Analysis at Linam Gas Plant.

Attachment C:
DCP Midstream – Eunice Gas Plant
Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring applicable to Four-Factor Analysis

Table 1. Summary of Process Flaring and SSM Flaring applicable to Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
SSM Emissions (Unit SSM)	303.4	11.0	**Yes**	9368.2	257.2	**Yes**

Eunice Plant's facility SSM emission include plant turnaround, plant startup (post turnaround), condensate tank degassing during VRU downtime, gas piping degassing, pig launcher degassing, vacuum trucks (all tank cleanout), engine startup, compressor blowdown, acid gas flare, ESD flare, SRU acid gas flare and Amanda Booster Flare. The permitted PTE are based on worst case scenario and actual year-to-year emissions vary but are significantly less than the permitted emissions based on which SSM activities were carried out during the year:

Table 2. Eunice Plant 2016 EPN: SSM - Flare emission

Unit No.	NOx	SO_2
	ton/yr	ton/yr
Total SSM Emissions	0	0.68

NO_x emission is based on emission factor from AP-42 Table 13.5-1 (9/91) (Reformatted 1/95) and SO_2 emission is calculated based on gas analysis and an assumed 98% combustion of H_2S (conversion of H_2S to SO2 was assumed to be 100%).

Since the sources of SSM emission originates from normal plant activities, without decreasing number of causes (i.e. plant turnarounds and routine maintenance events), DCP notes that it's impractical to employ such measures in order to decrease flaring emissions. DCP further notes that Eunice plant currently has an existing BMP process and strive for continuous improvement on non-routine flare reduction.

Therefore, based on a comprehensive review of the non-steady state flaring emission sources, DCP concludes that there are no reasonable nor technically feasible emission reduction measures for flare sources subject to Four Factor Analysis at Eunice Gas Plant.

D.3 El Paso Natural Gas Company

Supporting documentation for El Paso Natural Gas Company is provided below. Facility-specific documentation is provided first, followed by documentation pertaining to multiple facilities and/or the owner/operator. The following documents are included in this section (in reading order):

- Blanco Compressor Station A:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (11/2019)
    - Follow-Up Submittal (2/14/2020)
    - Revised Four-Factor Analysis (6/5/2023)
- Pecos River Compressor Station:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (11/2019)
    - Follow-Up Submittal (2/14/2020)
- Washington Ranch Storage Facility:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (11/2019)
    - Follow-Up Submittal (2/14/2020)
- Multiple Facilities and/or Owner/Operator:
    - Follow-Up Submittal (2/23/2020)
    - Follow-Up Submittal (9/9/2020)
    - Follow-Up Submittal (10/9/2020)

Economic Evaluation

Cost Component		All Units (Combined)	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	-	On 2/14/20, EPNG provided a $1469/hp all-in Total Capital Cost (TCC) metric for EMD. On 9/9/20, EPNG provided an alternate cost estimate developed using "the KM-Cost Estimating Group's Developmental Cost Estimating Tool". The alternate estimate applied an unusual and insufficiently documented methodology that involved a base cost estimate for replacement RICE that was adjusted using EMD-specific costs and RICE-specific costs. Using detailed cost information provided by other facilities, NMED developed a TCC metric of $2,084/hp (2023$) for the installation of EMD. Costs associated with requisite substation and utility line upgrades were estimated separately and added to TCC to estimate Total Capital Investment (TCI).

Re: Submittal of Four-Factor Analysis on Control Measures under the Clean Air Act Regional Haze Program
El Paso Natural Gas Company, L.L.C.
Blanco Compressor Station A

Dear Ms. Bisbey-Kuehn,

On July 18, 2019 El Paso Natural Gas Company, L.L.C. (EPNG) received notification from New Mexico Environment Department (NMED) that the Blanco Compressor Station A in San Juan County, New Mexico is a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

EPNG evaluated three technically feasible options for controls of nitrogen oxides (NOx) for the fourteen (14) Cooper Bessemer GMV10-TF reciprocating internal combustion engines that are located at the compressor station. The control options are listed in Table 1 of the enclosed four-factor analysis. Table 2 outlines the cost effectiveness (dollars per ton of pollutant reduction) of these control options based on 2016 emissions inventory data.

As requested by NMED, this four-factor analysis is being submitted no later than November 1, 2019. If you have any questions, please contact me at (719) 520-3786 or via email at Travis_Ray@kindermorgan.com.

Sincerely,
El Paso Natural Gas Company, L.L.C.

EXECUTIVE SUMMARY

The Blanco Compressor Station A, owned and operated by El Paso Natural Gas Company, L.L.C. (EPNG), is located near Bloomfield in San Juan County, New Mexico. The Blanco Compressor Station A is a natural gas compressor station that compresses natural gas for the purpose of transportation to another facility or a major transportation pipeline.

The New Mexico Environment Department (NMED) has requested a report containing a complete Four-Factor Analysis for the Blanco Compressor Station A. The analysis has identified possible NO_x and SO_2 control options for the fourteen (14) compressor engines operating at the Blanco Compressor Station A and followed the Western Regional Air Partnership (WRAP) assessment protocol by assessing the following four factors:

Factor 1: Cost of compliance;
Factor 2: Time necessary for compliance;
Factor 3: Energy and non-air quality environmental impacts; and
Factor 4: Remaining useful life of the source.

NMED is requiring that a separate analysis be performed for each pollutant (nitrogen oxide and sulfur dioxide) with a potential to emit (PTE) greater than ten (10) pounds per hour (lb/hr). As sulfur dioxide (SO_2) emissions from the Blanco Compressor Station A are less than the 10 lb/hr threshold, an analysis of control options was not completed.

The evaluation concluded that there are no technically feasible options to reduce nitrogen oxide (NO_x) emissions for the engines at the Blanco Compressor Station A. Taking into account the age of the engines, the costs associated with the installation of controls or engine modifications, possible loss in engine efficiency, and the timeframes in which the modifications would be completed, any changes to reduce the NO_x emissions from the engines is not practicable at this time. NO_x control strategy options that are evaluated as part of the Four-Factor Analysis for the engines are included in Table 1. The table also shows the estimated NO_x emission rate for each control option.

TABLE 1: NO_X CONTROL OPTIONS FOR ENGINES

	Option 1	Option 2	Option 3

SECTION 1.0 INTRODUCTION

In 1977, serious degradation of scenic views at national parks and wilderness areas prompted Congress to require the U.S. Environmental Protection Agency (EPA) to take action. Initial work was conducted to identify specific facilities whose emissions clearly caused regional haze in these nationally treasured places, and the eventual result was the 1999 Regional Haze Rule. This rule mandates gradual progress toward restoring "natural" visibility conditions by the year 2064 at designated national parks, wilderness areas, monuments, forests, seashores, and wildlife refuges, collectively referred to as Class I areas (CIA). The rule was revised in 2017 to strengthen visibility protection, emphasizing that states must reduce human-caused emissions of air pollutants that impair visibility at these special places held in the public trust.

On July 1, 1999, the EPA published regulations implementing Section 169A of the Clean Air Act (CAA), establishing a comprehensive visibility protection program for Federal Class I areas (the Regional Haze Rule). The Regional Haze Rule requires each state to develop, and submit for approval by EPA, a state implementation plan (SIP) detailing the state's plan to protect visibility in Class I areas. The Regional Haze Rule established a schedule setting forth deadlines by which the States must submit their initial regional haze SIPs and subsequent revisions to the SIPs. Regional Haze SIPs for the initial planning period were due in 2007, with subsequent SIP updates due in 2018 and every 10 years thereafter. The second planning period Regional Haze SIPs must be submitted to EPA for review by July 31, 2021.

For the second planning period, EPA guidance recommends that each state should evaluate about 80 percent of emissions impact at each CIA from major and minor stationary sources along with area sources to ensure a reasonably large fraction of emissions potentially impacting CIA visibility deterioration. The over-arching goal in assessing emissions is to ensure states identify anthropogenic sources that are most likely impacting the 20 percent most impaired days (MID) at one or more Class I areas.

NMED identified twenty-four (24) Title V permitted facilities across New Mexico that may potentially have an impact on visibility at Federal Class I Areas protected by the Regional Haze Rule. This determination was based on a screening analysis, the Q/d evaluation, developed by the Western Regional Air Partnership (WRAP), along with guidance from the U.S. Environmental Protection Agency (EPA).

EPNG has prepared a Four-Factor Analysis for the control of nitrogen oxides (NO_x) emissions from the Blanco Compressor Station A. The evaluation is in response to the NMED letter dated July 18, 2019. The evaluation includes an assessment of potentially available emission reduction measures for the four statutory factors listed in 40 CFR 51.308(f)(2), and takes into consideration EPA's *Air Pollution Control Cost Manual, Assessment of Non-EGU NO_x Emission Controls, Cost of Controls, and Time for Compliance Final TSD,* and the EPA's RACT/BACT/LAER Clearinghouse. Technically feasible NO_x emission reduction measures are evaluated for the following four factors:

- Factor 1: The cost of compliance;
- Factor 2: The time necessary to achieve compliance;

• Factor 3: The energy and non-air quality environmental impacts; and
• Factor 4: The remaining useful life of any existing source subject to such requirements.

The Four-Factor Analysis for the Blanco Compressor Station A is presented in the following sections.

SECTION 2.0 SOURCE CATEGORY ANALYSIS

2.1 FACILITY DESCRIPTION

The Blanco Compressor Station A is a natural gas compressor station that compresses natural gas for the purpose of transportation to another facility or a major transportation pipeline. Emission sources located at the Blanco Compressor Station include fourteen (14) Cooper Bessemer GMV10-TF natural gas-fired reciprocating internal combustion engines (RICE).

The Blanco Compressor Station A currently operates under Title V permit number P048-R3 and New Source Review (NSR) permit number 0613-M10. NSR permit number 0613-M10 was issued jointly to three (3) companies as part of an NMED and EPA agreement that established common control between the three (3) companies and three (3) of their adjacent facilities. These companies include: EPNG, Harvest Midstream and Enterprise Products Operating, L.L.C.

2.2 CLEAN AIR ACT AND STATE REGULATIONS REQUIRING CONTROL

This Four-Factor Analysis is being requested by NMED and the EPA under the Federal Clean Air Act, 42 USC §7401; and the Code of Federal Regulations, 40 CFR §51.300 to §51.309 (regional Haze Rule).

There are currently no air pollution controls installed on the compressor engines evaluated in this report. The compressor engines at the Blanco Compressor Station A were constructed in 1953 and do not have any Federal or State regulatory requirements to control emissions. An air permit for the Blanco Compressor Station A is required under 20.2.74 NMAC (PSD construction permits) and 20.2.70 NMAC (operating permits) as the site is a major source of air pollutants.

2.3 NO_X AND SO_2 EMISSIONS FROM THE SOURCE CATEGORY

NO_x and SO_2 emissions are generated by the engines from the combustion of natural gas, which is used as fuel. Engine manufacturer emission factors, EPA developed emission factors (AP-42), engine manufacturer rated horsepower, and other engine manufacturer rated capacities are used to estimate emissions for RICE. As these engines are fired with natural gas and SO_2 emissions are based on the grains of Sulfur per dry standard cubic foot of gas (gr/dscf), there are negligible SO_2 emissions. The estimated and permitted value of NO_x emissions for the engines at the Blanco Compressor Station A are 21.9 lb/hr (each) and SO_2 emissions from the engines are estimated to be less than 1.0 lb/hr (each).

2.3.1 NO_X CONTROL OPTIONS

The engines do not currently have controls installed and operate under the original manufacturer design. The potential control options that were analyzed include:

- Option 1: High pressure electronic fuel injection to achieve a NOx target of 3 g/hp-hr
- Option 2: High-pressure electronic fuel injection plus exhaust manifold replacement and catalytic silencer to achieve a NOx target of 1 g/hp-hr

- Option 3: alternate option including high-pressure electronic fuel injection, engine uprate of 9 units and potential retirement of 5 units.

See Table 1 for more information. Selective Catalytic Reduction (SCR) was evaluated but eliminated due to technical infeasibility for this engine type.

SECTION 3.0 FOUR-FACTOR ANALYSIS

3.1 FACTOR 1: COST OF COMPLIANCE

Control costs include both the capital costs associated with the purchase and installation of retrofit and new control systems, as well as the net annual costs (annual recurring costs) associated with system operation. The basic components of total capital costs are direct capital costs, which includes purchased equipment and installation costs, and indirect capital expenses.

Direct capital costs consist of such items as purchased equipment, instrumentation and process controls, ductwork and piping, electrical components, and structural and foundation costs. Labor costs associated with construction and installation are also included in this category.

Indirect capital expenses are comprised of engineering and design costs, contractor fees, supervisory expenses, and startup and performance testing. Contingency costs – which represent such costs as construction delays, increased labor and equipment costs, and design modifications – are an additional component of indirect capital expenses. Capital costs also include the cost of process modifications. Annual costs include amortized costs of capital investment, as well as costs of operating labor, utilities, and waste disposal.

Only control options that are appropriate to the engines at the Blanco Compressor Station A were analyzed. See Table 1 for a list of the potential control costs.

3.2 FACTOR 2: TIME NECESSARY FOR COMPLIANCE

The time necessary for compliance is separate from the other three factors. The time necessary for compliance depends on reasonable installation times and compliance deadlines for selected control measures. Combustion modifications and post-combustion NO_x controls may require significant time for engineering, construction, and facility preparedness. As an exact timeframe cannot be projected for the analyzed control options, an estimate was made for each option. Furthermore, not all engines would be able to be modified simultaneously as pressure must be maintained within the transmission pipeline at all times. Estimates were made between 1 and 3 years, after the issuance of the revised construction permit from NMED, depending on the control selected. See Table 1 for the estimated time frames to fully implement each control option.

3.3 FACTOR 3: ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS

Various controls may impact energy use; equipment efficiency; fuel usage; non-air impacts such as noise pollution, odor, climate impacts, and solid, liquid, or hazardous waste generation; and deposition of atmospheric pollutants on land or water. The analyzed controls may impact waste generation and disposal, water consumption, electrical power use, and potentially decrease engine efficiency.

3.4 FACTOR 4: REMAINING USEFUL LIFE OF THE SOURCE

The remaining useful life of individual emissions units (engines) can vary greatly depending on

the age of the unit, size of the unit, maintenance frequency, and other factors. As the engines at the Blanco Compressor Station A are over 60 years old, it is difficult to estimate the remaining useful life of these sources. The EPA's Air Pollution Control Cost Manual suggests the remaining useful life should be based on the control method and not the emissions source itself; therefore, it is assumed that the remaining useful life of any chosen control or modification is 20 years.

RE: Response to the Request for Additional Information for Four-Factor Analyses under the Regional Haze Program

Dear Mr. Jones and Mr. Singleton:

This letter addresses the additional information request for the El Paso Natural Gas Company, L.L.C. (EPNG) – Blanco A Compressor Station Four-Factor Analysis ("Analysis") received on December 23, 2019. For the Blanco A Compressor Station there were a total of fifteen item requests pertaining to the NO_X emissions for the engines. Please see the responses for each item request below.

a. *Please provide a discussion that explains the various control technologies listed in Table 1; why certain technologies are required for each options 1, 2, and 3; and the associated technical information for all of the listed technologies (e.g., HyperFuel, cylinder upgrades, wet to dry manifold conversion).*

   The attached proposal from Hoerbiger Engineered Solutions (HES) provides more details of the options listed in Table 1 of the Analysis. EPNG requested information on technologies to achieve 5 g/hp-hr NOx, 3 g/hp-hr NOx, and less than 1 g/hp-hr NOx. HES concluded that the technologies to achieve 5 g/hp-hr and 3 g/hp-hr NOx are the same so the 3 g/hp-hr option is noted as Option 1, the 1 g/hp-hr option is noted as Option 2, and the <1 g/hp-hr option is noted as Option 3.

   The listed options represent combustion controls that prevent NOx formation rather than an add-on control that reduces post-combustion NOx emissions. The components that are included in these retrofits (Hyperfuel, cylinder upgrades, wet to dry manifold conversion, etc.) work together to provide optimal air-fuel mixture to improve emissions performance.

b. *Oxidation catalysts are listed as a proposed NOx control, but controlling NOx emissions requires a technology that includes a reduction catalyst, such as Selective Catalytic Reduction (SCR). Please explain and clarify the inclusion of oxidation catalyst technology in Table 1.*

   To obtain NOx reduction with clean burn technology, the air-to-fuel ratio must be driven lean. There is a tradeoff relationship between NOx and CO when air fuel ratio is adjusted (i.e., as NOx is reduced, CO may increase). The oxidation catalyst is to prevent the CO from increasing beyond currently permitted levels when the NOx is reduced.

c. *Consider and include an analysis on typical retrofit low-emissions combustion technology (LEC) for internal combustion engines such as, air-fuel ratio controllers, improved combustion chamber design, enhanced air-fuel mixing, and improved ignition system.*

These items were all taken into consideration in the development of the three options. See attached proposal from Hoerbiger.

d. *Explain how engine efficiency is potentially lost due to the controls listed in Table 1 and specify which controls cause a loss in efficiency.*

The technology itself does not cause a loss in engine thermal efficiency; it is a result of the tradeoff between air fuel ratio and heat rate. As mentioned above, the air fuel ratio has to be driven lean to acquire the NOx reduction.

e. *Provide the basis for the costs used in the cost analysis in Table 1.*

Please see the attached Hoerbiger proposal for details of the costs

f. *Consider and include an analysis on CleanBurn™ Technologies (CBT), which are equivalent to LEC technologies, but designed specifically for Cooper Bessemer engines. Please identify any CBT that may be analogous to any of the technologies already listed in Table 1 of the November 2019 four-factor submittal.*

Please see item c above.

g. *Provide the manufacturer's and/or vendor's specifications and cost used for the four-factor analysis.*

Please see attached Hoerbiger proposal.

h. *Include a technical feasibility analysis for selective catalytic reduction (SCR).*

U.S. EPA, Ap-42, Section 3.2 "Natural Gas-Fired Reciprocating Engines" currently states:

> "For engines which typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed."

A review of the RBLC tables found no examples of SCR being used as a control for 2SLB engines. The lack of availability or comparable use of an SCR on these Cooper-Bessemer engines presents the case that this control technology is considered technically infeasible.

i. *Consider Good Combustion Practice's (GCP) and routine maintenance as controls and provide the details of a maintenance schedule, employee training and operating procedures to achieve emissions reductions.*

EPNG employs GCP at Blanco A via the routine maintenance schedule pursuant to A314.B in NSR Permit No. 0613-M10. In addition, EPNG performs periodic testing on the compressor engines

pursuant to A314.A in order to monitor NO_X, CO, and VOC emissions. Additionally, employees are required to complete training on equipment before they are authorized to operate it, and standard operating procedures and maintenance practices have been developed based on manufacturer's recommendations to keep the equipment in operating condition.

Additionally, each employee has an Operator Qualification (OQ) Checklist that is completed and tracked in the OQ system. Operators are paired with other operators and work as trainees until they are deemed qualified on the piece of equipment and operation at the site. During the training period, they are exposed to station operations, responding to call outs with operators, station shutdowns, and purging and pressurizing stations. This training period lasts on average about one (1) year. A sample qualification checklist used to track employee training is attached.

j. Provide an explanation of why El Paso Natural Gas (EPNG) feels that the time necessary for compliance is too long when it is listed as 12 to 36 months? Are there plans to shut down all or portions of the facility? EPA guidance recommends a compliance time of up to five years from State Implementation Plan (SIP) approval.

In Section 3.2 of the November 1, 2019 submittal, EPNG states that the estimated time frame of 12 to 36 months. Not all engines would be able to be modified simultaneously as pressure must be maintained within the transmission pipeline at all times in order to meet our delivery obligations. EPNG concluded that the options presented are not cost effective but did not conclude that the time for compliance was too long.

There are no plans to shut down all or portions of the facility.

k. Please verify the waste generation and disposal and water consumption are considered in the cost analysis. If not, this should be included in the cost analysis.

Waste generation and disposal and water consumption are included in the cost analysis.

l. In Table 2, provide the basis for calculating the 2016 emissions inventory. For example, is this based on the emission limits and operating hours, or test data and operating hours?

The 2016 emissions inventory is based on the emission limits and operating hours of the engines.

m. Consider and include a discussion on the feasibility and cost of technology that limits engine capacity and reduce NOx emissions. Also evaluate limitations on engine operating hours or shutting down engines that are no longer needed to reduce emissions. Based on the emissions inventory for 2016, it appears that seven of the fourteen engines operated for very few hours during the year and other engines appear to have operated for only a portion of the year.

