Section 3

Application Summary

The **Application Summary** shall include a brief description of the facility and its process, the type of permit application, the applicable regulation (i.e. 20.2.72.200.A.X, or 20.2.73 NMAC) under which the application is being submitted, and any air quality permit numbers associated with this site. If this facility is to be collocated with another facility, provide details of the other facility including permit number(s). In case of a revision or modification to a facility, provide the lowest level regulatory citation (i.e. 20.2.72.219.B.1.d NMAC) under which the revision or modification is being requested. Also describe the proposed changes from the original permit, how the proposed modification will affect the facility's operations and emissions, de-bottlenecking impacts, and changes to the facility's major/minor status (both PSD & Title V).

The **Process Summary** shall include a brief description of the facility and its processes.

Startup, Shutdown, and Maintenance (SSM) routine or predictable emissions: Provide an overview of how SSM emissions are accounted for in this application. Refer to "Guidance for Submittal of Startup, Shutdown, Maintenance Emissions in Permit Applications (http://www.env.nm.gov/aqb/permit/app_form.html) for more detailed instructions on SSM emissions.

The Prewitt Escalante Generating Station (PEGS) is a nominal 273 megawatt single unit coal-fired electric generating station owned and operated by Tri-State Generation and Transmission Association, Inc (Tri-State). PEGS is located at UTM Zone 12, UTM Easting 764.96 km, UTM Northing 3922.88 km, NAD 83, in Township 14N, Range 12W, Sections 22-27, 4 miles north of Prewitt, New Mexico in McKinley County (see Figure 8-2). PEGS operates under Permit #PSD-NM-285-M4R1 issued July 24, 2016 and Title V Operating Permit #P012-R3 issued February 24, 2017.

Tri-State Generation and Transmission Association, Inc. (Tri-State) is submitting a technical revision to Permit #PSD-0285-M4R1 per 20.2.72.219.B.1.a NMAC for Prewitt Escalante Generating Station (PEGS). Tri-State is permanently shutting down the coal-fired boiler, associated coal and limestone handling equipment, and the cooling tower after all existing coal stored at the site is combusted. Additionally, Tri-State will be transferring ownership and operation of the existing auxiliary boiler and water treatment plant to McKinley Paper Company's Prewitt Mill. Transfer of ownership of the existing auxiliary boiler and water treatment plant to McKinley Paper Company's Prewitt Mill is scheduled for September 30, 2020. Tri-State will continue to operate the existing auxiliary boiler and water treatment plant under the revised PEGS permit until McKinley Paper Company is issued a minor NSR permit (see the agreement letter between Tri-State and McKinley Paper Company at the end of this section). McKinley Paper Company submitted their 20.2.72 NMAC minor NSR permit application on July 15, 2020.

The modification of this permit will occur in two permitting phases. Phase 1 includes the shutdown of the coal-fired boiler, associated coal and limestone handling equipment, and the cooling tower after all existing coal stored at the site is combusted. Phase 2 includes the transfer of operation of the existing auxiliary boiler and water treatment plant to McKinley Paper Company, which will occur after the new 20.2.72 NMAC minor NSR permit has been issued for the Prewitt Mill.

Table 3-1 lists the present emission units permitted under Permit #PSD-NM-285-M4R1. Column 3 – 5 presents each emission sources status through Phases 1 and 2. Column 3 lists the emission units that will remain after Phase 2 of this technical permit revision. Column 4 lists the emission units that will be removed during Phase 1 of this technical permit revision. Column 5 lists the emission units that will be removed during Phase 2 of this technical permit revision.

TABLE 3-1: List of Existing Equipment and Status after Phase 1 and Phase 2

RE: Tri-State Generation and Transmission Association, Inc.
Compliance Progress Report – NSR Permit No.- 0285-M4R2

Dear Mr. Kimbrell:

Tri-State Generation and Transmission Association, Inc. (Tri-State) is notifying NMED through this letter the cessation of E79 – Main Boiler Unit at the Prewitt Escalante Generating Station, as per condition A112.E in the NSR Permit 0285-M4R2. E79 –Main Boiler Unit ceased operations on August 31, 2020, ahead of its December 31, 2020 deadline. Phase 2 is still on track and should be completed when Air Quality Permit 8889 is issued to McKinley Paper Company's Paper Mill.

Tri-State will submit a NSR significant permit modification application within 90 days of the cessation of E79 – Main Boiler Unit (November 29, 2020) as required in condition A112.C(3), to remove all conditions from the permit that no longer apply and to add new conditions for the remaining plant heating boiler, road fugitives and other items.

Please contact Jennifer McCurdy or me at 303-452-6111 if you have questions.

Sincerely,

RE: Tri-State Generation and Transmission Association, Inc.
Prewitt Escalante Generating Station – Cancellation of Title V Permit No: P012-R3 and Acid Rain Permit No: P012A-R3

Dear Sir or Madam:

Tri-State Generation and Transmission Association, Inc. (Tri-State) is requesting the cancellation of Prewitt Escalante Generating Station's (PEGS) Title V permit No: P012-R3 and its Acid Rain permit No: P012A-R3 as per the shutdown schedule in the NSR permit No: 0285-M4R2, condition A112. The Main Boiler – E79 ceased operation on August 31, 2020 and is permanently retired, thus PEGS is no longer a major source and is not subject to the Acid Rain regulations. Enclosed are the cancellation forms for the Title V permit and Acid Rain permit for your approval. As well as, EPA's retired unit exemption form, sent to EPA and confirmation that the unit has been retired in CAMD.

Please contact Jennifer McCurdy or me at 303-452-6111 if you have any questions regarding this submittal.

Sincerely,

Barbara A. Walz
Senior Vice President
Policy and Compliance/
Chief Compliance Officer

7	Address: 1100 W 116th Ave, Westminster, CO 80234		
8	Check all boxes below for which this submittal applies:	AI #: 911	Permit #: P012-R3 & P012A-R3

☐ NSR Construction Permit (20.2.72 NMAC) X TV Operating Permit (20.2.70 NMAC)	☐ NOI (20.2.73 NMAC) (Sections 2-B, 2-D) ☐ Notice of Exemption (20.2.72.202.B NMAC) (Section 2-F)	☐ PSD Permit (20.2.74 NMAC) ☐ Nonattainment Permit (20.2.79 NMAC)

Section 2: Details of Submittal

Only print and submit the pages necessary for your submittal. Print double sided head-to-toe, flip on short end (tablet). The Permit Section responds to all TV Administrative amendments and responds only to denials of NSR administrative revisions. Courier proof of delivery is required if you want confirmation that the Department received this submittal. Check the box(es) applicable to this submittal:

☐ 2-A(i) & 2-A(ii): Identical Engine or Turbine Replacements

☐ 2-B: Owner, Operator, and Name Changes to NOIs or Construction Permits

☐ 2-C: Ownership or Operational Control Changes for Title V Permits

☒ 2-D: Closing a Facility or Removing Units from a Permit

☐ 2-E: Correct Typographical Error

☐ 2-F: Reporting Exempt Equipment for Minor Construction Permits or for No Permit Required (NPR) Facilities

☐ 2-G: Add Minor NSR Exempt Equipment to Construction Permits for PSD or Nonattainment Sources

☐ 2-H: Title V Responsible Official Designations

☒ 2-I: Submittals to the Permit Programs Manager

Section 3: Certification – Required for All Changes

Section 4: Form Instructions

Section 2-D: Closing a Facility or Removing Units from a Permit

(Administrative Revision)

Check the appropriate boxes and provide complete information in the table. Closing the permit does not relieve the permittee from any outstanding permit fees.

If any of the units being removed are emission control equipment explain how a permit, federal regulation, or state regulation will not be violated by removal of the control equipment.

☐ Cease operations of the entire facility and cancel the construction permit (20.2.72.219.A(1)(c) NMAC).

Date the facility ceased operating:

☐ Retire an emissions unit and remove it from the construction permit (20.2.72.219.A(1)(c) NMAC).

Date unit(s) retired:
List all retired unit numbers to be removed from the permit:

☐ Cancel a construction permit for a facility or remove an emissions unit that has not and will not be constructed (20.2.72.219.A(1)(d) NMAC).

☐ Facility (plant) will not be constructed, or	☐ The following units will not be constructed and should be removed from the permit:

☐ Retire an emissions unit and remove it from the TV permit (20.2.70.404.A(1)(c) NMAC).

Date unit(s) retired:
List all retired unit numbers to be removed from the permit:

☒ Voluntary Discontinuation of the TV permit (20.2.70.400.I NMAC).

Date the TV permit was no longer required: August 31, 2020
Explanation: E79 Main Boiler ceased operation on August 31, 2020, and is permanently retired, therefore PEGS is no longer a major facility under Title V.

☒ Cancel a construction permit that is no longer required.

Explanation: E79 Main Boiler ceased operation on August 31, 2020 and is permanently retired. The facility is no longer subject to the Acid Rain regulations and Tri-State would like to cancel the Acid Rain Permit No: P012A-R3. See NSR permit No: 0285-M4R2 for Specific Condition A112 for the shutdown schedule.

☐ Removal of minor NSR exempt equipment.

Explanation:

Section 2-I: Submittals to the Permit Programs Manager

As Required by Permit Conditions or Other Regulations

(Notification or Administrative Revision)

Use this section for submittals to the Permit Programs Manager of notifications or administrative permit revisions/amendments required by permit conditions that do not correspond with any other section of this submittal form. Explain your request, including any permit condition or regulatory citations that requires this submittal, and include the necessary attachments.

For example:

- Your permit has a condition that allows a specific change through an administrative revision.
- Your permit has a condition that requires submittal of information to the attention of the Permit Programs Manager such as a good combustion practice plan.
- A condition that allows a deadline to be extended through an administrative permit revision.
- Notification per General Condition B116 Short Term Engine Replacement
- Notification of TV Operating Permit Section 502(b)(10) Changes (20.2.70.302.H(1) NMAC).
  - Before submitting a 502(b)(10) change request, contact the Major Source Program Manager or the TV Program Manager to discuss what information should be included in the request to ensure that the request is federally enforceable if enforceable limits are needed to avoid a construction permit application. Visit www.env.nm.gov/air-quality/permitting-section-home-page/ for contact information.
  - If the change must be made immediately, you may send the request by email to one of the managers listed above.

As per NSR permit No: 0285-M4R2, Condition A407 Acid Rain Permit, P0212AR3 (This condition will not be applicable after completion of Phase 1 and the Title IV and V permits have been cancelled).

Phase 1 was completed on August 31, 2020 when E79 Main Boiler ceased operation.

Section 3: Certification – Required for All Applications

Company Name: Tri-State Generation and Transmission Assoc., Inc.

I, Barbara A. Walz, hereby certify that the information and data submitted in this application are true and as accurate as possible, to the best of my knowledge and professional expertise and experience.

Signed this 28TH day of September, 2020, upon my oath or affirmation, before a notary of the State of Colorado.

Barbara A Walz — 9/28/20

Ref: **Air Quality Operating and Acid Rain Permits P012-R3 and P012A-R4**
Prewitt Escalante Generating Station
NSR Permit No. PSD0285-M4R2
Agency Interest No. 911 - PRT20200001
AIRS No: 350310032

Dear Ms. McCurdy:

The Air Quality Bureau is in receipt of Tri-State Generation and Transmission Association, Inc.'s September 28, 2020 request to voluntarily discontinue the Prewitt Escalante Generating Station Title V Operating Permit No. P012-R3 and Title IV Acid Rain Permit No. P012A-R4, pursuant to 20.2.70.400.I NMAC. An existing Title V major source may apply for a permit under 20.2.72 NMAC to obtain federally enforceable conditions that restrict the facility's potential to emit to below Title V Major Source thresholds.

The Air Quality Bureau received Tri-State Generation and Transmission Association, Inc.'s NSR Permit application on July 29, 2020 for Prewitt Escalante Generating Station located in Township 14N, Range 12W, Section 25 in McKinley County, New Mexico. Tri-State Generation and Transmission Association, Inc.'s NSR permit 2448-M4R2, with federally enforceable limitations on the potential to emit and schedule shutdown plan, was issued on August 27, 2020.

The Air Quality Bureau has verified that the actions required to reduce the potential to emit of this facility to below Major Source thresholds have been met. Therefore, the Department has cancelled Title V Operating Permit No. P012-R3 and Title IV Acid Rain Permit No. P012A-R4 for the Prewitt Escalante

Generating Station as of September 28, 2020 and Tri-State Generation and Transmission Association, Inc.'s facility will be removed from the list of Title V sources in New Mexico.

If you have any questions, please call Joseph Kimbrell in Santa Fe at 505-476-4347.

Sincerely,

Elizabeth Kuehn

Joe Kimbrell, Permit Engineer
Melinda Owens, Title V Supervisor
Rhonda Romero, NSR Minor Source Manager
New Mexico Environment Department
Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, NM 87505-1816

Dear Ms. Owens, Ms. Romero and Mr. Kimbrell:

McKinley Paper Company (MPC) is writing to notify the New Mexico Environment Department (NMED) of the just concluded transfer of ownership of the following facilities from Tri-State Generation and Transmission Association (Tri-State) to MPC as of the date of this letter:

- Soda Ash Silo (Regulated Source 8),
- Soda Ash Silo Unloading (Regulated Source 9),
- Lime Silo (Regulated Source 10),
- Lime Silo Unloading (Regulated Source 11), and the
- Auxiliary Steam Boiler (Regulated Source 13)

These regulated units collectively referred to as "Conditional Sources" are all identified in MPC's NSR Minor Source Permit (NSR Permit #8886). Based on the above, Phase II of the Tri-State NSR Minor Source Permit (NSR Permit #0285-M4R2 & 3) has been completed. In addition, all applicable permit requirements relative to the Conditional Sources in MPC's NSR Minor Source Permit (NSR Permit #8886) are now enforceable in the MPC air permit.

Thank you for NMED's assistance in working with MPC. Please let us know if you have any questions.

Respectfully,

Isaac Rosas
McKinley Paper Company

D.14 Xcel Energy

Supporting documentation for Xcel Energy is provided below. Facility-specific documentation is provided first, followed by documentation pertaining to multiple facilities and/or the owner/operator. The following documents are included in this section (in reading order):

- Cunningham Station Power Plant:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (11/2019)
    - Follow-Up Submittal (2/2020)
    - Follow-Up Submittal (11/2/2020)
    - Follow-Up Submittal (1/25/2021)
    - Follow-Up Submittal (7/18/2023)

NMED Final Cost Evaluation

Unit 1: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	784	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	3,778,560,621	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3815	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.1540	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0154	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information

Use payroll data, if available, or check current edition of the Bureau of Labor Statistics, National Occupational Employment and Wage Estimates – United States (https://www.bls.gov/oes/current/oes_nat.htm).
Interest Rate (Percent)	5.5	Default bank prime rate		Use known interest rate or use bank prime rate, available at https://www.federalreserve.gov/releases/h15/.

Unit 1: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	784	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	6,661,338,506	scf/Year	
Actual Annual fuel consumption (Mactual) =		3,778,560,621	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.567	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	4969	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	90.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	108.63	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	269.89	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.13		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	3,180.81	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	42	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	146	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	19	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	6,600	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	464.14	kW

Unit 1: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$18,081,890	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$455,835 in 2024 dollars
Indirect Annual Costs (IDAC) =	$1,777,546 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$2,233,382 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$90,409 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$51,118 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$230,629 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$83,679 in 2024 dollars
Direct Annual Cost =		$455,835 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,713 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,773,833 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,777,546 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$2,233,382 per year in 2024 dollars
NOx Removed =	270 tons/year
Cost Effectiveness =	$8,275 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Xcel Energy - Cunningham Station Power Plant

Unit 2: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	1951	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	10,935,818,623	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3815	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.1540	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0154	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71	lbs/ft^3
29.4% aqueous NH_3	56	lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.

Unit 2: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	1,951	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	16,576,876,819	scf/Year	
Actual Annual fuel consumption (Mactual) =		10,935,818,623	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.660	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	5779	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	90.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	270.45	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	781.47	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.13		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	7,915.71	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	105	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	362	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	48	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	16,300	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	1155.01	kW

Unit 2: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$32,704,356	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$1,187,256 in 2024 dollars
Indirect Annual Costs (IDAC) =	$3,212,888 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$4,400,143 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$163,522 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$148,010 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$667,481 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$208,242 in 2024 dollars
Direct Annual Cost =		$1,187,256 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$4,590 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$3,208,297 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$3,212,888 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$4,400,143 per year in 2024 dollars
NOx Removed =	781 tons/year
Cost Effectiveness =	$5,631 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Xcel Energy - Cunningham Station Power Plant

Unit 3: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	1400	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	3,211,445,199	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3815	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.0570	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0114	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 3: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	1,400	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	11,895,247,333	scf/Year
Actual Annual fuel consumption (Mactual) =		3,211,445,199	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.270	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	2365	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	63.84	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	75.49	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	5,015.86	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	25	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	86	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	11	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	3,900	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	828.81	kW

Unit 3: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$26,358,555	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$474,060 in 2024 dollars
Indirect Annual Costs (IDAC) =	$2,589,984 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$3,064,044 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$131,793 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$14,298 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$196,015 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$131,955 in 2024 dollars
Direct Annual Cost =		$474,060 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$4,210 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$2,585,774 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$2,589,984 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$3,064,044 per year in 2024 dollars
NOx Removed =	75 tons/year
Cost Effectiveness =	$40,588 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Xcel Energy - Cunningham Station Power Plant

Unit 4: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	1400	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	4,216,294,859	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3815	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.0480	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0096	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F	*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour	

Concentration of reagent as stored (C_{stored})	29	percent*	*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*	
Number of days reagent is stored ($t_{storage}$)	14	days	

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Unit 4: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	1,400	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	11,895,247,333	scf/Year
Actual Annual fuel consumption (Mactual) =		4,216,294,859	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.354	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	3105	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	53.76	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	83.46	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	4,999.22	Cubic feet

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	828.81	kW

Unit 4: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$26,358,555	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$536,465 in 2024 dollars
Indirect Annual Costs (IDAC) =	$2,589,984 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$3,126,448 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$131,793 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$15,808 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$257,347 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$131,517 in 2024 dollars
Direct Annual Cost =		$536,465 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$4,210 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$2,585,774 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$2,589,984 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$3,126,448 per year in 2024 dollars
NOx Removed =	83 tons/year
Cost Effectiveness =	$37,459 per ton of NOx removed in 2024 dollars

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across with United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).* This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).* The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed Xcel Energy (Xcel), that its Cunningham Station (Cunningham) was identified as one of the sources potentially contributing to regional haze at the CarlsbadCaverns National Park Class I area.

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. The NMED's July 18, 2019 notification letter to Xcel specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The NMED also provided additional guidance that only steady-state emissions shall be considered in the four-factor analysis. Therefore,

the emergency generator (Unit EGR1) is not discussed in this report. The equipment at the facility that is subject to the analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability of the Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Natural Gas-Fired Boiler (Unit 1)	235.20	1030.00	Yes	2.90	12.90	No
Natural Gas-Fired Boiler (Unit 2)	585.30	2564.00	Yes	7.30	32.20	No
Natural Gas-Fired Turbines – Normal Operation (Units 3 &4)	78.10	170.90	Yes	22.10	55.10	Yes
Natural Gas-Fired Turbines – Augmented Operation (Units 3 &4)	129.00	38.70	Yes	-	-	No

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at recommendation of the NMED[1], this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. Summaries of the result of this search are provided and discussed under Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis is then conducted for those controls that are technically feasible.

2.1. COMBUSTION TURBINES

As reported in Table 1 Cunningham's two natural gas-fired simple cycle peaking turbines, Units 3 and 4, are NO_x and SO_2.

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[2]

The treatment of the exhaust gases exiting the turbine dictates the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[3] The units at Cunningham are simple cycle turbines.

NO_X is formed via three fundamentally different mechanisms. The principle NO_X formation mechanism, thermal NO_X, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_X forms in the highest temperature regions of the combustion chamber. The second NO_X formation mechanism, fuel NO_X, arises from the evolution and reaction of fuel bound nitrogen compounds with oxygen. The final NO_X formation mechanism, prompt NO_X, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_X is negligible in comparison to thermal and fuel NO_X. Fuel NO_X will also be negligible for Cunningham's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_X.

The PTE from each turbine referenced from the facility's PSD (0622) and Title V (P080) permits are summarized in Table 1. There are two operational modes associated with these units: with and without power augmentation. NO_x composition of stack gas during normal operations is approximately 15 ppmv, whereas the composition during power augmentation is 25 ppmv. A safety factor is then applied to these emissions to calculate the PTE represented in the permits for these unit.

SO_2 emissions from turbines are generated when sulfur in fuel gas is combusted in the turbine. The PTE for SO_2 is calculated with an assumed conservative fuel gas sulfur content of 5.25 gr S/100 scf. The PTE for these units is calculated based on this fuel sulfur content and is represented in Cunningham's NSR and Title V permits as 22.1 lb/hr/unit.

[3] Ibid.

2.1.2. Potential NO_X Controls for a Combustion Turbine

There are three general methods of controlling NO_X emission from gas turbines; (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation, (2) dry controls that use advanced combustor design to suppress NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[4]

The retrofit control equipment that was identified for combustion turbines during a comprehensive review of the RBLC, available literature, and manufacturer's input is reported in Table 2. A more detailed table summarizing the RBLC review is provided in Appendix A. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control is provided below.

Table 2. Potential Control Equipment for Combustion Turbines

Control Equipment	Technically Feasible	NO_X Control Efficiency
Dry low NO_X	**Currently Installed**	**N/A**
Improved dry low NO_X	**No**	**N/A**
Water Injection	**Yes**	**15%**
Steam Injection	**No**	**N/A**
Selective Catalytic Reduction	**Yes**	**65%**

2.1.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at Cunningham. However, these practices are currently in use at Cunningham, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.1.2.2. Improved Dry Low NO_X Hardware

The dry low NO_X (DLN) control, also seeks to reduce the combustion temperature and residence time of fuel in the combustor (thereby decreasing NO_X formation) by increasing the air-to-fuel ratio in the combustion

[4] Ibid.

chamber. There are several levels of improvements that can be made to the combustion chamber, which achieve this NO_X control at varying levels.

DLN combustors are currently installed on the combustion turbines operating at this facility. While emissions may fluctuate, on average, the turbines installed at this facility are capable of achieving a NO_X stack concentration of 15 ppm and 25 ppm during normal and power augmented operation, respectively. According to Seimens, there are no improved low NO_X burners commercially available for these units.

2.1.2.3. Water/Steam Injection

Water or steam injection is a technology that has been demonstrated to effectively suppress NO_X emissions from gas turbines. The effect of steam and water injection is to increase the thermal mass by dilution and thereby reduce peak temperatures in the flame zone. With water injection, there is an additional benefit of absorbing the latent heat of vaporization from the flame zone. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.

Xcel engineers stated that Steam injection may not be implemented on the combustion turbines at Cunningham.

The pilot nozzle is the main contributor to thermal NO_x formation and water injection is capable of reducing NO_x emissions with a minimum control efficiency of 15%.[5]

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust downstream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[6] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O \quad \text{(Equation 1)}$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O \quad \text{(Equation 2)}$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituent, thermal sintering, or compacting, of active sited due to high temperatures in the reactor, fouling caused by ammonia-sulfur salts and particulate matter in the gas, and erosion due to high gas velocities.[7]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[8]

---

[5] Ibid.
[6] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.
[7] Ibid.
[8] Ibid.

In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[9] The exhaust temperature of the turbines assessed here is approximately 580 °F.

SCR units can achieve a minimum NOx reduction of 65%.[10] However, if the upstream NO_X concentration is already low, as is the case with these units, it is difficult to achieve these control efficiencies.

There may also be site-specific space limitations that prevent the installation of the necessary equipment for this control method (i.e., SCR module and reagent storage systems).

Moreover, installation of SCR on simple cycle peaking turbines is much more difficult than installation on combined cycle turbines operating as base load units for several reasons, as follows:

- There are significant technical and financial challenges associated with the elevated exhaust temperature from simple cycle operation;
- Combined-cycle facilities have heat recovery steam generator (HRSG) ductwork that can better accommodate catalyst installation; and
- Combined-cycle cogeneration units typically operate in a continuous mode compared to peaking units which do not operate continuously and ramp up and down quickly from standing start to full load operation.

Assuming that the space and temperature limitations can be overcome, SCR is considered a technically feasible control option for this process.

2.1.3. Potential SO_2 Controls for a Combustion Turbine

2.1.3.1. Good Combustion Practices and Fuel Selection

As stated in the background information for emissions from combustion turbines, SO_2 emissions from these units are based on the sulfur content of the fuel gas. The current permitted SO_2 PTE for the turbines is based on a fuel sulfur content of 5.25 gr/100 scf. These emissions were originally permitted under PSD Permit No. 0622-M2 issued on 2/10/1997. At the time, this was consistent with Xcel's definition of "sweet gas" and the representative sulfur content was considered appropriately conservative. However, the actual sulfur content at the facility is typically 0.3 gr/100 scf and does not ever exceed 1.25 gr/100 scf. According to 2016 emission inventory data, which is based off continuous emission monitoring system (CEMS) data, actual SO_2 emissions for these units are less than 1 lb/hr on average. No additional sulfur reduction controls are reasonable or necessary.

2.2. INDUSTRIAL BOILERS

2.2.1. Industrial Boilers Background

As with natural gas turbines, of the three NO_X formation mechanisms, both fuel and prompt NO_X are negligible for natural gas industrial boilers. Thermal NO_X results from the oxidation of atmospheric nitrogen in the high-temperature, post-flame region of a combustion system. The major factors that influence thermal NO_X formation

[9] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines".

[10] Ibid.

are temperature, concentrations of oxygen and nitrogen, and residence time. If the temperature or the concentration of oxygen or nitrogen can be reduced quickly after combustion, thermal NO_X formation can be suppressed or quenched.

The formation of thermal, prompt, and fuel NO_X in combustion systems is controlled by modifying the combustion gas temperature, residence time, and turbulence. Of primary importance are the localized conditions-within and immediately following the flame zone where most combustion reactions occur. In utility boilers, temperature, residence time, and turbulence are determined by factors associated with boiler and burner design, fuel characteristics, and boiler operating conditions.

2.2.2. Potential NO_X Controls for Industrial Boilers

The retrofit control equipment identified for industrial boilers during a comprehensive review of the RBLC are reported in Table 3. A detailed discussion including a description, the technical feasibility, and the estimated performance of each control, is provided below.

Table 3. Potential Control Equipment for Industrial Boilers

Control Equipment	Technically Feasible	NO_X Control Efficiency
Good Combustion Practices	**Base Case**	**N/A**
Combustion Control Techniques	**Base Case for Unit 2, No for Unit 1**	**N/A**
Flue Gas Recirculation	**No**	**N/A**
Selective Catalytic Reduction	**Yes**	**80%**

2.2.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from boilers; therefore, it has been determined that this method of NO_X control is feasible for the units at Cunningham. However, these practices are currently in use at Cunningham, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.2.2.2. Combustion Control Techniques

Similar to low NO_X burners for turbines, these controls reduce NO_X by sectioning the combustion process into stages. Staging partially delays the combustion process, resulting in a cooler flame which suppresses thermal NO_X formation. Minimum NO_X emission reductions of 40% have been observed with low NO_X burners [11].

Xcel has implemented an overfire air control on Unit 2 at this facility, which involves modifying the fourth level of combustion burners in the boiler. Unit 1 at the facility only has three levels of combustion burners and cannot be modified to include the overfire air technique used on Unit 2. Moreover, there are no commercially available controls that may be installed on these units at this time.

Based on this information, Xcel cannot implement any additional low NO_X burners or staging modifications at this time and no options are evaluated in this report.

2.2.2.3. Flue Gas Recirculation

In a Flue Gas Recirculation (FGR) system, a portion of the flue gas is recycled from the stack to the burner windbox. Upon entering the windbox, the recirculated gas is mixed with combustion air prior to being fed into the burner. The recycled flue gas consists of combustion products which act as inerts during combustion of the fuel/air mixture. The FGR system reduces NO_X emissions by two mechanisms. Primarily, the recirculated gas acts as a diluent to reduce combustion temperatures, thus suppressing the thermal NO_X formation mechanism. To a lesser extent, FGR also reduces NO_X formation by lowering the oxygen concentration in the primary flame zone. The amount of recirculated flue gas is a key operating parameter influencing NO_X emission reduction potential for these systems.

FGR on these boilers would require ductwork and structural steel additions to bring exhaust gas from the stack back into the furnace windboxes. This would necessitate a re-design of the windboxes so that they could properly receive the new source and damper changes to properly mix the flow and maintain the proper air/fuel ratio. This option would also require an additional fan in the new duct work to match the pressure of the existing FD fan. Additionally, the air portion of the burner nozzles in the boilers would also need to be enlarged. The entire system would require extensive controls changes to balance air and fuel. While the cost of the FGR would likely not justify this modification, since the technique would provide a limited reduction in NO_X, the modifications needed to implement FGR are prohibitive. Moreover, Xcel has determined that the structural changes required to implement this control cannot be incorporated in due to space limitations at the facility.

This option is not considered technically feasible and is therefore not evaluated further in this report.

2.2.2.4. Selective Catalytic Reduction

The selective catalytic reduction (SCR) system for industrial boilers involves injecting ammonia (NH_3) into the flue gas in the presence of a catalyst to reduce NOx emissions. No data were available on SCR performance on

[11] U.S. EPA, AP-42, Section 1.4, "Natural Gas Combustion"

natural gas-fired boilers at the time of this publication. However, the Alternative Control Techniques (ACT)[12] document for utility boilers estimates a minimum NO_X reduction efficiency of 80%.[13]

This control is considered technically feasible and is assessed further in this report.

[12] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

[13] U.S. EPA, AP-42, Section 1.4, "Natural Gas Combustion"

Xcel has evaluated the costs of implementing the technologically feasible control technologies as thoroughly as possible in the time provided to complete this assessment. These cost estimates are calculated according to the methods and recommendations in the EPA Air Pollution Control Cost Manual or are estimated based on cost estimated provided by equipment vendors.[14] The cost effectiveness discussion and summary tables for the turbines are provided in Table 4.