The compressor units at Blanco operate on a demand basis and full utilization of all of the units may be required at a given time. As such, EPNG is not able to limit operating hours. Because of the nature of storage and compression utilization on the EPNG lines, any operational restrictions could have the potential to have significant disruptions to operations on site as well as to our upstream and downstream customers.

n. *Consider and include a discussion on the feasibility of replacing natural-gas fueled engines with commercial electric powered compressors.*

The cost for replacing with electric compression can vary widely, depending on on-site conditions and the proximity to an existing high-voltage transmission line. A recent analysis for EPNG's Washington Ranch facility concluded replacement with electric compression would be approximately $2,676 per horsepower including additional electric utility line installation Using this assumption, replacement of the fourteen (14) 943-hp units at Blanco would cost approximately $35 million. Although a full four-factor analysis has not been performed for this replacement, this is cost prohibitive. No unit replacements are planned at this time.

o. *Please provide the electronic spreadsheets used for all cost analysis calculations.*

See attached spreadsheets.

If you have questions or need clarification, please contact me at (719) 520-3786 or via email at Travis_Ray@kindermorgan.com

Sincerely,
El Paso Natural Gas Company, L.L.C.

RE: Quote for optimization and emission retrofits for fourteen (14) GMV-10TF units located at the Blanco New Mexico Compressor Station.

Dear Mr. Goss,

HOERBIGER Engineering Services (HES) is pleased to respond to your request for a budgetary estimate concerning engine and compressor optimization retrofits for the Cooper GMV 10TF units located in Blanco New Mexico. This is a ***budgetary estimate*** for the scope of work listed in Section 1. Since no site visit has been made prior to this proposal, certain assumptions where made to be able to offer this estimate. It is not uncommon for final pricing to be within +/- 20% of this estimate after a site visit is conducted.

As a budgetary estimate, this proposal includes *all* of the expected materials and labor efforts required to meet the project guarantees. If the proposal, as written, fails to meet the guarantees, HES will bear the cost of any changes necessary to meet the requirements.

A detailed summary of this estimate can be found below within the Detailed Bid Description. HES reserves the right to correct clerical errors in this proposal. This proposal is valid for 90 days and acceptance is dependent upon reaching acceptable terms.

HES looks forward to the opportunity to work with Kinder Morgan on this project. If there are any questions concerning this estimate, please do not hesitate to call me at (512) 633-4001.

Sincerely,

Justin Spillman

TECHNICAL DESCRIPTION

Customer currently has, in operation, fourteen (14) Cooper GMV-10TF units located at their Blanco, New Mexico Compressor Station. This station sits at an elevation of 5,605 ft above sea level and each unit is currently rated at 913 Hp for a station total of 12,782 Hp. The current emissions output for these units are between 12 – 15 g/bhp-hr for NOx and 1.4 g/bhp-hr for CO. The customer has requested solutions, pricing and options to reduce these limits to 5g, 3g and <1 g for NOx and not to exceed their baseline of 1.4 g/bhp-hr output for CO. After an Engineering review, HOERBIGER has put together the following options that will be needed to achieve the customer requests. To achieve the 5 g/bhp-hr or 3 g/bhp-hr emissions limits, the required technology is the same which will give the customer the potential savings and flexibility when considering other engine upgrades. At these levels, we will be able to meet or exceed the NOx requirement and avoid a negative impact on CO which will eliminate those associated expenses.

OPTION 1 - $784,014 per unit

Skid Mounted VFD Electric motor driven blower with Aftercooler
***HyperFuel*™ System**
Engine auxiliary cooling system

If the customer elects to achieve NOx levels of 1 g/bhp-hr or lower, on these units, additional technology will be needed to address the rise in baseline CO.

OPTION 2 - $1,624,286 per unit

Skid Mounted VFD Electric motor driven blower with Aftercooler
***HyperFuel*™ System**
Engine auxiliary cooling system
Wet to Dry Manifold Conversion
Muffler with Oxidation Catalyst
Cylinder Heads with PCC

In addition to the two options listed above, a third option has been discussed which would include uprating 9 units at this station and retiring the remaining 5. In order to maintain the overall station HP level of 12,782 each unit will be uprated to 1,463 Hp.

OPTION 3 - $1,334,282 per unit

Turbocharger
***HyperFuel*™ System**
Compressor Cylinder Upgrade
Power Cylinder Upgrade

1. Detailed Bid Description

HES agrees to provide the customer, Kinder Morgan, with all of the equipment, engineering, installation, and documentation necessary to perform engine and compressor optimization/emissions retrofits for the GMV-10TF at the Blanco New Mexico Compressor Station. This estimate includes the following parts and services but not limited to:

1.1 HES Scope of Work

This bid is provided as a fixed price "turn-key" bid, it includes the following parts and services:

1.1.1. All design and project engineering required for unit specific adaptation and installation of the following systems:
- 1.1.1.1. VFD Electric motor driven blower with Aftercooler
- 1.1.1.2. PCC Ignition System
- 1.1.1.3. *ePCC*™ System
- 1.1.1.4. *HyperFuel*™ System
- 1.1.1.5. Exhaust system
- 1.1.1.6. Dry exhaust manifold
- 1.1.1.7. Engine auxiliary cooling system

1.1.2. All manpower necessary to remove the replaced systems and install the new systems listed in section 1.1.1.

1.1.3. All commissioning and start up services.

1.1.4. All drawings necessary to document modifications and support the installation.

1.1.5. Training for maintenance and operations of the installed systems.

1.1.6. Disposal of removed/retired equipment and HES refuse.

1.2. HES Scope of Supply (On-engine)

HES will supply ALL of the components necessary to complete the installation of the systems listed in section 1.1 above. Following is a list of the primary components of the installed systems. It is not a comprehensive list and does not relieve HES of the obligation to supply unnamed but necessary components.

1.2.1. Electric Motor Driven Blower (Skid Mounted)
- 1.2.1.1. Inlet filter
- 1.2.1.2. Isolation valve
- 1.2.1.3. Check valve
- 1.2.1.4. Blow off silencer
- 1.2.1.5. Blow off valve
- 1.2.1.6. Coupling and guard
- 1.2.1.7. Expansion joint
- 1.2.1.8. Spool pieces
- 1.2.1.9. VFD motor
- 1.2.1.10. 6 stage blower
- 1.2.1.11. Structural base
- 1.2.1.12. Disconnect and/or motor starter

1.2.2. Aftercooler

1.2.2.1. Aftercooler heat exchanger core
1.2.2.2. Aftercooler inlet transitions
1.2.2.3. Aftercooler outlet transitions
1.2.2.4. New 3-way control valve and transitions for AMT control
1.2.2.5. Aftercooler flexible pipe joints
1.2.2.6. Aftercooler inlet automatic air bleeder valve
1.2.2.7. Aftercooler outlet automatic air bleeder valve
1.2.2.8. Aftercooler water inlet/outlet thermowell
1.2.2.9. Aftercooler water inlet/outlet temperature gauge
1.2.2.10. Aftercooler outlet pressure gauge
1.2.2.11. Fittings, flanges, bolts and gaskets for all piping
1.2.2.12. Cooling water inlet and outlet piping modifications

1.2.3. Ignition System (PCC)
1.2.3.1. One Cooper pre-chamber per cylinder or Eco-Jet System
1.2.3.2. One Modified Head (Not Eco-Jet System)
1.2.3.3. All bolts, Gaskets and washers to support installation (Not Eco-Jet System)
1.2.3.4. (For Eco-Jet) One Cooper EcoJet™ pre-chamber per cylinder
1.2.3.5. Coolant Pump (1.5HP, 3Φ, Explosion Proof)
1.2.3.6. Water filter
1.2.3.7. Spark plugs
1.2.3.8. Conduit, wiring, fittings and tubing

1.2.4. The *ePCC* System is a Class I, Division 2, Group D system and is installed according to those guidelines and it includes the following major components:
1.2.4.1. One *ePCC* Controller and HMI for each engine
1.2.4.2. One 110 VAC to 24 VDC power supply for each engine
1.2.4.3. One *ePCC* valve for each PCC
1.2.4.4. One fuel hose for each *ePCC*
1.2.4.5. All necessary tubing and fittings
1.2.4.6. All necessary conduit, wire and fittings

1.2.5. The *HyperFuel* Valve™ System is a Class I, Division 2, Group D system and is installed according to those guidelines and it includes the following major components:
1.2.5.1. One *HyperFuel Valve* for each cylinder
1.2.5.2. One *HyperFuel Valve* Control System for each engine
1.2.5.3. Fuel manifold
1.2.5.4. Excess flow safety valve
1.2.5.5. Pneumatically operated block and bleed valves
1.2.5.6. Unit level fuel filtration
1.2.5.7. Filter DP gauge
1.2.5.8. Unit level fuel pressure regulation
1.2.5.9. 110 Volt AC to 24 DC Volt power supply
1.2.5.10. Magnetic pickups
1.2.5.11. All necessary conduit, wire and fittings
1.2.5.12. All necessary tubing, hoses and fittings

1.2.6. Dry Exhaust Manifold
1.2.6.1. Segmented exhaust manifold

1.2.6.2. Water header
1.2.6.3. Transition outlet spool

1.3. HES Scope of Supply (Off-engine)

1.3.1. Exhaust system
1.3.1.1. Silencer/catalyst combination
1.3.1.2. Removable oxidation catalyst
1.3.1.3. Backfire relief valve
1.3.1.4. Insulation blankets
1.3.1.5. Tail pipe strakes
1.3.1.6. Exhaust pipes and transitions
1.3.1.7. Coating
1.3.2. Engine auxiliary cooling system
1.3.2.1. Air cooled heat exchanger
1.3.2.2. Expansion tank
1.3.2.3. 3 way control valve
1.3.2.4. Valves, pipes and fittings

1.4. Customer Scope of Supply

1.4.1. Unit Fuel Gas System to within 30' of engine (Conditioned and Heated)
1.4.1.1. Metered and Conditioned Fuel Gas to within 30 ft of unit. Provide 1" female NPT port ball valve for HES to connect. Pressure to be regulated to a minimum of 550 (psig)
1.4.1.2. The fuel gas measurement end devices for each unit will require an accuracy of ±1% with a flow rate update frequency of at least 1 Hertz.
1.4.1.3. Filtered to remove 99% of all particles and liquids greater than 1 micron.
1.4.1.4. HES recommends that the fuel gas be heated to a temperature above the highest ambient dew point (~100 °F) to prevent the formation of condensation on the fuel gas piping.
1.4.2. Fuel Gas Custody Transfer Metering and Reporting.
1.4.3. Supply all electrical requirements to station (MCC).
1.4.4. Engine operator to start, stop and operate the unit as necessary for testing and commissioning.
1.4.5. Environmental permitting.
1.4.6. Removal and disposal of Spectra Energy hazardous materials
1.4.6.1. Provide penetrations in transite siding and dispose of hazardous waste if required. At this point in the design phase HES does not expect to disturb any of the existing transite siding.
1.4.7. NDE testing and construction inspection as required.
1.4.8. Bring chromatograph from station to panel.
1.4.9. Supply necessary documentation to HES for engineering and automation changes.
1.4.10. Piping and Installation of the Exhaust system
1.4.11. Piping and Installation of the Aux Cooling system
1.4.12. Installation of pad for the Blower Package skid
1.4.13. Automation systems, hardware or programming required to support these upgrades

1.4.14. Customer will allow HES and it's subcontractors to use plant facilities for accumulation of parts.
1.4.15. The customer will make repairs to the unit or its support equipment if the equipment is not operating as designed.
1.4.15.1. Repair service may be requested of HES. Repairs will be quoted and billed on a time and material basis.
1.4.16. Supply Noise attenuation requirements.
1.4.17. Provide a chromatograph reading at the station.
1.4.18. Provide space for HES office trailers, restrooms, and connex buildings for the duration of the project.

2. Clarifications and Exceptions to HES Proposal

The following items have been identified as Exceptions to the project.

2.1.1. Time spent waiting by HES personnel or its sub-contractors due to delays caused by station problems or station non-preparedness are not included in the base proposal. Should such delays be encountered, HES shall be compensated in accordance with the attached rate sheets and schedule shall be extended by the length of the delay. Additional waiting time will be billed on a time and materials basis.
2.1.2. Price does not include any applicable sales, use, or other regulatory taxes. Such taxes will be calculated and billed at the time of HES invoicing.
2.1.3. Price does not include unit panel , unit panel programming or communication connects to the customer's Station PLC. This can be quoted separately upon request.

3. At Risk Items

The following items have been identified as marginally suitable (at risk) for the project. HES agrees to try and incorporate the existing items into the proposed upgrade to reduce the project cost. However, HES makes no guarantee as to the successful use of the identified items. If the at risk items prove unsuitable at the time of commissioning, the customer will be responsible for paying the cost of replacing the at risk item with components that are suitable for the application.

3.1. The following items are identified as "at risk" for this project:

3.1.1. No identified at risk items at this stage.

4. Minimum Unit Health and Performance Assumptions

4.1. Current Unit Condition

The following assumptions were made during preparation of this budgetary estimate. HES scope will have to be added to the project or the customer scope of supply will be amended if any of the assumptions are not valid.

4.1.1. Current unit hardware and configuration is meeting current emissions requirements.
4.1.2. Units have CPU-2000 or other flywheel referenced ignition system
4.1.3. Unit is in good health, with no mechanical defects.
4.1.4. The compressor building is rated Class I, Division 2, Group D.

4.1.5. Current unit valves and related limit switches are functioning properly.
4.1.6. Gas analysis with periodic updates

5. Compliance Statement and Exceptions to Bid Request

At the completion of this proposal HES has not identified exceptions to the Bid Request.

6. Proposed Installation Schedule

HOERBIGER will work with Kinder Morgan on an acceptable project schedule

7. Project Guarantees and General Warrantees

7.1. Performance Guarantees - TBD

HES guarantees that the addition of the equipment listed in section 1. Detail Bid Description will allow the unit to operate with the following brake specific emissions mass rates.

7.1.1. Emissions

NOx	Options given for 5 g/bhp-hr, 3 g/bhp-hr and < 1 g/bhp-hr
CO	Not to exceed baseline of 1.4 g/bhp-hr

7.2. Warranties

7.2.1. The standard manufacturer's warranties for all third party components are in place at the time of shipment.
7.2.2. The standard warranty for *ePCC* system (Valves and Controller) is 24 months, beginning at the start of commissioning.
7.2.3. The standard warranty for the *HyperFuel* Valve is 12 months, beginning at the start of commissioning.
7.2.4. The standard warranty for the *HyperFuel* Valve System Controller is 24 months, beginning at the start of commissioning.
7.2.5. Any exceptions to these warranties are noted on the cover page.

8. Payment and Invoicing Conditions

HES will invoice the customer directly for all work done in support of the project. HES contractors will invoice HES only, and will not submit invoices directly to the customer.

8.1. Project Invoicing

Invoicing will be agreed upon and detailed in the contract.

8.2. Cancellation

The Customer shall notify HES in writing at least twenty-four (24) hours in advance of termination. The Customer shall compensate HES for all documented costs if the Customer cancels the order. These costs include, but are not limited to, parts, engineering, shipping, down payments, restocking charges, labor and travel expenses.

8.3. Payment Terms

All HES invoices will be for the full amount owed. If the customer has a policy of retaining a percentage of contract price pending completion, the customer will be responsible for calculating the retainage. All retained monies are to be released within 30 days of final acceptance, not to exceed 60 days after completion of commissioning.

Retainages in excess of 10% are generally unacceptable to HES. Withholding in excess of 10% must be agreed to in writing at the time of contract execution.

8.3.1. All invoices are to be paid within 30 days from date of invoice.

9. Indemnification and Limits of Liability (Will be identified in contract)

10. Codes and Standards

All work shall be installed and tested in accordance with all applicable sections of the latest edition of the following codes and standards. Differences in company and code requirements could result in added charges:

NEC (NFPA 70)	National Electric Code
CFR Title 49, Part 192	Minimum Safety Standards for Gas Lines
ANSI 2223.1	National Fuel Gas Code
API 1104	Welding of Pipelines and Related Facilities
ANSI B31.8	Gas Transmission and Distribution Piping Systems
ANSI B31.3	Process Piping Systems
ANSI B16.5	Pipe Flanges and Flange Fittings
ASME Sections VIII & IX	Boiler and Pressure Vessel Code

Re: EPNG's Blanco A Compressor Station Regional Haze Four Factor Analysis, Revised

Dear Ms. Olson:

El Paso Natural Gas Company, L.L.C. (EPNG) is submitting the enclosed revised Regional Haze Four Factor Analysis (4FA) for the Blanco A Compressor Station. This analysis replaces, in its entirety, the 4FA that was submitted by EPNG on or about November 1, 2019. EPNG appreciates the opportunity to correct deficiencies mutually identified in the original document.

As we discussed during our meeting on May 3, 2023, EPNG has recently submitted an Alternate Emission Standard (AES) Plan and is about to submit an Alternative Compliance Plan (ACP) in accordance with the New Mexico Ozone Precursor Rule 20.2.50 NMAC (Ozone Rule). The ACP in particular addresses the units at Blanco A that are analyzed in the enclosed 4FA. EPNG notes that the timeframe for action under the Ozone Rule is significantly sooner than under the Regional Haze Rule. As such, decisions made by NMED for implementation of the Ozone Rule could significantly alter the facts upon which the enclosed 4FA analysis is based.

Additionally, as we previously discussed, EPNG is concerned that different decisions may be reached under each of the two rules. To this end, and to the extent that controls or limitations may be required under either the Ozone Rule or the Regional Haze Rule, EPNG desires to be actively and continuously engaged with the pertinent New Mexico Environment Department review groups as the reviews progress under both rules.

If you have any questions on any of this information, please contact me at 713.420.3463 or at tom_mitchell@kindermorgan.com.

Sincerely,

R. Thomas Mitchell

1. EXECUTIVE SUMMARY

The Blanco A Compressor Station (Blanco A), owned and operated by El Paso Natural Gas Company, L.L.C. (EPNG), is located near Bloomfield in San Juan County, New Mexico. Blanco A is a natural gas compressor station that compresses natural gas for the purpose of transportation to a local distribution company, an industrial facility or another transportation pipeline.

The New Mexico Environmental Department (NMED) has requested a report containing a complete Four-Factor Analysis (4FA) for the Blanco A under the Regional Haze requirements of the Clean Air Act. The analysis has identified possible NOx control options for 14 reciprocating internal combustion engines operating at the Blanco A using the Western Regional Air Partnership (WRAP) assessment protocol by assessing the following four factors:

- Cost of the control;
- Time necessary to install the control;
- Energy and non-air quality impacts of the control; and
- The remaining useful life of the emission point.

The evaluation concluded that:

- Selective Catalytic Reduction (SCR) and Selective Non-Catalytic Reduction (SNCR) are technologically infeasible.
- Low Emission Combustion (LEC) Retrofit is economically infeasible with a cost effectiveness ranging from $18,356 to $97,332,475 depending on the LEC option and engine.
- Good Combustion Practices (GCP) are technically and economically feasible and constitute Best Available Retrofit Technology (BART).

EPNG notes that GCP is already employed for the subject engines.

However, as noted in the report, there is overlap between the New Mexico Ozone Precursor Rule 20.2.50 NMAC and the Regional Haze Rule. Although not required under either rule, EPNG proposes that NMED allow EPNG to retire seven units at Blanco A if, an only if, the retirement is approved as a compliance strategy under both regulations and by FERC. Importantly, this solution would allow EPNG to decrease NOx emissions in a manner that allows it to meet its FERC obligations (subject to FERC approval). While not economically feasible as defined by the Regional Haze Rule, this solution is lower cost than other more-costly or technically infeasible NOx-reduction options. Accordingly, EPNG requests that NMED consider this environmentally advantageous solution under both rules even though it is not mandated by either rule.

2. BACKGROUND INFORMATION

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

(1) *Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A)*

This is known as a four-factor analysis.

(2) *Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*

The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the NMED reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed EPNG that the Blanco A was identified as one of the sources contributing to regional haze at the nearest Mesa Verde National Park Class I area. On 1 November 2019, EPNG provided its initial analysis to NMED. This report replaces that 1 November 2019 submission.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to EPNG, it specifies that any single piece of equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and/or 5 tons

per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at Blanco A subject to the 4FA is summarized in Table 1. Because SO_2 emissions from the 14 reciprocating engines at Blanco A Compressor Station are less than the 10 lb/hr threshold, NOx is the only pollutant subject to evaluation in this four-factor analysis.

Table 1. EPNG Blanco A – RH Second Planning Period 4FA – Subject Sources

Equipment Type	Max Capacity*	NMED Unit No.	Make Model	Construction Date
2SLB Reciprocating Engine	943 HP	A-01	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-02	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-03	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-04	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-05	Cooper Bessemer, GMV10-TF	8/1/1953

2SLB Reciprocating Engine	943 HP	A-07	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-08	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-09	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-10	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-11	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-12	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-13	Cooper Bessemer, GMV10-TF	8/1/1953
2SLB Reciprocating Engine	943 HP	A-14	Cooper Bessemer, GMV10-TF	8/1/1953

*The site rating for each engine is 913 HP at the site elevation of 5,605 ft above sea level.

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED,[1] this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. A summary of identified available retrofit controls along with a technical feasibility assessment for each control is provided in Section 3. The four-factor analysis is then conducted for those controls that are technically feasible.

3.1. TWO-STROKE LEAN-BURN ENGINES

The Blanco A Compressor Station compresses natural gas for the purpose of transportation to a local distribution company, an industrial facility or another transportation pipeline. Emission sources located at the Blanco A Compressor Station include 14 natural gas-fired two-stroke lean-burn (2SLB) reciprocating internal combustion engines (RICE), all of which are subject to this four-factor analysis. The two-stroke design completes the power cycle in a single revolution of the crankshaft. NO_X is formed in reciprocating engines via three mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Blanco A reciprocating engines use pipeline quality natural gas fuel, which contains a negligible amount of nitrogen compounds. Therefore, the formation of prompt and fuel NO_X will be insignificant. This analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[2] Lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12 % or more.[3]

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:

(1) Operational control methods, such as adjusting the timing or other operating parameters.
(2) Combustion control techniques, for example reducing the peak flame temperature by introducing inserts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.

3.2. POTENTIAL NOX CONTROLS FOR 2SLB ENGINES

To identify all feasible control technologies, the RBLC database, WRAP guidance, as well as available technical literature was reviewed. Using these sources, potentially applicable NOx control technologies for 2SLB engines were identified and are summarized in Table 2. A detailed description and discussion of the technical feasibility and anticipated performance of each control are provided below.

[2] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[3] "Emission Control Technology for Stationary Internal Combustion Engines," Manufacturers of Emission Controls Association, 2015

Table 2. Potential Control Options for 2SLB RICE

Control Equipment	Technically Feasible	NO_X Control Efficiency
Selective Catalytic Reduction	**No**	**N/A**
Low Emission Combustion	**Yes**	**27% - 82%**
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**
Reduce Capacity and/or Operating Hours	**No**	**N/A**
Selective Non-Catalytic Reduction	**No**	**N/A**

3.2.1. Selective Catalytic Reduction (SCR)

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[4] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic controls to accurately meter the quantity of reagent injected as a function of engine load, speed, temperature, and NOx emissions to be achieved. The lifespan of the catalyst is primarily determined by the erosion caused by the flue gas, deactivation caused by ammonium bisulfate (NH_4HSO_4) poisoning, as well as the build-up and fouling by the catalyst.

The characteristic exhaust temperature for 2SLB engines shows higher excess O_2 in the exhaust stack. For 2SLB engines, with typical exhaust O_2 from 14 to 16% (depending on make, model and operating condition), typical exhaust temperature is in the range of 450 to 600°F. Exhaust temperature is a critical design parameter for SCR performance, and accordingly, the catalyst material is selected based on the design temperature of the exhaust. Based on current technology and practices, SCR's optimal exhaust temperature is between 600 - 850°F for base-metal catalyst and 750 – 1100°F for zeolite catalysts. Therefore, SCR's use as a control technology is limited to sources where the exhaust temperature is within those ranges.

Precious metal catalyst may perform at temperatures below 450°F, however complications such as reagent decomposition, reagent slip, catalyst contamination due to unreacted reagent (salt formation), etc. may arise. Temperatures below the desired range reduce the reduction efficiency – i.e., increase NO_X and ammonia emissions.

At higher temperatures, ammonia may "slip," meaning that a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. Unreacted reagent in the exhaust can form ammonium sulfates, which may plug or corrode downstream equipment, and/or catalyst damage may

[4] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

occur. Streams carrying large amounts of ammonium sulfates may blind the catalyst and may necessitate the application of a soot blower.

When compared to the typical 450 – 600°F temperature range for 2SLB engines, no single catalyst material offers high, stable performance across that range. Thus, even if other SCR technical issues (e.g., associated with reagent control) are addressed, current catalysts are not adequate to ensure stable, high-level performance for 2SLB engines.

In addition to the temperature issues, use of an aqueous reagent is common for engine applications. The water associated with aqueous urea (or ammonia) injection for an engine with higher NO_X emissions (e.g., NO_X is not controlled) could decrease exhaust temperature by 5 to 20 °F. This further complicates system engineering and catalyst material requirements.

For engines that typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia injection to gain the reductions needed.[5] In the case of the Blanco A, the 14 reciprocating engines run at ongoing variable loads.

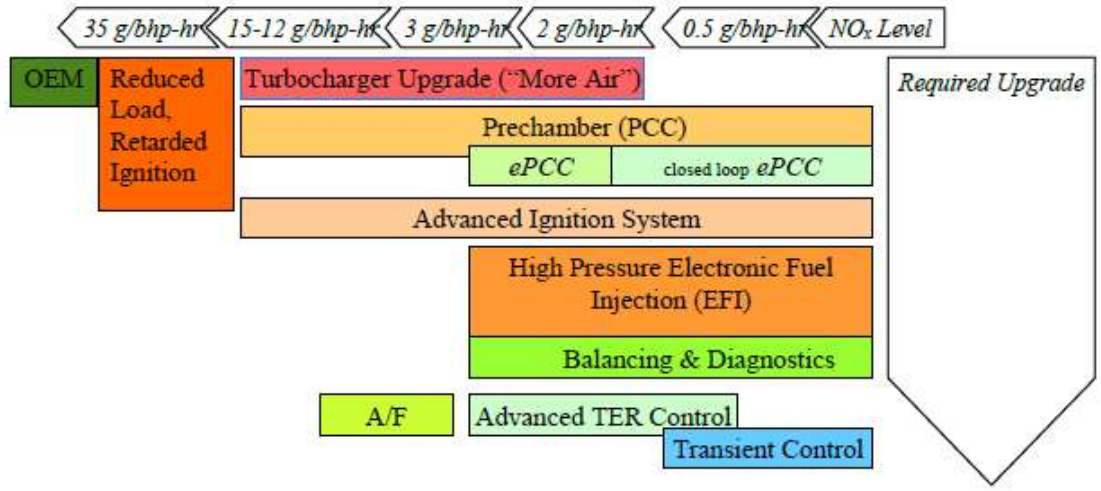
Finally, there has been no application of SCR on this model of Cooper Bessemer engines (see attached RBLC results). A thorough twenty-year review of the RBLC tables was conducted and there were no examples of an SCR being used as a control for 2SLB engines at this time. The lack of availability or comparable use of an SCR on these Cooper Bessemer engines presents the case that this control technology is considered technically infeasible. Consequently, SCR is not evaluated further in this four-factor analysis.

3.2.2. Low Emission Combustion (LEC) Retrofit

LEC retrofit, including the Cooper Bessemer trademark name Clean Burn Technology (CBT), is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding or enhancing an air-to-fuel ratio controller, making the unit capable of operating at optimal air-to-fuel ratios.

As described in Section 3.1 of this report, lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1). A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions because fuel-lean mixtures lowers the combustion temperature by diluting energy input. There is a tradeoff between air-fuel ratio and heat rate; higher air-to-fuel ratio in lean burn engine results in lower heat rate (energy input into the system), causing a loss in engine thermal efficiency.

Many 2SLB engines, such as naturally aspirated engines at the Blanco A, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high-energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[6]



2SLB engines are mechanically capable of being retrofitted with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NO_X emissions. Therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at the Blanco A

[5] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[6] Ibid

Compressor Station. Air-to-fuel ratio adjustment generally achieves a 5 to 30% reduction in NO_X emissions; however, this reduction is very specific to each engine and typical loading[7].

The 14 reciprocating engines at the Blanco A currently do not have controls installed and operate under the original manufacturer design. EPNG obtained an estimate from Hoerbiger Engineering Services (HES) for retrofitting the 14 reciprocating engines at the Blanco A with LEC technology. Hoerbiger utilizes a "Layered Approach Strategy" (Figure 1) to efficiently run the units while reducing NOx formation. The layered approach includes a turbocharger, advanced ignition system, Pre-Combustion Chambers (PCC) System, High Pressure Fuel Injection, and an Automatic Balancing Platform. Based on manufacturer guidance, the addition of these clean burn technologies allows the engines to range from 3 to 0.5 g/hp-hr in NO_X emissions. Further assessment of these control practices is discussed below.

Figure 1. Hoerbiger's Layered Approach Strategy for Clean Burn Technologies

3.2.2.1. LEC Option 1 (LEC 1) – Target NOx Emissions of 3 g/hp-hr

Based on the Hoerbiger Budgetary Estimate from September 2019, LEC 1 would include adding skid mounted VFD electric motor driven blower with Aftercooler, *HyperFuel*™ System, and Engine auxiliary cooling system. With the LEC 1 control option, the reciprocating engines at the Blanco A would achieve 3 g/hp-hr for NOx output. HES has indicated that it will be able to meet the NOx requirement and avoid a negative impact on CO emissions with LEC 1.

To maintain acceptable engine performance at lean conditions, a high energy ignition system is required for ignition of the air fuel charge in the LEC design that promotes flame stability at very lean conditions. The *HyperFuel Valve*™ System is an all-electronic high pressure fuel injection system that improves engine performance and emissions through enhanced mixing.

After-cooling is a technology to lower the intake charge air temperature thereby lowering peak cylinder temperatures and NOx formation. Cooler intake temperatures offer the potential for increased power output and improved fuel economy.

[7] Ibid

3.2.2.2. LEC Option 2 (LEC 2) – Target NOx Emissions of 1 g/hp-hr

LEC 2 would include adding Wet to Dry Manifold Conversion, Muffler with Oxidation Catalyst, and Cylinder Heads with PCC to the LEC 1 base option. With the LEC 2 control option, the reciprocating engines at the Blanco A would achieve 1 g/hp-hr for NOx output while maintaining CO emissions at the current permitted level.

LEC is combustion of a very fuel lean mixture. A fuel lean mixture acts as a heat sink, lowers cylinder temperatures and further reduces NOx formation. There is a tradeoff relationship between NOx and CO when air fuel ratio is adjusted. Lower NOx level will result in higher CO level. To address the concerns for elevated CO emissions in LEC, oxidation catalyst is added to prevent the CO emission from increasing beyond the currently permitted level when the NOx emission is reduced.

Pre-combustion chambers (PCC) have been utilized for improved mixing and enhanced ignition. The purpose of the PCC is to speed the combustion process, and to increase power output by increasing engine speed. The addition of a PCC increases heat loss to the cooling system and thereby lowers engine efficiency.

3.2.2.3. LEC Option 3 (LEC 3) – Target NOx Emissions of 0.5 g/hp-hr

LEC 3 would include uprating nine (9) engines at the Blanco A and retiring the remaining five (5) engines. In order to maintain the overall station horsepower (HP) level of 13,202, each of the 9 engines would be uprated to 1,463 HP. LEC 3 would include adding a *HyperFuel*™ System, Turbocharger, Compressor Cylinder Upgrade, and Power Cylinder Upgrade.

In the lean burn engines, increasing the air to fuel ratio decreases the NOx emissions. Extra air dilutes the combustion gases, thus lowering peak flame temperature and reducing thermal NOx formation. In order to avoid de-rating, combustion air to the engine must be increased at constant fuel flow, requiring a turbocharger. Turbocharger compresses more air flow into the engine's cylinder**.** When air is compressed the oxygen molecules are packed closer together. This increase in air means that more fuel can be added for the same size naturally aspirated engine. This then generates increased mechanical power and overall efficiency improvement of the combustion process. Turbochargers are added to provide the additional combustion air to achieve the ultra-low NOx emission level. The turbochargers proposed by HES are of high efficiency design which provides for the widest possible operating range. Intercoolers are installed to complement the turbocharging. This will keep the air manifold temperature at a fixed temperature at all operating and ambient conditions.

3.2.3. Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review for the control of NO_X emissions from large natural gas-fired lean-burn stationary internal combustion engines; therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at the Blanco A. EPNG

has an operation and maintenance program for the reciprocating engines, which is based on manufacturer recommendation, and EPNG has systems in place to ensure that the engines are operated in accordance with the program at the Blanco A. No further assessment of these control practices is included in this report.

3.2.4. Reducing Capacity

These engines, and in fact, the entire fleet of ENPG's engines and turbines, are part of interstate natural gas pipelines that are subject to regulation by the Federal Energy Regulatory Commission (FERC) under the federal Natural Gas Act. See, e.g., 18 C.F.R.§284.7(a) (setting forth requirements for interstate natural gas firm transportation service). FERC approves or "certificates" the pipeline to deliver natural gas. EPNG's pipeline system, as certificated by FERC, so that EPNG can move gas 24 hours a day, 365 days a year at its designed capacity. Reducing capacity of one or more of EPNG's engines or turbines would require that EPNG seek and obtain approval from FERC. Abandonment proceedings can take up to 11-13 months.

Additionally, as noted in Section 3.2.6 below, replacement of units, and by extension retirement of existing units, is beyond the scope of the Regional Haze Rule. The Clean Air Act, 42 USC Section 7491(g)(2) and elsewhere uses the term "best available retrofit technology." The term "retrofit" denotes modifications to existing equipment and not replacement of equipment. EPA itself acknowledged this in Appendix Y to 40 CFR Part 51 entitled "Guidelines for BART Determinations under the Regional Haze Rule".

However, in evaluating its response to both the New Mexico Ozone Precursor Rule 20.2.50 NMAC and the Regional Haze Rule, EPNG notes that both rules potentially affect Blanco A. In brief, under the Alternative Compliance Plan (ACP) soon to be submitted to the State, EPNG is proposing to retire seven units at Blanco A as part of the overall emission reduction efforts even though the engines are not technically subject to the Ozone Precursor Rule if, an only if, the retirement is approved as a compliance strategy under both regulations and by FERC. Part of the retirement plan is the good will reduction in NOx emissions beyond what is required by the Ozone Precursor Rule. The retirement would also provide benefits under the Regional Haze Rule. While not economically feasible as defined by the Regional Haze Rule, this solution is lower cost than other more-costly or technically infeasible NOx-reduction options.

Accordingly, EPNG requests that NMED consider this environmentally advantageous solution under both rules even though it is not mandated by either rule.

3.2.5. Selective Non-Catalytic Reduction (SNCR)

SNCR is applicable to lean burn natural gas fired engines. SNCR involves injecting ammonia or urea into exhaust with temperatures greater than 1400-1500°F. The NOx in the exhaust are reduced to nitrogen and water vapor. The exhaust temperatures from these engines at the Blanco A are typically in the range of 450-600°F, thus, SNCR is not feasible to reduce NOx emissions in these engines.

3.2.6. Replacement with Electric Drive Motors

NMED's "Recommended Format for Four-Factor Analyses for Regional Haze Planning in New Mexico[9]" provides guidance on selection process for NOx emissions control options. Specifically, it requests affected source to "[D]escribe all of the existing and potential control options to be analyzed (e.g., combustion modifications, post-combustion NOx controls, or fuel substitution…". (Emphasis added.)

The use of "control" here contemplates that emissions sources will evaluate the cost-effectiveness of technically feasible controls on the existing emission sources to reduce emissions – not eliminate or replace those emissions sources altogether. NMED's evaluation of technical feasibility and cost-effective control measures have been limited to specific control technologies available for the existing units. This is an appropriate scope, and EPNG agrees that replacement of the compressor engines with electric drive motors would be beyond the scope of the requirement of the RHR and NMED's authority.

4.1. FACTOR 1: COST OF COMPLIANCE

Control costs include both the capital costs associated with the purchase and installation of retrofit and control systems, as well as the net annual costs (annual recurring costs) associated with system operation. The basic components of total capital costs are direct capital costs, which includes purchased equipment and installation costs, and indirect capital expenses.

Direct capital costs consist of such items as purchased equipment, instrumentation and process controls, ductwork and piping, electrical components, and structural and foundation costs. Labor costs associated with construction and installation are also included in this category.

Indirect capital expenses are comprised of engineering and design costs, contractor fees, supervisory expenses, and startup and performance testing. Contingency costs – which represent such costs as construction delays, increased labor and equipment costs, and design modifications – are an additional component of indirect capital expenses. Capital costs also include the cost of process modifications.

Annual costs include amortized costs of capital investment, as well as cost of operating labor, additional operation and maintenance cost associated with the controls, additional utility costs, and waste disposal.

Only control options deemed technically feasible to the engines at the Blanco A were analyzed. Detailed calculations for each option can be found in Appendix B.

4.1.1. Low Emission Combustion Option 1

The cost of compliance for LEC 1 was analyzed using vendor cost estimates along with the procedures found in the EPA Air Pollution Control Cost Manual (CCM) as applicable. The LEC 1 assumes a NOx emissions rate of 3 g/hp-hr after controls.

Overall, economic feasibility is evaluated on a dollar-per-ton (2019 $/ton)[8] basis using the annual operating cost ($/yr) divided by the annual emission reduction achieved by the control device (ton/yr). The initial total capital investment (TCI) was annualized over a 20-year period and added to the annual operating costs, and the interest rate reflects EPNG's actual cost of borrowing**.** This approach is consistent with EPA's Cost Control Manual (CCM) Section 1, Chapter 2, where EPA states that "…if firm-specific nominal interest rates are not available, then the bank prime rate can be an appropriate estimate for interest rates…" Therefore, in keeping with EPA's CCM, using firm-specific interest rate to develop the cost analysis is appropriate. For the cost analysis, EPNG reviewed the operating data and emission test data from 2015-2019; the highest actual test data and the highest annual operating hours were used to calculate the projected uncontrolled annual emissions (ton/yr). This approach of projecting uncontrolled annual emissions is more conservative than assigning a 5% increase to the average of 2016-2018 actual emissions. The findings of the cost effectiveness of LEC 1 is summarized in Table 3.

[8] NMED Recommended Format for Four-Factor Analysis for Regional Haze Planning in New Mexico

Table 3. Summary of Cost Effectiveness for LEC 1

Unit ID	Uncontrolled NOx Emissions (tpy)	Controlled NOx Emissions (tpy)	NOx Emissions Reduction (tpy)	Total Annualized Cost ($/yr)	Cost Effectiveness ($/ton reduced)
A-01	24.22	20.98	3.24	$435,943	$134,528
A-02	1.92	6.86	No Reduction*	$367,978	--
A-03	36.70	18.57	18.14	$424,314	$23,394
A-04	0.23	1.59	No Reduction*	$342,638	--
A-05	0.80	0.88	No Reduction*	$339,202	--
A-06	29.76	17.36	12.40	$418,519	$33,762
A-07	40.38	25.96	14.42	$459,914	$31,900
A-08	0.01	0.01	No Reduction*	$335,012	--
A-09	12.96	9.79	3.16	$382,112	$120,854
A-10	0.02	0.02	No Reduction*	$335,079	--
A-11	32.73	26.24	6.49	$461,228	$71,045
A-12	13.94	11.10	2.84	$388,407	$136,939
A-13	20.08	23.36	No Reduction*	$447,381	--
A-14	6.07	22.80	No Reduction*	$444,706	--

*The highest test results for units 2, 4, 5, 13, and 14 are less than the NOx target of 3 g/hp-hr; therefore LEC 1 would not achieve NOx emission reductions for these units. Units 8 and 10 have limited projected hours to show any NOx emission reductions.

Therefore the cost per ton of NOx reductions for LEC 1 is between $23,394 and $136,939 per engine. Based on a cost effectiveness threshold of $7,500/ton, LEC 1 is economically infeasible for all engines.

4.1.2. Low Emission Combustion Option 2

The cost of compliance for LEC 2 was analyzed using the same approach as that of LEC 1. LEC 2 assumes a NOx emissions rate of 1 g/hp-hr after controls. The findings of the cost effectiveness of LEC 2 is summarized in Table 4.

Table 4. Summary of Cost Effectiveness for LEC 2

Unit ID	Uncontrolled NOx Emissions (tpy)	Controlled NOx Emissions (tpy)	NOx Emissions Reduction (tpy)	Total Annualized Cost ($/yr)	Cost Effectiveness ($/ton reduced)
A-01	24.22	6.99	17.23	$713,721	$41,427
A-02	1.92	2.29	No Reduction*	$576,554	--
A-03	36.70	6.19	30.51	$690,252	$22,620
A-04	0.23	0.53	No Reduction*	$525,414	--
A-05	0.80	0.29	0.50	$518,479	$1,029,568
A-06	29.76	5.79	23.97	$676,261	$28,213
A-07	40.38	8.65	31.73	$762,098	$24,021
A-08	0.01	0.00	0.01	$510,022	$97,332,475
A-09	12.96	3.26	9.69	$605,081	$62,433
A-10	0.02	0.01	0.01	$510,156	$39,628,377
A-11	32.73	8.75	23.98	$764,751	$31,887
A-12	13.94	3.70	10.24	$617,784	$60,340
A-13	20.08	7.79	12.29	$736,804	$59,957
A-14	6.07	7.60	No Reduction*	$731,406	--

*The highest test results from units 2, 4, and 14 are less than the NOx target of 1 g/hp-hr; therefore LEC 2 would not achieve NOx emission reduction for these units.