3.1. TURBINE CONTROLS

Table 4. Cost Analysis Summary of Technically Feasible Controls for Combustion Turbines

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
Water Injection	3	$81,395 per ton	Equipment costs, Annual operating costs.
	4	$41,515 per ton	
Selective Catalytic Reduction	3	$97,583 per ton	Equipment costs, Annual operating costs.
	4	$49,771 per ton	

3.1.1. Water Injection

Xcel received a cost estimate to implement water injection control on the combustion turbine at the Cunningham Station. This cost estimate is reported to be $2.24 million per unit for equipment, plus an additional $340,000 associated with annual operating cost. The control efficiency for water injection is estimated to be 15% resulting in an emission rate reduction of 6.48 tpy and 12.71 tpy for Units 3 and 4, respectively. This results in an estimated cost effectiveness of $81,395and $41,515 per ton of reduced emissions for Units 3 and 4, respectively.

3.1.2. Selective Catalytic Reduction

Xcel obtained total cost estimates for a turbine SCR from CECO-Peerless. The estimate incorporates direct capital cost for equipment and vendor labor, indirect costs associated with Xcel's internal labor, and overhead and contingency costs for the project. According to this estimate, the SCR would cost $30.2 million per unit with $207,794 per year in operating costs. According to the manufacturer guaranteed control performance, the unit will reduce NO_X emissions with an 65% efficiency resulting in an emission rate reduction of 28.08 tpy and 55.06 tpy for Units 3 and 4, respectively. This results in an estimated cost effectiveness of $97,583 and $49,771 per ton of reduced emissions for Units 3 and 4, respectively.

[14] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

3.2. INDUSTRIAL BOILER CONTROLS

Table 5. Cost Analysis Summary of Technically Feasible Controls for Industrial Boilers

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
Selective Catalytic Reduction	1	$9,451 per ton	Equipment costs, Annual operating costs
	2	$5,229 per ton	

3.2.1. Selective Catalytic Reduction

To estimate the cost of a SCR unit for the boilers operating at the Cunningham Station, Xcel utilized the EPA Cost Control Manual spreadsheet. According to the cost estimation spreadsheet, the cost for Unit 1 would be $11.1 million with $145,035 annual direct costs, and $830,337 in annual indirect costs. The lifetime of the control is estimated to be 20 years and the emissions reduction from this control is estimated to be 114.00 tpy based on an assumed 80% control efficiency and uncontrolled annual emissions of 142.5 tpy (2016 emission inventory data). This results in a cost of $9,451/ton NO_X removal.

Unit 2 would cost $21.98 million with $620,558 in annual direct costs, and $1.84 million in annual indirect costs. The lifetime of the control is estimated to be 20 years and the emissions reduction from this control is estimated to be 471.12 tpy based on an assumed 80% control efficiency and uncontrolled annual emissions of 588.90 tpy (2016 emission inventory data). This results in a cost of $5,229/ton NO_X removal.

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of Xcel's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

4.1. TURBINE CONTROLS

4.1.1. Water Injection

Xcel estimates that approximately 18 months will be needed to order, deliver, and install this equipment at the Cunningham Station.

4.1.2. Selective Catalytic Reduction

Xcel estimates that approximately 30 months will be needed to budget, design, procure, and construct this equipment.

4.2. INDUSTRIAL BOILER CONTROLS

4.2.1. Selective Catalytic Reduction

Xcel estimates that approximately 30 months will be needed to budget, design, procure, and construct this equipment.

5.1. TURBINE CONTROLS

5.1.1. Water Injection

Water injection is usually accompanied by an efficiency penalty (typically 2% to 3%), but an increase in power output (typically 5% to 6%).[15] The increased power output results from the increased mass flow required to maintain turbine inlet temperature at manufacturer's specifications. Both CO and VOC emissions are significantly increased by water injection, with the level of CO and VOC increases dependent on the amount of water injection.[16] This increase in emissions could potentially warrant the installation of an oxidation catalyst, levying significant additional costs on Xcel to implement this control.

Additionally, depending on the model and capacity of a turbine, approximately 31 to 70 gpm may be needed to properly implement this control.[17] For a continuously operating turbine, this would represent a total water usage of 16.3 to 36.8 million gallons per year, per unit, without taking into consideration leaks and evaporative losses that would occur during transport. The implementation of this control across the Permian Basin may pose a significant burden on this semi-arid region's watershed, in which water availability is relatively sparse.

5.1.2. Selective Catalytic Reduction

The implementation of SCR on the turbines at the Cunningham Station would result in several energy and non-air environmental impacts. The primary impact of this control would be a significant increase in energy consumption, which would be necessary to power the units. Xcel does not anticipate any issues with meeting this increased energy burden.

In addition to the increased energy burden, there are several non-air environmental impacts associated with the handling and storage of the reagent used in the SCR system, typically ammonia or urea. Ammonia is a Toxic Air Pollutant (TAP) regulated under 20.2.72.502 NMAC with an occupational exposure limit (OEL) of 18 mg/m^3. In both soil and water, urea is hydrolyzed quickly to ammonia and carbon dioxide by urease, an extracellular enzyme that originates from microorganisms and plant roots.[18] Short-term inhalation exposure to high levels of ammonia in humans can cause irritation and serious burns in the mouth, lungs, and eyes. Chronic exposure to airborne ammonia can increase the risk of respiratory irritation, cough, wheezing, tightness in the chest, and impaired lung function in humans. Animal studies also suggest that exposure to high levels of ammonia in air may adversely affect other organs, such as the liver, kidney, and spleen.[19] Unavoidable releases of ammonia could have significant and irreversible impacts on the living and physical environment affected. Storage and handling of urea or ammonia onsite would result in an increased risk to the health and safety of facility operators.

5.2. INDUSTRIAL BOILER CONTROLS

5.2.1. Selective Catalytic Reduction

The implementation of SCR on the boilers at the Cunningham Station would result in several energy and non-air environmental impacts. The primary impact of this control would be a significant increase in energy consumption, which would be necessary to power the units. Xcel does not anticipate any issues with meeting this increased energy burden.

In addition to the increased energy burden, there are several non-air environmental impacts associated with the handling and storage of the reagent used in the SCR system, typically ammonia or urea. Ammonia is a Toxic Air Pollutant (TAP) regulated under 20.2.72.502 NMAC with an occupational exposure limit (OEL) of 18 mg/m^3. In both soil and water, urea is hydrolyzed quickly to ammonia and carbon dioxide by urease, an extracellular enzyme that originates from microorganisms and plant roots.[20] Short-term inhalation exposure to high levels of ammonia in humans can cause irritation and serious burns in the mouth, lungs, and eyes. Chronic exposure to airborne ammonia can increase the risk of respiratory irritation, cough, wheezing, tightness in the chest, and impaired lung function in humans. Animal studies also suggest that exposure to high levels of ammonia in air may adversely affect other organs, such as the liver, kidney, and spleen.[21] Unavoidable releases of ammonia could have significant and irreversible impacts on the living and physical environment affected. Storage and handling of urea or ammonia onsite would result in an increased risk to the health and safety of facility operators.

6.1. TURBINE CONTROLS

6.1.1. Water Injection

The estimated lifetime of a water injection control system is 15 years. This estimate has been incorporated in the cost analysis section to calculate the total annualized cost of the control.

6.1.2. Selective Catalytic Reduction

The estimated lifetime of a SCR control system is 20 years. This estimate has been incorporated in the cost analysis section to calculate the total annualized cost of the control.

6.2. INDUSTRIAL BOILER CONTROLS

6.2.1. Selective Catalytic Reduction

The estimated lifetime of a SCR control system is 20 years. This estimate has been incorporated in the cost analysis section to calculate the total annualized cost of the control.

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input on the available control technologies for the natural-gas fired turbines located at the Cunningham Station, Xcel has determined that it is not technically feasible or cost effective to implement any controls on equipment at this time.

Combustion Turbines 1-3
Industrial Boilers 1-4
Cost of Compliance 1-6

APPENDIX A: VENDOR DOCUMENTION 1-7

APPENDIX B: HYSPLIT MODELING ANALYIS 1-8
HYSPLIT Model – Overview 1-9
HYSPLIT Model - Procedure 1-9

APPENDIX C: GOOD COMBUSTION PRACTICES MANUAL 1-12

The NMED posed the following questions regarding the emissions control options Enterprise presented for the two (2) turbines and two (2) boilers located at the Xcel Energy Cunningham Station.

COMBUSTION TURBINES

1. *Provide the details regarding Good Combustion Practices (GCP) and the routine maintenance schedule and procedures that are currently used to mitigate NO_X emissions that are employed as the base case.*
   Response: Xcel Energy implements robust Good Combustion Practice which are detailed in a Good Combustion Practices Manual that has been developed specifically for the Cunningham Station facility. This document is provided with this submission.

2. *Can documentation be obtained from Siemens to support the claim that there are no commercially available dry low NO_X (DLN) burners that would provide lower emissions than those already installed on the combustion turbines?*
   Response: Correspondence from Dan Johnson (Siemens Energy) is attached in Appendix A confirming that DLN and ULN upgrades are not commercially available for the Siemens D5A turbines installed at the Cunningham Station.

3. *Provide documentation with details from Xcel engineers that steam injection may not be implemented on the combustion turbines*.
   Response: An email from Siemens is attached in Appendix A discussing the fact that steam injection is not available for these units. The reasons include physical limitations in the combustion chamber and cost, among others. Moreover, Siemens stated that steam injection has not been installed on these units. In addition to the technical barriers the technology has not been commercially demonstrated and is therefore not considered to be a viable control option for the Turbines at the Cunningham Station

4. *Although the analysis indicates that selective catalytic reduction (SCR) may be considered a technically feasible control option, if space and temperature limitations can be overcome, please provide additional discussion on the possible space limitations; the potential significant technical and financial challenges associated with elevated exhaust temperature from the simple cycle turbines; and the drawbacks from employing this technology on peaking units when compared to continuous operation of combined-cycle units.*
   Response: As discussed in the original submission, Xcel considered space limitations and determined that there is enough space to install the SCRs. While exhaust temperature may present some issues, if needed Xcel could install a hot side SCR, which is suggested by Siemens in the email attachment to number 3, above. Specific cost and performance factors were not considered for a hot side SCR as the EPA cost estimate manual and generic AP-42 control efficiencies were used to evaluate the cost effectiveness of these units.

INDUSTRIAL BOILERS

5. *Provide the details regarding GCP and the routine maintenance schedule and procedures that are currently used to mitigate NOX emissions and are employed as the base case.*
   Response: Per the above response, please see the Good Combustion Practices manual for Cunningham Station.

6. *Please provide additional detail on the reasons why the three levels of combustion burners on Boiler Unit 1 cannot be modified to include the overfire air technique currently employed on Unit 2.*
   Response: Unit 1 is a much smaller boiler than unit 2. Overfired air involves removing the top layer of burners and replacing them with air registers. If this modification were implemented, there would not be enough burners to operate the unit. The Unit would need to be redesigned and rebuilt to add another burner layer, with air registers installed at the top. The locations of the burners would change and would require a redesign and rebuild of the piping and ductwork for air and gas delivery. Alternatively, the boiler itself could be completely redesigned and rebuilt to accommodate the implementation of overfire air. However, as stated in the Guidelines for BART determinations Under the Regional Haze Rule, the general types of modifications that shall be considered under this analysis include the implementation of lower emitting processes or practices and add-on controls. Moreover, the guidance states that this analysis shall not be considered as a "requirement to redesign the source when considering available control alternatives."[1] Therefore, neither of these options to accommodate overfire air are a viable option.

7. *There are other NOX reduction technologies that may be applicable to the Cunningham Station's boilers. Please include a discussion on the technical feasibility on the following technologies:*
   a. *ECOTUBE;*
      Response: The ECOTUBE technology is a combination of SCR and overfire air technology. Since overfire air controls cannot be implemented on Unit 1, this would not be feasible on that unit, as well. Moreover, since overfire air is currently installed on Unit 2 and we have evaluated SCR controls for that unit, it is not clear that there would be any additional benefit from this control.

      The Eastern Research Group prepared a report for the Clean Air Strategic Alliance on Control technologies for the Electricity Framework.[2] (). The report noted that this technology had not been commercially demonstrated on demonstrated on large boilers. The technology was therefore excluded from the analysis. The Navajo Generating Station in Tempe, AZ conducted a BART analysis for the previous Regional Haze Rule Planning period. The ECOTUBE technology was eliminated from consideration using this same reasoning. This determination was submitted to and accepted by WRAP. This technology will not be considered further by Xcel for use on the boilers operating at Cunningham Station.

   b. *LoTOx;*
      Response: LoTOx technology is a relatively recent technology that to this point has not been widely used. While the Manufacturer, Linde, LLC, states that the technology is commercially available, no technical documentation could be found to demonstrate robust commercial use of

[1] 40 CFR 51 Appendix Y Section IV.D.1.5

[2] Electricity Framework 5 Year Review – Control Technologies Review, ERG No. 3689.00.001.001, Prepared for Clean Air Strategic Alliance by Eastern Research Group (2009) http://www.assembly.ab.ca/lao/library/egovdocs/2009/ca6/casa/173276.pdf

the technology. Very limited information exists on this technology: this control technology was not found in the RBLC and no discussions on this control were included in AP-42, the EPA Cost Guidance Manual, Alternative Control Techniques Document, or any other government agency or third-party organization documents.

c. *natural gas reburn;*
Response: Natural gas reburning is a synonym for overfire air burning. This technique is currently implemented on Unit 2 and cannot be implemented on Unit 1, as discussed in the response to question 2, above.

d. *$NO_X Star^{TM}$ and $NO_X Star\ Plus^{TM}$;*
Response: In the Electricity Framework 5 Year Review[3], the NO_XStar and NO_XStar Plus technology was also reported as not being commercially demonstrated on large boilers. According to the EPA Cost Manual Section 1.2.6, the NO_X control efficiency of these units at a minimum have only been demonstrated to be 45% but the cost is high; the manual states that the cost of a NO_XStar unit is approximately $60 to $75 per kW. Unit 1 and 2 have rating of 82 MW and 234 MW, respectively, yielding approximate costs of $6.15 million and $17.55 million. While SCR units have total capital costs of $11.11 and $21.98 million, they provide a much higher NOx control efficiency of 80%. Because this technology is not widely used, has not been commercially demonstrated on large boilers, and would not be cost effective, the unit is not being considered as a viable option.

e. *regenerative SCR (RSCR);*
Response: No literature was found to be available on regenerative SCRs. It is noted that SCR catalyst elements may be regenerated, but it is not clear how this differs significantly from a standard SCR.

f. *selective non-catalytic combustion*
Response: Selective non-catalytic reduction techniques have relatively poor performance compared to SCRs; AP-42 Section 1.4.4 states a NO_X control efficiency of 24%. Additionally, the unit was not identified as a control that has been implemented in the last 10 years in the RBLC. For this reason, the control was not considered.

Although the unit is somewhat cheaper than a SCR, Xcel does not believe this would demonstrate that this technology would be more cost effective. According to the EPA Air Pollution Control Technology Fact Sheet for SNCR units the cost estimates for the units would be as follows:

Costs from the "Air Pollution Control Technology Fact Sheet" for Selective Non-Catalytic Reduction		
Capital Cost ($/MW)	$	25,000
O&M Cost ($/MW)	$	5,000
Other Annualized Costs ($/MW/yr)	$	1,000

[3] Ibid.

	Unit 1	Unit 2	Notes
Boiler Rating (MW)	82	234	
Capital Cost	$ 2,050,000	$ 5,850,000	
O&M Cost	$ 410,000	$ 1,170,000	
Lifetime Annualized Costs	$ 1,640,000	$ 4,680,000	SNCR lifetime is assumed to be 20 years
Total Cost	$ 4,100,000	$ 11,700,000	Capital, O&M, and other annualized costs
Annualized TCI	$ 343,085.25	$ 979,048.16	Amortized over 20 years w/ 5.5% interest
Baseline Emissions (tpy)	142.50	588.90	2016 emission inventory data
Control Efficiency (%)	24%	24%	AP-42 Section 1.4.4
Tons Controlled (tpy)	34.20	141.34	Control efficiency * baseline emissions
Cost Per Ton ($/ton)	$10,031.73	$6,927.10	Annualized TCI / tons controlled

Based on the above cost information, the SNCR technology is slightly less cost effective than SCR technology. Xcel does not anticipate that there are any site-specific environmental or non-air impacts from this control technology.

COST OF COMPLIANCE

1. *Please provide copies of all vendor quotes used for determining the cost of compliance and copies of electronic spreadsheets used to calculate cost effectiveness.*
   Response: A vendor quote of the water injection quote is provided in Appendix A. Additional cost associated with the installation and operation of water injection were calculated using the EPA Cost Manual. SCR equipment costs are calculated using the EPA Cost Manual spreadsheets. Other installation costs associated with this unit were estimated by Xcel. Documentation of all these costs are included in an electronic spreadsheet.

2. *Provide a vendor quote to refine the cost effectiveness estimates for installation of SCR units on the boilers.*
   Response: With the understanding that vendor quotes were not required to estimate equipment cost and in accordance with guidance from the NMED (as provided on the Regional Haze website), the EPA Cost Manual Spreadsheets were used to estimate the costs of SCR units for the boilers. The electronic spreadsheet is attached with the EPA cost spreadsheets included.

Doug,

The Cheng cycle seems to be something new to the market. A few data points from their web page:

- Not possible to get a 50-90% MW increase. Shaft limit prevents it, even on a hot day. Not certain if Xcel can utilize a rate increase without NSR?
- It's doubtful that the generator would accept that power increase, either, so – new generator required = $$$$$.
- It is doubtful that a GT will accept the "massive" amount of steam that Cheng describes without serious consideration of dynamics/flame stability. Could be more a hindrance than a benefit if just for emissions reduction.
- We do not agree with the efficiency increase promised without a HRSG driven steam turbine.
- Can't tell how much make-up water will be consumed to make the massive amounts of steam. It could be quite a bit which would get expensive.
- Even if the Cheng cycle could be economically implemented on a GT, the Isophase bus duct, GSUT or T&D in the yard would likely be the next bottleneck.

Before doing any thermodynamics, the feasibility is low. The concept is interesting, but sketchy at the same time and the website is scant on details.

Success seems more likely if used on a new unit installation so that all BOP could be sized correctly.

Siemens has not installed steam injected on D5A DLN units.

In order for to do steam injection a HRSG is necessary and site engineering and construction would be expensive. In Siemens opinion, Cunningham should look at a hot SCR.

Dan

To: Johnson, Dan (GP SPG RNA PSS MW) <danny.johnson@siemens.com>
Subject: Question about power augmentation steam injection

Dan,
Were the original Westinghouse 501 D5A units we have at Cunningham set up to do steam injection as an option? I know we did wet compression on these units, but NMED is asking questions about options to improve NOx control. I already told them that Siemens doesn't offer DLN for these units.

I saw an after market offering from Cheng Power Systems call the Cheng Cycle, which uses a small single pressure HRSG to generate steam for this, and they say they have retro-fitted a D5A with this. I'm very leery of even talking to them about this. I was thinking the F machines had a steam injection port but I thought the D5A did not. Please advise.
Thanks,
Doug

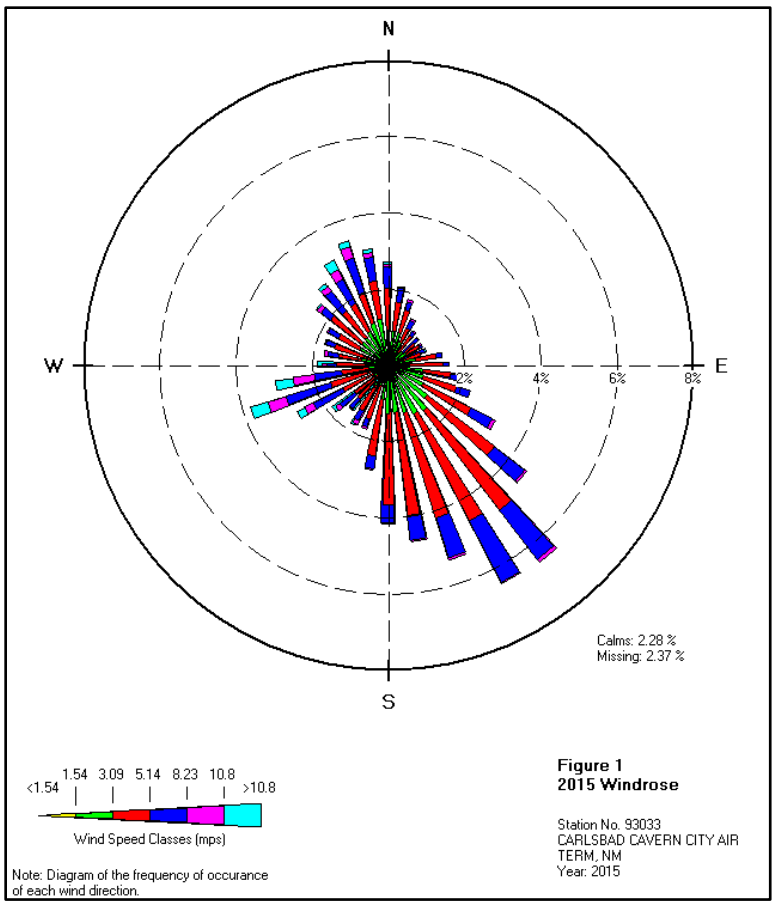
Letter Containing Confidential Vendor Information Omitted

Xcel Energy's Cunningham Station was identified as a facility that may potentially have an impact on visibility at the Carlsbad Caverns National Park. The NMED used a Q/d analysis of all the major sources in New Mexico to make this determination, where "Q" is the facilities emission rate of NO_X and SO_2 and "d" is the distance of the facility to a national park. There are several disadvantages to evaluating facility impact in this manner. The methodology does not take into consideration the plethora of minor sources with a much closer proximity to the Class I area. Additionally, the driving factor of a facility's relative impact on a Class I area is the prevailing meteorological conditions in the region.

The Cunningham Station is located 69.3 miles away from the Carlsbad Caverns Class I area at a wind vector of 58 degrees (northeast). The wind roses reported in Figures 1 and 2 below show that the prevailing wind direction in Carlsbad are bi modal blowing mostly from the SE and NW and the wind in Hobbs, NM blow mostly from the south. The wind climatology of these locations does not favor pollutant transport from the Cunningham Station to the Carlsbad Cavern Class I area.

It is understood, however that pollutants are not transport in a straight line and that, over an extended period of time, while unlikely, it is plausible that pollutants emitted by the Cunningham Station could be transported to the Carlsbad Caverns. To evaluate this transport, HYSPLIT modeling has been employed. The results of this modeling are discussed in this Appendix.

Figure 1. 2015 Wind Rose of Wind Speed vs. Wind Direction in Carlsbad, NM.



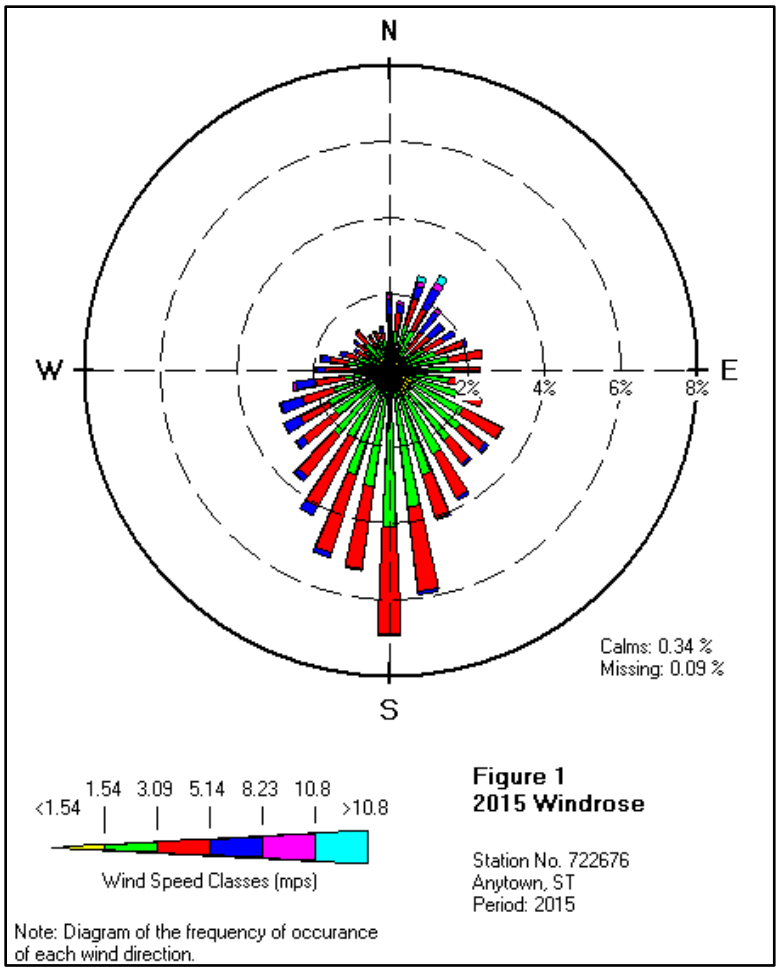


Figure 2. 2015 Wind Rose of Wind Speed vs. Wind Direction in Hobbs, NM.

HYSPLIT MODEL – OVERVIEW

HYSPLIT is a hybrid model using both the Lagrangian approach, which uses a moving frame of reference for the advection and diffusion calculations as the trajectories or air parcels move from their initial location, and the Eulerian methodology, which uses a fixed three-dimensional grid as a frame of reference to compute pollutant air concentrations. The dispersion of a hypothetical pollutant is calculated by assuming either puff or particle dispersion. The back-trajectory analysis utilized applies a particle model, where a fixed number of particles are advected about the model domain by the mean wind field and spread by a turbulent component. The model's default configuration assumes a 3-dimensional particle distribution (horizontal and vertical).

HYSPLIT MODEL - PROCEDURE

There are two HYSPLIT modeling techniques available: dispersion Modeling, which models the concentration of dispersed pollutants in a plume, or trajectory modeling which calculates the mean transport of pollution along a finite path. Using the trajectory modeling tool, back-trajectories were calculated every hour starting January 1, 2014, and ending December 31, 2018. The location modeled was the site of the Carlsbad Caverns IMPROVE monitor (32.1783°N, 104.4406°W).

There are several options available for meteorological datasets. In order resolve topographic features and mesoscale meteorological phenomena, the 12 km NAMM meteorological dataset was used.

The following protocol was implemented:

- A five-year look-back period (2014 through 2018) was modeled;
- The model was run for each hour of each day (i.e., 24 runs per day);
- A 48 hour back-trajectory was calculated for each of the 24 runs to capture the transport of pollutants from all nearby sources to the Carlsbad Caverns National Park. The model calculated the back-trajectories in 1-hour time steps; and
- The sigma height option was used, with an initial target height of 0.5 sigma which represents half the height of the boundary layer. This height is considered to be representative of the mean ground level ambient air, since the boundary layer is well-mixed/homogenous.

Based on the availability of meteorological data, the HYSPLIT model was able to calculate back-trajectories for 43,753 hours out of 43,824 hours (99.84%). The back-trajectories were then synthesized in a single plot that displays the frequency that trajectories pass through a grid cell. A 0.1° (approximately 10 km) grid cell network was generated using the "trajfreq" executable file that NOAA has included with their suite of HYSPLIT software. For each grid cell (i,j) in the modeling domain, the frequency (F) is calculated using the following equation:

$$F_{i,j} = 100 \Sigma T_{i,j} / N \qquad \text{(equation 1)}$$

Where T is the number of trajectories that intersect a grid cell (i,j) and N is the total number of trajectories analyzed (47,353).

To generate a figure from this data, the "concplot" executable was used, which allows the user to select the contour levels, colors, map projection and output format. Figures 3 shows the frequency plot for the Carlsbad Caverns Class I area.

Figure 3. A HYSPLIT back trajectory frequency plot for 2014 to 2018 for the Carlsbad Caverns National Park.