Therefore the cost per ton of NOx reductions for LEC 2 is between $22,620 and $97,332,475 per engine. Based on a cost effectiveness threshold of $7,500/ton, LEC 2 is economically infeasible for all engines.

4.1.3. Low Emission Combustion Option 3

LEC 3 would include the retirement of five engines at the Blanco A while uprating the remaining nine engines in order to maintain the overall station HP level of 13,202. LEC 3 assumes a NOx emissions rate of 0.5 g/hp-hr. Note the 0.5 g/hp-hr NOx emission rate is difficult to sustain on a consistent basis due to

operational variations in natural gas compressor applications. The findings of the cost effectiveness of LEC 3 is summarized in Table 5.

Table 5. Summary of Cost Effectiveness for LEC 3

Unit ID	Uncontrolled NOx Emissions (tpy)	Controlled NOx Emissions (tpy)	NOx Emissions Reduction (tpy)	Total Annualized Cost ($/yr)	Cost Effectiveness ($/ton reduced)
A-01	24.22	3.50	20.73	$636,317	$30,702
A-02	1.92	1.14	0.78	$523,034	$669,495
A-03	36.70	3.09	33.61	$616,934	$18,356
A-04	0.23	0.27	No Reduction*	$480,798	--
A-05	0.80	0.15	0.65	$475,071	$731,144
A-06	29.76	2.89	26.86	$604,981	$22,521
A-07	40.38	4.33	36.05	$676,271	$18,757
A-08	0.01	0.00	0.01	$468,087	$75,013,871
A-09	12.96	1.63	11.32	$546,593	$48,268
A-10	0.02	0.00	0.02	$468,196	$28,808,988
A-11	32.73	4.37	28.36	$678,461	$23,927
A-12	13.94	1.85	12.09	$557,085	$46,083
A-13	20.08	3.89	16.18	$655,381	$40,501
A-14	6.07	3.80	2.27	$650,923	$286,897

*The highest emission test result for unit 4 is less than the NOx target of 0.5 g/hp-hr; therefore LEC 3 would not achieve NOx emission reduction for unit 4.

Therefore the cost per ton of NOx reductions for LEC 3 is between $18,356 and $75,013,871 per engine. Based on a cost effectiveness threshold of $7,500/ton, LEC 3 is economically infeasible for all engines.

4.1.4. Good Combustion Practices

Utilizing good combustion practices and fuel selection were identified as technical feasible for the control of NOx emissions. EPNG has developed Engine Inspection and Maintenance Schedules Best Practices procedures based on manufacturer recommendation, and EPNG has systems in place to ensure that its engines are operated in accordance with the schedules. These practices are currently in used at the Blanco A. By maintaining good combustion practices and using pipeline quality natural gas as fuel, the units will operate as intended with the lowest NO_X emissions possible. No further assessment of these control practices is included in this report.

4.2. FACTOR 2: TIME NECESSARY FOR COMPLIANCE

The time necessary for compliance is separate from the other three factors. The time necessary for compliance depends on reasonable installation times and compliance deadlines for selected control measures. Combustion modifications and post-combustion NOx controls may require significant time for engineering, construction, and facility preparedness. As an exact timeframe cannot be projected for the analyzed control options, an estimate was made for each option. Furthermore, not all engines would be able to be modified simultaneously as pressure must be maintained within the transmission pipeline at all times. Estimates were made between 1 and 3 years, after the issuance of the revised permit from NMED, depending on the control selected.

4.3. FACTOR 3: ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS

The proposed emission reduction strategies include high-pressure fuel injection systems, which take electricity to operate over and above the electricity usage of the facility in its current configuration. The proposed use of a catalyst in LEC 2 would generate waste and disposal issues when the catalyst is cleaned or replaced. The construction phase of the project would also generate solid and potentially hazardous waste for disposal, potentially create odor and noise pollution, and additional temporary combustion emissions from equipment. The LEC control technology may also decrease engine efficiency.

4.4. FACTOR 4: REMAINING USEFUL LIFE OF THE SOURCE

Slow speed engines such as the Cooper Bessemer GMV10-TF installed at Blanco A are very robust engines. The oldest engines in the Kinder Morgan fleet were designed and installed in the 1940s. When properly maintained, these engines will continue to operate for the foreseeable future with periodic routine maintenance. Cooper continues to make parts for replacement. Additionally, the EPA's Air Pollution Control Cost Manual suggests the remaining useful life should be based on the control method and not the emissions source itself. Therefore, it is assumed that the remaining useful life of any chosen control or modification is 20 years.

5. SUMMARY & CONCLUSIONS

NMED has indicated costs in excess of $7,500/ton of pollutant reduced are economically infeasible. This cost threshold is cited in the preamble to rulemaking for 20.2.50 NMAC and has been utilized by other States to define an acceptable level for determination of cost effectiveness for control technologies. As shown in this analysis, the economic feasibility values are above $7,500/ton of pollutant reduced for each of the technological feasible emission controls for the 14 engine units at the Blanco A. Based on a comprehensive review of the RBLC, available literature, and vendor input of available control technologies for the natural gas fired engines located at the Blanco A, EPNG has determined that good combustion practices and using pipeline quality natural gas as fuel are the only technically feasible control options for the 14 reciprocating engines.

However, EPNG recognizes that there is overlap between the New Mexico Ozone Precursor Rule and the Regional Haze Rule. Although not required under either rule, EPNG proposes that NMED allow EPNG to retire seven units at Blanco A if, an only if, the retirement is approved as a compliance strategy under both regulations and by FERC.

In summary, subject to FERC approval and if, and only if, NMED approves this compliance strategy under both the Ozone Precursor Rule and the Regional Haze Rule EPNG is proposing for compliance with the Regional Haze Rule:

- Retirement of seven of the 14 engines at Blanco A, and
- Continued implementation of GCP on the remaining seven engines.

6. SUPPORTING DOCUMENTATION

Appendix A – RBLC Table

Appendix B – Cost Analysis

APPENDIX A – RBLC TABLE

RBLC Analysis for Natural Gas-Fired Lean-Burn Stationary Internal Combustion Engines – NO_x

	Control Technology	Selective Catalytic Reduction (SCR) [a,b]	Non-Selective Catalytic Reduction (NSCR) [b]	Clean Burn Technology	Good Combustion Practices and Fuel Selection [c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_x to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.	This technique uses residual hydrocarbons and CO in rich-burn engine exhaust as a reducing agent for NO_x. In an NSCR, hydrocarbons and CO are oxidized by O_2 and NO_x. The excess hydrocarbons, CO, and NO_x pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_x to N_2. [b]	Natural gas fueled engines that operate with a fuel-lean air/fuel ratio are capable of low NO_x emissions.	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.
	Other Considerations	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.	N/A	N/A	N/A
ELIMINATE TECHNICALLY INFEASIBLE OPTIONS	RBLC Database Information	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.
	Feasibility Discussion	Technically infeasible. For engines which typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed.	Technically infeasible. The NSCR technique is limited to engines with normal exhaust oxygen levels of 4 percent or less. This includes 4-stroke rich-burn naturally aspirated engines and some 4-stroke rich-burn turbocharged engines. Lean-burn engines could not be retrofitted with NSCR control because of the reduced exhaust temperatures.	Technically feasible.	Technically feasible.

Economic Evaluation

Cost Component		All Units (Combined)	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	-	On 2/14/20, EPNG provided a $1469/hp all-in Total Capital Cost (TCC) metric for EMD. On 9/9/20, EPNG provided an alternate cost estimate developed using "the KM-Cost Estimating Group's Developmental Cost Estimating Tool". The alternate estimate applied an unusual and insufficiently documented methodology that involved a base cost estimate for replacement turbines that was adjusted using EMD-specific costs and turbine-specific costs. Using detailed cost information provided by other facilities, NMED developed a TCC metric of $2,084/hp (2023$) for the installation of EMD. Costs associated with requisite substation and utility line upgrades were estimated separately and added to TCC to estimate Total Capital Investment (TCI).
Other Direct Capital Costs 1 ($)	ODC1	$ -	-	
Other Direct Capital Costs 2 ($)	ODC2	$ -	-	
Indirect Capital Costs ($)	IDC	$ -	-	
Total Capital Costs - Direct ($)	TCC	$ 44,701,800	See Note	
Additional Capital ($)	AC	$ 15,270,000	EPNG estimate dated 9/9/20 and ERG experience	15 miles of medium voltage line @ $750k/mile; substation upgrade ($3M in 2020$ converted to 2023$ using CEPCI)

NMED Final Cost Evaluation
El Paso Natural Gas Company - Pecos River Compressor Station

Unit A-01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	212,973,230	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.6392	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1278	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft³/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft³
29.4% aqueous NH_3	56 lbs/ft³

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	8.53	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit A-01: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year	
Actual Annual fuel consumption (Mactual) =		212,973,230	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.406	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	3553	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	31.60	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	56.14	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3064	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	268.91	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	12	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	42	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	6	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	2,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1059

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	36.59	kW

Unit A-01: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,352,801	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$47,399 in 2024 dollars
Indirect Annual Costs (IDAC) =	$357,891 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$405,290 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$16,764 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$10,632 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$12,999 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$7,003 in 2024 dollars
Direct Annual Cost =		$47,399 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,829 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$355,062 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$357,891 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$405,290 per year in 2024 dollars
NOx Removed =	56 tons/year
Cost Effectiveness =	$7,220 per ton of NOx removed in 2024 dollars

Unit A-02: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	382,308,826	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	2900	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.5886	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1177	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft³/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft³
29.4% aqueous NH_3	56 lbs/ft³

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	8.53	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

NMED Final Cost Evaluation
El Paso Natural Gas Company - Pecos River Compressor Station

Unit A-02: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,352,801	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$64,571 in 2024 dollars
Indirect Annual Costs (IDAC) =	$357,891 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$422,461 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$16,764 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$17,576 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$23,335 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$6,896 in 2024 dollars
Direct Annual Cost =		$64,571 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,829 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$355,062 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$357,891 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$422,461 per year in 2024 dollars
NOx Removed =	93 tons/year
Cost Effectiveness =	$4,553 per ton of NOx removed in 2024 dollars

Unit A-03: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	331,897,769	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	2900	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days	Number of SCR reactor chambers (n_{scr})	1
Number of days the boiler operates (t_{plant})	365	days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR	0.6558	lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1312	lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050		Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
			Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK acfm

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours	Gas temperature at the SCR inlet (T)	650 °F
Estimated SCR equipment life	20	Years*	Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK ft^3/min-MMBtu/hour

* For industrial boilers, the typical equipment life is between 20 and 25 years.

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	8.53	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information

Unit A-03: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year	
Actual Annual fuel consumption (Mactual) =		331,897,769	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.632	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	5537	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	32.42	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	89.77	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3064	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	270.27	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	13	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	43	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	6	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	2,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1059

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	36.59	kW

Unit A-03: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,352,801	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$61,062 in 2024 dollars
Indirect Annual Costs (IDAC) =	$357,891 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$418,953 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$16,764 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$17,002 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$20,258 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$7,039 in 2024 dollars
Direct Annual Cost =		$61,062 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,829 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$355,062 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$357,891 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$418,953 per year in 2024 dollars
NOx Removed =	90 tons/year
Cost Effectiveness =	$4,667 per ton of NOx removed in 2024 dollars

1. INTRODUCTION

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*
>
> The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long-Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed El Paso Natural Gas Company LLC (EPNG) that its Pecos River Compressor Station (Pecos River) facility was identified as one of the sources potentially contributing to regional haze at the Carlsbad National Park Class I area.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to EPNG, it specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at Pecos River, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Natural Gas-Fired Regenerative Cycle Turbine (Unit A-01)	53.10	232.58	Yes	0.43	1.87	No
Natural Gas-Fired Regenerative Cycle Turbine (Unit A-02)	53.10	232.58	Yes	0.43	1.87	No
Natural Gas-Fired Regenerative Cycle Turbine (Unit A-03)	53.10	232.58	Yes	0.43	1.87	No

NO_X is the only pollutant subject to evaluation in this four-factor analysis for the three turbines located at Pecos River: Units A-01, A-02 and A-03. These units are General Electric (GE) model M3712R (also known as Model A turbines) natural gas-fired, regenerative cycle turbines. They are rated at 7,150 horsepower each and were manufactured in 1953.

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED[1], this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. A summary of identified available retrofit controls along with a technical feasibility assessment for each control is provided in Section 2. The four-factor analysis is then conducted for those controls that are technically feasible.

2.1. COMBUSTION TURBINE BACKGROUND

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[2]

The treatment of the exhaust gases exiting the turbine dictate the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[3] The units at Pecos River are regenerative cycle turbines, which are essentially simple cycle gas turbines with an added heat exchanger.

NO_X is formed in turbines via three mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Pecos River turbines use natural gas fuel, which contains a negligible amount of nitrogen compounds. Therefore, the formation of prompt and fuel NO_X will be insignificant. This analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time in the combustion chamber. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[4]

The PTE from each turbine is reported in the facility's New Source Review (3260M1) and Title V (P129R3M1) permits, as well as summarized in Table 1 of this report.

2.2. POTENTIAL NO_X CONTROLS FOR COMBUSTION TURBINES

There are three general methods of controlling NO_X emission from gas turbines; (1) dry controls, which use advanced combustor design to suppress NO_X formation, (2) wet controls that use steam or water injection to reduce combustion temperatures and NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[5]

[2] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[3] Ibid.
[4] Ibid.
[5] Ibid.

The retrofit control equipment that was identified for combustion turbines during a comprehensive review of the RBLC, available literature, and manufacturer's input is reported in Table 2. A more detailed table summarizing the RBLC review is provided in Appendix A. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible?	NO_X Control Efficiency
Good Combustion Practices	Yes	Base Case
Lean Head End Liner	No	N/A
Improved Combustion Technology	No	N/A
Water/Steam Injection	No	N/A
Selective Catalytic Reduction	Yes	65% - 90%

2.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at Pecos River. EPNG has developed Turbine Inspection/Maintenance Schedules Best Practices procedures, included in Appendix B of this report, which are based on manufacturer recommendation, and EPNG has systems in place to ensure that its engines are operated in accordance with this. These practices are currently in use at Pecos River as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices is included in this report.

2.2.2. Lean Head End Combustion Liner

The key factors affecting thermal NO_X formation are the combustion temperature and residence time of fuel in the combustor. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio. "Lean" combustion refers to combustion occurring at a high air-to-fuel ratio, which reduces the firing temperature.

A Lean Head End (LHE) Combustion Liner is an enhanced liner for the combustion chamber that increases the air-to-fuel ratio by adjusting the number, diameter, and location of the mixing and dilution holes in the chamber.

This diverts excess air toward the flame end, thereby reducing the flame temperature and NO_X formation. GE estimates that NO_X reduction from this control method varies from 15% to 40%, depending upon the design.[6]

Based on communications with GE, there are currently no LHE liner control options for the GE Model A turbines. The earliest model on which the LHE liner can be installed is the Model J generation, which was produced starting in 1969 and has significant design differences to the Model A fleet. The LHE liner control technology has never been installed on units older than the Model J, and there is no way to determine what, if any, emissions reduction could be achieved through a retrofit.

Per 40 CFR Part 51, Appendix Y, "a technology is considered 'available' if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term."[7] Further, source owners are not expected to "construct a process or control device that has not already been demonstrated in practice."[8] Because LHE liners are not currently available for and have never been installed on the Model A fleet of turbines, there is no historical data to support that installation of these controls would result in significant reductions of NO_X emissions. For this reason, it has been determined that this control technology is infeasible for the turbines located at Pecos River.

2.2.3. Improved Combustion Technology

The improved combustion technology control option, commonly referred to as Dry Low NO_X (DLN) control, also seeks to reduce the combustion temperature and residence time of fuel in the combustor (thereby decreasing NO_X formation) by increasing the air-to-fuel ratio in the combustion chamber. There are several levels of improvements that can be made to the combustion chamber, which achieve this NO_X control at varying efficiencies.

Based on communications with GE, the DLN control option involves a thorough overhaul of the combustion section of the turbine, including replacement of the air and fuel injection nozzles, modifications to, or complete replacement, of the combustion chamber, and replacement of the electrical control system for the unit.

As with the LHE liners, there are currently no developed improved combustion controls available for the Model A fleet of GE turbines. The earliest model on which the DLN technology can be installed is the Model J turbines, and the technology has never been retrofitted for units older than the Model J. There is no way to determine what, if any, emissions reduction could be achieved through a retrofit. As there is no historical data to support that significant reductions of NO_X emissions would result from installation of this control, it has been determined that this control technology is infeasible for the turbines located at Pecos River.

2.2.4. Water/Steam Injection

Water or steam injection is a control technology for gas turbines that has been demonstrated to effectively suppress NO_X emissions. Injection of steam and water has the effect of increasing the thermal mass by dilution and thereby reducing the peak temperature in the flame zone. There is an additional benefit of absorbing the latent heat of vaporization from the flame zone when water injection is utilized. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.[9]

---

[6] General Electric Power Systems, GER-4211, "Gas Turbine Emissions and Control", 03/2001
[7] 40 CFR 51, Appendix Y, Section IV.D.2
[8] 40 CFR 51, Appendix Y, Section IV.D.1
[9] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"

Water/steam injection was not identified in this review of RBLC as a potential control of NO_X emissions from natural gas-fired combustion turbines; however, AP-42 Section 3.1 does list water/steam injection as an available control technique for gas turbines.[10]

However, communications with GE have indicated that water/steam injection is not currently available for the Model A turbines located at Pecos River. The technology has never been retrofit for units older than the Model J, and there is no way to determine what, if any, emissions reduction could be achieved through a retrofit. Furthermore, GE has indicated that they have since retired this control option and do not recommend water injection be installed to control emissions from any of their turbine units. As this technology has never been installed on any GE Model A turbine, there is no historical data to support that installation of these controls would result in significant reductions of NO_X emissions. For this reason, it has been determined that this control technology is infeasible for the turbines located at Pecos River.

2.2.5. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[11] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituent, thermal sintering, or compacting, of active sited due to high temperatures in the reactor, fouling caused by ammonia-sulfur salts and particulate matter in the gas, and erosion due to high gas velocities.[12]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. As urea is an ammonia precursor, ammonia slip will occur regardless of the reagent employed. Ammonium sulfate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[13]

In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[14] The exhaust temperature of the turbines assessed here is approximately 580 °F.

[12] Ibid.
[13] Ibid.
[14] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"

SCR is considered a technically feasible control option for the turbines located at Pecos River. SCR units typically achieve 65% to 90% NO_X reduction, dependent on the exhaust temperature and upstream NO_X concentration.[15]

[15] Ibid.

3. COST OF COMPLIANCE

EPNG has evaluated the costs of implementing the technically feasible control technologies as thoroughly as possible in the time provided to complete this assessment. These cost estimates are calculated according to the methods and recommendations in the EPA Air Pollution Control Cost Manual.[16] Cost effectiveness considerations for the turbines are discussed below, with costs summarized in Table 3.

Table 3. Cost Analysis Summary of Technically Feasible Control Options for Combustion Turbines

Control Equipment	Unit	SCR Capital Cost ($)	Building Modifications ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Selective Catalytic Reduction	A-01	3,802,798	2,500,000	656,640	36.0	18,252
	A-02	3,802,798	2,500,000	664,748	66.9	9,931
	A-03	3,802,798	2,500,000	662,707	61.0	10,858

*Total Annual Cost includes the annualized SCR capital and building modification costs, as well as the direct and indirect annual operating costs.

EPNG has selected to use the EPA Air Pollution Control Cost Spreadsheet for SCR to estimate the costs associated with implementing an SCR control system on the turbines at Pecos River. The estimate incorporates direct capital cost for equipment and vendor labor, direct annual costs (maintenance, operating labor, reagent cost, electricity cost, and catalyst cost), and indirect costs associated with EPNG's internal labor, overhead and capital recovery for the project.