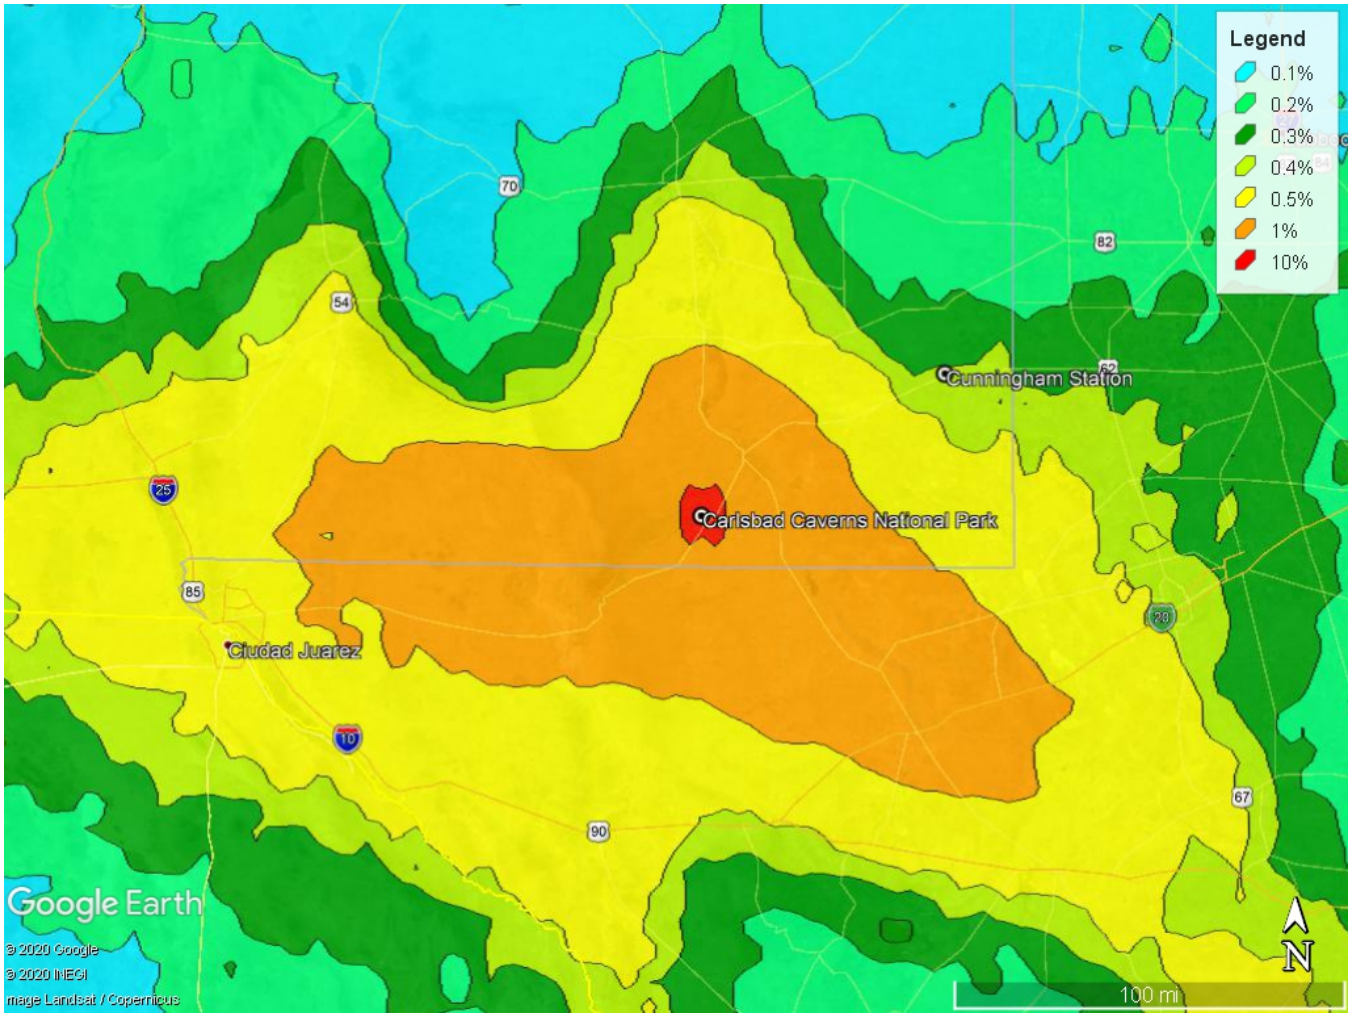

Figure 3 shows that ambient air at Cunningham Station only passes through the grid cell where the Carlsbad Caverns IMPROVE monitor is located with a frequency of approximately 0.4% or 175 hours out of the 43,753 hours that were modeled. While the costs effectiveness of controls alone would preclude the Cunningham Station from implementing any control technologies, this modeling demonstrates that such modifcations would not have an impact on visibility at the Carlsbad Caverns.

APPENDIX C: GOOD COMBUSTION PRACTICES MANUAL

Particulate Matter (total suspended):	7.0	tons/y	EPA emission factors (e.g., AP-42)
Sulfur Dioxide:	0.6	tons/y	Continuous Emission Monitoring (CEMS)
Volatile Organic Compounds (VOC):	1.3	tons/y	EPA emission factors (e.g., AP-42)

Subject Item Comments

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Utility

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the MW rating at full load capacity (Bmw)?	82	MW
What is the higher heating value (HHV) of the fuel?	1,052	Btu/scf
What is the estimated actual annual MWhs output?	342,456	MWhs
Enter the net plant heat input rate (NPHR)	10	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3815 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	187.75	days
Number of days the boiler operates (t_{plant})	187.75	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.29	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.087	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	25	Years*

* For utility boilers, the typical equipment life of an SCR is at least 30 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	700	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	15.84	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0361	$/kWh			* $0.0361/kWh is a default value for electicity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	Bmw x NPHR =	221	MMBtu/hour	
Maximum Annual MW Output (Bmw) =	Bmw x 8760 =	718,320	MWhs	
Estimated Actual Annual MWhs Output (Boutput) =		342,456	MWhs	
Heat Rate Factor (HRF) =	NPHR/10 =	1.03		
Total System Capacity Factor (CF_{total}) =	(Boutput/Bmw)*(tscr/tplant) =	0.477	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	4176	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	44.93	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	93.81	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	3506.5	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	5.0	/hour	
Residence Time	1/V_{space}	0.1995	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.1792	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	699.53	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	4	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	65	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	4	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	2.0	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	296	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	17	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	60	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	8	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	2,800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0745

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = Bmw for utility boilers	465.07	kW

Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$11,118,368	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$145,035 in 2018 dollars
Indirect Annual Costs (IDAC) =	$830,337 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$975,372 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$55,592 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$9,841 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$70,116 in 2018 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$9,485 in 2018 dollars
Direct Annual Cost =		$145,035 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,019 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$828,318 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$830,337 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$975,372 per year in 2018 dollars
NOx Removed =	94 tons/year
Cost Effectiveness =	$10,397 per ton of NOx removed in 2018 dollars

Subject Item Comments

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Utility

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the MW rating at full load capacity (Bmw)?	234	MW
What is the higher heating value (HHV) of the fuel?	1,052	Btu/scf
What is the estimated actual annual MWhs output?	1,881,360	MWhs
Enter the net plant heat input rate (NPHR)	9.5	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3815 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	335	days
Number of days the boiler operates (t_{plant})	335	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.16	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.03	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For utility boilers, the typical equipment life of an SCR is at least 30 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	628	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	15.8	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	Bmw x NPHR =	927	MMBtu/hour	
Maximum Annual MW Output (Bmw) =	Bmw x 8760 =	2,049,840	MWhs	
Estimated Actual Annual MWhs Output (Boutput) =		1,881,360	MWhs	
Heat Rate Factor (HRF) =	NPHR/10 =	0.95		
Total System Capacity Factor (CF_{total}) =	(Boutput/Bmw)*(tscr/tplant) =	0.918	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8040	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	117.19	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	471.12	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	13,780	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	3.69	/hour	
Residence Time	1/V_{space}	0.27	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	3,733.67	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	14	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	88	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	17	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	4.1	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	388	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	46	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	157	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	21	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	7,100	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = Bmw for utility boilers	1281.81	kW

Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$21,981,248	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$620,558 in 2018 dollars
Indirect Annual Costs (IDAC) =	$1,843,561 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$2,464,119 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$109,906 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$49,423 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$372,039 in 2018 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$89,190 in 2018 dollars
Direct Annual Cost =		$620,558 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,731 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,839,830 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,843,561 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$2,464,119 per year in 2018 dollars
NOx Removed =	471 tons/year
Cost Effectiveness =	$5,230 per ton of NOx removed in 2018 dollars

Facility Annual Emissions - Subject Item Submittal Review
Thursday, September 12, 2019

Agency ID: 604
Facility Name: Xcel Energy - Cunningham Station Power Plant
Organization Name: Southwestern Public Service Co dba Xcel Energy
Submittal Status: 2016 Submittal (Certified, Awaiting NMED Approval)

Subject Item ID: EQPT-3
Designation: 003
Description: Simple Cycle Gas Turbine
Type: Turbine
SCC: Internal Combustion Engines, Electric Generation, Natural Gas, Turbine
GHG Reporting: Reports GHG to EPA

Supplemental Parameters

	Amount	Unit of Measure
Fuel Type:	Natural Gas	
Input Materials Processed:	Natural Gas (INPUT)	
Materials Consumed:	1523.0	MM SCF
Fuel Heating Value:	1051.9	BTU/SCF
Percent Sulfur of Fuel:	0.0	percent
Percent Ash of Fuel:	0.0	percent
Percent Carbon Content:	73.0	percent

Operating Detail

	Value
Operating Time in Hours per Day:	24
Operating Time in Days per Week:	7
Operating Time in Weeks per Year:	52
Operating Time in Hours per Year:	1597
Percent of Operation During Winter:	0
Percent of Operation During Spring:	25
Percent of Operation During Summer:	42
Percent of Operation During Fall:	33

Actual Pollutants

Pollutant	Amount	Unit of Measure	Calculation Method
Carbon Monoxide:	2.4	tons/y	Actual stack test
Formaldehyde:	0.57	tons/y	EPA emission factors (e.g., AP-42)
Nitrogen Dioxide:	43.2	tons/y	Continuous Emission Monitoring (CEMS)
Particulate Matter (10 microns or less):	5.285	tons/y	EPA emission factors (e.g., AP-42)
Particulate Matter (2.5 microns or less):	5.285	tons/y	EPA emission factors (e.g., AP-42)
Particulate Matter (total suspended):	5.285	tons/y	EPA emission factors (e.g., AP-42)
Sulfur Dioxide:	0.4	tons/y	Continuous Emission Monitoring (CEMS)
Volatile Organic Compounds (VOC):	1.682	tons/y	EPA emission factors (e.g., AP-42)

Subject Item Comments

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Utility

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the MW rating at full load capacity (Bmw)?	135	MW
What is the higher heating value (HHV) of the fuel?	1,052	Btu/scf
What is the estimated actual annual MWhs output?	127,680	MWhs
Enter the net plant heat input rate (NPHR)	10	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3815 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	70	days
Number of days the boiler operates (t_{plant})	70	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.30	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.10	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For utility boilers, the typical equipment life of an SCR is at least 30 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	700	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	15.84	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0361	$/kWh			* $0.0361/kWh is a default value for electicity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	Bmw x NPHR =	183	MMBtu/hour	
Maximum Annual MW Output (Bmw) =	Bmw x 8760 =	1,182,600	MWhs	
Estimated Actual Annual MWhs Output (Boutput) =		127,680	MWhs	
Heat Rate Factor (HRF) =	NPHR/10 =	1.03		
Total System Capacity Factor (CF_{total}) =	(Boutput/Bmw)*(tscr/tplant) =	0.108	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	946	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	65.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	35.17	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	16.63	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.81		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2897.6	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	5.3	/hour	
Residence Time	1/V_{space}	0.1896	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.0493	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	549.39	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	3	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	62	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	3	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	1.9	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	284	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	14	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	47	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	6	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	2,200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = Bmw for utility boilers	765.67	kW

Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$15,373,721	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$106,805 in 2018 dollars
Indirect Annual Costs (IDAC) =	$1,288,207 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$1,395,011 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$76,869 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$1,745 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$26,142 in 2018 dollars
Annual Catalyst Replacement Cost =		$2,049 in 2018 dollars
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	
	$B_{MW} \times 0.4 \times (CoalF)^{2.9} \times (NRF)^{0.71} \times (CC_{replace}) \times 35.3$	
	$(Q_B/NPHR) \times 0.4 \times (CoalF)^{2.9} \times (NRF)^{0.71} \times (CC_{replace}) \times 35.3$	
Direct Annual Cost =		$106,805 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$1,426 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,286,780 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,288,207 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,395,011 per year in 2018 dollars
NOx Removed =	17 tons/year
Cost Effectiveness =	$83,887 per ton of NOx removed in 2018 dollars

Facility Annual Emissions - Subject Item Submittal Review
Thursday, September 12, 2019

Agency ID: 604
Facility Name: Xcel Energy - Cunningham Station Power Plant
Organization Name: Southwestern Public Service Co dba Xcel Energy
Submittal Status: 2016 Submittal (Certified, Awaiting NMED Approval)

Subject Item ID: EQPT-7
Designation: 004
Description: Simple Cycle Gas Turbine
Type: Turbine
SCC: Internal Combustion Engines, Electric Generation, Natural Gas, Turbine
GHG Reporting: Reports GHG to EPA

Supplemental Parameters

	Amount	Unit of Measure
Fuel Type:	Natural Gas	
Input Materials Processed:	Natural Gas (INPUT)	
Materials Consumed:	2778.0	MM SCF
Fuel Heating Value:	1051.9	BTU/SCF
Percent Sulfur of Fuel:	0.0	percent
Percent Ash of Fuel:	0.0	percent
Percent Carbon Content:	73.0	percent

Operating Detail

	Value
Operating Time in Hours per Day:	24
Operating Time in Days per Week:	7
Operating Time in Weeks per Year:	52
Operating Time in Hours per Year:	2848
Percent of Operation During Winter:	10
Percent of Operation During Spring:	22
Percent of Operation During Summer:	25
Percent of Operation During Fall:	43

Actual Pollutants

Pollutant	Amount	Unit of Measure	Calculation Method
Carbon Monoxide:	2.9	tons/y	Actual stack test
Formaldehyde:	1.04	tons/y	EPA emission factors (e.g., AP-42)
Nitrogen Dioxide:	84.7	tons/y	Continuous Emission Monitoring (CEMS)
Particulate Matter (10 microns or less):	9.642	tons/y	EPA emission factors (e.g., AP-42)
Particulate Matter (2.5 microns or less):	9.642	tons/y	EPA emission factors (e.g., AP-42)
Particulate Matter (total suspended):	9.642	tons/y	EPA emission factors (e.g., AP-42)
Sulfur Dioxide:	0.9	tons/y	Continuous Emission Monitoring (CEMS)
Volatile Organic Compounds (VOC):	3.068	tons/y	EPA emission factors (e.g., AP-42)

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Utility

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the MW rating at full load capacity (Bmw)?	135	MW
What is the higher heating value (HHV) of the fuel?	1,052	Btu/scf
What is the estimated actual annual MWhs output?	218,880	MWhs
Enter the net plant heat input rate (NPHR)	10	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3815 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	120	days
Number of days the boiler operates (t_{plant})	120	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.18	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.054	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For utility boilers, the typical equipment life of an SCR is at least 30 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	700	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	15.84	ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	603.1	2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0361	$/kWh			* $0.0361/kWh is a default value for electicity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	-	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.

Interest Rate (Percent)	5.5	Default bank prime rate		Use known interest rate or use bank prime rate, available at https://www.federalreserve.gov/releases/h15/.

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	Bmw x NPHR =	334	MMBtu/hour	
Maximum Annual MW Output (Bmw) =	Bmw x 8760 =	1,182,600	MWhs	
Estimated Actual Annual MWhs Output (Boutput) =		218,880	MWhs	
Heat Rate Factor (HRF) =	NPHR/10 =	1.03		
Total System Capacity Factor (CF_{total}) =	(Boutput/Bmw)*(tscr/tplant) =	0.185	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	1621	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	42.03	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	34.07	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	5285.4	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	5.2	/hour	
Residence Time	1/V_{space}	0.1920	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.1029	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	1,015.06	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	6	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	62	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	6	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	2.5	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	287	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	16	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	56	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	8	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	2,600	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = Bmw for utility boilers	765.67	kW

Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$15,373,721	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$133,161 in 2018 dollars
Indirect Annual Costs (IDAC) =	$1,288,567 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$1,421,728 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$76,869 in 2018 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$3,574 in 2018 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$44,815 in 2018 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$7,903 in 2018 dollars
Direct Annual Cost =		$133,161 in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$1,786 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,286,780 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,288,567 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,421,728 per year in 2018 dollars
NOx Removed =	34 tons/year
Cost Effectiveness =	$41,725 per ton of NOx removed in 2018 dollars

Subject:	[EXT] Information Request - Cunningham Station Regional Haze
Date:	Monday, November 2, 2020 2:36:57 PM
Attachments:	Attachments.pdf

Mr. Singleton,

Please find attached a response to your question and clarifications for Cunningham Station as part of the NMED's Regional Haze project. Confidential information is being submitted under separate cover.

1. **NMED revised the cost estimate based on 2016 – 2018 average emissions and operating hours. The cost calculations assumed the default bank prime rate of 5.5%; however, the instructions indicate that the current bank prime rate should be used. Was the bank prime rate verified and/or documented during preparation of the analysis?** Xcel Energy is a utility regulated by the New Mexico and Texas Public Utility Commissions. We do not borrow money in a way that could accurately be represented by the bank prime rate. According to a recent agreement with NM PUC, see attached partial Uncontested Comprehensive Stipulation page 3 Section I.3, the "cost of capital" for Cunningham Station is 7.19%. This is not directly analogous to the prime rate, so we used 5.5%, which was the default in the EPA spreadsheet, to be conservative.
2. **The cost basis for water injection was based on a 2008 quote from Siemens, corrected to CEPI ratios. Any estimates older than 5 years will attract more scrutiny from other stakeholders, including the Federal Land Managers and EPA. Xcel should obtain an updated quote from the vendor for water injection.** We have received a "budgetary" estimate from Siemens Energy for water injection systems for Cunningham Units 3 and 4. Per unit, the equipment cost was $1.95 million and total cost including installation was $3.66 million. Installation costs are calculated using a spreadsheet that Xcel considers to be Confidential Business Information (CBI). We have included a summary of that spreadsheet detailing the total estimated costs of the water injection systems. An informational letter from Siemens Energy is also included as Confidential Business Information (CBI) on another email.
3. **The Xcel estimates for the costs associated with installation, engineering, and labor for an SCR system seem excessive, almost equivalent to the equipment costs. Additional information is required to justify this estimate.** Xcel has reviewed the costs with a vendor and using our estimation spreadsheets/model and determined that costs for installation should be lower. Xcel received a budgetary-level estimate from Siemens Energy for SCR controls on Cunningham Units 3 and 4. Per unit, the equipment cost was approximately $11.9 million and total cost including installation was approximately $21 million. An email from Siemens Energy is included with equipment costs. Installation costs are calculated using a spreadsheet that Xcel considers to be CBI. We have included a summary of that spreadsheet detailing the total estimated costs of the SCR systems.
4. **The calculations for Units 1 & 2 indicate an SCR life expectancy of 20 years, but the Cost Control spreadsheet (Data Inputs) indicates that the life expectancy for SCR on utility boilers is 30 years. NMED cost calculations account for this longer life expectancy for the boilers. Shouldn't the life expectancy for SCR on the turbines also be set at 30 years?** Both Cunningham Unit 1 and Unit 2 were constructed in the 1960s. They are approaching their end of life. Cunningham 1 will shut down before December 31, 2025. Cunningham 2 will shut down before December 31, 2028. The Unit 3 and 4 turbines are currently projected to shut down in 2040. With the engineering, construction, and installation, a 20-year life expectancy still allows for the flexibility necessary for such a long-term projection.
   Please explain why the lower end of the range for control efficiency by SCR (65%) was used in the analysis for the turbine retrofits. Because there has been no design work on SCRs for the turbines, an accurate estimate is not known. Xcel chose the low end of the range listed in AP-42 Section 3.1.4.3, 65%-90%. Because we haven't had a full design, Xcel believes that the upper range should not be used in this level of analysis. As a result, we believe using 80% as the estimate for the SCR

control efficiency would be best.

UNCONTESTED COMPREHENSIVE STIPULATION

The Signatories to this Uncontested Comprehensive Stipulation ("Stipulation"), which is dated as of January 13, 2020, are:

- Utility Division Staff of the New Mexico Public Regulation Commission ("Staff");
- Southwestern Public Service Company ("SPS");
- Occidental Permian Ltd. ("OPL");
- Federal Executive Agencies ("FEA");
- Louisiana Energy Services, LLC d/b/a URENCO USA ("LES");
- Hector H. Balderas, the Attorney General of the State of New Mexico ("AG");
- New Mexico Large Customer Group ("NMLCG");
- COG Operating LLC ("COG");
- Coalition for Clean Affordable Energy ("CCAE");

- Sierra Club ("SC");
- Western Resource Advocates ("WRA").

New Mexico Gas Company does not oppose this Stipulation. Roosevelt County Electric Cooperative, Inc., and Central Valley Electric Cooperative, Inc. take no position on this Stipulation. Accordingly, this Stipulation is uncontested.

The parties who are joining this Stipulation shall be referred to individually either as a Signatory or by the acronym assigned above, and collectively as the Signatories. The Signatories submit this Stipulation to the New Mexico Public Regulation Commission ("Commission") as representing a just and reasonable disposition of the issues related to this case consistent with the public interest. The Signatories request approval of this Stipulation and entry of findings, conclusions, and ordering paragraphs consistent with that approval.

On July 1, 2019, in accordance with the Public Utility Act ("PUA"), SPS filed its application with the Commission seeking authority to revise its base rates. SPS's application requested that the Commission: authorize SPS to increase its base rate charges for the New Mexico retail jurisdiction by $50,778,291. SPS also requested that the Commission: authorize SPS to modify the service life of Tolk Generating Station Units 1 and 2 ("Tolk") to 2032 and approve abandonment of Tolk during that year, and grant all other approvals, authorizations, and variances that the Commission determines are necessary for SPS to effectuate and implement the relief granted in this case.

By this Stipulation, the Signatories agree to resolve all issues among them related to SPS's application, and agree as follows:

I. Agreement as to Base Rate Increase

SPS's Initial Application sought a base rate revenue requirement increase of $50,778,291. Several parties recommended base rate revenue requirement increases ranging from $21,947,452 to $29,903,958. The Signatories agree that SPS should be authorized to implement an increase in base rate revenues of $31,000,000 in its New Mexico retail service area. The stated cost of service components associated with the increase (including the items required to be provided pursuant to Ordering Paragraph G of the Procedural Order in this matter) are as follows:

1. The return on equity is 9.45%.
2. The capital structure consists of 54.77% common equity and 45.23% long-term debt.
3. The tax-unadjusted weighted average cost of capital is 7.19%.
4. Depreciation rates are provided in Exhibit C. The incremental increase in depreciation expense relative to current rates is $8,067,214.
5. Rate case expenses for this rate case of $1,200,000, to be amortized over one year.
6. The annual amortization of SPS's Z2 expense is $520,490.
7. The annual amortization of SPS's NOx expenses deferred from prior years is $34,890.
8. The revenue requirement for the Hale Wind Project ("Hale") is $26,055,632. The total company gross plant-in-service for Hale in this case is $700,246,760. That equates to $1,465 per kW installed (total company), which is less than the $1,675 per kW installed (total company) cap required by the Order in Case No. 17-00044-UT.

The increase by class and revenue proof is reflected in Exhibit A to this Stipulation ("Exhibit A"). The rate tariffs for the increase and all other stipulated tariff changes are provided in Exhibit B to this Stipulation ("Exhibit B"). Depreciation rates are provided in Exhibit C to this Stipulation ("Exhibit C"). Reconciliation statements are provided in Exhibit D to this Stipulation ("Exhibit D").

The stipulated base rate revenue increase is not associated with any specific calculation involving any of the stated cost of service components herein, or approval or disapproval of any

Hi Mark,

Hope you had a good weekend and sorry for the delay. I had a few more conversations and hopefully the following will work for what you need. The picture below is what would be provided:

Of course, you could not just drop this in and run the unit. Up front engineering work would be needed including review of the electrical systems, analysis of the existing BOP, etc. The number I received for above would be approximately $10M (per unit) with the engineering and other work being in addition to that.

How does that line up with what you provided initially?

Thanks and let me know what you think!

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Here are our answers to question 5.

5.a. O&M Costs – This number for each unit is the annual average for the current 5 year budget cycle. I split the number out, since I wasn't sure whether fuel should be included or not.

Cunningham 3	
Average Total O&M	$ 4,642,561
Average Fuel Expense	$ 2,446,749
Average Fixed Fuel Expense	$ 408,585
Average Fixed O&M	$ 1,787,227

Cunningham 4	
Average Total O&M	$ 5,378,726
Average Fuel Expense	$ 3,107,972
Average Fixed Fuel Expense	$ 525,001
Average Fixed O&M	$ 1,745,753

5.b. – Overhaul Costs. The average for the currently planned overhauls (2025, 2026, and 2027)

Unit 3 – $136,500

Unit 4 – $180,808

In addition, hot gas path inspections are planned for 2023 (Unit 4 – $8.7 million) and 2024 (Unit 3 – $6.7 million). The next one of those will possibly occur in 2030 or so.

Appendix E: Coordination and Outreach Supporting Documentation

E.1 Coordination with Local Jurisdictions and Other States

Supporting documentation for New Mexico Environment Department (NMED) coordination with local jurisdictions and other states is provided below. The following documents are included in this section (in reading order):

- NMED Communication to Texas Commission for Environmental Quality (TCEQ) on Draft SIP Revision Process:
    - NMED Comments and Questions (4/24/20)
    - NMED Comments and Questions (1/08/21)
    - NMED Additional Comments (2/2/21)
- NMED Notice to State and Local Agencies of available NMED draft Regional Haze SIP [FLM Review Version]
    - NMED Email to Contiguous States and City of Albuquerque - EHD (6/20/24)
- Contiguous State Comments to NMED
    - Arizona Department of Environmental Quality (7/18/24)
    - TCEQ (7/16/2024)

Subject: New Mexico Environment Department (NMED) Comments and Questions for TCEQ on Regional Haze Consultation

Dear Deputy Director Baer,

Thank you for the opportunity to review Texas Commission on Environmental Quality's (TCEQ's) April 8th presentation, "Results of Photochemical Modeling for Regional Haze for Consultation with New Mexico." NMED and the City of Albuquerque/Bernalillo County (which is a separate air quality jurisdiction from NMED) have developed initial questions and comments on the presentation, including emission inventory development; screening approaches used in the analysis; selection of additional potential controls; air-related issues specific to the Permian Basin; and more technical questions on model performance and accuracy. NMED appreciates your review and evaluation of the questions and looks forward to discussing these items with the TCEQ Regional Haze team.

Emissions Inventory for Modeling

NMED has been working with the Western Regional Air Partnership (WRAP) on developing inventories for regional haze planning and other technical aspects of our regional haze SIP planning. Information on the WRAP development of emission inventories for modeling is available on the WRAP work group site at https://www.wrapair2.org/RHP_InvMod.aspx. Over several years, TCEQ and NMED worked with EPA on developing the 2016 collaborative regional haze modeling inventory platform.

NMED would like a better understanding of how TCEQ developed the regional haze base case and future year projections used in the analysis and specifically how they differ from EPA's inventories for the 2016 and 2028 platforms. Please describe the inventory that was used for New Mexico and how these emissions affect the Class I areas in New Mexico and Texas. Please also discuss what source sector or county level changes in emissions were projected for Texas and New Mexico in the inventories.

Screening Approaches

As part of a robust stakeholder outreach process, NMED performed targeted public outreach and meetings to explain the screening and selection process. Questions remain regarding how the screening

and selection process was conducted by TCEQ. To assist in NMED's understanding of this process, please detail how TCEQ screened the sources that were required to perform a four-factor analysis, including:

1. What data sets were used to determine the Q/d threshold to select sources for four-factor analysis, and are these data sets available to NMED? What factors did TCEQ consider for selecting sources on a per pollutant basis, rather than combined emissions of SO_2 and NO_x?
2. What percentage of total NO_X and SO_2 emissions are captured with a Q/d>5?
3. Were emissions from minor and area sources considered in determining what sources are subject to a four-factor analysis?
4. Will TCEQ post four-factor analyses on its website for review?

WRAP recently completed preliminary Weighted Emissions Potential (WEP) and Area of Influence (AOI) results for Class I areas in the Western United States. NMED would like to discuss these results with TCEQ to compare methods and results to TCEQ's analysis. The WRAP results may be accessed on their Technical Support System (TSS) at https://views.cira.colostate.edu/tssv2/.

Additional Potential Controls Selection and Consultation

NMED has been working with the sources conducting the four factor analysis to develop potential additional control scenarios to be modeled for future impacts on Class I areas. Additionally, WRAP is currently working on modeling the 2028 future year conditions with and without potential control scenarios. NMED and the City of Albuquerque/Bernalillo County have shared with EPA Region 6 a summary of the Potential Additional Controls (PAC) that are being tested in WRAP's modeling. In the future, WRAP plans to run at least one additional control scenario to look at PACs for 2028 under the Regional Haze SIP.

NMED would like to discuss the potential controls TCEQ and NMED are considering for four-factor sources and how those potential controls will affect Class I areas in New Mexico, especially sites near the Texas-New Mexico border. In addition, NMED would like to understand what additional NO_X and SO_2 controls are being evaluated for those anthropogenic sources that impact visibility at Salt Creek and other Class I areas in New Mexico.

Permian Basin

Oil and gas sources and related emissions in the Permian Basin have been increasing in the last several years, resulting in significant NO_x and SO_2 emissions from the increased production and development. TCEQ's presentation showed impacts from Texas on Class I areas in New Mexico, particularly in the vicinity of the Permian Basin; however, it did not appear as if any oil and gas facilities were part of the four-factor analysis.

In our preliminary modeling evaluations, ammonium sulfate is a primary contributor to anthropogenic visibility impairment. NMED is interested in learning more about the sources of sulfate emissions in the Permian Basin that may be contributing to the impairment, such as information in TCEQ inventories from flaring and how this data has been integrated into the project. Are strategies being considered to reduce flaring emissions of SO_2 in the Permian Basin to address regional haze?

The Salt Creek Wilderness area in New Mexico shows monitored and modeled progress quite a bit above the URP glidepath on several modeling scenarios for EPA, TCEQ, and WRAP. Are there other sites in the West that have this issue? Perhaps this is a case where we need to perform further evaluation of the sources impacting visibility at this area.

The impacts at the Carlsbad Caverns Class I area, which is 40 km northeast of Guadalupe Mountains National Park, was not discussed in the TCEQ presentation. Since these two Class I areas are on the border with Texas and New Mexico, NMED believes that the states should discuss these two sites and what sources may be contributing to visibility impairment. These Class I areas are using the same IMPROVE monitoring data.

Modeling Performance and Comparisons

Several performance issues have been observed in the first stage of EPA modeling for regional haze. It seems that the normalized mean error in the EPA version of the modeling for SO_4 in the southwest is 67%. EPA's Technical Support Document states that "Further improvements in emissions inputs, boundary conditions, and model chemistry may help improve model performance in specific regions, particularly in the Northern Rockies and Plains, Northwest, West, and the Southwest." Has TCEQ worked to improve the model performance for their estimations of impacts on Class I areas? If so, has TCEQ modeling shown better performance? Is a model performance evaluation report for nitrates and sulfates available for NMED review?

Information on the WRAP regional modeling, including a white paper and a draft document on source apportionment, are available on the WRAP Regional Technical Operations Workgroup website at https://www.wrapair2.org/RTOWG.aspx. How did TCEQ decide on source apportionment categories for their modeling?

Consultation

NMED and the City of Albuquerque/Bernalillo County are currently working together on the SIP development process. NMED has a dedicated website to the development of the 2021 regional haze SIP at https://www.env.nm.gov/air-quality/reg-haze/.

The WRAP is providing more detailed information in the coming months on what potential contributions New Mexico sources may have on Texas Class I areas. NMED would like to continue the consultation process with TCEQ and the EPA regional office as more of this information is completed and delivered to the WRAP TSS Site at https://views.cira.colostate.edu/tssv2/. The WRAP TSS site will provide modeling and analysis information for Western States and is being used to help WRAP states develop their 2021 SIPs. The WRAP has various work groups dedicated to regional haze including the WRAP Coordination and Glidepath workgroup accessible here: https://www.wrapair2.org/RHP_coordination.aspx.

WRAP has developed a specific guidance document titled *Communication Framework for Regional Haze* that includes suggestions and a format for consultation and coordination amongst states. The document is available on the WRAP website at https://www.wrapair2.org/pdf/WESTAR-WRAP_Communication_Framework.pdf and is used as a guide to help agencies communicate early and frequently with the states and Federal Land Managers (FLMs). Please see in particular Chapter 3, "Regional Haze Rule Consultation Requirements."

NMED will likely have additional questions. We look forward to working with TCEQ on these items and staying in close communication as both agencies move forward. This is especially critical given that the two states share Class I areas near the border. It may be valuable to work with EPA Region 6 on the main areas of the consultation, such as emissions reductions necessary to make reasonable progress, since both states fall within the same EPA region.

NMED also recognizes that TCEQ will have questions and may also have consultation needs with other WRAP states or tribes, and it may be possible to discuss some of these items, including the modeling, on a collective basis with WESTAR-WRAP.

NMED is looking forward to working closely with TCEQ to ensure a robust, ongoing consultation process as we move forward with the evaluation of potential additional controls and Regional Haze SIP development. This will help ensure that our states fulfill their responsibility to take prudent action to reduce visibility impacts at Class I areas. NMED is eager for a new level of cooperation on other state initiatives aimed at improving air quality in the areas near the New Mexico/Texas border.

Please don't hesitate to contact Mark Jones, mark.jones@state.nm.us, or Kerwin Singleton, kerwin.singleton@state.nm.us with any questions.

We look forward to meeting with your staff to discuss these matters and a process to move the collaboration forward.

Sincerely,

Sandra Ely

Re: New Mexico Environment Department (NMED) Comments and Questions on TCEQ's proposed 2021 Regional Haze State Implementation Plan Revision for the Second Planning Period (Project No. 2019-112-SIP-NR)

Dear Director Baer,

NMED submitted a letter to TCEQ on April 24, 2020, "New Mexico Environment Department (NMED) Comments and Questions for TCEQ on Regional Haze Consultation," which requested a robust, ongoing consultation process as we move forward with the evaluation of potential additional controls and Regional Haze State Implementation Plan (SIP) development. As part of this process, NMED has reviewed TCEQ's proposed 2021 Regional Haze SIP Revision (Project No. 2019-112-SIP-NR). NMED comments on the 2021 Regional Haze SIP revision are detailed below and will also be submitted via eComments:

1. Overarching: NMED agrees in principle with the National Park Service (NPS) consultation document, "Regional Haze Consultation Documentation for NPS/Texas; October 8, 2020," stating that many of the emission reduction opportunities considered by TCEQ may be more affordable than presented and that the cumulative benefit of emission reductions over time will be necessary to achieve the Clean Air Act and Regional Haze Rule goals. NMED also generally agrees with the NPS, as well as the U. S. Forest Service (USFS) formal comments submitted on the proposal and evaluations that TCEQ should evaluate additional sources and should implement emission controls that substantively address the need for incremental improvement. TCEQ's presentation of modeling results showed visibility impacts from Texas on Class I Areas in New Mexico, particularly in the vicinity of the Permian Basin.

2. Commissioners Page 3: "Consultation with other states and the FLMs is ongoing and because other states are at different stages of development of their Regional Haze State Implementation Plan (SIP) revisions, this proposal does not include a complete record of consultation. Documentation of additional consultation after July 31, 2020 will be included at adoption." NMED would like to continue consultation calls with TCEQ as we review and interpret our modeling results and potential additional control strategies through March of 2021.

3. Page ES-1: What percentage of the overall NOx and SO2 emissions does the Q/D = 5 represent?

4. Pages 3-4: Consultation Summary 3.4.5 Federal Land Managers: NPS requested that TCEQ look at fifteen (15) additional sources that have a Q/d >5 that were not included in the analysis, asked why Bandelier National Monument (BAND), Big Bend National Park (BIBE), and Carlsbad Caverns (GUMO) were not included in the SO_2 Area of Influence (AOI) analysis, and that Salt Creek Wilderness Area (SACR) should have been included for both pollutants. See Appendix A. Were these concerns addressed in the proposed SIP revision? NPS also encouraged TCEQ to consider expanding their engine rule for ozone non-attainment areas to the Permian Basin as an effective method of addressing oil and gas (O&G) area source emissions that are impairing visibility at Carlsbad Caverns and Guadalupe Mountains National Parks. Was this addressed in the SIP revision? The Salt Creek Wilderness Area in southeast New Mexico shows monitored and modeled progress above the uniform rate of progress glidepath on several modeling scenarios conducted by EPA, TCEQ, and the Western Regional Air Partnership (WRAP). Is TCEQ taking any action to help address this issue, since TX emissions contribute to visibility impairment at this site?

5. Pages 6-9: NO_X and SO_2 emissions from area sources increased due to increased natural gas production and flaring at O&G wells. Were emissions from minor and area sources considered in determining what sources are subject to a four-factor analysis? Will TCEQ post four-factor analyses on its website for review?

6. Pages 7-4 and 7-5, Figures 7-1, 2: What major O&G sources are located within the AOI for White Mountain Wilderness Area (WHIT), Bosque del Apache Wilderness Area (BOAP), SACR and GUMO Class I Areas? What were the Q/d values for those sources? NMED would like to review the Q/d analyses for these Class I areas.

7. Pages 7-12: Units with NO_X or SO_2 <5% of the total emissions of the same pollutant were removed from further control measure analysis screening, based on consideration of the cost to control and anticipated improvement in visibility. If a source had a Q/d >5, then TCEQ should complete the 4-factor analysis for these sources. NMED requests additional justification for selecting 15 years as the remaining useful life of control equipment. A justification for this assumption would help explain why the selected remaining useful like is practical.

8. Page 7-13: The upper end of the cost threshold, $10,000/ton, was determined to be inappropriate to apply to existing sources not undergoing any kind of physical or operational change. To how many of the screened sources would this apply?

9. Appendix A: TCEQ used a 10% interest rate in their cost calculations instead of the bank prime rate for both EGUs and non-EGUs as a conservative assumption. An appropriate interest rate (current bank prime) should be used instead of an assumed rate without any basis. It could make a difference on whether additional controls are cost effective at a particular facility.

10. What factors did TCEQ consider for selecting sources on a per pollutant basis, rather than combined emissions of SO_2 and NO_X? The question of analyzing the pollutants separately was previously raised with TCEQ. Sources were screened for Q/d individually using NO_X or SO_2. Is TCEQ aware of other states that are conducting their Q/d analyses in this manner? NPS comments suggest that there are facilities that would be required to undergo four-factor analysis if the cumulative Q/d was considered. The Q/d screening criteria used to evaluate the

impact of new facilities on Class I Areas considers cumulative emissions from all criteria pollutants (2010 FLAG guidance, page 18, Initial Screening Criteria).

11. A capital recovery factor (CRF) of fifteen (15) years was used to estimate annualized capital costs for each potential control measure. New Mexico facilities' CRFs were generally 20-25 years. Did TCEQ use 15 years across the board? Based on NMED's review of different control technology, this capital recovery factor may not be appropriate.

12. WRAP has recently posted updated Weighted Emissions Potential (WEP) and AOI modeling results for Class I areas (CIAs) on the Technical Support Site (TSS): http://views.cira.colostate.edu/tssv2/. A number of CIAs in New Mexico show that facilities from Texas are within the top 20 of the facility-level rank point results for NOx and SO_2. Several of these, having a Q/d (where Q is on an individual pollutant basis) of greater than 5, have not been analyzed by TCEQ in their Four Factor Analysis. If a cumulative NOx and SO_2 basis for Q is used, even more sources are unaccounted for in the analysis. These facilities should undergo further four factor analysis review and consideration of additional controls to reduce impacts at Class I areas in NM. Rank point results show the top facilities ranked by weighted emissions potentials whose emissions have the potential to contribute to visibility impairment due to their emissions on the Most Impaired Days (MID) for each year in 2014-2018. More information on the rank point results is available on the TSS, as well as results for the CIAs in each state, including NM and TX.

NMED and the City of Albuquerque/Bernalillo County are currently working together on the development of our respective Regional Haze State Implementation Plan revisions. NMED has a dedicated website to the development of the 2021 Regional Haze SIP at https://www.env.nm.gov/air-quality/reg-haze/. We would like to continue the consultation process with you and our EPA Regional Office as more of this information is completed and delivered to the WRAP TSS Site at https://views.cira.colostate.edu/tssv2/. The WRAP TSS site will provide modeling and analysis information for Western States and is being used to help WRAP states develop their 2021 SIPs. Both NMED, City of Albuquerque/Bernalillo County and TCEQ should work cooperatively to try to help ensure that the Federal Land Managers concerns are addressed. This will help ensure that both states fulfill their responsibilities to take prudent actions so that the views at our CIAs will continue to improve. This will also help set the stage for better cooperation on other state initiatives aimed at improving air quality in the areas near our border.

We look forward to meeting with you again soon to discuss these issues and next steps. Should you have questions or require clarification, please contact Mark Jones, mark.jones@state.nm.us, or Kerwin Singleton, kerwin.singleton@state.nm.us.

Re: Additional Comments on TCEQ's Proposed 2021 Regional Haze State Implementation Plan (SIP) Revision for the Second Planning Period (Project No. 2019-112-SIP-NR)

Dear Director Baer,

The New Mexico Environment Department (NMED) reviewed the Texas Commission on Environmental Quality's (TCEQ) Proposed 2021 Regional Haze SIP Revision (Project No. 2019-112-SIP-NR) and submitted formal comments on January 8, 2021. As a follow-up to our submittal, Walker Williamson of the TCEQ Regional Haze Team contacted NMED on January 11, 2021 concerning comments #4 and #12, and requested clarification and specific requests concerning facilities for which NMED would like TCEQ to conduct further analysis. This follow up letter clarifies those requests and supplements the comments we submitted on January 8, 2021.

The Weighted Emissions Potential (WEP) and Area of Influence (AOI) modeling results for Class I Areas (CIAs), available on the Western Regional Air Partnership (WRAP) Technical Support Site (TSS): http://views.cira.colostate.edu/tssv2/, identify a number of Texas facilities that are within the top 20 of the facility-level rank point results for NO_X and SO_2. These facilities are reasonably anticipated to affect visibility conditions at several CIAs in New Mexico. NMED asks that TCEQ evaluate the facilities listed in the attached, *Appendix A: Texas Facilities with Reasonable Potential to Impact Visibility Impairment at New Mexico Class I Areas*, for potential additional controls and visibility impacts. Furthermore, NMED asks that TCEQ evaluate for potential additional controls any additional facilities identified by the U.S. National Park Service (NPS) contained in Appendix A of TCEQ's Proposed 2021 Regional Haze SIP Revision.

We look forward to meeting with TCEQ to discuss our original and supplemental comments as part of the ongoing consultation process. Should you have questions or require clarification, please contact Mark Jones, mark.jones@state.nm.us, or Kerwin Singleton, kerwin.singleton@state.nm.us.

Sincerely,

Liz Bisbey-Kuehn
Chief, Air Quality Bureau
New Mexico Environment Department

Dear Regional Haze Representatives from Texas Commission on Environmental Quality,

The New Mexico Environment Department (NMED) Regional Haze planning team has completed a draft Regional Haze SIP revision for the second planning period (2019-2028) [Version 2024-05-20, attached]. The plan is intended to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. Please note that this draft is not for public distribution, as we are currently in the middle of the formal FLM consultation period and are only sharing it with governmental entities at this time.

We are providing it to you today, June 20, 2024, to further facilitate communication with states during this pre-hearing coordination and consultation phase. We request that you provide any comments on this draft by July 19, 2024.

If you have any questions you may contact me at the phone number or email address provided below.

Best Regards,
Mark

Hi Mark,

Thank you for the opportunity to review NMED's draft regional haze SIP revision. We have no comments on the plan or requests at this time, so I'm providing the affirmations below based on the template language from our own regional haze interstate consultation.

Please let me know if you have any questions and thank you again.

At this time, ADEQ confirms the following statements regarding our interstate consultation with New Mexico Environment Department ("NMED") for the regional haze second implementation period:

1. Pursuant to 40 CFR 51.308(f)(2)(ii)(A), ADEQ and NMED have not agreed on any measures during our state-to-state consultation.
2. Pursuant to 40 CFR 51.308(f)(2)(ii)(B), the following statements are true:
   a. ADEQ has shared the measures they have identified, to date, as being necessary to make reasonable progress in a mandatory Class I Federal area with NMED.
   b. ADEQ has not requested for NMED to consider any measures to achieve its apportionment of emission reduction obligations in a mandatory Class I Federal area.
3. Pursuant to 40 CFR 51.308(f)(2)(ii)(C), there are currently no disagreements between ADEQ and NMED on the emission reduction measures necessary to make reasonable progress in a mandatory Class I Federal area.

Thank you,

Alex Ponikvar

Subject: Pre-hearing Review of NMED Draft Regional Haze SIPr Narrative (v 2024-05-20)

Dear Mark Jones:

Thank you for providing an external review draft of New Mexico Environment Department's (NMED) Regional Haze (RH) State Implementation Plan (SIP) revision for the second planning period. Texas Commission on Environmental Quality Air Quality Division staff reviewed NMED's draft and offer the following feedback concerning emissions assessment elements in the draft SIP revision.

The emissions inventory (EI) for NMED's draft SIP revision relies on a 2014 base year and a 2016 projection base year. While certain portions of Western Regional Air Partnership (WRAP) states' EIs have been updated with more recent data, the U.S. Environmental Protection Agency's (EPA) 2014v2 and 2016v1 modeling platforms for Texas contain older emissions data. As a result, the NMED RH Plan overestimates Texas' 2028 projected emissions.

NMED's draft SIP revision is predicting slightly over one million tons of 2028 nitrogen oxides (NO_X) emissions in Texas while the most recent 2020 Texas EI indicates 800,000 tons of NO_X emissions statewide, with on-road mobile comprising the majority (55%) of those emissions. Predicting a statewide NO_X emissions increase of 25% over an eight-year period is unrealistic. Mobile source emissions have declined over the past years and are anticipated to continue to decline due to existing EPA engine standards, recent EPA rulemaking, and continued fleet turnover.

The Texas on-road mobile EIs in NMED's draft SIP revision appear to be developed using EPA's Motor Vehicle Emissions Simulator (MOVES) version 2014 (MOVES2014), instead of the more recent MOVES3 or MOVES4 models. The newer versions of MOVES incorporate the most recent national emission standards, vehicle populations and activity, and fuels data. The non-point EI data in the 2014v2 and 2016v1 modeling platforms rely heavily on EPA's 2011 and/or 2014 national emissions inventory (NEI).

For the majority of Texas' non-point sectors (area source, all non-road mobile sources except airport sources, and on-road mobile sources), TCEQ notes that the EPA modeling platform 2016v3 would be more appropriate for the following reasons:

- 2016v3 has 2017 NEI updates;
- 2016v3 uses MOVES3 to estimate on-road mobile source emissions while 2016v1 uses the older MOVES2014; and
- 2016v3 includes Texas' updated oil and gas emissions.

TCEQ notes that both the 2016v1 (currently used for NMED's draft SIP revision) and the 2016v3 modeling platforms contain significant errors for Texas point source and airport sector emissions. For further reference, TCEQ submitted comments on EPA's proposed Federal Implementation Plan (FIP) Addressing Regional Ozone Transport for the 2015 Ozone National Ambient Air Quality Standard (NAAQS) regarding these errors.[1] TCEQ's 2022 point source data submitted to EPA and, for the airport sector, TCEQ's 2020 NEI submission are more representative of Texas' emissions.

We appreciate NMED providing for early review during development of its regional haze SIP revision. Please contact Jamie Zech (jamie.zech@tceq.texas.gov) of my staff with questions concerning TCEQ's comments or to coordinate additional regional haze consultation.

Sincerely,

Donna F. Huff, Deputy Director
Air Quality Division

Mark,

Thanks so much for your consideration of our comments and your response. This sets a model for how states and FLM can work together as we enter this second round of regional haze efforts. Please be assured that we shall do everything we can to assist you in this effort, and please do not hesitate to contact us whenever appropriate.

> The New Mexico Environment Department Air Quality Bureau (NMED AQB) has decided to approve the selection of a screening threshold that accounts for 80% of the emissions from major sources in NM. The 24 prioritized sources (including one source within the jurisdiction of Albuquerque/Bernalillo County), have been contacted to explain the Regional Haze Rule and the four-factor analysis process. CABQ EHD contacted the source within their jurisdiction. Furthermore, because the Blanco C&D Compressor Station is jointly permitted with the Harvest Pipeline – San Juan Gas Plant and the El Paso Natural Gas Company – Blanco Compressor Station A, NMED is requesting a combined four-factor analysis for these three facilities.

Subject: [EXT] Re: [EXTERNAL] RE: NM Regional Haze Source Selection for 4-Factor Analysis

Hi Mark,

Thanks for the revised lists of potential facilities for RP analyses.

We appreciate your efforts and can support your "List of 26 Facilities Q/d>5 81.5% Title V emissions" and your "List of 24 Facilities Q/d>5.7 80.1%" with one modification. It is our understanding that Blanco Compressor Station A has been treated as part of a facility that includes the San Juan Gas Plant and the Blanco Compressor C & D Station for NSR purposes. (Please see the attached permit.) Because both the San Juan Gas Plant and the Blanco Compressor C & D Station are on your lists (as well as ours--along with Blanco Compressor Station A), it seems appropriate to continue to evaluate these three sources together.

Would NMED conduct the RP analysis for the GCC Rio Grand Portland Cement Plant even though it is in Bernallio County?

Please feel free to contact me with any questions and comments.

NPS feedback on Xcel Cunningham Station boilers 4-factor analysis

Shepherd, Don <Don_Shepherd@nps.gov>

Fri 9/4/2020 8:25 PM

To: Mark Jones <mark.jones@state.nm.us>; Singleton,Kerwin, NMENV <Kerwin.Singleton@state.nm.us>

2 attachments (221 KB)

Xcel Cunningham 122B.xlsm; Xcel Cunningham 121B.xlsm;

Hi Mark & Kerwin,

As requested, i am providing some initial feedback on Xcel 's Cunningham Station boilers 4-factor analysis. I applied EPA's Control Cost Manual (CCM) workbook with inputs from CAMD/AMP. I used the current prime interest rate (3.25%) as recommended by the CCM, along with the CCM estimate of 30-year SCR life. Assuming that SCR could achieve 78% - 80% control efficiency, the CCM method yields cost-effectiveness of $5055/ton to remove 175 tpy from Boiler 121B and 5438/ton to remove 328 tpy from Boiler 122B. These costs were escalated to 2019$ by application of the CEPCI and are very reasonable compared to thresholds used in Round #1 (up to $7300/ton).

Please let me know if you hav e any questions.

---

Hi Mark & Kerwin,

As you requested, i am providing additional feedback (sine our 9/2020 feedback--attached) on Xcel's Cunningham Generating Station.

I think the main issues are the ability of modern SCR to achieve very low NOx emissions rates on natural gas-fired boilers and the interest rates applicable to certain public utilities.

I suggest that there are two fundamental constraints on modern SCR systems; an upper bound on efficiency, and a lower bound on emission rate (in lb/mmbtu). It is generally accepted that modern SCR can achieve at least 90% NOx control, but efficiency is ultimately limited by the concentration of NOx in the gas stream to be treated.

In the TSD for Cunningham, NMED assumed 80% NOx control, which would result in a NOx emission rate of about 0.03 lb/mmBtu.

I searched 2020 (CAMD) data and found hundreds of examples of gas-fired emission units with SCR achieving lower NOx emission rates. I refined my search to just NG-fired boilers (like the two Cunningham boilers) and still found the 13 shown in the attached spreadsheet.

If we assume that SCR can achieve 90% control on those two Cunningham boilers, we get an emission rate of about 0.02 lb/mmBtu, and we see that there are at least six boilers (in CA) that could meet this limit. I concluded that 90% NOx control by SCR is achievable at Cunningham, so i entered 0.02 lb/mmBtu into the Control Cost Manual (CCM) workbooks. (attached)

I am also beginning to realize that some utilities borrow money at rates higher than the prime, so i entered the Xcel rate (7.19%) into the CCM workbook.

I linked my CCM results to the table NMED produced for Cunningham boilers to provide a direct comparison between the two sets of estimates. I estimate that almost 600 ton/yr of NOx could be reduced by adding SCR to both Cunningham boilers at cost-effectiveness values < $7000/ton.

I hope this helps. Please feel free to contact me if you have any questions.

Tel (505) 629-6626

Dear Michael:

USDA's Forest Service recently published a 10-year strategy to reduce wildfire - *Confronting the Wildfire Crisis: A Strategy for Protecting Communities and Improving Resilience in America's Forests* (https://www.fs.usda.gov/sites/default/files/Confronting-Wildfire-Crisis.pdf). Prescribed fire is one of the best tools to increase the pace and scale of wildfire risk mitigation work. Regionally we have been increasing the use of prescribed fire well above the Western Regional Air Partnership's (WRAP) baseline emission inventory, which is based on activity levels present from 2014. In addition, we anticipate that prescribed fire will increase by 20 million acres on Forest Service land in the West and by 30 million acres on other ownerships over the next 10 years.

Prescribed fire smoke is considered man-made air pollution under the Regional Haze Rule. The Regional Haze process allows the State of New Mexico to adopt an adjustment for prescribed fire into their Regional Haze State Implementation Plan. We believe doing so is the best way to fully utilize the provisions of the Regional Haze Rule and disclose the reality of additional prescribed fire smoke as we work to improve the ecological condition of our national forests and address the growing wildfire risk within the State. The prescribed fire adjustment as represented in the WRAP's Future Fire Scenario 2 represents a critical commitment by the State of New Mexico in our shared forest management objectives. If you have questions, please reach out to Anita Rose (anita.rose@usda.gov) or Bret Anderson (bret.a.anderson@usda.gov). Thank you for your consideration of this important issue.

Sincerely,

ELAINE KOHRMAN

Prescribed Fire Talking Points for New Mexico

- The USDA FS takes our affirmative responsibility to protect Class I Areas seriously as mandated in the Clean Air Act.
- The Regional Haze process allows the State of New Mexico to adopt an adjustment for prescribed fire. We believe doing so is the best way to disclose the reality of additional prescribed fire smoke as we work to improve the ecological condition of our National Forests and address the growing wildfire risk within the State.
- We recognize that the prescribed fire adjustment produces only a small change in the visibility assessments; however, it represents a critical commitment by the State of New Mexico in our shared Forest Management objectives.
- We continue to see longer and more severe wildfire seasons and recognize the need for a significant investment and treatment of our landscapes to mitigate the catastrophic effects of unwanted wildfire.
- Prescribed fire is one of the best tools to increase the pace and scale of wildfire risk mitigation work.
- Fire plays an important role in shaping the vegetation and landscape in New Mexico and surrounding states. Recurring fire has been a part of the landscape for thousands of years.
- Aggressive fire suppression, coupled with an array of other disturbances has changed the historic composition and structure of the Forests. Periodic prescribed burning and other vegetation management can recreate the ecological role of fire in a controlled manner.
- Fire and fuels management supports a variety of desired conditions and objectives across the Forests and Grasslands (e.g., community protection, hazardous fuels reduction, native ecosystems restoration, historic fire regimes restoration, wildlife openings, and open woodland creation, etc.).
- The USDA FS along with our partners in the New Mexico Energy Minerals and Natural Resources Department (EMNRD) Forestry Division plan to significantly increase the use of prescribed fire to accomplish these goals.
- The Federal Infrastructure Bill directs Agency priorities and supports prescribed fire use as a tool for increasing the pace and scale of risk mitigation projects. The upward trend of prescribed fire implementation will continue growing significantly in the coming years.
- Acknowledging increased prescribed fire activity and its effect on visibility through the adoption of the end-point adjustment demonstrates the support of prescribed fire projects designed to protect landscapes and people in New Mexico.
- The USDA FS is not alone in requesting the end-point adjustment. State and Federal land management agencies stand together to recognize the critical role prescribed fire plays in risk mitigation work and plan to capitalize on funding and increase the application of prescribed fire across the State.
- We request the State adopt the increased prescribed fire end-point adjustment, and we stand ready to assist with any data needs or coordination.

New Mexico Draft Revised RH SIP – USDA FS Southwestern Region Comments

Chapter 1

Chapter 2

- Descriptions of Pecos (p. 26) and San Pedro Parks (p. 30) Wilderness Areas include comments about grazing that are irrelevant to this SIP and we respectfully request that they be removed. Protection of certain grazing rights in Wilderness Areas are established by Congress: Section 4(d)(4)(2) of the Wilderness Act states: "the grazing of livestock where established prior to the effective date of this Act, shall be permitted to continue subject to such reasonable regulations as subject to such reasonable regulations as are deemed necessary by the Secretary of Agriculture".

Chapter 3

- (p. 37) link at footnote 56 is broken: https://views.cira.colostate.edu/tssv2/Lists/Glossary.aspx
- (p. 41) consider adding a footnote w/link at the end of the paragraph that concludes with the sentence "Full versions of the bar graphs in this map, and other detailed visualizations of monitor trends, are available on the WRAP TSS."
- (p. 51 and p. 54) Figures 3-6 and 3-8 show NC 2064 on clearest days as negative numbers for WHPE1 and SAPE1 – consider providing clarification as to why that is.

Chapter 4

Chapter 5

Chapter 6

Section 6.4 – Tier Two – PTE

"NMED determined that a four-factor analysis would only be required on individual equipment with a PTE greater than ten pounds per hour of NO_x or SO_2 pursuant"

- No change needed, just curious if NMED anticipates analyzing these smaller sources in the future?

Chapter 7

Chapter 8

- Figure 8-8 – the word Wheeler needs to be added to the figure title,

Chapter 9

Chapter 10

Chapter 11

Chapter 12

“EPA sends the funds to the National Park Service (NPS) via an interagency agreement for them to operate the network”

- While it is true that NPS is the central contracting agency for IMPROVE, which gives them de facto operational control of all aspects of the portion funded by EPA (though NPS heavily weighs the opinions of the Steering Committee), this statement seems a bit misleading since the sites themselves are operated with personnel from all the other participating agencies, including the Forest Service, and the infrastructure is maintained without funding from NPS/EPA. Please considering clarifying.

Subject:	Notification of Upcoming Availability of Public Review Drafts of Regional Haze SIP Revision and Companion Rule 20.2.68 NMAC
Date:	Monday, August 19, 2024 3:16:40 PM

Dear representatives from the U.S. Forest Service,

NMED's Regional Haze planning team is working to complete its draft Regional Haze state implementation plan (SIP) revision for the second planning period (2019-2028) in anticipation of petitioning the New Mexico Environmental Improvement Board (EIB) to hold a hearing on the plan in late fall or early winter. The NMED team is currently finishing substantive revisions to the draft SIP based on the feedback we received from the FLMs during the 60-day consultation period. NMED then plans to release public review drafts of the revised SIP and a new companion rule, 20.2.68 NMAC – Regional Haze Requirements, for review and comment by the members of the public, industry, and other stakeholders before finalizing the plan and rule and formally proposing them to the EIB. The purpose of the new companion rule is to establish enforceable emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress during the second planning period, and provisions to make these measures practically enforceable.

The NMED team anticipates sharing the public review drafts via our website, https://www.env.nm.gov/air-quality/reg-haze/, on or about **August 26, 2024**. As key partners in the Regional Haze program, we are giving you advance notice of the upcoming review period and the opportunity to submit additional feedback or comments on the revised SIP and new companion rule to us by the end of the day on **September 20, 2024**. We note that you can also submit comments on the proposed plan and rule during the formal 30-day public comment period that precedes the hearing. Although the exact dates are not known now, we will provide updates on our Regional Haze website (https://www.env.nm.gov/air-quality/reg-haze/) as we continue this process. Once notice of the hearing has been published in the New Mexico Register, the proposed SIP and related documents will be posted to our public notices web page (https://www.env.nm.gov/public-notices/), and the formal public comment period will begin. We anticipate this will occur sometime in November, barring any unexpected delays.

NMED values continuing coordination between FLMs and other partners in the Regional Haze Program. If you have any questions or feedback for the NMED Regional Haze planning team, please contact me, Mark Jones (mark.jones@env.nm.gov) and cc Ken Miller (kenneth.miller@env.nm.gov), Alex Sanchez (alex.sanchez@env.nm.gov), and Eric Peters (eric.peters@env.nm.gov).