In addition, there are site-specific space limitations that prevent the installation of the necessary equipment for this control method (i.e., SCR module and reagent storage systems). Based on the current configuration of the turbines, the exhaust system ducting would require significant modifications in order to install the catalyst. Specifically, the stack for each unit would need to be relocated and additional ducting would be required. At this time, EPNG believes that there is insufficient room within the existing building that houses the turbines to complete the necessary modifications and installation of the catalyst. The cost necessary to modify the turbine housing has been estimated by EPNG and is accounted for in this cost effectiveness calculation.

This cost estimate assumes that the SCR will reduce NO_X emissions with a 70% efficiency.[17] There is no historical data to support a higher control efficiency assumption. In addition, due to the age of the units and current availability of control equipment for them, it is assumed that there would be significant difficulties retrofitting each of these turbines with an SCR control. Therefore, a retrofit difficulty factor of 1.5 is used for this analysis.

These cost estimates have been developed based on the actual emissions from each unit assessed here, calculated using June 2016 stack test data for each unit and the actual hours of operation from the 2016 Emission Inventory submittal for Pecos River. The stack test data utilized for these calculations is included in Appendix C of this report and a copy of the EPA Air Pollution Control Cost Spreadsheet for each unit is included in Appendix D.

[17] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

4. TIME NECESSARY FOR COMPLIANCE

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of EPNG's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

EPNG estimates that approximately 36 months will be necessary to make the building modifications and install the SCR control equipment. Factors that have been considered for this anticipated timeline include project development, engineering, lead time to acquire the necessary materials, construction, and commissioning.

5. ENERGY AND NON-AIR ENVIRONMENTAL IMPACTS

This section addresses the potential energy and non-air environmental impacts that installation of the technically feasible control options poses on a source. The consideration of energy impacts involves assessing the impact of a control measure on the energy that is consumed by the source. Non-air environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

The implementation of SCR on the turbines at Pecos River would result in several energy and non-air impacts. The primary impact of this control would be a significant increase in energy consumption, which would be necessary to power the units. The estimated energy consumption for each unit is summarized in Table 4, and is based on the EPA Air Pollution Control Cost Manual.[18] The calculation for these values is included in Appendix E of this report. EPNG does not anticipate any issues with meeting this increased energy burden.

Table 4. Energy Consumption Analysis Summary

Unit	Annual Energy Consumption (MWh)
A-01	158.3
A-02	227.7
A-03	206.6
Total	592.6

In addition to the increased energy burden, there are several non-air environmental impacts associated with the handling and storage of the reagent used in the SCR system, typically ammonia or urea. Ammonia is a Toxic Air Pollutant (TAP) regulated under 20.2.72.502 NMAC with an occupational exposure limit (OEL) of 18 mg/m^3. In both soil and water, urea is hydrolyzed quickly to ammonia and carbon dioxide by urease, an extracellular enzyme that originates from microorganisms and plant roots.[19] Short-term inhalation exposure to high levels of ammonia in humans can cause irritation and serious burns in the mouth, lungs, and eyes. Chronic exposure to airborne ammonia can increase the risk of respiratory irritation, cough, wheezing, tightness in the chest, and impaired lung function in humans. Animal studies also suggest that exposure to high levels of ammonia in air may adversely affect other organs, such as the liver, kidney, and spleen.[20]

Unavoidable releases of ammonia could have significant and irreversible impacts on the living and physical environment affected. Storage and handling of urea or ammonia onsite would result in an increased risk to the health and safety of facility operators. Pecos River is a natural gas compressor station, which already maintains a high level of health and safety risk. EPNG considers any increase to this risk unacceptable.

6. REMAINING USEFUL LIFE OF SOURCES

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system. Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.[21]

Based on their current age and operating efficiency, it is estimated that the remaining useful life of the turbines will be longer than the SCR units. The turbines have operated for more than 65 years without any significant deterioration in operating efficiency; therefore, this analysis of the remaining useful life of the equipment will be based on the anticipated useful life of the SCR control device installed.

The estimated useful life of the SCR equipment is 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[22]

[21] 40 CFR 51, Appendix Y, Section II.B.4.f

[22] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

7. SUMMARY & CONCLUSIONS

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input of the available control technologies for the natural-gas fired turbines located at Pecos River, EPNG has determined that SCR is the only technically feasible control option for these units. The cost of compliance to install SCR controls on each of these units has been estimated based on the EPA Air Pollution Control Cost Manual.[23] The estimated cost effectiveness and NO_X emission reduction for each unit are summarized in Table 5, below.

Table 5. Summary of Cost Effectiveness and NO_X Reduction for SCR Control of the Turbines

Control Equipment	Unit	NO_X Reduction (tpy)	Cost Effectiveness ($/ton)
Selective Catalytic Reduction	A-01	36.0	18,252
	A-02	66.9	9,931
	A-03	61.0	10,858

It is projected that the useful life of these units will be 20 years, based on the life expectancy of the SCR controls. The primary energy and non-air impacts from this control method will be increased energy consumption and health and safety risk. EPNG estimates that 36 months would be an achievable compliance timeline for this control.

RBLC Analysis for Natural Gas Fired Turbines – NO_X Control

	Control Technology	Good Combustion Technique	Improved Combustion Technology (Low-NO_X Combustors, Ultra-Low NO_X Combustors and other improved combustion technology)[a]	Water/Steam Injection[b]	Selective Catalytic Reduction (SCR)[c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. Primary combustion occurs at lower temperatures under oxygen-deficient conditions. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_X emissions.	Low-NO_X burners employ multi-staged combustion to inhibit the formation of NO_X. Primary combustion occurs at lower temperatures under oxygen-deficient conditions; secondary combustion occurs in the presence of excess air. This category includes Improved Combustion Technology Lean Head End Liners for the GE turbines assessed here.	Injected water/steam acts as a heat sink, lowering combustion zone peak temperatures, resulting in a decrease in thermal NO_X.	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_X to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.
	Other Considerations	N/A	N/A	Results in a small efficiency penalty but an increase in power output. May increase CO and VOC emissions. Not available in certain models.	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.

APPENDIX B – EPNG TURBINE BEST PRACTICES PROCEDURES

Table of Contents

1. Scope 1
1.1. General 1
1.2. G.E. Gas Turbine Inspection/Maintenance Schedules 1
2. Recommendations 1
3. Procedure 1
4. Documentation 3
5. References 4

1. Scope

1.1. General

Historically, some “Best Practices” documents were developed to cover specific regions, pipelines, or other limited-scope situations. While such documents may not agree with all provisions of Company Operating and Maintenance (O&M) Procedures, they contain vital information and considerations that may prove useful to many users.

Best Practices documents are intended to *complement* Company O&M Procedures. As such, this procedure provides *recommendations* and *guidance* to supplement the Company and Code Requirements defined within O&M Procedures, Engineering Standards, and other Company Compliance Documents.

In all applications, Company O&M Procedures and Engineering Standards shall prevail as Company Requirements.

1.2. G.E. Gas Turbine Inspection/Maintenance Schedules

Regular analysis, inspection, and maintenance of G.E. gas turbines contribute to a reliable, efficient, and safe operation of the Company turbine fleet.

2. Recommendations

G.E. gas turbines should be maintained following the maintenance programs set forth below. These are minimum recommendations and should be adjusted for each location as operating conditions warrant.

A) Typically, the life-limiting components are in the hot section. Parameters affecting the schedules for inspection and repair or replacements are material erosion, including oxidation and corrosion, stress rupture, and fatigue. Each engine component will have different critical limits and may react differently to specific environments and/or deviation from the basic design condition. Therefore, each location should monitor the condition of their unit and take necessary actions to ensure a safe and reliable operation.

B) It is recommended that a start counter be installed on each unit and all full load trips be logged in order to ensure applicable maintenance scheduling. Repeated starts and trips from full load impose large thermal stresses on parts leading to an increased potential for Low Cycle Fatigue (LCF) failure. These high thermal stresses are common in most gas turbine materials because the alloying elements used to achieve material strength at high temperatures are the same ones that produce low thermal conductivity. Thus, it is important to account for all starts and trips on all units.

   Anything that can be done to reduce trips at full load will reduce the potential for component failures resulting from low cycle fatigue.

3. Procedure

A) General Electric Frame 3 and Frame 5 Turbines

   1) Every 800-1,200 Fired Hours Operated

      a. Take lube oil sample for laboratory analysis.

b. Check oil level in the oil sump. Verify that no oil is present in the skid sump vent line.

2) Every 8,000 Fired Hours Operated

a. Check controls and recalibrate if necessary.
b. Calibrate recycle valve positioner and ensure valve operates at required speed.

3) 8,000-11,000 E.H.O.* - Combustor Inspection

*For GE Frame 3 Turbines: E.H.O. = hours operated + (# of starts x 10) + (# of full load trips x 100) (A full load trip is any trip of the turbine when operating above 75% load.)

Combustor inspection should include:

a. Boroscope of blading, buckets, and nozzles
b. Inspection of the combustion liners
c. Inspection of the cowl caps
d. Inspection of the transition pieces
e. Inspection of the Axial Flow Compressor (AFC) and stator blading including the washing
f. Removal of fuel nozzles for cleaning and inspection for cracks/other defects
g. Check of igniters and flame detectors
h. Greasing all the auxiliary couplings
i. Repair of any maintenance items required
j. Inspect all tubing, hoses, and fittings.

4) 26,000-28,000 E.H.O.* - Hot Gas Path Inspection

*For GE Frame 3 Turbines: E.H.O. = hours operated + (# of starts x 10) + (# of full load trips x 100) (A full load trip is any trip of the turbine when operating above 75% load.)

Hot gas path inspection should include:

a. Inspection of the combustion liners
b. Inspection of the cowl caps
c. Inspection of the transition pieces
d. Inspection of the Axial Flow Compressor (AFC) and stator blading including the washing
e. Removal of the shell half
f. Inspection of the first stage nozzles
g. Check alignment from the turbine to compressor.
h. Grease all the auxiliary couplings.
i. Repair any maintenance items required.
j. The turbine should be cleaned and inspected for cracks, chips, hot spots, or other damage.
k. Damaged or defective parts will be repaired or replaced, as required.

5) Overhaul - 38,000 - 42,000 E.H.O. for units with composite wheels,

Overhaul - 48,000 - 50,000 E.H.O. for units with non-composite wheels.

Each Overhaul should include:

a. Inspection of the combustion liners
b. Inspection of the cowl caps
c. Inspection of the transition pieces
d. Inspection of the Axial Flow Compressor (AFC) and stator blading including the washing
e. Removal of the shell half
f. Inspection of the First stage nozzles
g. Removal of all the rotating assemblies
h. Inspection of the accessory gear section
i. Inspection of the load coupling
j. Grease all the auxiliary couplings.
k. Inspection of the Second Stage nozzles

l. Inspection of the starting means
m. Inspection of the high-speed coupling
n. Removal and inspection of the air and oil seals
o. Removal and inspection of all the bearings
p. Check alignment from the turbine to compressor.
q. Bump check compressor.
r. Calibrate all logic controls at major overhaul.

B) GE LM500 TURBINES

1) Weekly -

a. Check oil levels.
b. Check oil pressure.
c. Check engine air pressure (P-3).
d. Check for leaks (air, oil, etc.).
e. Check for signs of hot spots on case.
f. Check for excessive noises or vibrations.
g. Check air and oil filter differentials.
h. Check for loose bolts, fittings, etc.
i. Check control gauges and transmitters for leaks.

2) Every 1,000 - 1,200 Hours Operated -

a. Conduct a thorough visual inspection of outer parts.
b. Take lube oil sample for laboratory analysis.
c. Check fuel and start gas lines for leaks.
d. Change oil filters with high differential pressure.
e. Change air inlet pre-filters if oily.
f. Check package air inlet filters.
g. Check V.G. control cable for wear or slack.
h. Check lock-wires on bolts and nuts for breaks.
i. Check chip detectors in lube oil lines.

3) Every 7,000-8,000 Fired Hours Operated -

a. Boroscope hot and cold ends and gas compressor.
b. Pull fuel nozzles and check for wear.
c. Pull and inspect half of low pressure power turbine case.

4) Annual not to exceed 15 months -

a. Check calibrations on all transmitters.
b. Check calibrations on controls (speed, EGT, P-3, etc.).
c. Check calibrations on Woodward governor fuel slopes.
d. Check calibration of vibration and shutdown devices.
e. Check and test all safety shutdowns.
f. Calibrate recycle valve positioner and ensure valve operates at required speed.

5) Overhauls on LM500 turbines are to be conducted as needed, based on Boroscope inspections.

a. Calibrate all logic controls at major overhaul.

4. Documentation

Some Pipelines and related Field Staff use one or more of the following:

- MAXIMO as an activities scheduling utility
- COMET for Compressor Data tracking

- Other Legacy Forms and Data Logs

Until such time as these systems (MAXIMO, COMET, etc.) are superseded, the following information is provided for user reference:

MAXIMO PM

- GE Frame 3 & Frame 5 - Oil Analysis - Every 2 months NTE 75 days or 1200 Fired Operated Hours
- GE Frame 3 & Frame 5 – Controls Calibration
- GE Frame 3 & Frame 5 - Combustor Inspection - 8000 NTE 11,000 E.H.O.
- GE Frame 3 & Frame 5 - Hot Gas Path Inspection - 26,000 NTE 28,000 E.H.O.
- GE Frame 3 & Fame 5 - Major Overhaul (Composite Turbine Wheels) - 38,000 NTE 42,000 E.H.O.
- GE Frame 3 & Frame 5 - Major Overhaul (Non-Composite Turbine Wheels) - 48,000 NTE 50,000 E.H.O.
- GE LM500 - Weekly Inspection - Weekly
- GE LM500 - 1,000 Hour Inspection - 1,000 NTE 1,200 Fired Hours Operated
- GE LM500 - 7000 Hour Inspection - 7000 NTE 8000 Fired Hours Operated
- GE LM500 - Controls Calibration - 1 Year NTE 15 Months

APPENDIX C – JUNE 2016 STACK TEST DATA

SUMMARY OF TEST RESULTS PECOS RIVER STATION

Permit P129R2M1 – October 4, 2011

Pecos River Station unit S001 GE Model M3712R A S/N95025

Annual performance testing was performed on unit 1 exhaust for NOx, CO, and O2 on July 12, 2016. Maximum achievable load compliance consisted of three (20) twenty minute sampling events which were used to calculate the average for the emission values. These averages were then compared with the unit permitted limits to determine the performance status. **Based on the test results, unit S001 PASSED the Performance Test Audit**

Parameter	Measured	Permit	Status
Emission Load (% HP)	94.09	n/a	n/a
NOx (lb/hr)	20.63	53.10	PASS
NOx (TPY)	89.79	233	PASS
CO (lb/hr)	4.36	8.00	PASS
CO (TPY)	19.00	35	PASS

SUMMARY OF TEST RESULTS PECOS RIVER STATION

Permit P129R2M1 – October 4, 2011

Pecos River Station unit S002 GE Model M3712R A S/N95053

Annual performance testing was performed on unit 2 exhaust for NOx, CO, and O2 on June 21, 2016. Maximum achievable load compliance consisted of three (20) twenty minute sampling events which were used to calculate the average for the emission values. These averages were then compared with the unit permitted limits to determine the performance status. **Based on the test results, unit S002 PASSED the Performance Test Audit**

Parameter	Measured	Permit	Status
Emission Load (% HP)	105.62	n/a	n/a
NOx (lb/hr)	26.69	53.10	PASS
NOx (TPY)	116.21	233	PASS
CO (lb/hr)	3.67	8.00	PASS
CO (TPY)	15.97	35	PASS

SUMMARY OF TEST RESULTS PECOS RIVER STATION

Permit P129R2M1 – October 4, 2011

Pecos River Station unit S003 GE Model M3712R A S/N95055

Quarterly performance testing was performed on unit 3 exhaust for NOx, CO, and O2 on June 21, 2016. Maximum achievable load compliance consisted of three (20) twenty minute sampling events which were used to calculate the average for the emission values. These averages were then compared with the unit permitted limits to determine the performance status. **Based on the test results, unit S003 PASSED the Performance Test Audit**

Parameter	Measured	Permit	Status
Emission Load (% HP)	91.00	n/a	n/a
NOx (lb/hr)	26.82	53.10	PASS
NOx (TPY)	116.80	233	PASS
CO (lb/hr)	4.11	8.00	PASS
CO (TPY)	17.87	35	PASS

APPENDIX D – COST ANALYSIS CALCULATIONS

El Paso Natural Gas Company, LLC

Pecos River Compressor Station

Turbine Cost Analysis Interest Rate: 5.50%

All Units Period (yrs): 20

Control Equipment	Unit	SCR Capital Cost ($)	Building Modification ($)	Total Annual Cost* ($)	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Selective Catalytic Reduction (SCR)	A-01	3,802,798	2,500,000	656,640	36.0	18,252
	A-02	3,802,798	2,500,000	664,748	66.9	9,931
	A-03	3,802,798	2,500,000	662,707	61.0	10,858

* Total Annual Cost includes the annualized capital cost as well as the direct and indirect annual operating costs.

Unit A-01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new turbine or retrofit of an existing turbine?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.5

* NOTE: You must document why a retrofit factor of 1.5 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?[1,2]	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	298,551,855	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 4982.50/8760 hours/year = 298.55 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (tplant)	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR[2]	0.3338	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR[3]	0.1001	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})[4]	35103.70	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Permitted NO_x emission rate / permitted heat input (53.1 lb/hr / 61.8 Mmbtu/hr)

[3] Air Pollution Control Technology Fact Sheet, SCR, EPA-452/F-03-032; 70% efficiency

[4] Calculated based on the estimated actual annual fuel consumption and maximum heat input rate.

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Interest Rate (Percent)	5.5	Default bank prime rate	

Unit A-01: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	61.8	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year	
Actual Annual fuel consumption (Mactual) =		298,551,855	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.569	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	4981	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	14.44	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	35.96	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2,075,900	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	9,383.94	/hour	
Residence Time	1/V_{space}	0.00	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.50		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	221.22	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	2,162	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	2,487	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	49.9	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	19	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	900	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Unit A-01: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Turbines

For Oil and Natural Gas-Fired Utility turbines between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility turbines >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial turbines between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial turbines >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,802,798	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$126,370 in 2018 dollars
Indirect Annual Costs (IDAC) =	$321,150 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$447,521 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$19,014 in 2018 dollars
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$3,773 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$10,699 in 2018 dollars
Annual Catalyst Replacement Cost =		$5,284 in 2018 dollars
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	
Direct Annual Cost =		$126,370 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,856 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$318,294 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$321,150 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$447,521 per year in 2018 dollars
NOx Removed =	36.0 tons/year

Emissions Reduction:	66.9 tpy		
Cost Effectiveness:	**$ 9,931.02**	**$/ton**	

Unit A-02: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new turbine or retrofit of an existing turbine?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.5

* NOTE: You must document why a retrofit factor of 1.5 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?[1,2]	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	429,357,414	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 7165.5/8760 hours/year = 429.3 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days	Number of SCR reactor chambers (n_{scr})	1
Number of days the turbine operates (tplant)	365	days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR[2]	0.4319	lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR[3]	0.1296	lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050		Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
*The SRF value of 1.05 is a default value. User should enter actual value, if known.			Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours		
Estimated SCR equipment life	20	Years*	Gas temperature at the SCR inlet (T)	650 °F
* For industrial turbines, the typical equipment life is between 20 and 25 years.			Base case fuel gas volumetric flow rate factor (Q_{fuel})[4]	50483.81 ft^3/min-MMBtu/hour
Concentration of reagent as stored (C_{stored})	29	percent*		
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14	days		

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Permitted NO_x emission rate / permitted heat input (53.1 lb/hr / 61.8 Mmbtu/hr)

[3] Air Pollution Control Technology Fact Sheet, SCR, EPA-452/F-03-032; 70% efficiency

[4] Calculated based on the estimated actual annual fuel consumption and maximum heat input rate.