Sincerely,

Mark

"Science | Innovation | Collaboration | Compliance"

E.3 Discussions with EPA

Supporting documentation for New Mexico Environment Department (NMED) coordination with EPA Region 6 is provided below. The following documents are included in this section (in reading order):

- EPA comments
    - EPA Recommendations to NMED for FLM Draft SIP (7/30/24)
    - EPA Comments to NMED for Draft New Rule 20.68 NMAC (9/9/24)

EPA Recommendations to NMED for FLM Draft SIP:

Enforceable Emission Limits:

> The NM RH SIP states: *"To make the emissions limitations in this Regional Haze SIPr Rd2 (2019-2028) permanent and federally enforceable, NMED plans to incorporate them into facilities' New Source Review (NSR) permits issued under 20.2.72 NMAC. Unlike a Title V operating permit, which has a 5-year term, the term of an NSR permit is permanent unless withdrawn or cancelled by NMED. To ensure reasonable progress controls are added by their respective compliance deadlines, facilities are required to submit applications to incorporate new emissions limitations into their NSR permits no later than one year after final approval of this Regional Haze SIPr Rd2 (2019-2028) by EPA."*

- The proposed permit modifications must be included in NMED's SIP proposal for public review and comment, and include the permanently enforceable emissions limitations, as well as monitoring, recordkeeping and reporting requirements, and compliance schedules. Specific provisions of the permit must be identified for inclusion in the SIP with language clarifying that those provisions cannot be modified without going through a SIP process and approval by EPA. Alternatively, an agreed order containing the necessary emission limits, monitoring, recordkeeping and reporting requirements, and compliance schedule can be submitted for approval into the SIP. At the time of submittal, the permit modifications (or Agreed orders) must be finalized and included in the SIP submission. EPA cannot approve the SIP revision without enforceable emission limits that are then made federally enforceable at the time EPA approves the SIP revision. Compliance dates can be triggered upon EPA approval, if necessary.
- Please provide any additional documentation supporting the closure of facilities and/or specific units. For example, on p. 135-136 of the SIP Narrative NMED is relying on an administrative permit revision removing all of the units NMED had selected at the Saunders Gas Plant for an analysis of potential controls as the basis for NMED determining that reasonable progress does not require new controls on any of the units. Has this administrative permit revision happened? The date provided is May XX, 2024, so it is unclear if the revision has occurred.

Ambient Monitor Data Analysis:

- For section 3.2, which the New Mexico Environment Department (NMED) used to address the visibility calculation requirements in CFR 51.308(f)(1)(i-v), we recommend that NMED update this portion of the SIP to reflect more recent IMPROVE data that is currently available. The draft SIP only includes data up to 2018 which is at the end of the first planning period and does not include data from the second planning period. IMPROVE data beyond 2018 is readily available and should be used to reflect the second planning period. NMED defined an interim period of 2008-2012 from the first planning period and subtracted that from the baseline as the progress made since the first planning period. "Progress since the first planning period" should instead reflect the whole first period and the difference between the 2000-2004 baseline period and the 2014-2018 period. "Progress to date" should include visibility progress beyond the 2014-2018 five year average to reflect progress made since the first planning period. For example, at a minimum current progress to date should be the

difference between the 2000-2004 baseline and the 2015-2019 period which extends beyond the first planning period.

- For section 3.3 and 3.4, which discusses light extinction IMPROVE monitoring trends, Figures 3-2 to 3-9 show aerosol species contributing to light extinction only includes data up to 2018. IMPROVE data beyond 2018 is readily available and should be used to reflect the second planning period. We recommend that NMED update these figures to reflect the more recent IMPROVE data that is currently available beyond the first planning period. For example, the 2015-2019 period extends beyond the first planning period and would be acceptable to use for current IMPROVE data for the aerosol species to reflect the second planning period.
- For section 3.6, which discusses the uniform rate of progress (URP) at New Mexico's Class I areas, and sections 9.2 to 9.3 which describes future most impaired and clearest days at New Mexico's Class I areas, we recommend that NMED include quantifiable numbers or tables in the narrative to explain the key data in figures 3-10 to 3-17; figures 9-1 to 9-8; and 9-9 to 9-16. The quantifiable data for the graphs are readily available and should be included in the narrative to explain the symbols on the graphs. For example, we recommend including quantifiable numbers in the narrative explaining the projected 2028 URP values for the most impaired and clearest days, the 2000-2004 baseline values, the future 2028 RPG values, the modeled 2028 SIP control values, and the 2064 natural conditions. Other comparisons like difference in adjusted and unadjusted values would be beneficial as well.

Costs:

"Margin of Safety"

> *"SCR retrofits require significant physical space (e.g., for catalyst beds, ducting, etc.) and therefore often involve extensive building and/or exhaust system modifications which can easily cost as much if not more than the SCR equipment itself. To account for the possibility, if not likelihood, that implementing SCR would involve significant ancillary costs, NMED determined that SCR should only be required for reasonable progress if its estimate of the total capital investment (TCI) for SCR includes a "margin of safety" of at least 100 percent, except in cases where its estimate of TCI for SCR expressly includes costs for building/exhaust system modifications."*
> *In this context, the margin of safety is equal to (TCI @ $10,000/ton – Estimated TCI) / Estimated TCI.*

- NMED's approach to SCR cost evaluation applies a "margin of safety" of 100%, which EPA believes is unsupported. In other words, SCR was only found to be cost-effective if the cost was below $5,000/ton because NMED assumes that ancillary costs not accounted for would result in costs up to 100% of the estimated SCR costs. This is similar to applying a retrofit difficulty factor of two to the cost of SCR, where a factor of one reflects the average costs of a typical installation. NMED should document any physical space limitations at the facilities, necessary modifications to a building's structure to accommodate SCR, or required modifications to existing ductwork and estimate the capital costs of associated with these modifications in implementing SCR rather than relying on a "margin of safety" approach. These costs should be incorporated into the detailed capital cost estimates and/or incorporated into justification for an appropriate retrofit factor. NMED should also discuss and more fully document the cost estimation methodology and the items included in the

capital cost that may already include estimates for the necessary modifications, the retrofit difficulty factor, and any contingency costs already included.

- In addition, NMED should consider the incremental costs and reductions between controls when multiple controls are in a cost-effective range.

- NMED did not provide Appendix D for review at this time, therefore, EPA is not able to provide a complete review of the cost information. Detailed cost analysis information for each control evaluated should be provided for review as part of the proposed SIP.

Source Selection:

- In Section 6.3 which discusses the Q/d analysis, EPA recommends that NMED provide a spreadsheet of the actual analysis to document the Q/d conclusion for how the sources were selected. Although a table was provided to show the 24 facilities that were screened in for selection, NMED should provide the source selection spreadsheet data to show where the sources were selected from. EPA also recommends providing more recent information, if available, to show that the most recent data still supports the source selection analysis.
- In Section 6.2 (p. 95)[1] NMED states that due to the lack of emissions information for minor stationary sources and area sources in NMED's and EHD's jurisdictions, NMED and EHD decided to conduct a source selection process for major (Title V) sources only. Under the Regional Haze Rule, States should consider evaluating major and minor stationary sources, mobile sources, and area sources in developing the long-term strategy (40 CFR 51.308(f)(2)(i)). We recommend that the SIP provide additional justification for limiting the evaluation to only Title V sources (point sources).
- EPA recommends that NMED provide more discussion for how the tier two PTE screening basis on p. 101-102 was determined. In other words, how did NMED determine that a four-factor analysis would only be required on individual equipment with a PTE greater than 10 pph of NO_X or SO_2?

Miscellaneous:

- Because EPA was not provided Appendix E, we were unable to assess NMED's consultation with other states, including Texas. It is also unclear from the SIP Narrative (Chapter 10) what resulted from the consultation specific to the Salt Creek robust analysis to address impacts demonstrated from Texas. Please provide additional discussion of consultation specific to Texas sources that may impact Salt Creek as part of the robust analysis.
- EPA recommends providing a discussion on environmental justice in the SIP. EPA's clarifications memo encourages consideration of whether there may be equity and

[1] Additionally, in FN 154 of the SIP Narrative, NMED states, "NMED and EHD lack detailed emissions inventory data for minor stationary sources and area sources for the current Regional Haze planning period. Sufficient statewide data was not available to adequately assess the potential visibility impact of such sources at Class I Areas. Therefore, NMED and EHD chose not to evaluate minor stationary sources or area sources for potential new control measures in the current Regional Haze planning period. Minor stationary sources and area sources may be addressed in future planning periods or addressed through other rule makings."

environmental justice impacts when developing regional haze strategies for the second planning period.

- Please differentiate between the emission reductions achieved through implementation of this SIP and emission reductions that have already occurred due to source shutdowns.

Note: These comments are in response to NMED's draft SIP Narrative and NMED's draft Appendix C. On p. xv, NMED notes "In addition to the main SIP narrative provided in Chapters 1-12, this SIP revision includes a number of appendices providing reference materials, technical support, and documentation. These include WRAP's emission inventory and modeling references (Appendices A and B), NMED's four-factor analyses and control measures determinations technical support document (Appendix C), and documentation related to NMED's four-factor analyses (Appendix D) and coordination and consultations (Appendix E)." The EPA has not reviewed the additional appendices in early engagement.

From:	Feldman, Michael
To:	Jones, Mark, ENV; Grady, James; Goudeau, Charlotte; Martinez, Michael

Subject:	[EXTERNAL] RE: Deadline has moved to Monday, Sept. 9th, 5:00 pm (MDT) to provide feedback/suggestions on the NMED draft new Regional Haze rule
Date:	Monday, September 9, 2024 3:04:02 PM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Mark - In response to your request below for informal comments by COB today, we were able to review the proposed rulemaking language and provide the comments below for your consideration. Please let us know if you have any questions. We will have opportunity to discuss at our regularly scheduled call tomorrow.

EPA Comments to NMED for New Rule 20.68 NMAC:

- 20.2.68.104 NMAC provides that certain emission testing (Subparts GG, IIII, JJJJ, and KKKK of 40 CFR 60 performance standards and Subparts ZZZZ and DDDDD of 40 CFR 63 NESHAPS) may satisfy the testing requirements for this part if the required testing is consistent with 20.2.68.104 NMAC and occurs at least once per calendar year. NMED should provide more information regarding how facilities will demonstrate that the emissions testing referenced (Parts 60 and 63) is consistent with the requirements of 20.2.68.104 NMAC.
- NMED should provide more information in the SIP narrative regarding the specific emission reductions from the retired units in Table 2.
- NMED should add more explanation in the SIP narrative to explain how the various emission limits in Table 1 were chosen. The narrative does not clearly explain how NMED arrived at the numerical limits for the various units. For example, for Blanco Compressor Station A, NMED does not clearly identify how it arrived at the 0.5 g/bhp-hr rate for each of the new units. Some of this information is found in footnotes to Table 8-1 or in the appendices but should be clearly identified in discussion of the four factor-analysis and control determination summary.
- NMED should provide discussion and justification in the SIP narrative for the compliance deadlines listed for each of the emission limitations in the rule.
- 20.2.68.102 C specifies that compliance for Cunningham units is determined on a 30-day rolling basis and 20.2.68.102 D specifies compliance with the multi-unit limitations for Mountainair and Roswell to be determined on a 12-month rolling average. For clarity, please also specify in 20.2.68.102 how compliance will be determined for all other emission limitations in Table 1.
- Under 20.2.68.104, for clarity please separate the discussion and equation for units with g/bhp-hr emission limits into a separate item rather than combined under B.
- Please include in 20.2.68.104 a description of how compliance with the 12-month rolling average will be demonstrated for Roswell and Mountainair units. Does this include calculation of emissions based on 12-month time of operations or fuel usage data for the units under the multi-unit limit?
- Consistent with 20.2.68.104 B.(1), recordkeeping requirements under 20.2.68.105 should include requirements to record specific data as required during testing such as load and other parameters used to demonstrate compliance with the limitations.

Thank you and the NMED RH team for all the work on this SIP package and for developing this draft rule language.

governor@poamail.org

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Vicente,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

[1] 40 CFR §§ 51.300-51.309.

DocuSign Envelope ID: 32853558-7CF9-4D96-A7CB-9BECDA187150

comments on the draft plan directly to Mark Jones by July 19, 2024. After this date, NMED will consider any comments which we have received before proceeding with public outreach.

Additional opportunities for public engagement are in the works for later this summer including, at a minimum, a formal 30-day public comment period during which Tribes, Nations, and Pueblos in New Mexico will have a second opportunity to provide comment on our plan. Once the public notice dates have been determined, they will be posted at https://www.env.nm.gov/public-notices/. Any information and dates pertaining future webinars, along with additional opportunities to participate in our decision-making processes, will also be available at this website.

For more information, a website dedicated to Regional Haze planning in New Mexico is available at the following link: https://www.env.nm.gov/air-quality/reg-haze/. This website describes Environmental Protection Agency (EPA) requirements, shows visibility trends at New Mexico's protected areas, and provides additional information on NMED's planning process and guiding principles. If you or someone in your government is interested in participating in or following the Regional Haze planning process more closely, you may also sign up for email and/or text updates here: https://public.govdelivery.com/accounts/NMED/subscriber/new and subscribe to the Air Quality Bureau Regional Haze Announcements topic. This email alert system, in conjunction with the public notice board website described below, is the best way to stay current on events regarding Regional Haze as the project moves forward.

If you require another method of communication, please call or write our main office or Tribal Liaison and request your preferred method of communication with your contact information. We will make every effort to accommodate your preferences. You may contact our main office or Tribal Liaison using the information provided below.

For additional information concerning this letter, please contact:

Cochiti, NM, 87072
governor@cochiti.org

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Arquero,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

[1] 40 CFR §§ 51.300-51.309.

DocuSign Envelope ID: 32853558-7CF9-4D96-A7CB-9BECDA187150

comments on the draft plan directly to Mark Jones by July 19, 2024. After this date, NMED will consider any comments which we have received before proceeding with public outreach.

Additional opportunities for public engagement are in the works for later this summer including, at a minimum, a formal 30-day public comment period during which Tribes, Nations, and Pueblos in New Mexico will have a second opportunity to provide comment on our plan. Once the public notice dates have been determined, they will be posted at https://www.env.nm.gov/public-notices/. Any information and dates pertaining future webinars, along with additional opportunities to participate in our decision-making processes, will also be available at this website.

For more information, a website dedicated to Regional Haze planning in New Mexico is available at the following link: https://www.env.nm.gov/air-quality/reg-haze/. This website describes Environmental Protection Agency (EPA) requirements, shows visibility trends at New Mexico's protected areas, and provides additional information on NMED's planning process and guiding principles. If you or someone in your government is interested in participating in or following the Regional Haze planning process more closely, you may also sign up for email and/or text updates here: https://public.govdelivery.com/accounts/NMED/subscriber/new and subscribe to the Air Quality Bureau Regional Haze Announcements topic. This email alert system, in conjunction with the public notice board website described below, is the best way to stay current on events regarding Regional Haze as the project moves forward.

If you require another method of communication, please call or write our main office or Tribal Liaison and request your preferred method of communication with your contact information. We will make every effort to accommodate your preferences. You may contact our main office or Tribal Liaison using the information provided below.

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Nieto,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

Governor Gaylord Siow
P.O. Box 194
Laguna Pueblo, NM, 87026
GSiow@lagunapueblo-nsn.gov

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Siow,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Phillips,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

[1] 40 CFR §§ 51.300-51.309.

DocuSign Envelope ID: 32853558-7CF9-4D96-A7CB-9BECDA187150

comments on the draft plan directly to Mark Jones by July 19, 2024. After this date, NMED will consider any comments which we have received before proceeding with public outreach.

Additional opportunities for public engagement are in the works for later this summer including, at a minimum, a formal 30-day public comment period during which Tribes, Nations, and Pueblos in New Mexico will have a second opportunity to provide comment on our plan. Once the public notice dates have been determined, they will be posted at https://www.env.nm.gov/public-notices/. Any information and dates pertaining future webinars, along with additional opportunities to participate in our decision-making processes, will also be available at this website.

For more information, a website dedicated to Regional Haze planning in New Mexico is available at the following link: https://www.env.nm.gov/air-quality/reg-haze/. This website describes Environmental Protection Agency (EPA) requirements, shows visibility trends at New Mexico's protected areas, and provides additional information on NMED's planning process and guiding principles. If you or someone in your government is interested in participating in or following the Regional Haze planning process more closely, you may also sign up for email and/or text updates here: https://public.govdelivery.com/accounts/NMED/subscriber/new and subscribe to the Air Quality Bureau Regional Haze Announcements topic. This email alert system, in conjunction with the public notice board website described below, is the best way to stay current on events regarding Regional Haze as the project moves forward.

If you require another method of communication, please call or write our main office or Tribal Liaison and request your preferred method of communication with your contact information. We will make every effort to accommodate your preferences. You may contact our main office or Tribal Liaison using the information provided below.

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Chaves,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Armijo,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

Re: Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan

Dear Honorable Governor Silvas,

The New Mexico Environment Department (NMED) writes to inform you of an opportunity to engage with our agency as we develop a plan, known as a State Implementation Plan, to reduce haze and improve visibility in certain National Parks and wilderness areas in New Mexico. The plan is aimed at fulfilling certain requirements of the federal Clean Air Act, which states must meet pursuant to the federal regulation known as the Regional Haze Rule.[1] The areas the Rule protects include Bandelier Wilderness Area; Bosque del Apache Wilderness Area; Carlsbad Caverns National Park; Gila Wilderness Area; Pecos Wilderness Area; Salt Creek Wilderness Area; San Pedro Parks Wilderness Area; Wheeler Peak Wilderness Area; and White Mountain Wilderness Area.

In developing this plan, NMED first reviewed visibility data from monitor sites located near each protected area. The data show overall improvement in visibility conditions at all areas over the past 20 years. To ensure this trend continues, NMED evaluated potential control measures to reduce emissions of sulfur dioxide (SO_2) and oxides of nitrogen (NO_X), which contribute to the formation of visibility-impairing pollutants, at 23 large industrial facilities around the State. The facilities selected for analysis were predominantly oil and gas facilities located in the southeastern and northwestern portions of the State. A map showing the locations of these facilities in relation to protected areas is attached to this letter for reference. Through this analysis, which was primarily based on the cost of available controls but also considered other factors, NMED determined that 44 individual emissions units at 13 separate facilities require new pollution controls. Once implemented, these controls will result in significant reductions of NO_X and SO_2 emissions annually, which in concert with other measures will help to improve visibility not just at protected areas, but throughout the State.

We are expressly seeking feedback and comments from Tribal governments in New Mexico on our plan, as it may impact Tribal Lands. A draft plan is available to you for review and comments here: https://service.web.env.nm.gov/urls/VycLCxYU. Please note, this draft is not for public distribution, and is meant for only review by representatives of Tribal government. We would also be happy to email you a copy directly or mail you a printed copy if that would be more convenient. We are also planning on holding an informational webinar for Tribal government representatives to provide an overview of the plan and answer any questions you may have if that would be of interest on June 18, 2024 from 10:30am until 12:00pm, MDT. The meeting details and link will be sent in an email closer to this date. If you are planning on attending the webinar, please contact Mark Jones at the phone number or email address provided below to inform us of your intention. We respectfully request that you provide any

[1] 40 CFR §§ 51.300-51.309.

DocuSign Envelope ID: 32853558-7CF9-4D96-A7CB-9BECDA187150

comments on the draft plan directly to Mark Jones by July 19, 2024. After this date, NMED will consider any comments which we have received before proceeding with public outreach.

Additional opportunities for public engagement are in the works for later this summer including, at a minimum, a formal 30-day public comment period during which Tribes, Nations, and Pueblos in New Mexico will have a second opportunity to provide comment on our plan. Once the public notice dates have been determined, they will be posted at https://www.env.nm.gov/public-notices/. Any information and dates pertaining future webinars, along with additional opportunities to participate in our decision-making processes, will also be available at this website.

For more information, a website dedicated to Regional Haze planning in New Mexico is available at the following link: https://www.env.nm.gov/air-quality/reg-haze/. This website describes Environmental Protection Agency (EPA) requirements, shows visibility trends at New Mexico's protected areas, and provides additional information on NMED's planning process and guiding principles. If you or someone in your government is interested in participating in or following the Regional Haze planning process more closely, you may also sign up for email and/or text updates here: https://public.govdelivery.com/accounts/NMED/subscriber/new and subscribe to the Air Quality Bureau Regional Haze Announcements topic. This email alert system, in conjunction with the public notice board website described below, is the best way to stay current on events regarding Regional Haze as the project moves forward.

If you require another method of communication, please call or write our main office or Tribal Liaison and request your preferred method of communication with your contact information. We will make every effort to accommodate your preferences. You may contact our main office or Tribal Liaison using the information provided below.

Background

- The Regional Haze Rule calls for state and federal agencies to work together to improve visibility in 156 national parks and wilderness areas across the United States; these protected areas are known as “Mandatory Class I Areas”
- States are required to develop plans to reduce the pollution that causes visibility impairment in protected areas; these plans must be revised every 10 years
- States coordinate and consult with EPA, other states, Tribal governments, the general public, and others when developing their Regional Haze plans

Background

Mandatory Class I Areas
North Cascades

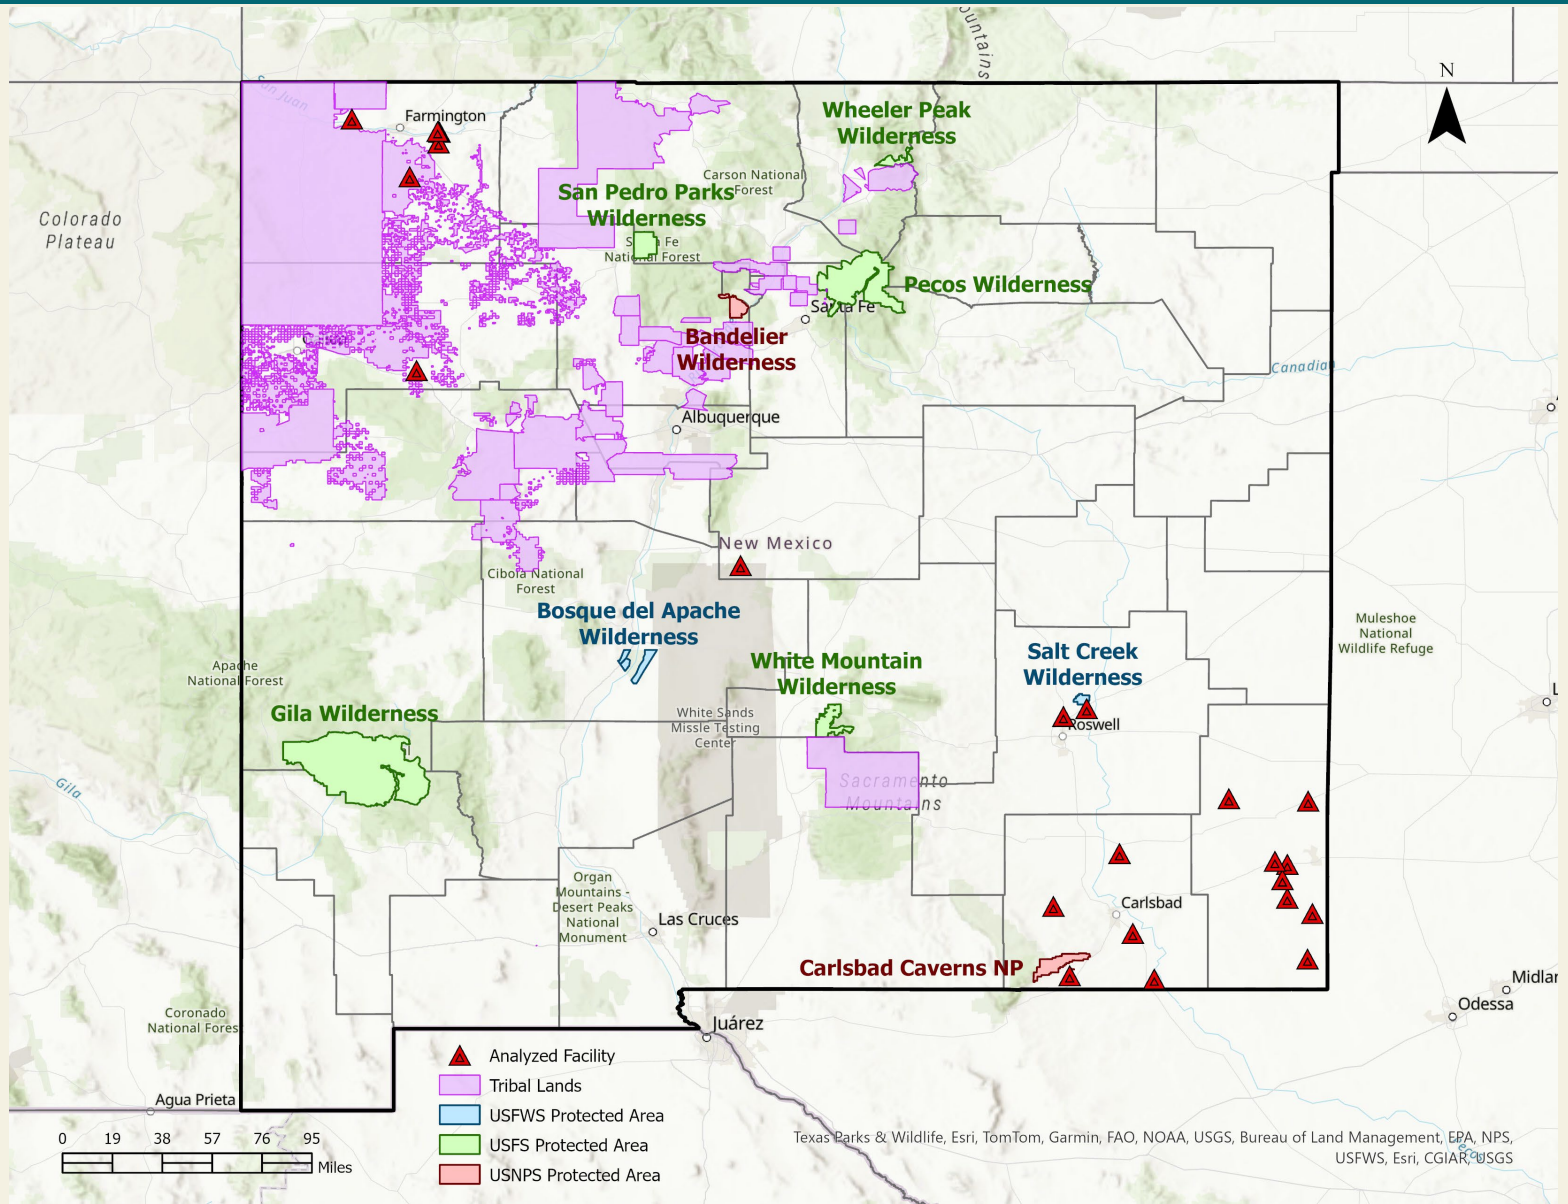
Impact on Tribes

- Reduced visibility due to regional haze impacts more than just protected areas; it impacts visibility in the rest of New Mexico including Tribal lands
- Regional haze is a symptom of broader air quality problems that affect not just visibility, but health too, including the health of Tribal members
- Tribes can submit their own plans to address regional haze if they choose, but generally rely on state plans
- NMED is committed to coordinating with Tribes and values your feedback on its draft Regional Haze plan



Overview of Draft Plan

SELECTED SOURCES

Selected Sources

- NMED used a screening process to select 23 facilities for an analysis of potential control measures
- NMED evaluated 133 individual emissions units at those facilities based on additional screening criteria
- The goal of NMED's screening process was to focus efforts on higher emitting units at the largest sources of air pollution that are most likely to affect visibility in protected areas based on their emissions and proximity to those areas

Selected Sources

Overview of Draft Plan

CONTROL EVALUATIONS

Control Evaluations

- Identify all feasible control options for each unit
- For each feasible option:
  - Determine cost to implement ($)
  - Estimate emissions reductions (tons/year)
  - Calculate cost effectiveness ($/ton)
- Determine appropriate cost threshold
- Select required controls

Control Evaluations

Case Example: Natural Gas Compressor Engine

Control Evaluations

- Annualized Cost of Control Options:
  - Low Emission Combustion = $837,000
  - Replacement = $1,213,000
  - Electrification = $1,361,000
- Estimated Emissions Reductions:
  - Low Emission Combustion = 118.3 tons/year
  - Replacement = 123.5 tons/year
  - Electrification = 131.2 tons/year
- Cost effectiveness:
  - Low Emission Combustion = $7,900/ton
  - Replacement = $11,600/ton
  - Electrification = $10,400/ton
- Required Control = Low Emission Combustion

Overview of Draft Plan

RESULTS OF ANALYSIS

Results of Analysis

- New Controls on 44 Emissions Units
- Permanent Retirement of 34 Emissions Units
- Measures to Ensure Continued Use of In-Place Controls on 11 Emissions Units
- Significant Reductions in Emissions of Pollutants that Contribute to Visibility Impairment
  - Nitrogen Oxides > 16,000 tons/year
  - Sulfur Dioxide > 5,000 tons/year

RE: **Tribal Feedback on State of New Mexico's Draft Regional Haze State Implementation Plan-Second Planning Period**

Dear Mr. Jones,

The Ute Mountain Ute Tribe (UMUT) Environmental Programs Department (EPD) appreciates that the New Mexico Environment Department sent consultation correspondence to the Ute Mountain Ute Tribe's Leaders for feedback on the New Mexico's Draft Regional Haze State Implementation Plan-Second Planning Period (Plan). The EPD is pleased to submit these comments on the Plan.

The Ute Mountain Ute Indian Reservation is located in extreme southwestern Colorado, southeastern Utah and northwestern New Mexico. The Reservation is approximately 933 square miles in total area of trust land which is homeland for the population of 2,100 members. Presently, there are several pollution sources in the area and in the region of Tribal Reservation Lands that have decreased the visibility in and around the Tribal Lands and the Ute Mountain Ute Tribe has concerns that pollutants are also acting to compound adversely to the health of the tribe's environment and population, and that of the region as well. Tribal landmarks are crucial to the members and community and we support the efforts of New Mexico Environmental Department to take measures to reduce visual pollution.

In general, the EPD supports the Plan that fulfills the goals of the EPA's rulemaking for an increase in visibility as a result for the near-term and long-term targets through reductions in emissions. Several of these emission reductions will also be advantageous to the UMUT reservation lands because they are with a 50 mile radius of the sources.

The comments regarding the draft NMED SIP for RHR Second Planning Period are in the attached file, *JA review NM Draft SIP June 2024.* We understand that the plan has been defined though the regulatory framework of the EPA. Comments include:

- not being in agreement with the conclusions drawn in parts of Section 5 detailed in the attached review file, and a few editorial mistakes,
- references for the data are provided, however, a thumbnail sketch of the dataset origination in the sections where they are used (Section 5) would have been immensely helpful for evaluation of this review or understanding in general.
- The EPD is specifically supportive of:
  - The Renewable Energy Goals in Section 5.4.7, which states the reduction in pollutant emissions from sources were reduced dramatically with the expansion of renewable energy goals; electricity generation by renewable resources surpassed coal production for the first time in 2022,
  - the regulatory methods in section 8.2 - these regulated emission limitations and compliance deadlines should be an effective and enforceable method for emissions reductions at the identified facilities.
  - the currently adopted regulations in Section 8.3.1, the Ozone Precursor Pollutants-Oil and Gas Sector Rule and the New Motor Vehicle Emission Standards Rule would further reduce emissions that cause visibility impairment.

The EPD would like to acknowledge appreciation to New Mexico (Environment Department) that New Mexico, who is also a member of the Western Regional Air Partnership (WRAP) aligned with the WRAP's Communications Framework for Regional Haze Planning, adopted by consensus, Sept. 3, 2019[i]. This document calls out that Tribes should be engaged and consulted in the state's RHR Planning process, especially those Tribes that are members, such as the Ute Mountain Ute Tribe. Unfortunately, not all of the WRAP partners followed this process in their planning.

One correction to Tribal contacts should be noted, Jerald Peabody, Director, Natural Resource Department, jerald.jpeabody@utemountain.org has been replaced by David Stoner, dstoner@utemountain.org.

If there are any questions or concerns relating to these comments, please feel free to contact Scott Clow, Environmental Programs Director, at 970-564-5432, or the Air Quality Program Manager, Janice Archuleta at 970-564-5433.

On Behalf of the Ute Mountain Ute Tribe Environmental Programs Department,

Respectfully Submitted,

Janice Archuleta

Ute Mountain Ute Comments on draft SIP narrative (7/19/24)

In reference to "Such consideration was not necessary because the First Period SIP did in fact demonstrate a projected continuous decline in mobile source emissions for the period 2003 to 2008:" Comment: This statement relies on Section 5.4.4 data which does not represent this statement. Somewhere in the mobile sources section in section 5. there could be a discussion about how to further reductions in emissions will be implemented with the planned regulatory actions mentioned in 8.3.1, those which would have an effect on mobile sources.
In reference to Section 5.4.4, "This Section presents data from WRAP consistent with a decline in mobile source emissions over the period 2003-2018." Comment: Table 5-3 does not support this statement. At the very least, it can be reported that 2 of the 4 pollutant categories have declined from 2002 to 2011.
In reference to Table 5-3 "Coarse Mass (Particulate Matter) (TPY). Comment: Coarse Mass increased from 2002, in 2008 and 2011.
In reference to Table 5-3 "Primary Organic Aerosols (TPY)." Comment: Primary Organics Aerosols increased from 2002, in 2008 and 2011.
In reference to Table 5-4. Comment: The totals for the PM10 are 48 TPY, and the totals for the PM2.5 are are 43 TPY. Taking into consideration the statistical errors embedded in the dataset or model, this amount of variation could be insignificant, i.e., the TPY's for 2014 and 2018 'are equal'. This would invalidate the statements above.
In reference to Section 5.4.7. Comment: Alternative energy to fossil fuels proves to reduce emissions. The UMUT has plans for new renewable projects as well.
In reference to Section 5.7.13- "The data shown in Section 5.4.5- Mobile Sources, confirmed this overall decline. Two comments. 1: The data presented in 5.4.4 did not confirm this statement. Only 2 of the pollutant categories supported this statement." 2: "4, See Section 5.4.4."
In reference to Section 5.7.4.1. "In Section 5.4.7, this is not true for NOx and may not be supported by the SOx TPY either."
In reference to the statement "Furthermore, increasing the CETV to $14,000/ton would result in just a few hundred additional tons per year of NOx reductions at considerable additional cost to the affected sources." Comment: This could be presented here and have the reader make this decision instead of speaking generally.
In reference to Section 8.2.1. Comment: The regulatory emission limitations and compliance deadlines are an effective and enforceable method for emissions reductions at the identified facilities.
In reference to the 2024-04-29 Ameredev Settlement under Section 10.3.4.2. Comment: Is a description of the outcome missing here?
In reference to Chapter 11, under Figure 11-1. Comment: The WRAP's Communications Framework for Regional Haze Planning, Sept. 3, 2019, could/should be mentioned somewhere in the document.

E.5 Discussions with Industry

Supporting documentation for NMED coordination with Industry is provided below. The following documents are included in this section (in reading order):

- NMED Communications
    - Notifications to Companies that Their Facility is Subject to Regional Haze Four-Factor Analysis and Control Measure Determinations (7/18/19)
    - Notice to Industry of Draft Final Cost Control Evaluation Availability for Review (12/14/2023)
    - Advance Notice to Industry of available NMED draft Regional Haze SIP revision and Companion Rule (8/19/24)

[1] Additional Supporting Documentation on Industry Communications on Four Factor Analysis is Provided in Appendix D.

Mr. Andy Berger
Tri-State Generation and Transmission Association
PO Box 33695
Denver CO, 80233

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Berger:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Escalante Generating Station in Prewitt, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Liz Bisbey-Kuehn
Chief, Air Quality Bureau

Ms. Alena Miro
Enterprise Field Services
PO Box 4324
Houston, TX 77210-4324

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Miro:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Enterprise – South Carlsbad Compressor Station in Eddy County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Midland, TX 79701

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Blackaller:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Jal No. 3 Gas Plant near Jal, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. Ms. Cynthia Klein
Targa Midstream Services
14000 Quail Springs Parkway, Suite. 215
Oklahoma City, OK 73134

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Klein:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Monument Gas Plant, Eunice Gas Processing Plant and Saunders Gas Plant in Lea County, New Mexico as facilities subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified 24 Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. Ms. Elena Hofmann
Davis Gas Processing
13201 NW Freeway, Suite 200
Houston, TX 77040

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Hofmann:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Denton Gas Plant in Lea County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Liz Bisbey-Kuehn
Chief, Air Quality Bureau

Mr. Kijun Hong
Harvest Four Corners, LLC
1755 Arroyo Drive
Bloomfield, NM 87413

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Hong:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Kutz Canyon Processing Plant and Harvest Pipeline – San Juan Gas Plant facilities in San Juan County, New Mexico as facilities subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership ("WRAP"), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

Because the Harvest Pipeline - San Juan Gas Plant is jointly permitted with the El Paso Natural Gas – Blanco Compressor Station A and the Enterprise Field Services, LLC – Blanco C&D Compressor Station under NSR Permit No. 0613-M12, NMED requests a combined four-factor analysis for these three facilities. The four-factor analysis for the Kutz Canyon Processing Plant should be submitted as a separate report. NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

6381 Main Street
Roswell, NM 88201

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Campbell:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Roswell Compressor Station No. 9 and the Mountainair No. 7 Compressor Station in Chaves and Torrance counties, respectively, as facilities subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Dallas TX, 75244

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Hines:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Bitter Lake Compressor Station located northeast of Roswell, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

July 18, 2019

Mr. Travis Ray
El Paso Natural Gas Company
8645 Railroad Drive
El Paso, TX 79904

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Ray:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Blanco Compressor Station A in San Juan County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

Because the Blanco Compressor Station is jointly permitted with the Harvest Pipeline - San Juan Gas Plant and the Enterprise Field Services, LLC – Blanco C&D Compressor Station under NSR Permit No. 0613-M12, NMED requests a combined four-factor analysis for these three facilities. NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Liz Bisbey-Kuehn
Chief, Air Quality Bureau

Ms. Zainab Naqvi
El Paso Natural Gas Company
8645 Railroad Drive
El Paso, TX 79904

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Naqvi:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Washington Ranch Storage Facility and the Pecos River Compressor Station in Eddy County, New Mexico as facilities subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified 24 Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Liz Bisbey-Kuehn

Mr. Trevor Baird
DCP Midstream
10 Desta Drive, Suite 500 West
Midland, TX 79705

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Baird:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the DCP – Linam Ranch Gas Plant facility in Lea County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. Mr. Nicholas Case
DCP Operating Company
10 Desta Drive, Suite 400 West
Midland, TX 79705

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Case:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Artesia Gas Plant in Eddy County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. Mr. Bill Glushko
DCP Operating Company, LP
10 Desta Drive, Suite 500 West
Midland, TX 79705

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Glushko:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Eunice Gas Plant northwest of Eunice, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or

about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Lieb:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Chaco Gas Plant and the Blanco C&D Compressor Station located in San Juan County, New Mexico as facilities subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

Because the Blanco C&D Compressor Station is jointly permitted with the Harvest Pipeline - San Juan Gas Plant and the El Paso Natural Gas Company – Blanco Compressor Station A under NSR Permit No.

0613-M12, NMED requests a combined four-factor analysis for these three facilities. The four-factor analysis for the Chaco Gas Plant should be submitted as a separate report. NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Liz Bisbey-Kuehn
Chief, Air Quality Bureau

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Serrano:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Oxy – Indian Gas Plant facility in Eddy County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. Albuquerque, NM 87107

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Ms. Gannon:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the San Juan Generating Station in Waterflow, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified 24 Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350.

Xcel Energy
PO Box 1261
Amarillo, TX 79105

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Worley:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Xcel Energy – Cunningham Station facility in Lea County, New Mexico as a facility subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. Mr. James Lieb
Enterprise Field Services
PO Box 4324
Houston, TX 77210-4324

Subject: Notification of Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program

Dear Mr. Lieb:

This letter is to inform you that the New Mexico Environment Department (NMED) has identified the Chaco Gas Plant and the Blanco C&D Compressor Station located in San Juan County, New Mexico as facilities subject to a four-factor reasonable progress analysis under the federal Clean Air Act, 42 U.S.C. § 7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule).

The NMED has identified twenty-four (24) Title V permitted facilities across the state that may potentially have an impact on visibility at Federal Class 1 Areas protected by the Regional Haze Rule. This determination was based on a methodology developed by the Western Regional Air Partnership (WRAP), consistent with guidance from the U.S. Environmental Protection Agency (EPA).

The four-factor analysis is necessary for NMED to develop a long-term strategy to address regional haze visibility impairment. The four-factor analysis considers emission reduction measures based on (1) the cost of compliance; (2) the time necessary for compliance; (3) the energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of an existing source subject to this requirement. We request that you analyze all the identified control measures in terms of the four factors specified in 40 CFR § 308(f)(2)(i), consistent with relevant EPA guidance.

Therefore, in accordance with the Regional Haze Rule, NMED requests that your company perform a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Note that equipment exempt under 20.2.72 NMAC or insignificant under 20.2.70 NMAC is not required to undergo the analysis. Likewise, individual equipment of the same source category is not required to be aggregated in order to determine if an analysis is required. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis.

Because the Blanco C&D Compressor Station is jointly permitted with the Harvest Pipeline - San Juan Gas Plant and the El Paso Natural Gas Company – Blanco Compressor Station A under NSR Permit No.

0613-M12, NMED requests a combined four-factor analysis for these three facilities. The four-factor analysis for the Chaco Gas Plant should be submitted as a separate report. NMED respectfully requests that your company submit a report containing the complete four-factor analysis no later than November 1, 2019. Prior to that date, NMED plans to hold a teleconference on or about September 4th to review progress in identifying technically feasible control measures and conducting the four-factor analysis for each subject source.

Following submission of the facility's report, NMED will determine whether any of the identified control measures are cost effective and technically feasible for the facility in terms of the four-factor analysis. Any measures that are cost effective and technically feasible will be submitted to WRAP along with data quantifying the projected emission reductions that will result by calendar year 2028 from implementation of these measures. The modeling results will determine if projected emissions reductions will result in visibility improvement to the affected Class 1 area. If visibility improvements are not predicted by the model, the control measures will not be recommended.

NMED will incorporate the identified cost-effective measures into a proposed Regional Haze State Implementation Plan, which NMED will bring to the Environmental Improvement Board (Board). NMED will petition the Board for a rulemaking hearing on the proposed SIP in the first half of calendar year 2021, in order to meet the federal regulatory deadline of July 31, 2021 for submittal to the EPA.

Please contact NMED if you have questions about the methodology for conducting a four-factor analysis under the Regional Haze Rule. We encourage your questions in order to help expedite the technical analysis required under the Rule. Staff would be happy to meet with you in person to discuss these requirements in more detail. NMED has developed a website for Regional Haze with important links to EPA's Cost Control Manual and other technical information that may assist in these efforts.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact Kerwin Singleton of my staff at (505) 476-4350, or Mark Jones at (505) 566-9746.

Sincerely,

Subject:	Draft Final Control Cost Evaluation for DCP Operating Company"s Linam Ranch Gas Plant
Date:	Thursday, December 14, 2023 5:12:13 PM
Attachments:	2023-12-14_Draft Final NMED Cost Evaluation_DCP - Linam Ranch Gas Plant.xlsx

Dear Mr. Cook,

Please find NMED's draft final control cost evaluation for the Regional Haze Second Planning Period for DCP Operating Company's Linam Ranch Gas Plant in the Excel workbook attached to this email.

We are providing this draft final evaluation as a courtesy so you can review it before NMED completes its draft SIP and begins the formal Federal Land Manager (FLM) consultation period required by EPA's Regional Haze Rule. Please review the sheets in the attached workbook for any errors or omissions in incorporating information that your company has previously submitted to NMED. Also, please use this opportunity to notify us of any previously undisclosed changes at your facility that could affect our pending control determinations, such as the decommissioning or replacement of units subject to Regional Haze, the addition of new pollution controls, or facility shutdowns. We reiterate that we are interested in any errors or omissions that you see as well as significant operational changes. For cases involving modifying or decommissioning units, relevant information would include how these are permitted to satisfy EPA's requirement that they be permanent and federally enforceable. Because NMED provided an opportunity to update cost information in summer and early fall 2023, we are no longer accepting updates to cost estimates. **The deadline to submit review comments by email to NMED is Jan 15, 2024**. We may not have time to review comments received after this deadline prior to completing our draft SIP.

As part of your review, please provide information on when units #8 and #9 will be removed through an administrative revision to the DCP – Linam Ranch Gas Plant Permit.

NMED has not yet completed its analysis of process flaring and SSM flaring emissions at DCP facilities. We will consider these emissions in a separate analysis covering multiple facilities unless we determine that a facility-specific analysis is required for any of DCP's facilities.

An updated overall timeline for the formal FLM review period and proposed hearing phase for New Mexico's Regional Haze State Implementation Plan for the second planning period will soon be available on our NMED Regional Haze planning website: https://www.env.nm.gov/air-quality/reg-haze/.

If you have any questions or feedback for our Regional Haze planning team, please contact me, Kirby Olson (Kirby.olson@env.nm.gov) and cc Mark Jones (mark.jones@env.nm.gov), Ken Miller (kenneth.miller@env.nm.gov) and Alex Sanchez (alex.sanchez@env.nm.gov).

Regards,

Kirby Olson

Dear Mr. Mitchell,

Please find NMED's draft final control cost evaluations for the Regional Haze Second Planning Period for El Paso Natural Gas Company, LLC's Blanco Compressor Station A, Pecos River Compressor Station and Washington Ranch Storage Facility in the Excel workbooks attached to this email.

We are providing these draft final evaluations as a courtesy so you can review them before NMED completes its draft SIP and begins the formal Federal Land Manager (FLM) consultation period required by EPA's Regional Haze Rule. Please review the sheets in the attached workbooks for any errors or omissions in incorporating information that your company has previously submitted to NMED. Also, please use this opportunity to notify us of any previously undisclosed changes at your facilities that could affect our pending control determinations, such as the decommissioning or replacement of units subject to Regional Haze, the addition of new pollution controls, or facility shutdowns. We reiterate that we are interested in any errors or omissions that you see as well as significant operational changes. For cases involving modifying or decommissioning units, relevant information would include how these are permitted to satisfy EPA's requirement that they be permanent and federally enforceable. Because NMED provided an opportunity to update cost information in summer and early fall 2023, we are no longer accepting updates to cost estimates. **The deadline to submit review comments by email to NMED is Jan 15, 2024**. We may not have time to review comments received after this deadline prior to completing our draft SIP.

Our NMED Regional Haze planning team could not locate recent emissions test reports for Blanco Compressor Station A Units A-01, A-05, A-06, A-07, A-08, A-10, A-12, or A-14, so we used average emissions from the other units as a surrogate for purposes of calculating baseline actual emissions. If available, please provide our team the most recent emissions test reports for these units so we can further refine our analysis.

An updated overall timeline for the formal FLM review period and proposed hearing phase for New Mexico's Regional Haze State Implementation Plan for the second planning period will soon be available on our NMED Regional Haze planning website: https://www.env.nm.gov/air-quality/reg-haze/.

If you have any questions or feedback for our Regional Haze planning team, please contact me, Kirby Olson (Kirby.olson@env.nm.gov) and cc Mark Jones (mark.jones@env.nm.gov), Ken Miller (kenneth.miller@env.nm.gov) and Alex Sanchez (alex.sanchez@env.nm.gov).

Dear Ms. Miro,

Please find NMED's draft final control cost evaluation for the Regional Haze Second Planning Period for ETC Transwestern Pipeline, LLC's Mountainair Compressor Station No. 7 and Roswell Compressor Station No. 9 in the Excel workbook attached to this email.

We are providing this draft final evaluation as a courtesy so you can review it before NMED completes its draft SIP and begins the formal Federal Land Manager (FLM) consultation period required by EPA's Regional Haze Rule. Please review the sheets in the attached workbook for any errors or omissions in incorporating information that your company has previously submitted to NMED. Also, please use this opportunity to notify us of any previously undisclosed changes at your facility that could affect our pending control determinations, such as the decommissioning or replacement of units subject to Regional Haze, the addition of new pollution controls, or facility shutdowns. We reiterate that we are interested in any errors or omissions that you see as well as significant operational changes. For cases involving modifying or decommissioning units, relevant information would include how these are permitted to satisfy EPA's requirement that they be permanent and federally enforceable. Because NMED provided an opportunity to update cost information in summer and early fall 2023, we are no longer accepting updates to cost estimates. **The deadline to submit review comments by email to NMED is Jan 15, 2024**. We may not have time to review comments received after this deadline prior to completing our draft SIP.

ETC Texas Pipeline LTD's Jal No.3 Gas Plant – Based on updated information provided by ETC (2023-07-31), most of the units subject to Regional Haze Second Planning Period including Unit 4A, 4B and 9S have been removed from the permit and decommissioned. Therefore no additional cost evaluation is necessary for these units. For the remaining units (amine unit controlled by AGI and flare(s)) we will consider the flares and associated flaring emissions in a separate analysis for multiple facilities.

An updated overall timeline for the formal FLM review period and proposed hearing phase for New Mexico's Regional Haze State Implementation Plan for the second planning period will soon be available on our NMED Regional Haze planning website: https://www.env.nm.gov/air-quality/reg-haze/.

Cc:	Miller, Kenneth, ENV; Sanchez, Alex, ENV; Butt, Neal, ENV; Peters, Eric, ENV; Hirsch, Josh, ENV
Subject:	Notification of Upcoming Availability of Public Review Drafts of Regional Haze SIP Revision and Companion Rule 20.2.68 NMAC
Date:	Monday, August 19, 2024 4:54:30 PM

Dear Ms. Gannon and Ms. Horn,

NMED is working to complete its draft Regional Haze state implementation plan (SIP) revision for the second planning period (2019-2028) in anticipation of petitioning the New Mexico Environmental Improvement Board (EIB) to hold a hearing on the plan in late fall or early winter. We recently completed the formal 60-day Federal Land Manager (FLM) consultation period required by the Regional Haze Rule and are considering FLM comments on our draft SIP. After we have reviewed all FLM comments and made any necessary changes to the draft SIP, we plan to release public review drafts of the SIP and a companion rule, 20.2.68 NMAC – Regional Haze Requirements, for review and comment by members of the public, industry, and other stakeholders before finalizing the plan and rule and formally proposing them to the EIB. The purpose of the companion rule is to establish enforceable emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress during the second planning period, and provisions to make these measures practically enforceable.

We anticipate sharing the public review drafts via our website, https://www.env.nm.gov/air-quality/reg-haze/, on or about **August 26, 2024**. As an affected entity, we are giving you advance notice of the upcoming review period, and we will be requesting that you submit any feedback or comments to us by the end of the day on **September 20, 2024**. There will be no extensions granted on this deadline, as we will be starting the next phase of this process in October, and we want to ensure that we have sufficient time to consider any comments received before the next phase begins. We note that you can also submit comments on the proposed plan during the formal 30-day public comment period that precedes the hearing. Although the exact dates are not known at this time, we will be providing updates on our Regional Haze website (https://www.env.nm.gov/air-quality/reg-haze/) as we continue through this process. Once notice of the hearing has been published in the New Mexico Register, the proposed SIP and related documents will be posted to our public notices web page (https://www.env.nm.gov/public-notices/), and the formal public comment period will begin. We anticipate this will occur sometime in November, barring any unexpected delays.

If you have any questions or feedback for the NMED Regional Haze planning team, please contact me, Mark Jones (mark.jones@env.nm.gov), and cc Ken Miller (kenneth.miller@env.nm.gov), Alex Sanchez (alex.sanchez@env.nm.gov), and Eric Peters (eric.peters@env.nm.gov).

Sincerely,

Mark

Date:	Monday, August 19, 2024 4:47:06 PM

Dear Mr. Cook,

NMED is working to complete its draft Regional Haze state implementation plan (SIP) revision for the second planning period (2019-2028) in anticipation of petitioning the New Mexico Environmental Improvement Board (EIB) to hold a hearing on the plan in late fall or early winter. We recently completed the formal 60-day Federal Land Manager (FLM) consultation period required by the Regional Haze Rule and are considering FLM comments on our draft SIP. After we have reviewed all FLM comments and made any necessary changes to the draft SIP, we plan to release public review drafts of the SIP and a companion rule, 20.2.68 NMAC – Regional Haze Requirements, for review and comment by members of the public, industry, and other stakeholders before finalizing the plan and rule and formally proposing them to the EIB. The purpose of the companion rule is to establish enforceable emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress during the second planning period, and provisions to make these measures practically enforceable.

We anticipate sharing the public review drafts via our website, https://www.env.nm.gov/air-quality/reg-haze/, on or about **August 26, 2024**. As an affected entity, we are giving you advance notice of the upcoming review period, and we will be requesting that you submit any feedback or comments to us by the end of the day on **September 20, 2024**. There will be no extensions granted on this deadline, as we will be starting the next phase of this process in October, and we want to ensure that we have sufficient time to consider any comments received before the next phase begins. We note that you can also submit comments on the proposed plan during the formal 30-day public comment period that precedes the hearing. Although the exact dates are not known at this time, we will be providing updates on our Regional Haze website (https://www.env.nm.gov/air-quality/reg-haze/) as we continue through this process. Once notice of the hearing has been published in the New Mexico Register, the proposed SIP and related documents will be posted to our public notices web page (https://www.env.nm.gov/public-notices/), and the formal public comment period will begin. We anticipate this will occur sometime in November, barring any unexpected delays.

If you have any questions or feedback for the NMED Regional Haze planning team, please contact me, Mark Jones (mark.jones@env.nm.gov), and cc Ken Miller (kenneth.miller@env.nm.gov), Alex Sanchez (alex.sanchez@env.nm.gov), and Eric Peters (eric.peters@env.nm.gov).

Dear Mr. Berger,

NMED is working to complete its draft Regional Haze state implementation plan (SIP) revision for the second planning period (2019-2028) in anticipation of petitioning the New Mexico Environmental Improvement Board (EIB) to hold a hearing on the plan in late fall or early winter. We recently completed the formal 60-day Federal Land Manager (FLM) consultation period required by the Regional Haze Rule and are considering FLM comments on our draft SIP. After we have reviewed all FLM comments and made any necessary changes to the draft SIP, we plan to release public review drafts of the SIP and a companion rule, 20.2.68 NMAC – Regional Haze Requirements, for review and comment by members of the public, industry, and other stakeholders before finalizing the plan and rule and formally proposing them to the EIB. The purpose of the companion rule is to establish enforceable emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress during the second planning period, and provisions to make these measures practically enforceable.

We anticipate sharing the public review drafts via our website, https://www.env.nm.gov/air-quality/reg-haze/, on or about **August 26, 2024**. As an affected entity, we are giving you advance notice of the upcoming review period, and we will be requesting that you submit any feedback or comments to us by the end of the day on **September 20, 2024**. There will be no extensions granted on this deadline, as we will be starting the next phase of this process in October, and we want to ensure that we have sufficient time to consider any comments received before the next phase begins. We note that you can also submit comments on the proposed plan during the formal 30-day public comment period that precedes the hearing. Although the exact dates are not known at this time, we will be providing updates on our Regional Haze website (https://www.env.nm.gov/air-quality/reg-haze/) as we continue through this process. Once notice of the hearing has been published in the New Mexico Register, the proposed SIP and related documents will be posted to our public notices web page (https://www.env.nm.gov/public-notices/), and the formal public comment period will begin. We anticipate this will occur sometime in November, barring any unexpected delays.

If you have any questions or feedback for the NMED Regional Haze planning team, please contact me, Mark Jones (mark.jones@env.nm.gov), and cc Ken Miller (kenneth.miller@env.nm.gov), Alex Sanchez (alex.sanchez@env.nm.gov), and Eric Peters (eric.peters@env.nm.gov).

Sincerely,

Mark

Subject:	Notification of Upcoming Availability of Public Review Drafts of Regional Haze SIP Revision and Companion Rule 20.2.68 NMAC
Date:	Monday, August 19, 2024 4:36:54 PM

Dear Ms. Snyder,

NMED is working to complete its draft Regional Haze state implementation plan (SIP) revision for the second planning period (2019-2028) in anticipation of petitioning the New Mexico Environmental Improvement Board (EIB) to hold a hearing on the plan in late fall or early winter. We recently completed the formal 60-day Federal Land Manager (FLM) consultation period required by the Regional Haze Rule and are considering FLM comments on our draft SIP. After we have reviewed all FLM comments and made any necessary changes to the draft SIP, we plan to release public review drafts of the SIP and a companion rule, 20.2.68 NMAC – Regional Haze Requirements, for review and comment by members of the public, industry, and other stakeholders before finalizing the plan and rule and formally proposing them to the EIB. The purpose of the companion rule is to establish enforceable emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress during the second planning period, and provisions to make these measures practically enforceable.

We anticipate sharing the public review drafts via our website, https://www.env.nm.gov/air-quality/reg-haze/, on or about **August 26, 2024**. As an affected entity, we are giving you advance notice of the upcoming review period, and we will be requesting that you submit any feedback or comments to us by the end of the day on **September 20, 2024**. There will be no extensions granted on this deadline, as we will be starting the next phase of this process in October, and we want to ensure that we have sufficient time to consider any comments received before the next phase begins. We note that you can also submit comments on the proposed plan during the formal 30-day public comment period that precedes the hearing. Although the exact dates are not known at this time, we will be providing updates on our Regional Haze website (https://www.env.nm.gov/air-quality/reg-haze/) as we continue through this process. Once notice of the hearing has been published in the New Mexico Register, the proposed SIP and related documents will be posted to our public notices web page (https://www.env.nm.gov/public-notices/), and the formal public comment period will begin. We anticipate this will occur sometime in November, barring any unexpected delays.

If you have any questions or feedback for our Regional Haze planning team, please contact me, Mark Jones (mark.jones@env.nm.gov), and cc Ken Miller (kenneth.miller@env.nm.gov), Alex Sanchez (alex.sanchez@env.nm.gov), and Eric Peters (eric.peters@env.nm.gov).

Sincerely,

Mark

E.6 General Outreach Education and Stakeholder Engagement

Supporting documentation for NMED general outreach, education and stakeholder engagement is provided below. The following documents are included in this section (in reading order):

- Regional Haze Planning Guiding Principles (1/3/19)
- Early Engagement National Parks Conservation Association Comments (5/22/20)
- NPCA comments to NMED regarding - Petition to EPA for Reconsideration of Regional Haze Final Guidance (5/29/20)
- Assessment of Cost Effectiveness Analyses for Controls Evaluated Four – Factor Analyses for Oil and Gas Facilities (7/2/20)
- Draft Regional Haze Plan Informational Webinar (9/9/2024 and 9/10/2024)

Air Quality Bureau

Guiding Principles for Developing the New Mexico Regional Haze State Implementation Plan (RH SIP)

Science

- Use sound scientific analysis and principles to understand visibility issues.
- Perform visibility studies using the most recent, complete, and accurate datasets available.
- Rely upon and lead with science to inform our understanding of the causes of haze, evaluate strategies and set future goals to improve visibility at Class I Areas.

Innovation

- Consider new ideas that potentially offer better solutions to problems of haze at Class I Areas.
- Allow for flexibility in the planning and development of the RH SIP revision to include new information as it becomes available.
- Include and evaluate the newest engineering methods and technology advances in potential control measures to help solve haze problems.

Collaboration

- Assist the Western Regional Air Partnership (WRAP) and its contractors performing regional technical analyses, and collaborate with all western states, Federal Land Managers (FLMs), the U.S. Environmental Protection Agency (EPA) and tribes.
- Work proactively with all stakeholders to minimize negative impacts for sources and maximize visibility improvements at Class I Areas.
- Acknowledge and consider a wide range of perspectives and ideas, regardless of the source, while respecting each person working toward the shared goal of improved visibility at Class I Areas.
- Keep stakeholders informed of all steps required for RH SIP planning and development; help them access technical information that informs the Department's decisions.
- Consult with EPA, FLMs, other states and, where appropriate, tribes at multiple stages in the development of the RH SIP revision.

Compliance

- Maintain a level playing field with the development of fair and equitable reasonable control measures.
- Develop a long-term strategy that ensures continued progress toward visibility goals.
- Assure approvability of the RH SIP revision by complying with federal rule requirements, adhering to EPA guidance and frequently consulting with EPA and FLMs.