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit A-02: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year	
Actual Annual fuel consumption (Mactual) =		429,357,414	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.818	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7163	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	18.68	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	66.91	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2,985,421	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	13,066.96	/hour	
Residence Time	1/V_{space}	0.00	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.50		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	228.47	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	3,110	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	3,576	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	59.8	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	25	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,200	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Unit A-02: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Turbines

For Oil and Natural Gas-Fired Utility turbines between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility turbines >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial turbines between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial turbines >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,802,798	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$134,478 in 2018 dollars
Indirect Annual Costs (IDAC) =	$321,150 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$455,628 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$19,014 in 2018 dollars
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$7,019 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$15,387 in 2018 dollars
Annual Catalyst Replacement Cost =		$5,458 in 2018 dollars
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	
Direct Annual Cost =		$134,478 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,856 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$318,294 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$321,150 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$455,628 per year in 2018 dollars
NOx Removed =	66.9 tons/year
Cost Effectiveness =	$6,809.34 per ton of NOx removed in 2018 dollars

El Paso Natural Gas Company, LLC

Unit A-03: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new turbine or retrofit of an existing turbine?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.5

* NOTE: You must document why a retrofit factor of 1.5 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?[1,2]	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	389,585,454	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 6501.75/8760 hours/year = 389.6 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365 days	Number of SCR reactor chambers (n_{scr})	1
Number of days the turbine operates (tplant)	365 days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR[2]	0.4340 lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR[3]	0.1302 lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050	Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
*The SRF value of 1.05 is a default value. User should enter actual value, if known.		Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000 hours		
Estimated SCR equipment life	20 Years*	Gas temperature at the SCR inlet (T)	650 °F
* For industrial turbines, the typical equipment life is between 20 and 25 years.		Base case fuel gas volumetric flow rate factor (Q_{fuel})[4]	45807.42 ft^3/min-MMBtu/hour
Concentration of reagent as stored (C_{stored})	29 percent*		
Density of reagent as stored (ρ_{stored})	56 lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14 days		

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

Unit A-03: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year	
Actual Annual fuel consumption (Mactual) =		389,585,454	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.742	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6499	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	18.77	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	61.01	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2,708,877	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	11,848.48	/hour	
Residence Time	1/V_{space}	0.00	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.50

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	228.63	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	2,822	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	3,245	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	57.0	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	25	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,200	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Unit A-03: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Turbines

For Oil and Natural Gas-Fired Utility turbines between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility turbines >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial turbines between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial turbines >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,802,798	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$132,437 in 2018 dollars
Indirect Annual Costs (IDAC) =	$321,150 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$453,588 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$19,014 in 2018 dollars
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$6,400 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$13,962 in 2018 dollars
Annual Catalyst Replacement Cost =		$5,461 in 2018 dollars
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	
Direct Annual Cost =		$132,437 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,856 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$318,294 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$321,150 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$453,588 per year in 2018 dollars
NOx Removed =	61.0 tons/year

Santa Fe, NM 87505

RE: El Paso Natural Gas LLC - Pecos River Compressor Station
Regional Haze Four-factor Analysis December 23, 2019 Request for Additional Information

Dear Mr. Jones and Mr. Singleton:

This letter addresses the additional information request received on December 23, 2019 regarding the El Paso Natural Gas (EPNG) - Pecos River Compressor Station Four-Factor Analysis report. For the Pecos River Compressor Station there were a total of seven item requests pertaining to the assessment for the turbines, units A-01, A-02, and A-03. Please see the responses for each item request below.

1. *Provide details of the training curriculum and schedule for employees that ensure Good Combustion Practices utilized continue to be implemented at the plant. Clarify whether these best practices are fully optimized or conform to permit conditions alone.*

   Pecos River complies with the routine maintenance schedule pursuant to A205.B in Title V Permit No. P129R3. Pecos River complies with periodic testing pursuant to A205.A in order to monitor NO_X and CO emissions. Standard operating procedures and maintenance practices have been developed based on manufacturer's recommendations to keep the equipment in operating condition.

   Additionally, each employee has an Operator Qualification (OQ) Checklist that is completed and tracked in the OQ system. Operators are paired with other operators and work as trainees until they are deemed qualified on the piece of equipment and operation at the site. During the training period, they are exposed to station operations, responding to call outs with operators, station shutdowns, and purging and pressurizing stations. This training period lasts on average about one (1) year. Attached is a sample OQ qualification checklist used to track employee training (Attachment 1).

2. *Provide documentation of your communications with GE that supports the conclusion that Lean Head End Liner, improved combustion technology and water injection is not technically feasible for these units.*

   Please see Attachments 2 and 3. Per Thomas Hadden, Outage Performance Manager at GE/Baker Hughes, due to the age of the units (original construction in the 1950s), there was no technology that had been developed to improve emissions on the units. GE recommended either performing engineering studies in order to determine the potential emissions improvement for emissions, or upgrade the units from an A model to an F/J model in order to subsequently install emissions controls on the units.

3. *Provide the documentation to support El Paso Natural Gas's (EPNG's) cost estimates for building modifications required to install and house a SCR system.*

   The proposed cost was projected by the EPNG Engineering Department based on similar historical projects. The total estimated cost included mobilization, crane and other rental equipment, removal of existing equipment (including modifications to the building skin/roof), excavations and new foundations, backfill, and demobilization. No formal documentation was compiled to support this estimate.

4. *Please expand on the difficulties that may result due to the age of equipment and the availability of control equipment that led to using a retrofit difficulty factor of 1.5.*

   Based on conversations with the manufacturer, there appears to have been minimal market demand for control technology for these older model turbines. The 1.5 difficulty factor is used because it is anticipated that the project would require an engineering study prior to supply of the control, in addition to physical adjustments to the unit to accommodate the installation. The manufacturer has not been available to support this assessment, however. Therefore, the cost of compliance calculations have been update to utilize the default 1.0 difficulty factor. The updated cost of compliance for each unit is shown below.

Unit	Cost Effectiveness ($/ton)
A-01	24,607.04
A-02	9,491.17
A-03	9,974.19

5. *Provide a discussion regarding the varying operating hours across the three units and compare 2016 operating hours to the unit's five year average (i.e., 2014-2018) to evaluate if this is a representative scenario for estimating cost of compliance.*

   The varying operating hours across the three units and five years is due to fluctuations in production and market demand. Hours of operation are certificated by the U.S. Federal Energy Regulatory Commission (FERC) to ensure effective operation of the facility to meet customer demands. EPNG must maintain the permitted loads and operating hours for the units in order to effectively operate and satisfy supply contracts in place.

   The operating hours for each unit from 2014 to 2018 are shown below.

Operating Hours Per Year			
Yr/Unit	A-01	A-02	A-03
2014	6,920.92	5,983.92	7126.67
2015	5,602.33	4,018.83	5585.25
2016	4,982.50	7,165.50	6501.75
2017	754.75	7,916.25	7693.25
2018	5,323.25	3,813.75	5,031.50

Based on guidance received from the NMED in email correspondence on September 13, 2019, the original Four Factor Analysis was submitted using actual emissions from 2016 as a representative year for emissions and utilization for units A-01, A-02, and A-03.

As discussed with Mark Jones of the NMED on February 12, 2020 (Attachment 4), EPNG used an averaged 2016-2018 utilization and emissions to estimate cost effectiveness of various control technologies instead using 2016 as a sample year. Accordingly, EPNG hereby provides updated cost estimates based on the updated 2016-2018 average. Taking an average same over three years is more representative than a single year because unit utilization can be

6. *Provide a discussion explaining the difference between the emissions used to calculate costs (i.e., 2016 stack test data and operating hours) and the actual emissions reported to the department in 2016. The cost calculations use NOX emissions of 51.39 tons/year (tpy), 95.62 tpy, and 87.19 tpy whereas NOx emission were reported to NMED as 132.29 tpy, 190.24 tpy, and 172.62 tpy.*

   The cost estimates provided with the four-factor analysis are estimated based on the actual NO_x emissions from each unit assessed here, calculated using the June 2016 stack test data provided for each unit and the actual hours of operation from the 2016 Emission Inventory submittal for Pecos River.

   The NO_x emissions reported to the department in the 2016 Annual Emission Inventory submittal were calculated based on the permitted emission rate of the units. 2016 Annual Emission Inventory emissions appear to have been overestimated, based on the stack test data available.

   Subsequently, with the decision to use the 2016-2018 average for cost estimation analysis, the emissions calculations used from 2017 and 2018 were also updated based on stack test data rather than PTE emissions factors.

7. *Provide the electronic spreadsheets used for control technology cost calculations and annual energy consumption.*

   The electronic spreadsheet is attached (Attachment 5).

If you have any other questions, please do not hesitate to reach me at 713-420-1841 or via email at Zainab_Naqvi@kindermorgan.com.

Sincerely,

Zainab Naqvi

COVERED TASK ASSIGNMENTS - GAS
Revised 3/23/2017

Employee Name:	EE Number:	Date:
Supervisor's Name:	Region/Location:	
Date Discussed with Employee:	***Supervisor's Signature***	

Submit this form with assigned covered tasks checked in the *Yes* column to your Regional OQ Coordinator.

CT #	Covered Task Title	Yes
01.01.01	Abnormal Operating Conditions	☐
02.01.01	Gas Detection & Alarm System Maintenance & Performance Test	☐
02.02.01	Isolation of Compressor Units	☐
02.03.01	Compressor Station Inspection & Testing of Remote Control Shutdown Devices	☐
03.01.01	Operating Compressor Units: Remote	☐
03.01.02	Operating Compressor Units: Manual	☐
03.02.01	Shutting Down Compressor Units: Remote	☐
03.02.02	Shutting Down Compressor Units: Manual	☐
03.03.01	Starting Compressor Units: Remote	☐
03.03.02	Starting Compressor Units: Manual	☐
04.01.01	Measure Damage on Installed Pipe and Components	☐
04.01.02	Corrosion Monitoring – Atmospheric, External, and Internal: Offshore Pipelines	☐
04.01.03	Visual Inspection of Buried Pipe and Components When Exposed	☐
04.01.04	Visual Inspection of Internal Surface of Pipe	☐
04.01.05	Visual Inspection for External/Atmospheric Corrosion (effective 6/30/17)	☐
04.01.06	Insert and Remove Coupons/Probes for Internal Corrosion Monitoring	☐
04.01.07	Nondestructive Testing – Magnetic Particle Testing of Pipe	☐
04.02.01	Coating Maintenance /Application and Repair – Sprayed, Brushed, or Rolled	☐
04.02.02	Coating Maintenance/Repair – Wrapped	☐

CT #	Covered Task Title	Yes
05.01.01	Cathodic Protection System Maintenance: Rectifiers	☐
05.01.02	Cathodic Protection System Maintenance: Electrical Isolation	☐
05.01.03	Cathodic Protection System Maintenance: Anodes, Anode Ground Beds, & AC Voltage Mitigation (task name change)	☐
05.01.04	Inspect or Test Cathodic Protection Bonds (task name change)	☐
05.01.05	Cathodic Protection System Maintenance: Reverse Current Switches	☐
05.01.06	Cathodic Protection System Maintenance: Automatic Potential Controlled Protection Systems	☐
05.01.07	Cathodic Protection System Maintenance: AC Voltage Mitigation System	☐
05.01.08	Cathodic Protection: Read Rectifier (effective 5/1/17)	☐
05.02.01	Cathodic Protection Systems – Electrical Connections	☐

Subject: RE: EXT: Kinder Morgan GE Frame 3

[This email message was received from the Internet and came from outside of Kinder Morgan]

Zainab, The 3 units at Pecos are Model A's. There is no modification available to this model to help with emissions due to age of the equipment (1950's era)

The LHE liner, water/steam injection, advanced tech upgrades would all require engineering studies before being able to provide any technical information for the Model A's.

SCR's have never been part of our scope of supply so I wouldn't be able to provide any technical information that would help with that.

I'll be at the KM offices this afternoon for a meeting at 1:00. Would you be available around 2:00 to talk?

Thanks,
Tom

Subject: RE: EXT: Kinder Morgan GE Frame 3

Also,

I should clarify, I know Christine reached out to you regarding some Model A's, but the units that I'm referring to are Model #M3712R, Serial #s 95025, 95053, and 95055. I'm not sure if based on the "F3 History" classification, they still fall under the A model umbrella or another one, and how that might change some of the questions below.

Thanks,
-Zainab

Subject: RE: EXT: Kinder Morgan GE Frame 3

Tom,

Tomorrow is fine if we want to have a conversation, but I'll detail what I'm looking for below, since there's a chance it might take some time to put together.

In short, the state of New Mexico is requiring a BACT analysis on the NOX emissions from the three GE Frame 3 turbines that are located in Pecos River as a part of the Regional Haze improvement goals they are hoping to meet. I read through the emails between you and Jonathan and Christine, and was hoping to get the following questions answered:

1. Jonathan mentioned a water/steam injection as being a potential modification on turbines but stated that it was not available for this vintage of machine. Can you provide some more technical information on what that entails, and why it's not an option (due to size, age, configuration, etc)?

2. Would it be possible to get a more technical understanding of why the LHE liner installation, DLN retrofit, LT12 module are infeasible? For the LHE liner, have these been implemented elsewhere, or would we be the trial run for the modification (you mentioned an engineering study)? For the DLN upgrades, you stated that the F3 F model would be replaced with the F3 J model. If our units are A models, what would it take to even get from an A to an F, and then subsequently to a J? Are we essentially saying complete or near-complete replacement of the units? Same question for the LT12 – would we need an entirely new unit in order to install the LT12 module?

3. I'm not sure if it's been discussed, but would the installation of an SCR be possible on these units? From everything I've seen regarding these units, it looks like the SCR is the only potential option short of unit replacement, unless it's technically infeasible. If this is the case, can you explain why it is technically infeasible (are temperatures too low for catalyst, are the units too vintage or untested with catalyst, would an engineering study need to be done to determine if a catalyst would work, what's the time and cost associated with such a study)? If an SCR was possible, what would the timing/cost look like for an SCR installation? Have other older GE turbines been retrofit with SCR tech to reduce NOx? What would the operational limitations be?

I understand that this is an expedited request, but I'd like to have to have these answers as soon as available but by Thursday COB if possible. The report is due to the NMED by November 1.

Feel free to give me a call if you guys want to talk through the questions.
Thanks,
-Zainab

Zainab, I'll be back in the office Thursday will that be ok? I have copied Gary to this response he would be able to provide answers as well.

Attachment 4

From: Jones, Mark, NMENV
To: Naqvi, Zainab
Subject: Discussion on submittal and 2016-2018 today
Date: Wednesday, February 12, 2020 11:12:40 AM
Importance: High

[This email message was received from the Internet and came from outside of Kinder Morgan]

Hi Zainab,

Thanks for your call today. For most of the four-factor facilities we are using the 2016-2018 average emissions from future 2028 baseyear estimate for modeling. For your facilities we added a 5% utilization increase to the 2016-2018 averages for the 2028 baseyear. Since costs will be assessed on the future projection; If you are able to, please add the 5% utilization rates to the 2016-2018 averages when you assess costs in your submittal.

We just added a 5% increase across the board to all the emissions categories for the El Paso four-factor facilities.

It should not make a huge difference so if you have already done 2016-2018, that will work and we can adjust for the 5% increase In the next step of the process.

Let me know if you need clarification. I'll be around all day.
Thanks,
Mark

Unit A-01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?[1,2]	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	220,915,390	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 4982.50/8760 hours/year = 298.55 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (tplant)	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR[2]	0.2751	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR[3]	0.0825	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})[4]	25975.21	ft³/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft³
29.4% aqueous NH_3	56 lbs/ft³

Select the reagent used: Ammonia

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Permitted NO_x emission rate / permitted heat input (53.1 lb/hr / 61.8 Mmbtu/hr)

[3] Air Pollution Control Technology Fact Sheet, SCR, EPA-452/F-03-032; 70% efficiency

[4] Calculated based on the estimated actual annual fuel consumption and maximum heat input rate.

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit A-01: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	61.8	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year
Actual Annual fuel consumption (Mactual) =		220,915,390	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	0.82	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.421	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	3685	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.90	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	21.93	tons/year
NO_x removal factor (NRF) =	EF/80 =	0.88	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	1,536,075	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	7,082.81	/hour
Residence Time	1/V_{space}	0.00	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia
Retrofit Factor (RF)	Retrofit to existing turbine	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	216.87	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	1,600	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	1,840	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	42.9	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	16	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Unit A-01: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Turbines

For Oil and Natural Gas-Fired Utility turbines between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility turbines >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial turbines between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial turbines >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,535,199	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$115,674	in 2018 dollars
Indirect Annual Costs (IDAC) =	$214,976	in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$330,650	in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,676	in 2018 dollars
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600	in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$2,300	in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$7,917	in 2018 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$5,181	in 2018 dollars
Direct Annual Cost =		$115,674	in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,780	in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$212,196	in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$214,976	in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$330,650	per year in 2018 dollars
NOx Removed =	21.9	tons/year

Is the combustion unit a utility or industrial turbine? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?[1,2]	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	377,406,695	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 7165.5/8760 hours/year = 429.3 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (tplant)	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR[2]	0.4249	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR[3]	0.1275	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})[4]	44375.44	ft³/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft³
29.4% aqueous NH_3	56 lbs/ft³

Select the reagent used: Ammonia

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Permitted NO_x emission rate / permitted heat input (53.1 lb/hr / 61.8 Mmbtu/hr)

[3] Air Pollution Control Technology Fact Sheet, SCR, EPA-452/F-03-032; 70% efficiency

[4] Calculated based on the estimated actual annual fuel consumption and maximum heat input rate.

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676	$/kWh			* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit A-02: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year
Actual Annual fuel consumption (Mactual) =		377,406,695	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	0.82	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.719	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6296	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	18.38	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	57.87	tons/year
NO_x removal factor (NRF) =	EF/80 =	0.88	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2,624,195	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	11,511.83	/hour
Residence Time	1/V_{space}	0.00	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia
Retrofit Factor (RF)	Retrofit to existing turbine	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	227.96	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	2,734	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	3,144	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	56.1	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	25	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Unit A-02: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Turbines

For Oil and Natural Gas-Fired Utility turbines between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility turbines >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial turbines between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial turbines >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,535,199	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$125,317	in 2018 dollars
Indirect Annual Costs (IDAC) =	$214,976	in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$340,293	in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,676	in 2018 dollars
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600	in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$6,071	in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$13,525	in 2018 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$5,445	in 2018 dollars
Direct Annual Cost =		$125,317	in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,780	in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$212,196	in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$214,976	in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$340,293	per year in 2018 dollars
NOx Removed =	57.9	tons/year
Cost Effectiveness =	$5,880.46	per ton of NOx removed in 2018 dollars

Unit A-03: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new turbine or retrofit of an existing turbine? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]	61.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?[1,2]	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	384,017,879	scf/Year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	2900	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 6501.75/8760 hours/year = 389.6 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the turbine operates (tplant)	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR[2]	0.3973	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR[3]	0.1192	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})[4]	45152.79	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	225.91	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	2,781	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	3,199	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	56.6	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	23	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,100	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Unit A-03: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Turbines

For Oil and Natural Gas-Fired Utility turbines between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility turbines >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial turbines between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial turbines >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial turbines >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,535,199	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$125,210	in 2018 dollars
Indirect Annual Costs (IDAC) =	$214,976	in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$340,187	in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,676	in 2018 dollars
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600	in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$5,776	in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$13,762	in 2018 dollars
Annual Catalyst Replacement Cost =		$5,397	in 2018 dollars
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$		
Direct Annual Cost =		$125,210	in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,780	in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$212,196	in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$214,976	in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$340,187	per year in 2018 dollars
NOx Removed =	55.1	tons/year

NMED Final Cost Evaluation
El Paso Natural Gas Company - Washington Ranch Storage Facility

Facility Information	
EPNG - Washington Ranch Storage Facility	**Facility**
Two 1980s vintage 2SLB RICE, 4,500 HP	**Units**
1 and 2	**Unit IDs**
LEC	**Evaluated Pollution Control**
0.5	**Target Emissions Rate (g NOx/bhp-hr)**

According to EPNG, units 1 and 2 already utilize LEC; they are equipped with a turbocharger, advanced ignition system, pre-combustion chambers (PCC) system, high pressure fuel injection, and an automatic balancing platform. Based on vendor information provided by EPNG, LEC can achieve a NOx emissions rate as low as 0.5 g/hp-hr - consistent with information provided by other facilities for Cooper-Bessemer RICE. Results from recent emissions testing indicate the current NOx emission rate from these units is already 0.5 and 0.8 g/hp-hr, respectively. Therefore, an evaluation of LEC is not appropriate or necessary.

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*
>
> The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed El Paso Natural Gas Company LLC (EPNG) that its Washington Ranch Storage (Washington Ranch) facility

was identified as one of the sources contributing to regional haze at the Carlsbad Caverns National Park Class I area.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to EPNG, it specifies that any single piece of equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and/or 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at Washington Ranch as listed in TV Permit P064-R3, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability of the Four-Factor Analysis

Equipment	NO_X PTE (lb/hr)	NO_X PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 PTE (lb/hr)	SO_2 PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Cooper-Bessemer / 12Q155HC2 2SLB RICE Unit A-01	27.3	119.5	Yes	0.48	2.1	No
Cooper-Bessemer / 12Q155HC2 2SLB RICE Unit B-02	27.3	119.5	Yes	0.48	2.1	No

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED,[1] this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. A summary of identified available retrofit controls along with a technical feasibility assessment for each control is provided in Section 2. The four-factor analysis is then conducted for those controls that are technically feasible.