Attn: Mark Jones & Cember Hardison
New Mexico Environment Department

May 22, 2020

Dear Mr. Jones and Ms. Hardison,

Thank you for the opportunity to discuss the options available for best mitigating haze-causing pollutants from sources in the oil and gas sector in New Mexico. We appreciate your work to develop a strong regional haze state implementation plan (SIP). While this letter is focused on emission reducing options for engines in the oil and gas sector, as we've identified elsewhere, other facilities in this and other sectors also contribute to regional haze, such as the San Juan Generating Station, and we maintain an interest in seeing the New Mexico haze SIP control pollution from those sources as well.

In response to your request for more information regarding selective catalytic reduction (SCR) for lean burn engines, we have attached an expert report prepared by Victoria Stamper and Megan Williams. As the report describes in detail, SCR is a feasible and cost-effective pollution control option. However, rather than require SCR, we urge NMED to require operators to replace gas-fueled engines with electric motors wherever feasible. To that end, the agency must establish clear and specific criteria for determining "infeasibility." Electrification is ultimately the best option for reducing or eliminating emissions of NO_x (and all other air pollutants from gas-fired engines), thereby better reducing visibility and public health harming emissions while helping New Mexico achieve its climate goals. Electrification can also be highly cost-effective. State and federal regulations establish the authority for NMED to require electrification of gas engines or replacement or set near-zero NO_x emissions limits, as detailed below. Where electrification is not feasible, SCR provides a feasible and cost-effective alternative.

I. Benefits of Electrification

Gas-fired engines used in oil and gas development contribute significantly to NO_x and other air pollution in New Mexico. Electric engines, by contrast, eliminate NO_x and other pollutants, decrease noise levels, and are easier to maintain. Compared to gas-fired engines, electric engines also result in fewer upset events at wells – events that can release large quantities of pollutants, including volatile organic compounds ("VOCs") and methane, a powerful greenhouse gas with 86 times the 20-year global warming potential of CO_2.[1] Mandatory electrification would significantly reduce methane emissions and waste, ozone, and haze, leading to improved air quality and thus improved visibility and health throughout New Mexico. It would also help New Mexico achieve its climate and energy goals, including but not limited to those articulated in Governor Michelle Lujan Grisham's January 2019 Executive Order

[1] *See* Vicki Stamper & Megan Williams, Nat'l Parks Conservation Ass'n, *Oil & Gas Sector Reasonable Progress Four-Factor Analysis of Controls For Five Source Categories* 57 (2020) [hereinafter Stamper & Williams, *Oil and Gas Four-Factor Analysis of Controls*].

2019-003, "Executive Order on Addressing Climate Change and Energy Waste Prevention."[2] Mandatory electrification would also complement and reinforce NMED's (and EMNRD's) ongoing efforts to reduce ozone and methane emissions through the Ozone Attainment Initiative (OAI) and Methane rulemakings, respectively.

Electrification can also be highly cost-effective. In 2001, the California Air Resources Board (CARB) found that electrification of units between 50 and 500 hp can control NOx pollution at a cost of about $900 to $1,100 per ton of NOx reduced.[3] CARB further concluded that for units between 500 and 1,000 hp the installed costs of electrification and internal combustion engines are about the same, and that below 500 hp the installed costs of electrification are lower than the installed costs of comparable internal combustion engines.[4] Given the significant advances in technology during the past 20 years, electrification is likely even more cost effective today.

II. Legal Authority for Electrification

Under state and federal law, NMED has the authority to mandate the electrification of engines used in oil and gas development, and/or to set NO_x emissions limitations near zero to favor electrification. Requiring SCR is also well within the scope of the state's regulatory authority. However, in order to create a SIP that will best meet state and federal clean air objectives, electrification should be required.

A. State Law

Broadly, New Mexico's Air Quality Control Act, Chapter 74, Article 2, NMSA 1978 ("Air Quality Control Act") requires the New Mexico Environmental Improvement Board (Board) to "prevent or abate air pollution."[5] The Board shall "adopt, promulgate, publish, amend and repeal rules and standards consistent with the Air Quality Control Act to attain and maintain national ambient air quality standards and prevent or abate air pollution," and "adopt a plan for the regulation, control, prevention or abatement of air pollution, recognizing the differences, needs, requirements and conditions within the geographic area of the environmental improvement board's jurisdiction . . ."[6]

Further, the Environmental Improvement Board may take action inclusive of "rules to protect visibility in mandatory class I areas to prevent significant deterioration of air quality and to achieve national ambient air quality standards in nonattainment areas . . . "[7] A rule requiring electrification of oil and gas engines would further NMED's duty to prevent or abate air pollution, including via adoption, promulgation, publication, or amendment of rules and adoption of a plan for the regulation, control,

[5] Air Quality Control Act, 74-2-5 (A) NMSA 1978 (emphasis added).

[6] Air Quality Control Act, 74-2-5 (B)(1) and (B)(2) NMSA 1978.

[7] Air Quality Control Act, 74-2-5 (C)(1) and (C)(2) NMSA 1978.

prevention or abatement of air pollution. Mandating electrification would also further NMED's duty to adopt rules to protect visibility in mandatory Class I areas to prevent significant deterioration of air quality.

Electrification would also account for the "character and degree of injury to or interference with health, welfare, visibility, and property" caused by engines and "the public interest, including the social and economic value of the sources *and subjects* of air contaminants."[8] (*Emphasis added*). Electrification of gas-fired RICE engines would eliminate 100% of NOx and other emissions.

These emissions degrade air resources in and around class 1 airsheds, which negatively impacts the health of nearby communities, and undercuts the economic benefits of the national parks and wilderness areas which comprise these airsheds. For example, NOx emissions from increased energy activity in the Permian Basin have led to noted degradation of visibility for park visitors, and repeated instances of 24-hour non-attainment of ozone near Carlsbad Caverns National Park, and deposition of NOx in the area's fragile ecosystem threatens its unique flora and fauna. Damage to the park's resources would greatly harm the area's economy; a 2019 National Park Service report shows that 466,000 visitors to Carlsbad Caverns National Park in 2018 spent $30.2 million in communities near the park. That spending supported 405 jobs in the local area and had a cumulative benefit to the local economy of $34 million.[9]

Given its technical feasibility and cost effectiveness, electrification also ensures that NMED considers measures through the lens of its duty to consider "technical practicability and economic reasonableness of reducing or eliminating air contaminants from the sources involved and previous experience with equipment and methods available to control the air contaminants involved."[10]

Finally, electrification of oil and gas drilling and other operations serves to fulfill cross-cutting initiatives by the state to address various air pollutant emissions. Electrification is mentioned as a pollution control technology for many methane emissions sources. The MAP Technical Report notes that due to the resulting elimination of criteria pollutants, HAPs, and methane, "In some situations, oil and gas operators determine that electrified compression is a viable and preferred technology in place of natural gas fired engines or turbines."(MAP Technical Report p. 99). Further discussion of recommendations for putting electrification into practice can be found in the following sections of the MAP Technical Report, to aid in establishing paths forward for achievement of air quality goals:

- Section 10.4, outlining utility co-op incentives to expand service territories in the pursuit of providing well sites with electricity;
- Section 10.8, recommends the establishment of interagency coordination to more efficiently and speedily develop electrical oilfield infrastructure in cooperation with utilities to manage distributed generation, increasing the ability of operators to cost effectively adopt electrification;
- Section 10.15, recommends that the state allow temporary gen set power on a site, in case of delays in getting line power to the site, mitigating methane as well as haze-causing pollutant emissions.

[8] Air Quality Control Act, 74-2-5 (E)(1) and (E)(2) NMSA 1978.
[9] U.S. National Park Service (NPS), "Tourism to Carlsbad Caverns National Park Creates $34 Million in Economic Benefits" (May 24, 2019), *Available at* https://www.nps.gov/cave/learn/news/tourism-creates-34-million-in-economic-benefits.htm
[10] Air Quality Control Act, 74-2-5 (E)(3) NMSA 1978.

We thus emphasize the need for interagency coordination among waste and pollution regulators and electric utility regulators, including the Public Regulation Commission, to facilitate policies to most effectively enable electrification.

B. Federal Law

In developing the state's regional haze plan under the federal Clean Air Act, the state has discretion to set NOx emissions limitations that favor electrification. In developing a regional haze SIP, a state must include reasonable progress requirements based on consideration of four factors, including the energy and non-air quality environmental impacts of compliance.[11] The state must also develop a long-term strategy for regional haze that includes enforceable emissions limitations, and emissions reduction measures necessary to make reasonable progress.[12] As explained above, and discussed in further detail in the March 6, 2020 report on Reasonable Progress Controls for the Oil and Gas Sector, electrification of engines used in oil and gas development is a cost-effective pollution control strategy with an array of environmental, climate, and public health co-benefits. The cost effectiveness of this NOx pollution control strategy supports requiring electrification of oil and gas engines and establishing a corresponding very low (near-zero) NOx limit for this source category.

Setting low NO_x emissions limits and considering technology that reduces or eliminates emissions, such as electrification, for oil and gas engines is well within the scope of regional haze analysis and SIP development, and is consistent with the Clean Air Act, and regulatory requirements for reasonable progress outlined in 40 C.F.R. § 51.308(d)(1). Regional haze SIPs must contain "emissions limits, schedules of compliance, and other measures as may be necessary to make reasonable progress toward the national goal." 42 U.S.C. § 7491 (b)(2). In determining what emissions reductions measures are needed to make reasonable progress, states must consider four factors: the cost of compliance, time necessary for compliance, energy and non-air quality environmental impacts of compliance, and remaining useful life of any potentially affected sources. 40 C.F.R. § 51.308(d)(1)(i)(A). Near-zero NO_x emissions limitations would be well within these parameters–and indeed would have positive energy and non-air quality environmental impacts.

Requiring the replacement of gas-fired engines with electric motors would serve as a reasonable progress measure applicable to a source type and would not constitute "redesigning the source" or otherwise fall outside the allowable scope of the state's regional haze planning authority. These engines assume a variety of applications, including gas compression, pumping, and power generation and the functionality of the source is undisturbed irrespective of whether it is subject to more or less stringent emission limitations. The difference is in the scale of pollution emitted or avoided as determined by the type of control strategy or technology employed to achieve an emission limit in order to help achieve a variety of benefits in the public interest, here motivated by requirements to achieve reasonable progress towards natural visibility conditions.

In looking at other regional haze requirements, the BART Guidelines allow states to "establish design, equipment, work practice or other operational standards when limitations on measurement technologies make emission standards infeasible." 40 C.F.R. Appendix Y to Part 51, Section I (E)(3). More broadly, Clean Air Act programs and analyses such as BACT, and PSD afford considerable flexibility

[11] *See* 40 C.F.R. § 51.308(d)(1)(i)(A), (f)(2)(i), (f)(3)(i).
[12] *See* 40 C.F.R. § 51.308 (f)(2)(i), (f)(3)(i).

to regulators in determining the range and type of pollution reduction practices or control strategies for states to consider as well. As the U.S. EPA Environmental Appeals Board has stated:

> "Permit issuers generally have broad discretion in conducting BACT determinations, but they are strongly discouraged from categorizing emissions control options as "impermissible redesign" without first taking the requisite "hard look" at the project. ***To skip this step might result in their "paving an automatic BACT off-ramp" that "frustrates congressional will" and may constitute a reversible abuse of discretion***. *In re N. Mich. Univ.*, 14 E.A.D. 283, 302 (EAB 2009); *accord La Paloma*, slip op. at 26, 16 E.A.D. ___. "[13] (Emphasis added).

Nothing in the Clean Air Act, applicable regulations or guidance, prohibits emissions limitations that reflect the reductions achievable through electrification. NMED should thus exercise its authority under state and federal law to require that oil and gas operators electrify oil and gas engines by either mandating electrification or establishing a NOx emission limit near 0 g/hp-hr. Doing so will expedite New Mexico's progress toward attaining natural visibility in national parks and other Class I areas, help the state in its Ozone Attainment Initiative and efforts to reduce methane emissions and waste, and help New Mexico achieve its climate goals, including but not limited to those outlined in Governor Lujan Grisham's Executive Order 2019-003.

III. SCR as a Feasible, Cost Effective Option Where Electrification is Infeasible

While replacement of gas-fired engines in oil and gas development with electric motors is our preferred pollution control measure, we recognize that there may be instances in which electrification is not feasible. If electrification is demonstrated to be infeasible in a given case, e.g., when there is no reasonable access or reasonable opportunity to create access to a power grid, we recommend that NMED require selective catalytic reduction (SCR), a cost-effective and practicable option as described in the attached Expert Report and the March 6, 2020 report on Reasonable Progress Controls for the Oil and Gas Sector. Some highlights from the Expert Report include:

- SCR has been an effective, feasible technology applied to lean burn engines for nearly four decades.

- Multiple emissions tests conducted in California for several lean burn engines with SCR showed 84% to 87% NO_x reductions, even after several years of operation.

- While space constraints can be a concern for SCR retrofits, there are several proven ways to address this issue. For example, SCR systems can be installed in place of existing exhaust mufflers on the roof of buildings.

- Given the relatively advanced age of most lean-burn engines for which NMED has requested reasonable progress analysis (with many manufactured before the Clean Air Act was enacted in 1970), NMED should also consider replacing these engines with new engines with

[13] *See, e.g., In Re: Arizona Public Service Company Ocotillo Power Plant,* 17 EAD 323, 336-37 (E.P.A. Sept. 1, 2016) *(citing In re N. Mich. Univ.,* 14 E.A.D. 283, 302 (EAB 2009*); In re La Paloma,* 16 EAD 267, 289 (EAB 2014)). ("Each such determination, like each BACT analysis itself, requires a case-by-case analysis and is highly fact- and circumstance-specific. *La Paloma,* slip op. at 26, 16 E.A.D. at ___ (citing CAA § 169(3), 42 U.S.C. § 7479(3)) (defining "BACT" as a "case-by-case" determination); GHG Guidance at 26.").

state-of-the-art low NO_x emission control technology, or, as advocated throughout this letter, replacing them with electric engines that would eliminate NO_x emissions (and other air pollutant emissions) altogether.

IV. Conclusion

Electrification is a feasible, cost-effective pollution control technology which NMED has the authority to require in its regional haze SIP. In addition to helping NMED achieve reasonable progress towards national visibility goals as required by the Clean Air Act, electrification has several co-benefits for climate, health, and ongoing regulatory and policy initiatives in New Mexico. Thus, we request that NMED require emission limitations as reasonable progress for gas-fueled engines reflective of replacement with electric-motors, with limitations reflective of SCR instead as an option when electrification is not feasible.

Thank you again for your continued engagement with the public during the regional haze SIP development process, even amidst the difficult conditions of the COVID-19 pandemic, and for your consideration of the recommendations and information in this letter and attached Expert Report. Please do not hesitate to contact us with any questions or concerns, or to discuss the attached SCR analysis or electrification further.

Review of Claims Made by New Mexico Oil and Gas Companies
Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines

May 21, 2020

By

Victoria Stamper and Megan Williams

We have reviewed most of the claims raised by New Mexico oil and gas companies regarding applicability of selective catalytic reduction (SCR) to lean burn engines and have conducted additional research beyond what was provided in our March 6, 2020 report. We are providing some additional information to address some of the issues raised in the New Mexico company submittals with respect to SCR on lean burn engines. Specifically, claims were raised that SCR has not been proven for lean burn engines or specifically for two-stroke engines.

As discussed in our March 6, 2020 report on Reasonable Progress Controls for the Oil and Gas Sector, SCR has been applied to lean burn engines since the 1980's. EPA's 1993 Alternative Control Techniques Document for RICE said they had found "23 SCR installations with lean-burn SI engines [] in the United States from information provided by catalyst vendors, in addition to over 40 overseas installations."[1]

EPA's 1993 Alternative Control Techniques (ACT) Document for RICE had emissions test information for 16 SCR applications at lean burn engines at 9 installations in California, including for Cooper-Bessemer engines.[2] Specifically, EPA provided performance data from a California vendor for an SCR application on a 660 hp Cooper-Bessemer Engine (Model GMV-6) that achieved 80% NOx control and data for two Cooper-Bessemer engines Model GMV-8 that also achieved 80% control of NOx.[3] Notably, the GMV-8 engines were using a load-following ammonia control, which is best suited for engines operated at variable load. In addition, EPA's 1993 ACT Document also provided emissions test data from California's Ventura County Air Pollution Control District for SCR used with lean burn RICE, including test data from 1987-1990 for two Cooper-Bessemer engines (Models GMV and GMV-8) and several Clark engines (Engine Models HRA-6 and HRA-32).[4] Note, some of the engines were no longer operating at the time of EPA's 1993 ACT Document due to being electrified as a result of Southern California Edison's incentive program.[5]

[4] *Id.*, Appendix A at A-16 (Table A-5).

[5] *Id.*

In September 2000, EPA issued an updated report on Stationary RICE controls.[6] Based on that EPA report, we said in our March 2020 report that "…while diesel engines are the most prevalent applications of SCR at RICE units, SCR has also been applied at lean-burn spark-ignition engines fired with natural gas, including at natural gas pipeline compressor stations."[7] The SCR installations at the time of EPA's 1993 and 2000 reports were mostly if not all from California. Several California air districts had adopted NOx limits for existing RICE that required SCR on lean burn engines particularly if low emissions combustion systems would not have allowed the unit to meet the applicable limits (or were not as cost effective as SCR), as was demonstrated in the cost reports relied on or cited in our report.[8]

In EPA's 2000 Update, it discusses one facility that operated SCR on a lean burn engine for 12 years (from 1984-1996). According to EPA, "[t]he SCR system met or exceeded the guaranteed level of NOx control (70 percent), allowing the facility to meet the applicable emission limit."[9] Indeed, emissions testing from 1993 of this lean-burn SCR retrofit as well as another lean-burn engine the company operated with SCR – eight to nine years after SCR installation – showed the SCR achieving between 84 to 87% NOx reduction.[10] This data certainly seems indicative of SCR working to significantly reduce NOx at lean-burn engines. The EPA 2000 Update identifies costs with operating the SCR, including the costs of continuous emissions monitoring systems (CEMs), cost of anhydrous ammonia, and cost of catalyst replacement.[11] The EPA 2000 Update also said that the facility found operation and maintenance required additional work not normally required for an engine.[12] These are cost issues with the control, but SCR is still a technically feasible control. Twelve years of operational data on a lean-burn engine with the engine continuing to meet high levels of NOx control even after several years of operation clearly show that SCR is a demonstrated technology for lean-burn engines. According to EPA, the company subsequently – twelve years after installation of SCR – replaced the engine with Low Emissions Combustion (LEC)-equipped engines.[13] Thus, there is no current emissions data for the engine reflective of SCR.

The EPA 2000 Update also refers to emissions test data from the Ventura County Air Pollution Control District (VCAPCD) for 7 lean burn engines with SCR, ranging in size from 291 bhp to 800 bhp.[14] The average percent NOx reduction from the test data was 84%.[15] Again, this data indicates that SCR is technically feasible for lean-burn engines. Instead, this data shows that SCR works to significantly reduce NOx from lean-burn engines. This test data was conducted from 1986 to 1993.[16] After 1993, EPA noted that the VCAPCD database did not include test data for lean-burn engines with SCR, but EPA also noted that several engines were replaced with electric motors and that a 1998 paper indicated that

[14] *Id.*
[15] *Id.*
[16] *Id.*

VCAPCD's more stringent NOx limits adopted in 1993 were intended to encourage electrification of engines.[17]

EPA's 2000 Update also cited to information from vendors of SCR systems, indicating that SCRs on lean-burn engines since 1993 have been designed to achieve 80-95% control and citing to a design outlet NOx emissions levels for three lean-burn engines at one natural gas pipeline compressor facility of less than 30 ppmv. Again, that information indicates that SCR continued to be applied to lean-burn engines, including those used at compressor stations.

Also, EPA's 2000 Update discussed test summary data for three 3,130 bhp 4-stroke lean-burn engines equipped with SCR systems that were believed to be urea-based.[18] These engines were at a liquid fuel pipeline pumping station and operated at variable loads and variable speeds, "depending on the quantity, pressure, and density of the fuel being pumped."[19] EPA stated, "[t]he SCR system utilizes a feedforward system based on engine load and speed and on exhaust temperature." According to EPA, the engines achieved their required NOx emission limit (15 ppmv or about 0.2 g/bhp-hr) during all testing with NOx emission ranging between 0.11 grams per brake horsepower per hour (g/bhp-hr) and 0.21 g/bhp-hr.[20]

EPA's 2000 Update also discussed a plot of CEM data over a 10 minute period from a heavy-duty diesel truck engine equipped with a feedforward urea SCR system. According to EPA:

> During this period, the engine varied from a speed of about 700 rotations per minute (rpm) at idle to about 2,300 rpm, with load varying concurrently from nearly 0 foot-pounds (ft-lbs) to about 800 ft-lbs. Inlet NOX concentrations varied closely with load, ranging from a less than 10 ppmv up to over 150 ppmv. Outlet NOX concentrations remained relatively stable, varying from nearly 0 ppmv up to about 20 ppmv.[21]

While this CEM data is from a diesel engine, this data shows how a feedforward urea system can address issues of variable NOx emissions due to variable loads and engines speeds – regardless of whether coming from a diesel-fired or gas-fired engine.

EPA further stated:

> Vendors of SCR systems indicate that the feedforward controls on modern systems provide for excellent NOX control in load-following applications. One representative indicated that the advance in technology has been driven by the interest of diesel engine manufacturers, working with catalyst vendors, in developing urea SCR for on-road vehicles. Such vehicles exhibit varying load by nature. [Fn omitted]. Another source also stressed that the PEMS feedforward system, with optional CEMS feedback system, has been advanced by a strong research and development effort. This vendor

[20] *Id.*
[21] *Id.*

> has supplied such SCR systems for a variety of applications, including stationary IC engines, ship engines, railroad engines, and diesel truck engines. [Fn omitted].[22]

In a more recent example of SCR being applied to two-stroke lean-burn engines, such engines at a power generating facility in Utah were successfully retrofit with SCR systems. Specifically, a Power Engineering article from 2006 discusses the retrofit of SCR systems along with catalytic convertors at lean burn engines at a Springville Utilities power station in Utah.[23] These engines burned 90% natural gas and 10% diesel. The article discusses one of the main problems using a catalyst on a two-stroke engine is the poisoning of the catalyst by the engine lubricant and states that the catalyst selected (manufactured by Miratech Corporation) was "designed to be durable and overcomes this problem."[24] While these units are used to generate electricity, this is still a relevant example of SCR being applied to two-stroke lean-burn engines. It is not known what the age of the two-stroke lean-burn engines that were retrofitted with SCR at the Springville Utilities power station in Utah. It appears that the power station being referred to is the Whitehead Power Plant, which (according to the Springville City website) was built in 1985 and was powered by Enterprise R4-V16 engines and EMD 645 engines.[25]

As another more recent example, a demonstration project was conducted at the Orange County Sanitation District's Central Power Generating Station, which is fueled by 95% landfill digester gas and 5% natural gas.[26] A demonstration project done at one Cooper Bessemer LSBV-12-SGC (a 3,471 hp lean-burn engine that drives a 2.5 MW generator) found that 78-86% NOx reduction could be achieved.[27]

SCR was also installed at the Bio Energy Washington landfill-gas dual-fuel power plant at which there are 18 dual-fuel 350 kW engine generators fueled by landfill gas and diesel.[28] This is a power plant located at the Cedar Hills gas processing facility in Washington.[29] An interesting fact about this application is that each SCR plus oxidation catalyst system treats the exhaust from 6 engines. Thus, only three SCR systems were required for 18 engines,[30] an approach that could greatly reduce the capital cost of NOx reduction and also address space constraints for SCR installation.

While we realize that space constraints can be an issue for SCR retrofits, this is something that has been dealt with on numerous instances for SCR retrofits for numerous industrial facilities. A concern about lack of space for an SCR should not be a reason to discount an SCR as not technically feasible without consultations with vendors about options for SCR locations. For example, the Manufacturers of

Emission Controls Association (MECA) describes situations where SCR systems have been installed in place of the existing exhaust muffler on the roof of buildings housing a lean-burn engine.[31]

In terms of SCR applications on lean-burn engines in the EPA's RACT/BACT/LAER Clearinghouse, we found several examples. The table below lists those RBLC entries that we found, which was not necessarily an exhaustive search.

EPA RACT/BACT/LAER Clearinghouse Entries for Lean-burn Engines with SCR

In addition to these specific examples of SCR applications, a 2011 report from the state of Delaware highlights many examples of commercially available retrofit NOx controls for engines and turbines used in gas compressor prime mover service, including SCR.[32] Several of the SCR systems were specifically

[31] Written Statement of the Manufacturers of Emission Controls Association on the San Joaquin Valley Unified Air Pollution Control District's Proposed Amendments to Rule 4702 (August 2, 2011), *available at:* http://www.meca.org/galleries/files/MECA_SJV_Rule_4702_testimony_080211.pdf.

[32] *See* Background Information Oil and Gas Sector Significant Sources of NOx Emissions, *available online at*: https://fossil.energy.gov/ng_regulation/sites/default/files/programs/gasregulation/authorizations/2011/applications/exhibits_11-161-LNG/36_DE_Nox.pdf.

advertised as being applicable to lean-burn natural gas fired engines utilized for gas compression (e.g., CleanAir Systems, Johnson Matthey, Miratech Corporation, Clean Air Power, etc.).[33] We highlighted some of these vendors in our March 2020 report, and pointed out how catalysts have been developed to operate over a wide range of temperatures.[34] Some of the information provided in the Delaware report included specific announcements for orders and installations at lean-burn natural gas compressor engines and / or at natural gas midstream sources (e.g., installations on large lean-burn natural gas compressor engines at gas storage sites in Texas and Mississippi).[35] The Delaware report discusses some of the SCR systems being formulated for operation at a wide range of temperatures, allowing for NOx control over a wide range of engine operation.[36] More generally, the Delaware Report dispels several technical issues specific to two-stroke lean-burn SCR retrofits, including the availability of: (1) modern controls and communication technologies to help overcome potential issues with remotely manned units; (2) catalysts that are effective over wide temperature ranges that are reflective of a wider range in engine operating loads (noting that SCR systems "have been installed on EGUs that start and stop on a daily basis, and change loads across a wider range while on line to balance electric generation to electric demand"); and (3) the ability to closely regulate fuel, air, and reagent flow to ensure proper SCR function over a broad range of operating condition.[37]

Targa's February 2020 Regional Haze Four-Factor Analysis Addendum stated the following in response to NMED's request for the "historical precedent that installation of SACR on two-stroke lean-burn (@SLB) engines can result in significant technical complications, require deration of engines, and unreliable operation post-retrofit:"

> Selective catalytic reduction technology has not been applied successfully to 2SLB engines. After researching SCR controls on 2SLB engines, the EPA document titled "Technical Issues Related to the Potential Use of Selective Catalytic Reduction (SCR) to Reduce NOx Emissions from Natural Gas-Fired Lean Burn Engines" is the only document found with information on the application of SCR's on 2SLB engines. This documentation shows that many units did not perform properly after SCR was installed. Targa was unable to find any historical installation of SCR on 2SLB engines in the RLBC tables. The only proven technology to control NOX for 2SLB engines is Clean Burn Technology. This is also the technology recommended by the engine control vendor to control NOX for the units at Targa's three gas plants.[38]

It must first be pointed out that the document that Targa referred to as an "EPA document" is a 1998 document prepared for the Gas Research Institute. Second, the document referred to is now twenty-two years old. We provided one example of SCR being successfully retrofit to lean-burn engines at the Springville Utilities Power Station in Utah. Further, the 2011 Delaware reported discussed above highlights several SCR vendors with a focus on lean-burn engines, including two-stroke lean-burn

engines. With respect to the RLBC not identifying any two-stroke engines using SCR, the RBLC entries that we found showing SCR being required on lean-burn engines generally do not specify whether the engines are two-stroke or four-stroke.

In summary, the information provided herein shows that SCR is considered a demonstrated technology that can be applied to lean-burn engines. The information presented above shows examples of SCR being applied to Cooper-Bessemer and Clark lean-burn engines. including two-stroke lean-burn engines. The reports cited above show application of SCR to natural gas-fired lean-burn engines used in the oil and gas industry starting in the 1980's to 1990's, and the RBLC data show SCR being required on lean-burn engines in more recent years including those used in the oil and gas industry. While application of SCR to lean-burn engines used in the oil and gas industry may not be commonplace, one cannot say it has not been required or implemented on lean-burn natural gas-fired engines used in the natural gas industry. Further, the fact that SCR has been retrofit and installed on lean-burn engines used in electricity production is still relevant information. Because most of those lean-burn engines operate as peaking or peak shaving power plants, the lean-burn engine load will vary greatly, more in line with how a compressor engine would operate. Thus, the use of SCR at natural gas-fired power generating lean-burn engines provides further support of the feasibility of SCR for lean-burn engines used in the oil and gas industry.

We understand that the age of the lean-burn engines for which NMED has requested reasonable progress analyses are quite old. Our review based on age of engines reported in permits for the New Mexico facilities shows that the age range of the lean-burn engines for which New Mexico has targeted for reasonable progress controls ranges from 39 years to as high as 72 years. Most of the engines were manufactured before the 1970 Clean Air Act was enacted. It appears that in most cases, the companies have not proposed any NOx controls for these older lean-burn engines in their reasonable progress analyses, claiming that SCR is not feasible and that Clean Burn (i.e., low emissions combustions) is too costly to retrofit. Given the age of these engines, consideration should be given to the control of replacing the engines with new engines with state-of-the-art low NOx emission control, or replacing the engines with electric engines powered off the grid which would reduce emissions of NOx (and all other pollutants from the engines) down to zero. As discussed in our March 6, 2020 Report, replacement of engines with electric motors can be quite cost effective.[39]

Re: Petition to EPA for Reconsideration of Regional Haze Final Guidance

Dear Ms. Ely:

We applaud the New Mexico Environment Department for developing a Regional Haze Rule while welcoming robust public engagement. By this letter, we are forwarding to you a copy of a Petition for Reconsideration submitted to the United States Environmental Protection Agency on May 8, 2020. This petition requests that EPA reconsider its "Guidance on Regional Haze State Implementation Plans for the Second Implementation Period," issued August 20, 2019 (Final Haze Guidance).