2. BACKGROUND INFORMATION & TECHNICAL FEASIBILITY

2.1. TWO-STROKE LEAN-BURN ENGINES

Washington Ranch has two (2) natural gas-fired two-stroke lean-burn (2SLB) reciprocating internal combustion engines (RICE), Units A-01 and B-02, that are subject to this four-factor analysis. The only pollutant subject to evaluation for these units is NO_X.

2.1.1. Two-Stroke Lean-Burn Engines Background

Natural gas-fired RICE are separated into multiple design classes, including 2SLB, 4-stroke lean-burn (4SLB), and 4-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1) with exhaust oxygen levels less than 4 %, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12 % or more.[2]

NO_X is formed in reciprocating engines via three mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Washington Ranch engines use natural gas fuel, which contains a negligible amount of nitrogen compounds. Therefore, the formation of prompt and fuel NO_X will be insignificant. This analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[3]

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:

(1) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.
(2) Combustion control techniques, for example reducing the peak flame temperature by introducing inerts that limit initial NO_X formation.
(3) Operational control methods, such as adjusting the timing or other operating parameters.

The PTE from each engine is reported in the facility's Title V permit P064-R3, as well as above in Table 1.

[2] "Emission Control Technology for Stationary Internal Combustion Engines," Manufacturers of Emission Controls Association, 2015
[3] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"

2.1.2. Potential NO_X Controls for 2SLB Engines

Retrofit control options identified for 2SLB RICE were identified via comprehensive review of the RBLC and available technical literature and are summarized in Table 2. A detailed description and discussion of the technical feasibility and anticipated performance of each control is provided below.

Table 2. Potential Control Options for 2SLB RICE

Control Equipment	Technically Feasible	NO_X Control Efficiency
Selective Catalytic Reduction	**No**	**N/A**
Clean Burn Technology	**Yes**	**27% - 82%**
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**

2.1.2.1. Selective Catalytic Reduction

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[4] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic controls to accurately meter the quantity of reagent injected as a function of engine load, speed, temperature, and NOx emissions to be achieved. The lifespan of the catalyst is primarily determined by the erosion caused by the flue gas, deactivation caused by ammonium bisulfate (NH_4HSO_4) poisoning, as well as the build-up and fouling by the catalyst.

The characteristic exhaust temperature for 2SLB engines shows higher excess O_2 in the exhaust stack. For 2SLB engines, with typical exhaust O_2 from 14 to 16% (depending on make, model and operating condition), typical exhaust temperature is in the range of 450 to 600°F. Exhaust temperature is a critical design parameter for SCR performance, and accordingly, the catalyst material is selected based on the design temperature of the exhaust. Based on current technology and practices, SCR's optimal exhaust temperature is between 450 and 850°F range. Therefore, SCR's use as a control technology is limited to sources where the exhaust temperature is within that range.

A catalyst may perform at temperatures below 450°F, however complications such as reagent decomposition, reagent slip, catalyst contamination due to unreacted reagent (salt formation), etc. may arise. Catalysts may perform at lower temperatures (e.g., 450°F or lower), but other complications can arise at lower temperature (e.g., urea decomposition, competing reactions that form nitrates). Temperatures below the desired range reduce the reduction efficiency – i.e., increase NO_X and ammonia emissions.

[4] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

At higher temperatures, ammonia may "slip," meaning that a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. Unreacted reagent in the exhaust can form ammonium sulfates, which may plug or corrode downstream equipment, and/or catalyst damage may occur. Streams carrying large amounts of ammonium sulfates may blind the catalyst and may necessitate the application of a soot blower.

When compared to the typical 450 – 600°F temperature range for 2SLB engines, no single catalyst material offers high, stable performance across that range. Thus, even if other SCR technical issues (e.g., associated with reagent control) are addressed, current catalysts are not adequate to ensure stable, high-level performance for 2SLB engines.

In addition to the temperature issues, use of an aqueous reagent is common for engine applications. The water associated with aqueous urea (or ammonia) injection for an engine with higher NO_X emissions (e.g., NO_X is not controlled) could decrease exhaust temperature by 5 to 20 °F. This further complicates system engineering and catalyst material requirements.

For engines that typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia injection to gain the reductions needed.[5] In the case of Washington Ranch, the two engines run at ongoing variable loads.

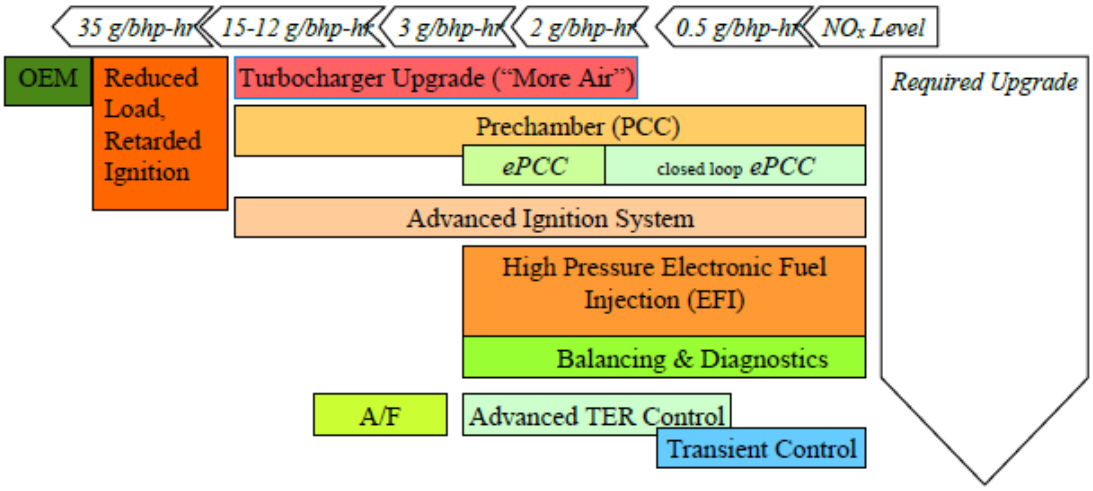
Finally, there has been no application of SCR on this model of Cooper engines (see attached RBLC results). A thorough twenty-year review of the RBLC tables was conducted and there were no examples of an SCR being used as a control for 2SLB engines. The lack of availability or comparable use of an SCR on these Cooper engines presents the case that this control technology is considered technically infeasible. Consequently, SCR is not evaluated further in this four-factor analysis.

2.1.2.2. Clean Burn Technology

Clean Burn Technology (CBT) is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding or enhancing an air-to-fuel ratio controller, making the unit capable of operating at optimal air-to-fuel ratios.

As described in Section 2.1.1 of this report, rich-burn engines are normally designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio of 16:1, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1). A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. 2SLB engines are typically designed to operate at the high air-to-fuel ratios employed in CBT; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease the NO_X emissions.[6]

In order to avoid derating the engine (which can result in lower engine efficiency), combustion air must be increased at constant fuel flow. To achieve this, the engine will need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel ratio controller.



[5] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[6] State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines, State of New Jersey Department of Environmental Protection, 2003.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high-energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[7]

2SLB engines are mechanically capable of being retrofitted with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NO_X emissions. Therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Washington Ranch. Air-to-fuel ratio adjustment generally achieves a 5 to 30% reduction in NO_X emissions; however, this reduction is very specific to each engine and typical loading[8].

EPNG employs Hoerbiger as a vendor for units A-01 and B-02. Hoerbiger utilizes the "Layered Approach Strategy" (Figure 1) to efficiently run the units at Washington Ranch. The two units at Washington Ranch are currently equipped with a turbocharger, advanced ignition system, Pre-Combustion Chambers (PCC) System, High Pressure Fuel Injection, and an Automatic Balancing Platform. Based on manufacturer guidance, the addition of these clean burn technologies allows the engines to range from 2.75 to 0.5 g/hp-hr, which allows for a 27% to 82% reduction in NO_X emissions; thus, no further assessment of these control practices is included in this report.

Figure 3. Hoerbiger's Layered Approach Strategy for Clean Burn Technologies

2.1.2.3. Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

[7] Ibid
[8] Ibid

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from large natural gas-fired lean-burn stationary internal combustion engines; therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Washington Ranch. EPNG has developed Reciprocating Mechanical Inspection and Maintenance Best Practices procedures, which are based on manufacturer recommendation, and EPNG has systems in place to ensure that the engines are operated in accordance with this at Washington Ranch. No further assessment of these control practices is included in this report.

3. SUMMARY & CONCLUSIONS

Based on a comprehensive review of the RBLC, available literature, and vendor input of available control technologies for the natural gas fired engines located at Washington Ranch, EPNG has determined that clean burn technology and good combustion practices are the only technically feasible control options for the two units. As EPNG already deploys these control technologies, there are no further factors to evaluate.

4. SUPPORTING DOCUMENTATION

Appendix A – RBLC Tables

Appendix B – EPNG Best Practices Procedures

APPENDIX A – RBLC TABLES

RBLC Analysis for Natural Gas-Fired Lean-Burn Stationary Internal Combustion Engines – NO_x

	Control Technology	Selective Catalytic Reduction (SCR) [a,b]	Non-Selective Catalytic Reduction (NSCR) [b]	Clean Burn Technology	Good Combustion Practices and Fuel Selection [c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_x to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.	This technique uses residual hydrocarbons and CO in rich-burn engine exhaust as a reducing agent for NO_x. In an NSCR, hydrocarbons and CO are oxidized by O_2 and NO_x. The excess hydrocarbons, CO, and NO_x pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_x to N_2.[b]	Natural gas fueled engines that operate with a fuel-lean air/fuel ratio are capable of low NO_x emissions.	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.
	Other Considerations	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.	N/A	N/A	N/A
ELIMINATE TECHNICALLY INFEASIBLE OPTIONS	RBLC Database Information	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.
	Feasibility Discussion	Technically infeasible. For engines which typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed.	Technically infeasible. The NSCR technique is limited to engines with normal exhaust oxygen levels of 4 percent or less. This includes 4-stroke rich-burn naturally aspirated engines and some 4-stroke rich-burn turbocharged engines. Lean-burn engines could not be retrofitted with NSCR control because of the reduced exhaust temperatures.	Technically feasible.	Technically feasible.

1. Scope

1.1. General

Historically, some "Best Practices" documents were developed to cover specific regions, pipelines, or other limited-scope situations. While such documents may not agree with all provisions of Company Operating and Maintenance (O&M) Procedures, they contain vital information and considerations that may prove useful to many users.

Best Practices documents are intended to *complement* Company O&M Procedures. As such, this procedure provides *recommendations* and *guidance* to supplement the Company and Code Requirements defined within O&M Procedures, Engineering Standards, and other Company Compliance Documents.

In all applications, Company O&M Procedures and Engineering Standards shall prevail as Company Requirements.

1.2. Reciprocating Mechanical Inspection/Maintenance - Low Speed

A Mechanical Inspection aids in evaluating an engine's condition, promoting high reliability and reduced maintenance costs.

2. Recommendations

A) A periodic Mechanical Inspection should be completed on each reciprocating engine and compressor. The Mechanical Inspection consists of a visual crankcase inspection, web deflection, bearing clearance checks, and distance piece/doghouse inspections.

B) The inspection interval for each inspection item is listed in Table A (below).

C) The inspection interval is to be developed by Operations, in consultation with the Field Engineer and the Mechanical Project Support Teams.

D) The inspection interval will consider engine type, utilization, condition, etc for each particular engine.

E) Also listed in Table A (below) is the maximum inspection interval in hours or months, whichever occurs first. Note that inspections may be performed more frequently than the values shown in Table A.

For additional technical reference on Bearing Inspection Procedures, Failure Modes, and checking Bearing Clearances, refer to **Attachment 1 - Technical References**, at the end of this document.

Inspection Items	Inspection Interval	Maximum Hours	Maximum Months
Crankcase Inspection	TBD	16,000	48
Crankshaft Deflection	TBD	16000	48
Bearing Clearances	TBD	16000	48
Bearing Inspection	TBD	As required	As required
Distance Piece/Doghouse	TBD	16000	48

Table A – Inspection Intervals

3. Procedure

All elements of the Mechanical Inspection should be performed. For additional technical reference on Bearing Inspection Procedures, Failure Modes, and checking Bearing Clearances, refer to Attachment 1 - Technical References, at the end of this document.

A) Crankcase Visual Inspection

1) Anytime a crankcase door is removed from an engine, that part of the crankcase should be inspected. In addition, the crankcase of each engine should be drained periodically and carefully inspected.

2) Thoroughly inspect the inside of the crankcase for any foreign matter such as babbitt, bronze dust, or iron filings which are the indicators of bearing or gear failures, piston and cylinder wear, etc.

3) When each door is removed, its crankcase side should be inspected for foreign material thrown there by the centrifugal force of the connecting rod.

4) The walls and bottom of the crankcase should always be carefully checked for metal particles.

5) Each main bearing cap and connecting rod cap should be checked for discoloration caused by over-heated bearings. The entire crankcase should be observed for any blue discoloration, and if any is found, a thorough investigation and dimensional check should be made.

6) All lubricating oil lines and fittings, such as those from the lube oil header to each main bearing, should be checked for integrity.

7) On units with pre-lube pumps, run the pump and visually check the oil from each side of the main bearings to determine if there is an abnormal oil flow.

8) Bolts, nuts, and studs require a complete inspection for tightness. Where it is not possible to use a wrench on a nut or bolt to check for tightness because cotter pins and wires are used for locking devices, a small hammer can be used to tap each bolt.

9) Review recent oil analysis reports and check the general condition of the oil by looking for lacquer formations on machined surfaces or deposits of sludge.

10) Each piston should be moved to top dead center and as much of the liner as possible checked for scuff or score marks. The piston should then be moved to bottom center and the piston skirt inspected for score marks and loss of piston plating.

B) Bearing Clearances

1) Bearing clearances are to be checked during the Mechanical Inspection of the engine, recorded on the Mechanical Inspection form and will become part of the permanent records of the engine.

C) Crankshaft Deflections

2) At the recommended inspection interval, web deflection readings are to be taken on each throw of the crankshaft.

3) Deflection readings are to be recorded on the Mechanical Inspection form and will become part of the permanent records of the engine.

D) Visual Inspection of Bearings

1) Bearings will be pulled and visually inspected when indications of bearing wear are noted (excessive bearing clearances).

E) Distance Piece/Doghouse Inspections

1) Collect the required measurements per the Mechanical Inspection Form

F) Mainframe Movement Checks

1) Prior to shutting down the unit for Mechanical Inspection, ensure that a Engineer Technician has performed a mainframe movement check. (Refer to **Best Practices COMP103-1 - Engine Maintenance Analysis**)

4. Documentation

Some Pipelines and related Field Staff use one or more of the following:

- MAXIMO as an activities scheduling utility
- COMET for Compressor Data tracking

Until such time as these systems (MAXIMO, COMET, etc.) are superseded, the following information is provided for user reference:

MAXIMO PM

- Mechanical Inspection - Varies but NTE 48 months or 16,000 hours operated.

Mechanical Inspection Forms Workbook (COMP-2007)

- Retention - Life of Equipment
- Retention Location - Site

5. References

- **COMP-2007 Mechanical Inspection Forms Workbook.xlsx**
- **Environmental, Health, and Safety Policy Manual**
- **O&M Procedures Manual**

Attachment 1 - Technical References

Bearing Inspection Procedure and Explanation

One cause of bearing failure is improper clearance between the bearings and the journal. Bearings are designed to run on a film of oil and will not normally come in contact with the journal when in operation. The flow of oil through the bearing dissipates the heat generated in the bearing, and too little or too much clearance between the bearing and journal upsets this balance of oil flow, heat dissipation, and temperature rise.

In the case of too little clearance, the oil film can 'thin out', allowing contact between the journal and bearing. Too much clearance allows the oil to escape from the bearing, allowing excessive impact to be transmitted into the bearing. This causes excessive wear or allows other bearings to become over-heated, because they are starved of oil.

Bearing failure can result in:

- Scored crankshaft
- Bent or destroyed shaft from excessive heat
- Heat checks in shaft
- Out-of-round journal
- Warped or distorted bearing support and bearing cap
- Destroyed connecting rod

Three acceptable methods for checking bearing clearances:

The feeler-gauge method consists of inserting a feeler gauge into the space between the shaft and the bearings. Vary the thickness until a thickness equal to the clearance is achieved. When the engine is shut down, the crankshaft should be resting on the bearing supports. It is important to determine this. A .0015-inch feeler gauge can be used to make this determination.

The Plastigage method requires that the bearing cap and one-half shell be removed. The Plastigage is then placed on the shaft. The bearing shell and cap are replaced and tightened. The Plastigage is squeezed into conformation with the clearance. When it is removed, its thickness may be measured, indicating the clearance. Soft fuse wire may be used instead of the Plastigage. Make sure that it is softer than the bearing material.

The Jack method consists of attaching a dial indicator to the frame of the engine with the button placed against the shaft. Place a jack under the shaft and jack up on the shaft; the clearance is measured on the dial indicator. Use skids or a metal plate to ensure that the load from the jack is distributed across the oil pan if necessary. On main bearings, it is necessary to make sure that the shaft is resting on the lower bearing shell. The jack should be placed on top of the shaft first, and pressure exerted on the shaft to determine if there is any downward movement that would be an indication the bearing is being bridged by the shaft. If a bridged bearing is detected, notify a Field Engineer immediately.

Any or all of these methods may be used. Each requires skill and practice to get repeatable readings. The manufacturer's instruction book should be checked for recommendations.

Any program of bearing inspection and maintenance should be designed to minimize the catastrophic results of bearing failure. Evidence that indicates possible failure may be any of the following:

- Excessive clearance
- Clearance closed up
- Loss of crush
- Bearing material particles in the crankcase or oil filter
- Bearing protective device shuts the engine down
- Discoloration of the bearing or bearing cap

Some general rules for bearing inspection:

Connecting Rod Bearings

On most engines, the connecting rod bearings must be removed to pull pistons. They should receive a close visual inspection at this time

They should be removed and inspected when visual evidence indicates possible failure.

If experience indicates that specific bearings require inspection after a certain length of time, they should be pulled and inspected.

Main Bearings

Main bearings should be removed and inspected when any evidence indicates possible failure.

RE: El Paso Natural Gas LLC – Washington Ranch Storage Facility
Regional Haze Four-factor Analysis December 23, 2019 Request for Additional Information

Dear Mr. Jones and Mr. Singleton:

This letter addresses the additional information request for the El Paso Natural Gas Company, L.L.C. (EPNG) – Washington Ranch Storage Facility Four-Factor Analysis report received on December 23, 2019. For the Washington Ranch Storage Facility there were a total of seven item requests pertaining to the NO_X emissions for both engines. Please see the responses for each item request below.

1. *Consider Good Combustion Practices (GCP) and routine maintenance as controls and provide the details of a maintenance schedule, employee training and operating procedures used to achieve emissions reductions.*

   Washington Ranch complies with the routine maintenance schedule pursuant to A201.A in NSR Permit No. 0428M7. Washington Ranch complies with periodic testing pursuant to A201.B in order to monitor NO_X, CO, and VOC emissions. Standard operating procedures and maintenance practices have been developed based on manufacturer's recommendations to keep the equipment in operating condition.

   Additionally, each employee has an Operator Qualification (OQ) Checklist that is completed and tracked in the OQ system. Operators are paired with other operators and work as trainees until they are deemed qualified on the piece of equipment and operation at the site. During the training period, they are exposed to station operations, responding to call outs with operators, station shutdowns, and purging and pressurizing stations. This training period lasts on average about one (1) year. Attached is a sample OQ qualification checklist used to track employee training (Attachment 1).

2. *Consider and include a discussion on the feasibility and cost of technology that limits engine capacity to reduce NOX emissions. Also evaluate limitations on engine operating hours or shutting down engines that are no longer needed to reduce total NOX emissions.*

   As the two units at Washington Ranch are two-stroke lean burn engines (2SLB), the technology for reducing NO_X emissions are limited.

   EPNG, being a transmission pipeline is also regulated by the Federal Energy Regulatory Commission (FERC). Hours of operation and facility horsepower are certificated by FERC to ensure effective operation of the facility to meet customer demands. EPNG must maintain the permitted loads and operating hours for the units in order to effectively operate and satisfy supply contracts in place. Accordingly, any operational restrictions could have the potential to

significantly disrupt gas supply in the area. Consideration of limiting capacity or operating hours will result in violation of EPNG's FERC commitment and will result in potential contract breach (with associated financial penalty), re-negotiating long-term contracts, and re-applying for a FERC certification.

3. *Consider and include a discussion of variations of Clean Burn Technology (CBT) used to reduce NOX emissions that may be more effective than the existing package if available. Please include cost and efficiencies in analysis. Show documentation of vendor quotes with cost and control efficiency.*

   As noted in the report submitted November 1, 2019, the engines are currently equipped with the most recent available control technologies. Research indicates that there are no additional control technology available for this type 2 SLB engines at Washington Ranch. The Clean Burn Technologies currently installed on the two units include a turbocharger, advanced ignition system, Pre-Combustion Chambers System, High Pressure Fuel Injection, and an Automatic Balancing Platform. The engines are currently permitted at 2.75 gr/bhp-hr. EPNG has determined that no other package is currently available for this type of equipment at this time.

4. *Please verify and provide documentation that control systems have not yet been developed for selective catalytic reduction (SCR) controls that can handle variable load engines. This appears to be one main reason that SCR has not been implemented on two-stroke lean burn (2SLB) internal combustion engines in oil and gas midstream operations.*

   U.S. EPA, Ap-42, Section 3.2 "Natural Gas-Fired Reciprocating Engines" currently states:

   > "For engines which typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed."

   As noted in the November Four Factor Analysis, a 20-year review of the RBLC found that no 2SLB engines had used SCR as a control technology. Therefore, EPNG cannot comment on whether an SCR has been developed for 2SLB engines.

5. *Please consider and include a discussion on the feasibility of replacing natural gas-fueled engines/turbines with commercial electric powered compressors.*

   EPNG conducted a review of the feasibility of replacing natural gas-fueled engines with commercial electric powered compressors. Although a complete four-factor analysis has not been conducted, an estimated cost summary was developed for the potential scope and has been included as Attachment 2.

   Although this project is technically feasible, it is cost prohibitive. Additionally, given the life of the existing units and the fact that there is no current plans to replace them, a unit replacement is considered outside the scope of the Regional Haze Rule four factor analysis. Per Appendix Y to Part 51—Guidelines for BART Determinations Under the Regional Haze Rule Section IV.D.1.5:

   > "We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-

fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis."

This report is essentially a BART analysis with only 4 factors which are reviewed. EPNG will only submit alternative control options and will not assess replacing equipment.

6. *Provide vendor specifications that include the cost information, recommendations, and equipment specifications for the engine control estimates. This information is required to complete review of the analyses.*

   At this time, there are no proposed control technologies to improve emissions on the engines at Washington Ranch. Therefore no vendor data is available for submittal at this time.

7. *Provide any electronic spreadsheets used for control technology calculations.*

   At this time, there are no proposed control technologies to improve emissions on the engines at Washington Ranch. Therefore no spreadsheets are available for submittal at this time.

If you have any other questions, please do not hesitate to reach me at 713-420-1841 or via email at Zainab_Naqvi@kindermorgan.com.

Sincerely,

Zainab Naqvi
Air Permitting and Compliance

Delivering Energy to Improve Lives

February 23, 2020

Mr. Michael Baca
Control Strategies Manager
New Mexico Environment Department
Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, NM 87505

El Paso Natural Gas Company, L.L.C. (EPNG)
Company-Specific Interest Rate Utilized in Regional Haze Four-Factor Analyses

Dear Mr. Baca:

The attached sheet, entitled "El Paso Natural Gas Company, L.L.C., Debt Capital, For the Twelve Months Ending December 31, 2019, as adjusted" shows a weighted average cost of debt of 8.53%. This weighted average cost of debt will be published in EPNG's Federal Energy Regulatory Commission (FERC) Form 2 filing for the year ended 2020 and will be publicly available. However, we do not expect this to be published until April 2021, and therefore this information should be treated as confidential business information, not subject to public review under N.M. Stat. Ann § 14-2-1 (H).

The most recent publicly available EPNG Form 2 filing for calendar year 2019 shows a cost of debt of 8.55%, which is based on EPNG's year-ended 2018 capital structure. This filing can be found at https://elibrary.ferc.gov/eLibrary/search by entering "4/29/2020" for the date range and entering "El Paso Natural Gas Form 2" in the Keyword Search field. The relevant data are located on pages 218a and pages 256-260 of the document. The methodology used to calculate this 8.55% cost of debt for the year ended 2018 is consistent with that used to calculate the 8.53% cost of debt for the year ended 2019 included in the attached sheet.

Sincerely,

David P. Michels
Chief Financial Officer

Attachments:	NMED Electric HP Capital Cost-R2.xlsx Base Cost Estimate - Centrifugal.pdf Base Cost Estimate - Recip.pdf

Michael,

Attached you will find the total costs associated with the replacement of the existing units with units with Electric Motor Drives (EMDs). These estimates are based on projects that have been completed within the company and are considered a +/- 25% reflection of the proposed projects.

The breakdown of the costs associated with the unit replacements have also been included (see attached PDF documents). The scope was built by estimating the cost of replacement turbines and engines, backing out the turbine/engine components, and adding in the EMDs. This was done to meet the NMED proposed timeline for the cost estimates.

The cost to provide sufficient utility to the stations has also been included in the capital costs. These were derived by evaluating the nearest power sources, and estimated the costs for a new substation and total power for each site.

The O&M costs for each facility were estimated based existing KM assets. These include operations and maintenance costs for an existing EMD facility (detailed in the O&M spreadsheet), as well as annual cost of utility.

Also, as you can see from the estimates, in all three facilities, the existing units were replaced with two equal sized EMD units. This was because EPNG needs to have redundancy in the system in order to maintain availability of the compressor station in the event of a unit failure (rather than one large unit). For Pecos River and Blanco A, due to the fact that the numbers of replacement units do not match the current numbers of units at each facility, the total emissions from the site were divided by the total cost of each project to derive the cost/ton. We took the same approach with Washington Ranch, though the replacement units would match the current units, in order to maintain consistency.

KM requests a phone call with the NMED to discuss these numbers, as well as path forward for the later September submittal. As stated, the attached numbers reflect a 25% margin of error; with a more precise effort, we could get the margin of error down to 10%, but it will be labor intensive on our end. Considering the cost per ton of the units at this time, KM would like to discuss the need for the effort to refine our estimates. We can complete the full four-factor analysis on the current proposed costs.

KM will continue to work on providing the answers to the outstanding questions prior to the end of the month.

Please let me know about the call!
Thanks,
-Zainab

AFUDC Debt:	3.23%		(Direct Cost + Contingency) in today's dollars (unescalated):	$29,764,790	$2,976 $/HP (D+C Only)
AFUDC Equity:	7.52%		Cost in today's dollars (unescalated):	**$31,672,754**	$3,167 $/HP (All In)
Escalation Factors (APR):	3.1%	Material (Compressor NOT included)	Cost escalation (to inservice date):	$595,678	$60 $/HP (All In)
	3.1%	Other	Cost in escalated dollars (to inservice date):	**$32,268,432**	$3,227 $/HP (All In)

Notes:

Major Material Included in estimate:
- Compressor Building, Control Building, Standby Generator, Cathodic Protection
- Compressed Air System, MCC, Gas Cooling & Filter Separation.

Other Assumptions:
- 3rd Party Engineering & Drafting
- 3rd Party Inspection
- $360k Land Acquisition
- $100k Power Assumed

---

Michael et all,

Please see our below response in a follow-up to the items listed as pending from the September 2nd email from the NMED. We are proceeding with the understanding that our phone conversations from September 1, September 11, and September 22, and email responses on September 9 and September 30 have addressed the majority of questions from the original August 21 email. Please let us know if the NMED would like clarification on any of the current or future issues. We appreciate working with NMED through this process.

Pending Overarching:

* A company-specific interest rate for the cost of capital for the installation of air pollution equipment or lower-emitting equipment.

Attached (EPNG 2019 AFUDC Rate Calc.pdf) is the documentation for EPNG's negotiated interest rate of 8.53%. Please note that EPNG submitted and used this rate for the four-factor-analyses that were conducted and submitted in Arizona.

* The 2016-2018 emissions used by NMED in the modeling inventory and cost analysis are not representative of actual emissions. The inventories used the permitted emission rate and actual operating hours, but stack tests show that the emission rate is much lower. NMED will move forward with the modeling aspect based on the submitted information, but will discuss the use of a more representative number when making the final determination of cost effectiveness.

Concurrent with submitting this response, EPNG is submitting updated 2016 – 2018 Emission Inventory calculations for Washington Ranch Storage Facility and Pecos River Compressor Station. As discussed, the updated emission inventory is based on stack test data and is representative of actual emissions for the calendar year. We have attached the updated Pecos River emissions inventories from 2016-2018 for your review. We appreciate NMED's consideration of the updated data in their analysis.

* Kinder Morgan will provide us with some really rough estimates for electrification of the compressor units at each facility within a week (September 8) to consider for the PAC #2 modeling run. They will refine their evaluation of the technical feasibility of this control measure and the cost analysis to the extent possible by September 30.

Subsequent to our September 9, 2020 submittal, NMED indicated that no further information on replacement with electric compressors is required at this time.

* NMED will discuss the draft ozone precursor rule and how it affects facilities subject to the RH rule with our management and relay concerns regarding regulatory certainty and long-term planning and investment. Kinder Morgan will be developing and submitting written comments on the draft rule.

EPNG submitted comments on the draft ozone precursor rule on September 16, 2020. We appreciate NMED pursuing the concerns regarding the overlap of the two rules.

Pending EPNG Blanco A Compressor Station:

* Please provide O&M Costs and recalculate Total Capital Investment (TCI) with amortization.

In the attached spreadsheet ("EPNG 4FA Costs-Blanco A – Rev09-2020.xlsx"), we have revised the cost calculations, including amortization of the TCI assuming a 20-year life expectancy and the company-specific interest rate of 8.53%. We have also included annual O&M costs, which were previously omitted. Please note that our calculations include the 2016 emissions as baseline, consistent with our previous analysis. Note there are two tabs to the spreadsheet, with our Options 1 and 2 on the first tab, and Option 3 on the second tab.

* Option 3 for LEC indicates that 9 units will be uprated, and 5 units will be retired. However you provided cost per ton value estimates for all 14 engines. Shouldn't the retired units be removed from Option 3 in Table 2: Cost Effectiveness Based on 2016 Emissions Inventory in your Four Factor Analysis? Please provide clarification on which engines would hypothetically be retired (e.g., A02, A05, A05, A08, A10?).

It is correct that for Option 3, the costs would be split amongst 9 units rather than 14 units. Since Option 3 would require a facility-wide approach (including the uprating of 9 units and retirement of 5 units) to provide equivalent facility-wide horsepower, we have accumulated the costs and emission reductions on a facility-wide basis. This eliminates the need to specify which units would be retired although presumably the units with limited utilization would be selected for retirement. The option remains economically infeasible at a cost of over $10,000 per ton on a facility-wide basis.

* Please provide estimates to determine if replacing the engines with electric compressors is cost prohibitive.

Subsequent to our September 9, 2020 submittal, NMED has indicated that no further information on replacement with electric compressors is required at this time.

*It is unclear how Energy and Non-Air Quality Environmental Impacts are different from normal operations. Please provide specifics to document the reasoning for those impacts listed.

The proposed emission reduction strategies include high-pressure fuel injection systems, which take electricity to operate over and above the electricity usage of the facility in its current configuration. The project would also generate waste and additional temporary combustion emissions from equipment during the construction process. Option 2 includes oxidation catalysts that are also a source of waste.

Pending El Paso Washington Ranch:

*Why are the Low Emission Control reduction efficiencies presented by EPNG so variable 27%-82%? Can you provide more information on the actual LEC performance on the engines in the analysis and how it may potentially be improved to provide better efficiency, if possible? If other LEC packages are available for this facility, provide cost estimates with the control technology.

The Clean Burn Technologies (CBTs) NOx emissions improvement range is not specific to the Cooper-Bessemer 12Q155HC2 engines at Washington Ranch; rather it is inclusive of all slow-speed, two-cycle lean burn engines. Engines from different OEM's, e.g. Cooper-Bessemer, Clark, Worthington, Ingersoll-Rand, and even model variations from the same OEM, contain design differences which impact how the engine breaths, the compression ratio (relates to overall combustion pressure/temperature), and how efficient it is at converting the fuel to energy. It is variations in engine performance rather than variations in the performance of aftermarket control technology that drive the variations in NOx endpoints.

For the existing Cooper-Bessemer units located at Washington Ranch, the various CBTs were installed over the life of the units. Each proposed CBT installation (turbocharger, advanced ignition system, Pre-Combustion Chambers (PCC) System, High Pressure Fuel Injection, and an Automatic Balancing Platform) resulted in a range of potential emissions improvement.

If there are any additional questions, please don't hesitate to reach out to Fariba Mehdizadeh, Leslie Nolting, or Travis Ray regarding clarifications or concerns.

Thanks,
-Zainab

Attachments:	EPNG Interest Rate documentation.pdf

Hi Michael,

Our responses to the most recent questions are below:

Company Specific Interest Rate:

Please see attached documentation ("EPNG Interest Rate documentation.pdf") signed by our Chief Financial Officer in support of the 8.53% cost of debt rate. Please note also our request to treat the supporting document with the background of the calculation as Confidential Business Information. Publicly-available support for the cost-of-debt rate is provided as a link in the attached document.

Operation and Maintenance (O&M) Costs:

We believe that in general the O&M costs reflect incremental costs, over and above existing O&M costs. However, the electricity vs fuel costs for Electric Motor Drive (EMD) replacements are the exception to this statement. For the replacement of gas-driven compression with EMD, we believe our +/- 25% estimate did not reflect the cost of fuel savings.

We estimate that the cost of fuel *based on calendar year 2016 operation* for each facility was approximately:

Washington Ranch: $375,000
Pecos River: $2,720,000
Blanco A: $615,000

Thank you again for your patience and assistance. Please let me know if there is anything further we can provide.

Delivering Energy to Improve Lives

February 23, 2020

Mr. Michael Baca
Control Strategies Manager
New Mexico Environment Department
Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, NM 87505

El Paso Natural Gas Company, L.L.C. (EPNG)
Company-Specific Interest Rate Utilized in Regional Haze Four-Factor Analyses

Dear Mr. Baca:

The attached sheet, entitled "El Paso Natural Gas Company, L.L.C., Debt Capital, For the Twelve Months Ending December 31, 2019, as adjusted" shows a weighted average cost of debt of 8.53%. This weighted average cost of debt will be published in EPNG's Federal Energy Regulatory Commission (FERC) Form 2 filing for the year ended 2020 and will be publicly available. However, we do not expect this to be published until April 2021, and therefore this information should be treated as confidential business information, not subject to public review under N.M. Stat. Ann § 14-2-1 (H).

The most recent publicly available EPNG Form 2 filing for calendar year 2019 shows a cost of debt of 8.55%, which is based on EPNG's year-ended 2018 capital structure. This filing can be found at https://elibrary.ferc.gov/eLibrary/search by entering "4/29/2020" for the date range and entering "El Paso Natural Gas Form 2" in the Keyword Search field. The relevant data are located on pages 218a and pages 256-260 of the document. The methodology used to calculate this 8.55% cost of debt for the year ended 2018 is consistent with that used to calculate the 8.53% cost of debt for the year ended 2019 included in the attached sheet.

Sincerely,

David P. Michels
Chief Financial Officer

Date:	Friday, May 26, 2023 2:15:40 PM
Attachments:	image001.png Cooper_Parts_Letter_52323.pdf

Ms. Olson:

Ms. Olson:

During our recent meeting, you and your staff asked 3 questions that we said we would get back to you about. Specifically:

- Operation and Maintenance Costs
  - Availability of maintenance parts for the engines and combustion turbines for 10 to 20 years
  - Estimates of maintenance costs for units
- Replacement - Costs for the replacement of the existing reciprocating internal combustion engines (RICE)/combustion turbines (CT) with new RICE/CT.
- Electrification - basis of the cost estimate ($/mile) for installing medium voltage electric utility distribution lines.

We are pleased to provide the following responses:

Operation and Maintenance Costs

Ongoing Operations

Cooper, the Original Equipment Manufacturer (OEM) for RICE at the stations in question, has stated that they have no plans to discontinue support of the installed engines. Please see the attached letter. Cooper has further stated they have millions of dollars of parts in stock to support these model engines as well as the many others that they have manufactured over the years, and they continue to place new orders for parts. Finally, it should be noted that the oldest engines in our fleet manufactured by Cooper were designed and installed in the early 1940s and are still operating. This demonstrates that the slow speed engines are very robust and that, when properly maintained, will operate for the foreseeable future.

KM's fleet of GE turbines is much the same. Additionally, there is a significant fleet of Frame 3 turbines operating throughout the world that GE has indicated they intend to continue to support.

Maintenance Costs

Regarding maintenance costs units, the slow speed engines require very little ongoing planned maintenance beyond consumables (e.g., oil changes, spark plugs, belts hoses etc.) due to the durability of the engines between routine overhauls. Similarly, the GE turbines also require little planned maintenance between routine overhauls. Routine overhauls are periodically required based on operating hours and currently cost approximately $750K each for the RICE and between $1.5 MM - $2 MM each for the CTs. Our budgeted planned maintenance costs for the entire fleet (25 units total including CTs and RICE units) at the 3 stations for 2023 is less than $200K with no overhauls planned in this calendar year.

Replacement Costs

As discussed during our meeting, KM believes that requiring replacement of existing equipment is beyond the scope of the Regional Haze rule. The Clean Air Act, 42 USC Section 7491(g)(2) and elsewhere uses the term "best available retrofit technology." The term "retrofit" denotes modifications to existing equipment and not replacement of equipment. EPA itself acknowledged this in Appendix Y to 40 CFR Part 51 entitled "Guidelines for BART Determinations Under the Regional Haze Rule" which stated in part as follows:

1. Step 1: How do I identify all available retrofit emission control techniques?
    1. Available retrofit control options are those air pollution control technologies with a practical potential for application to the emissions unit and the regulated pollutant under evaluation…

(40 CFR Appendix Y, IV.D.1)

Thus the CAA's use of "best available retrofit technology" has as its central requirement that it be applied to existing equipment, rather than being replaced with totally new equipment. Additionally, even if replacement of units was within the scope of the rule – which it is not –, replacement costs would be economically infeasible. In the interest of providing general background information on the subject, KM has found that replacement cost for RICE or CTs compressor drivers are generally consistent across both drive types. Costs, as measured in $/hp, vary according to size installed, with lower HP installations generally costing more. For project scoping, KM generally uses a rule of thumb of $3,200/hp for greater than 15,000 hp installed and $4,200 for less than 15,000 hp installed based on a number of recent detailed project estimates.

Electrification

Even if replacement of units was within the scope of the rule – which it is not –, mandating the use of EMDs would be economically infeasible. In addition to the cost of the EMD itself, electrification generally requires additional electrical lines and substations. Based on current estimating practices for projects, KM uses between $500k-$1MM per mile of overhead electrical line and, depending on total horsepower being electrified, approximately another $5MM for a substation.

Note that in response to questions from our original 2019 submittal, KM cited a cost of $500K/mile for overhead electrical lines. We expect that current costs per mile would be higher – more towards the middle of the above cited $500k-$1MM per mile. However, for Blanco, the nearest high voltage line is underground. To estimate the Blanco costs, we used a cost estimate for a then current project that had underground utilities and scaled to the distance needed for Blanco.

If you have any questions on the above response, please contact Weiwen, Richard or myself. Thank you and we look forward to working with you and your team.

COOPER | MACHINERY SERVICES

May 23, 2023

Mr. James Trent
Staff Engineer
Kinder Morgan
1001 Louisiana Street
Houston, TX 77002

Dear James,

Cooper Machinery Services was founded in 1833, and for much of its existence has been focused on designing, producing, and servicing natural gas engines and compressors.

The production of new spare parts and emissions upgrades are the core of our current business model and will continue to be so for the foreseeable future.

Thus, I would like to confirm that Cooper Machinery Services has no plans to stop producing new parts for Cooper equipment, and will continue to service your GMV-10TF, GMW-10, 6V-250 and 12Q155HC2 models for as long as our company exists.

If you have any questions or need more details on Cooper's parts offering, please feel free to contact me.

Sincerely,

Patrick Gillespie
Vice President of Sales - Americas
(832) 316-9506

Economic Evaluation

Cost Component		T-C01	T-C02	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	$ -	-	Enterprise provided a cost estimate for electrification using EPA Cost Control Manual Section 5.2, which pertains to acid gas scrubbers. As this is not applicable to replacement with EMD, a Total Capital Cost metric of $2,084 (2023$/hp) was calculated using detailed cost information provided by other facilities. The TCI figure assumes no costs associated with substation or distribution line upgrades. This assumption underestimates costs given that Enterprise indicated in its August 2023 update that utility infrastructure upgrades would be needed to support electrification at all three of its facilities.