The regional haze program under the Clean Air Act sets as its goal the restoration of natural visibility conditions in national parks and other Class I areas. States are now preparing implementation plans for the second round of planning, which are critical to achieving haze reduction goals. As detailed in the Petition for Reconsideration, however, EPA's Final Haze Guidance undercuts progress on regional haze. Instead, states must follow statutory and regulatory directives as they prepare haze plans:

- States must select sources for analysis in compliance with 40 C.F.R. § 51.308(f)(3)(ii)(A). States must comprehensively identify sources of human-caused visibility-impairing emissions across source categories and develop technically sound and transparent information on the process by which sources are selected for review and four factor analyses. States cannot arbitrarily defer some sources to another implementation period.
- States have only limited discretion to decide which sources they consider for reasonable progress.

- State plans must result in reasonable progress and will be found deficient where they fail to require emission reductions that collectively make reasonable progress towards natural visibility at every Class I area in each and every planning period; no backsliding is permitted.
- States cannot arbitrarily circumvent a four-factor analysis for sources that intend to retire.
- States cannot consider being under the uniform rate of progress when selecting sources for a four-factor analysis. The glidepath is not a safe harbor; rather a state must take measures necessary to make progress towards natural visibility by reducing visibility-impairing pollution.
- Previous installation of certain types of controls does not excuse a state from considering more stringent levels of control.
- States should ensure that modeled emissions are tied to enforceable limits for sources with appropriate averaging times that reflect year-round abilities of existing controls or operation.
- States must include both dominant and non-dominant pollutants in their analyses of controls.
- States cannot eliminate VOC and ammonia emissions from consideration.
- Light extinction thresholds should be tailored to Class I areas and low enough to bring in most sources of visibility-impairing pollution.
- States should include all visibility-impairing pollutants when calculating a source's annual emissions.
- States must use methods permitted by statute and regulation to identify its sources that potentially affect visibility at Class I areas in other states, not merely any "reasonable method."
- States must consider cumulative impacts of sources or groups of sources to all affected Class I areas.
- States must prioritize emissions within their borders to achieve reasonable progress.
- States should identify and consider the best available emission control measures in the four-factor reasonable progress analysis.
- States must adhere to the accounting principles of the Control Cost Manual and should compile and make publicly available the documentation for generic cost estimates.
- States should analyze the climate and environmental justice impacts of measures to achieve reasonable progress.
- States cannot allow sources to discontinue the use of currently operating controls.
- States should use regional scale modeling to support their regional haze plans.
- If a state's reasonable progress goal is above the uniform rate of progress, the state's "robust demonstration" must include a consideration of specific items identified by EPA.
- States must submit to EPA the emission inventory used in a regional haze SIP.
- States must ensure that Federal Land Managers' opinions and concerns are made transparent to the public, considered by the state and addressed in the haze plan.
- Decisions on which controls to require as part of the long-term strategy cannot merely ratify past determinations.

- EPA must ensure that long-term strategies include appropriate measures to prevent future as well as remedy existing impairment of visibility.

Weakening the above directives would contradict New Mexico's guiding principles in developing a statewide Regional Haze Rule which ensures the health and safety of the state's residents, and the visibility and cleanliness of the air in and around Class 1 airsheds. For the New Mexico Environment Department to be able to adequately and legitimately shape as strong a Regional Haze Rule as possible, consistent federal guidance which complies with the Clean Air Act and Regional Haze Rule is necessary.

One of the directives above is that "States cannot arbitrarily circumvent a four-factor analysis for sources that intend to retire." This is of particular relevance in New Mexico, where the San Juan Generating Station in the northwest corner of the state has not yet submitted a four-factor analysis for controls. The station is under no federally enforceable retirement directive, and assumption of ownership of the facility is presumed to go to Enchant Energy – the station must submit a plan to the state of its analysis of implementing pollution controls at its facilities, as it is the greatest emitter of haze-causing pollutants in the Four Corners Region.

The aggressive expansion of oil and gas development on public lands throughout New Mexico—in particular, the Permian and San Juan Basins—has resulted in repeated and egregious occurrences of exceedance in allowable concentrations of haze-causing, and human-health degrading, air pollutants. State rulemaking processes are aiming to reduce concentrations of some of these air pollutants near energy hotspots where they disproportionately damage human health, the environment, and the iconic landscapes connected with nearby communities. Methane, ozone, and haze-causing pollutant sources are currently undergoing review as NMED develops methods for reducing pollution in the face of unchecked development and associated ecological degradation. These rulemaking processes and the regional haze SIP development process present an opportunity to ensure that air quality protections in New Mexico are mutually reinforcing, and thus stronger overall. EPA's guidance should not undermine these opportunities.

Not only are these regulatory processes occurring along similar timelines, with regulations often encompassing overlapping parts of the industrial/emissions process, the pollutants themselves are often precursors to other toxins—at the ground level, ozone is created in harmful concentrations by a chemical reaction between oxides of nitrogen (NOx) and volatile organic compounds (VOC) in the presence of heat and sunlight. The EPA's guidance must not excuse VOCs from regulation under the regional haze rule. Asthma and other illnesses linked to poor air quality disproportionately impact communities in and around the Permian and San Juan Basin regions where drilling has increased exponentially over the past several years – particulate matter, methane, ozone, VOCs, NOx, SOCs, and others greatly compromise these communities' overall public health.[1][2][3]

[1] http://www.stateoftheair.org/city-rankings/states/new-mexico/eddy.html
[2] https://www.hcn.org/issues/51.10/public-health-the-hidden-consequences-of-new-mexicos-latest-oil-boom
[3] https://nmlegis.gov/handouts/IAC%20100417%20Item%208%20Drilling%20on%20and%20Near%20Sacred%20Sites%203.pdf

The crucial need to curtail emissions from both operational and abandoned oil and gas wells and infrastructure, and improve air quality across the state, is particularly pressing in light of the COVID-19 public health crisis. A report, published on the preprint health services platform Medrxiv.com in early April, found that long-term exposure to particulate matter is positively correlated with the severity of COVID-19 cases contracted.[4] The guidance provided by the EPA for states to fulfill the Regional Haze Rule must underscore the importance of strong air pollution controls to protect human health and the environment, now and after the crisis.

With states moving forward on haze plans, state officials should be aware of deficiencies in the Final Haze Guidance, and should ensure that state plans still reinforce relevant state rulemakings and guiding principles and comply with the Clean Air Act and the Regional Haze Rule.

Thank you for your attention to our Petition for Reconsideration. We are available to continue discussing second round regional haze issues, including those raised by the Petition, at your convenience.

Sincerely,

Re: Petition for Reconsideration of Guidance on Regional Haze State Implementation Plans for the Second Implementation Period

Dear Administrator Wheeler:

I. Introduction

National Parks Conservation Association, Sierra Club, Natural Resources Defense Council, Western Environmental Law Center, Appalachian Mountain Club, Coalition to Protect America's National Parks, and Earthjustice (hereinafter "Conservation Organizations") hereby petition[1] the Administrator of the United States Environmental Protection Agency ("EPA") to reconsider the entitled "Guidance on Regional Haze State Implementation Plans for the Second Implementation Period" (hereinafter "Final Guidance" or "Guidance")[2] and replace it with

[1] This Petition is filed pursuant to section 4(d) of the Administrative Procedure Act ("APA"), 5 U.S.C. § 553(e), and, to the extent it may be applicable and relevant, section 307(d)(7)(B) of the Clean Air Act, 42 U.S.C. § 7607(d)(7)(B).

[2] EPA issued the Final Guidance on August 20, 2019 via Memorandum from Peter Tsirigotis, Director at EPA Office of Air Quality Planning and Standards to EPA Air Division Directors.

guidance that comports with the Clean Air Act ("CAA") and the Regional Haze Rule, and aids states in making progress towards achieving the national goal of natural visibility conditions at all Class I areas.[3] The Final Guidance is a significant departure from the Draft Guidance[4] issued in 2016 for the second planning period and contains provisions that are expressly at odds with the Clean Air Act and Regional Haze Rule. The table below summarizes how key provisions of the Final Guidance should be revised to comply with the requirements of the applicable statutes and regulations.

The Guidance unlawfully directs states on how they may exclude certain emission sources from four-factor consideration and delay or altogether avoid reducing emissions necessary to meet Congress's mandate that the states make reasonable progress towards the national goal of restoring natural visibility to Class I area national parks and wilderness areas. 42 U.S.C. § 7491(b)(2). The Guidance not only conflicts with the text and purpose of the Clean Air Act and the Regional Haze Rule itself, but it conflicts with EPA's 2016 Draft Guidance by arbitrarily constraining EPA review authority, diminishing the science of regional haze, and recasting technical and analytical requirements for State Implementation Plans ("SIPs"). Implementation of the Final Guidance will result in inconsistencies between SIPs, create arbitrary exceptions allowing states to avoid controlling emission sources, impede progress toward the national goal of a restoring natural visibility, and may actually degrade visibility at some Class I areas.

Section of the Petition	Summary of Issue	Applicable Regional Haze Rule or other Regulations[5]
III.A.	States must comprehensively identify sources of human-caused visibility-impairing emissions across source categories and cannot arbitrarily defer some sources to another implementation period.	Section 51.308(f)(3)(ii) of the Regional Haze Rule and Clean Air Act section 169A(b)
III.B.	States have only limited discretion to decide which sources they consider for reasonable progress. SIPs will be found deficient where they fail to require emission reductions that collectively make reasonable progress towards natural visibility at all Class I areas in each planning period; no backsliding is permitted.	82 Fed. Reg. at 3,088 and sections 51.308(f)(2)(i), 51.308(f)(3)(ii)(A), 51.308(f)(3)(ii)(B)
III.C.	States cannot arbitrarily circumvent a four-factor analysis for sources that intend to retire.	Sections 51.308(f)(2)(i), 51.308(f)(2)(iv)(C)

[3] 42 U.S.C. §§ 7491, 7492; 82 Fed. Reg. 3078 (Jan. 10, 2017); 71 Fed. Reg. 60,612 (Oct.13, 2006); 70 Fed. Reg. 39,104 (July 6, 2005); 64 Fed. Reg. 35,714 (July 1, 1999).

[4] Draft Guidance on Progress Tracking Metrics, Long-term strategies, Reasonable Progress Goals and Other Requirements for Regional Haze State Implementation Plans for the Second Implementation Period, (hereinafter "Draft Guidance") 81 Fed. Reg. 44,608 (July 8, 2016).

[5] Clean Air Act section 110(k)(5) provides EPA the authority to review a SIP and assess the adequacy of that SIP. Therefore any aspect of this guidance that interferes with that authority is in conflict.

III.D.	States cannot consider being under the uniform rate of progress ("URP") when selecting sources for a four-factor analysis. The glidepath is not a safe harbor; rather a state must take measures necessary to make progress towards natural visibility at any Class I areas its emissions affect.	82 Fed. Reg. at 3,093
III.E.	Previous installation of certain types of controls does not excuse a state from considering more stringent levels of control.	Section 51.308(f)(2)(iv)(D)
III.G.	States must include both "dominant" and "non-dominant" pollutants in their analyses of controls.	82 Fed. Reg. at 3,088 and sections 51.308(f)(3)(ii)(A), 51.308(f)(3)(ii)((B), 51.308(f)(2)(i)

XI.B.	Decisions on which controls to require as part of the long-term strategy cannot merely ratify past determinations.	Section 51.308(f)(2)(i)
XI.C.	EPA must ensure that long-term strategies include appropriate measures to prevent future as well as remedy existing impairment of visibility.	Clean Air Act section 169A(a)

This Petition seeks reconsideration and substantial revision of the Final Guidance so that the Guidance will direct states to deliver on the statutory objective of preventing future and remedying existing Class I area visibility impairment that results from human-caused pollution. As issued, the Final Guidance conflicts with this statutory objective, previous rulemaking and guidance; misdirects states as to how they can go about complying with their legal obligations to make reasonable progress towards restoring natural visibility to protected public lands; and otherwise fails to set expectations that comport with legal requirements for the second planning period.

In addition to the provisions noted in the table above, the Conservation Organizations incorporate several recommendations from their Comments on EPA's Draft Guidance[7] and request that EPA reconsider and revise the Final Guidance to direct states with regard to the following issues:

- States should ensure that modeled emissions are tied to enforceable limits for sources with appropriate averaging times that reflect year-round abilities of existing controls or operation.
- Light extinction thresholds should be tailored to Class I areas and low enough to bring in most sources of visibility-impairing pollution.
- States should include all visibility-impairing pollutants when calculating a source's annual emissions.
- States should identify and consider the best available emission control measures in the four-factor reasonable progress analysis.

[6] EPA, Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations (May 2017), https://www.epa.gov/sites/production/files/2017-07/documents/ei_guidance_may_2017_final_rev.pdf.
[7] Conservation Organizations incorporate by reference their full Comments on the 2016 proposed Draft Guidance.

- States should analyze the climate and environmental justice impacts of measures to achieve reasonable progress.

The gains made in the first regional haze planning period established a critical, if delayed, foundation for our national parks and wilderness areas to make progress towards the natural visibility which they and their visitors and neighboring communities are due. The Final Guidance not only hinders future gains but in some cases actually jeopardizes the gains made in the first planning period. Conservation Organizations urge EPA to reconsider its Final Guidance and instead issue a revised guidance that directs states to fulfill regulatory requirements for reasonable progress in the second planning period to help attain clearer skies at America's prized national parks and wildernesses.

II. SIP development steps

As EPA states in the Final Guidance, the key steps to developing a regional haze SIP start with identifying the twenty percent most anthropogenically impaired days and the twenty percent clearest days and determining baseline, current, and natural visibility conditions for each Class I area within the state, and then determining which Class I area(s) in other states may be affected by the state's own emissions.[8] States must then screen sources and conduct a four-factor analysis of which controls are required before establishing reasonable progress goals.[9] Once a state has determined the reasonable progress measures to require at specific sources, the state must quantify the "reasonable progress goal"—i.e., the visibility improvement that will result from implementing the controls merited by a four-factor analysis.[10] Additional steps include regional scale modeling of the long-term strategy to set the RPGs for 2028 and progress, degradation, and URP glidepath checks.[11]

Some of the most problematic provisions of the Final Guidance, which are contrary to several requirements of the Regional Haze Rule and Clean Air Act, involve the selection of sources for analysis. After discussing these provisions, this Petition discusses the determination of affected Class I areas in other states, ambient data analysis, the characterization of factors for emission control measures, decisions on what control measures are necessary to make reasonable progress, regional scale modeling of the long-term strategy to set the RPGs for 2028, progress, degradation, and URP glidepath checks, and additional requirements for regional haze SIPs. After addressing how these various provisions of the Guidance are contrary to the regulatory requirements, the Petition provides several overarching recommendations that EPA should consider when revising the Guidance, including advising states that in order for a SIP to be approvable it must result in measures to reduce visibility impairing pollution beyond those required from the past planning period and reflective of an adequate reasonable progress analysis.

[11] *Id*. at 5-6.

III. Selection of sources for analysis

A. Selection of sources under section 51.308(f)(3)(ii)(A).

In the Final Guidance, EPA presents a statement at the beginning of the section II.B.3 that is in conflict with the Regional Haze Rule's requirements:

> A key flexibility of the regional haze program is that a state is not required to evaluate all sources of emissions in each implementation period. Instead, a state may reasonably select a set of sources for an analysis of control measures. . . . Accordingly, it is reasonable and permissible for a state to distribute its own analytical work, and the compliance expenditures of source owners, over time by addressing some sources in the second implementation period and other sources in later periods.[12]

This statement by EPA is contrary to the requirements in section 51.308(f)(3)(ii) of the Regional Haze Rule and section 169A(b) of the Clean Air Act.

In a footnote, EPA indicates that "analysis of control measures" refers to an analysis of what emission control measures for a particular source are necessary in order to make reasonable progress and must include consideration of the four statutory factors and consideration of the five additional factors listed in 40 C.F.R. § 51.308(f)(2)(iv).[13] This important requirement of how sources should be selected by states for analyses is presented as if it were a secondary consideration. In other words, EPA's Guidance now advises states that they can arbitrarily delay the selection of sources for evaluation, or exclude certain sources as noted *infra*, and thereby "distribute [their] analytical work" and the "compliance expenditures of source owners" as if it is a stand-alone, top-level decision that states can make, divorced of the need to apply the four statutory factors and the five additional factors to actually make reasonable progress.

If a state were to arbitrarily "distribute its own analytical work, and the compliance expenditures of source owners, over time"[14] as the guidance provides, it would not be able to address section 51.308(f)(3)(ii)(B), which requires:

> If a State contains sources which are reasonably anticipated to contribute to visibility impairment in a mandatory Class I Federal area in another State for which a demonstration by the other State is required under (f)(3)(ii)(A), the State must demonstrate that there are no additional emission reduction measures for anthropogenic sources or groups of sources in the State that may reasonably be anticipated to contribute to visibility impairment in the Class I area that would be reasonable to

[12] *Id.* at 9.
[13] *Id.* at 9 n.22.
[14] *Id.* at 9.

> include in its own long-term strategy. The State must provide a robust demonstration, including documenting the criteria used to determine which sources or groups or sources were evaluated and how the four factors required by paragraph (f)(2)(i) were taken into consideration in selecting the measures for inclusion in its long-term strategy.

A state that arbitrarily excludes sources from consideration cannot determine if it actually has "sources which are reasonably anticipated to contribute to visibility impairment in a mandatory Class I Federal area." To satisfy that requirement, a state must first have a reasonable understanding of the emissions from all of its sources and it must have a reasoned methodology for excluding sources from a four-factor analysis (e.g., those sources are inconsequential or do not have cost-effective control options). Similarly, if a state, which arbitrarily excludes sources from evaluation, has a RPG that is above the URP, it cannot satisfy section 51.308(f)(3)(ii)(A)[15], which requires that it demonstrate "there are no additional emission reduction measures for anthropogenic sources or groups of sources in the State that may reasonably be anticipated to contribute to visibility impairment in the Class I area that would be reasonable to include in the long-term strategy." In contrast, not only was this advice absent from EPA's Draft Guidance, the Draft Guidance provided detailed, valid information on source selection.[16]

Additionally, as mentioned *infra* section IV.A, the Final Guidance also arbitrarily allows states to decide whether they contribute to out-of-state Class I areas by claiming states can use any reasonable method for quantifying the impacts of its own emissions on out-of-state Class I areas.[17] The Final Guidance also allows a state to disregard its impacts on an out-of-state Class I area that a neighboring state may identify as being affected by emissions from the state developing the long-term strategy.[18] By allowing states to arbitrarily make these determinations, EPA is attempting to slice the program into inconsequential bits and pieces that set the

---

[15] EPA noted in the 2017 Regional Haze Rule revision:

> [I]n a situation where the RPG for the most impaired days is set above the glidepath, a contributing state must make the same demonstration with respect to its own long-term strategy that is required of the state containing the Class I area, namely that there are no other measures needed to provide for reasonable progress. The intent of this proposal was to ensure that states perform rigorous analyses, and adopt measures necessary for reasonable progress, with respect to Class I areas that their sources contribute to, regardless of whether such areas are located within their borders.

[16] Draft Guidance at 57-83.

[17] Final Guidance at 8.

[18] *Id.* at 9.

provisions of the Final Guidance against fulfilling the requirements of the Clean Air Act and Regional Haze Rule that compel a comprehensive "regional" approach to restoring visibility. EPA should strike the above-mentioned language discussing selection of sources under section 51.308(f)(3)(ii)(A) from the Final Guidance and restore the language from the Draft Guidance.

B. States have only limited discretion to decide which sources they consider for reasonable progress.

In Section II.B.3.d of the Final Guidance, EPA states, "[t]he source-selection step is intended to add flexibility and discretion to the state planning process – ultimately, the state decides which sources to consider for reasonable progress."[19] This blanket statement, written as if a state has unbounded discretion to determine which sources it evaluates under reasonable progress, is incorrect. A state cannot arbitrarily determine which sources it evaluates under the Regional Haze Rule's reasonable progress requirements. Ultimately, a state's source selection criteria is a part of its long-term strategy. As EPA indicated in the Regional Haze Rule revision, a state does not have discretion to arbitrarily exclude sources from a four-factor analysis. Specifically, EPA stated:

> [W]e expect states to exercise reasoned judgment when choosing which sources, groups of sources or source categories to analyze. Consistent with CAA section 169A(g)(1) and our action on the Texas SIP, a state's reasonable progress analysis must consider a meaningful set of sources and controls that impact visibility. If a state's analysis fails to do so, for example, by arbitrarily including costly controls at sources that do not meaningfully impact visibility or failing to include cost-effective controls at sources with significant visibility impacts, then the EPA has the authority to disapprove the state's unreasoned analysis and promulgate a [Federal Implementation Plans ("FIPs")]. [20]

A state with a RPG below the URP that followed this guidance and arbitrarily excluded sources from a four-factor analysis runs afoul of section 51.308(f)(3)(ii)(A), which requires a "robust demonstration" that "there are no additional emission reduction measures for anthropogenic sources or groups of sources in the State that may reasonably be anticipated to contribute to visibility impairment in the Class I area that would be reasonable to include in the long-term strategy." If a state that followed this guidance had emission sources that potentially affect visibility at a Class I area in another state, it would similarly be unable to satisfy the same requirement found in section 51.308(f)(3)(ii)(B). EPA should reconsider this provision, and delete it from the Final Guidance.

C. States cannot arbitrarily circumvent a four-factor analysis for sources that intend to retire.

[19] Final Guidance at 20.
[20] 82 Fed. Reg. at 3088.

In Section II.B.3.d of the Final Guidance, EPA also states "[i]f a source is expected to close by December 31, 2028, under an enforceable requirement, a state may consider that to be sufficient reason to not select the source at the source selection step."[21] EPA goes on to extend this deadline by adding an indeterminate grace period: "The year 2028 is not a bright line for these considerations, so a state may be able to justify not selecting a source for analysis of control measures because there is an enforceable requirement for the source to cease operation by a date after 2028."[22] EPA further advises states that consideration of source retirement and replacement schedules required by Section 51.308(f)(2)(iv)(C) are automatically considered if a state decides to not subject sources which will retire by 2028 to a four-factor analysis.[23]

This is a departure from EPA's long-standing requirement in the regional haze program and is in conflict with basic requirements of the Regional Haze Rule. Remaining useful life is one of the four statutory factors that a state must consider when selecting the sources for which it will determine what control measures are necessary to make reasonable progress.[24]

The Clean Air Act does not define the phrase "remaining useful life." However, EPA, in regulations and guidance, has clarified the meaning of the phrase. EPA has consistently stated that the potential retirement of a facility can be used to shorten a source's remaining useful life only if the retirement is federally enforceable.[25] Thus, in order to affect the remaining useful life, a retirement commitment must be included in a pre-existing document that can be enforced in federal court, such as a consent decree entered by a federal court, or a state must incorporate the retirement date into its SIP. If a potential retirement is not federally enforceable, it cannot be relied upon to shorten the remaining useful life of a source.

EPA's 2007 Guidance on reasonable progress incorporates and refers to the best available retrofit technology ("BART") Guidelines,[26] which instruct states on how to calculate the remaining useful life of a source. EPA defines a source's "remaining useful life" as the difference between the date that controls would be installed and "the date the facility permanently stops

[25] *E.g.*, 83 Fed. Reg. 62,204, 62,232 (Nov. 30, 2018) ("We are proposing to agree with Arkansas' cost analysis for dry scrubbers and switching to low sulfur coal for Independence Units 1 and 2, and with the state's decision to assume a 30-year capital cost recovery period in the cost analysis. It is appropriate to assume a 30-year capital cost recovery period in the cost analysis since Entergy's plans to cease coal combustion at the Independence facility are not state or federally-enforceable."); 83 Fed. Reg. 43,586, 43,604 (Aug. 27, 2018) (Considering the retirement of certain units where there was evidence that the units had actually been retired at the time of the rulemaking and that the plant had requested cancellation of its air permit).
[26] RPGs Guidance at 5-3. There is no conflict with the 2007 Guidance's interpretation of "remaining useful life" and the Final Guidance. *See* Final Guidance at 34.

operations."[27] If the remaining useful life affects the selection of controls, "this date should be assured by a federally- or State-enforceable restriction preventing further operation."[28] EPA discusses a situation where a source "intends to shut down a source by a given date, but wishes to retain the flexibility to continue operating beyond that date in the event."[29] In that instance, EPA instructs a state to include in its SIP the controls that would be required if the source continues to operate past the planned retirement date.[30] "The source would not be allowed to operate after the 5–year mark without such controls."[31]

Allowing states to avoid a four-factor analysis based on alleged intent to retire would render the other statutory factors meaningless and violate the requirements of the Regional Haze Rule.[32] Many states have already begun analyzing their sources to determine which should be brought forward for a four-factor analysis. Consequently, a source that retires by December 31, 2028 (or later), has at least eight years of potential emission reductions. Even considering this shortened remaining useful life, cost-effective controls, which often can be installed in months, can frequently be justified. For instance, a source could simply switch to a lower sulfur content coal or fuel oil, which would require little to no installation time and may be quite cost-effective. Despite EPA's advice, any source that demonstrably or potentially impacts visibility at a Class I area and would otherwise be subject to a four-factor analysis under section 51.308(f)(2)(i), regardless of its retirement date, must undergo a real analysis to determine if cost-effective controls are available.[33] EPA should revise the Final Guidance to reiterate that only enforceable retirements may alter the remaining useful life and otherwise require that states subject sources that intend to retire to a four-factor analysis if a state selects the source for analysis of emission control measures.

D. States cannot consider being under the URP when selecting sources for a four-factor analysis.

In Section II.B.3.e of the Final Guidance, EPA makes two flawed statements regarding a state's RPG that were not present in the Draft Guidance. First, EPA states "[t]he fact that visibility conditions in 2028 will be on or below the URP glidepath is not a sufficient basis by itself for a state to select no sources for analysis of control measures; however, the state may

[27] 40 C.F.R. pt. 51, App. Y § (IV)(D)(4)(k)(2).
[28] *Id.*
[29] *Id.* § (IV)(D)(4)(k)(3).
[30] *Id.*
[31] *Id.*
[32] The United States Court of Appeals for the Fifth Circuit recently found that EPA must consider statutory factors listed in a similar provision of the Clean Water Act when revising best available technology ("BAT") limits. *See Southwestern Elec. Power Co. v. EPA*, 920 F.3d 999, 1026-27 (5th Cir. 2019).
[33] EPA's draft guidance also allowed for states to forgo a four-factor analysis on sources secured by an enforceable commitment to retire by 2028. We disagree with that position for the reason expressed above. However, EPA tempered its reasoning in its draft guidance by stating that its position rested on the fact that due to the shortened second planning period (unlike future planning periods), there would be a shorter interval for states to install controls. Also, EPA did not state that states could extend source retirements beyond 2028 as it does in the final guidance.

consider this information when selecting sources."[34] EPA then cites to the 2017 Regional Haze Rule revisions; however, those citations make it absolutely clear that states cannot in fact follow this guidance:

> We disagree that the states should be able to reevaluate whether a control measure is necessary to make reasonable progress based on the RPGs. The CAA requires states to determine what emission limitations, compliance schedules and other measures are necessary to make reasonable progress by considering the four factors. The CAA does not provide that states may then reject some control measures already determined to be reasonable if, in the aggregate, the controls are projected to result in too much or too little progress. [35]

Consequently, states have no path available to them to "consider this information when selecting sources."

Similarly, EPA's later advice that "[r]ather, that fact [that a state's RPG is below the URP] would serve to demonstrate that, after a state has gone through its source selection and control measure analysis, it has no 'robust demonstration' obligation per 40 CFR 51.308(f)(3)(ii)(A) and/or (B)"[36] is potentially at odds with the Regional Haze Rule. In the above cited portion of the 2017 Regional Haze Rule revision, EPA actually stated, "if a state has reasonably selected a set of sources for analysis and has reasonably considered the four factors in determining what additional control measures are necessary to make reasonable progress, then the state's analytical obligations are complete if the resulting RPG for the most impaired days is below the URP line."[37] A state's "robust demonstration" obligation does not end because it has merely "gone through its source selection and control measure analysis." Rather, as EPA actually explained, the state must have "reasonably selected a set of sources for analysis and has reasonably considered the four factors in determining what additional control measures are necessary to make reasonable progress." [38] EPA must reconsider this provision, and delete it from the Final Guidance.

E. Previous installation of certain types of controls does not excuse a state from considering more stringent levels of control.

In section II.B.3.f of the Final Guidance, EPA discusses circumstances under which a state can choose not to select a source that has previously installed controls for a four-factor analysis.[39] Much of this information conflicts with previous guidance and the Regional Haze

[38] *Id.*
[39] *Id.* In comparison to the blanket exemptions in EPA's Final Guidance, the Draft Guidance only considered exempting power plant units, "in certain limited situations," with "highly effective control technology within the 5 years prior to submission of the SIP, such as year-round operation of flue gas desulfurization (FGD) with an

Rule. First, EPA states, "[i]n general, if post-combustion controls were selected and installed fairly recently . . . to meet a [Clean Air Act] requirement, there will be only a low likelihood of a significant technological advancement that could provide further reasonable emission reductions having been made in the intervening period."[40] EPA presents no basis for making this conclusion.

There are many instances in which post-combustion controls have been installed in which those controls do not operate at peak efficiency. This includes controls that are not operated continuously, controls that were never designed to operate at peak efficiency (e.g., undersized sulfur dioxide ("SO_2") scrubber or selective catalytic reduction ("SCR") systems) and partially bypassed controls (e.g., SO_2 scrubber or SCR systems). In fact, EPA has made it a point in past actions to ensure that existing controls are examined to determine if they can be cost-effectively upgraded. For instance, the 2005 BART revision to the Regional Haze Rule devotes several paragraphs to specific potential scrubber upgrades it recommends be examined.[41]

EPA also demonstrated that scrubber upgrades to a number of coal-fired power plants utilizing outdated and inefficient scrubber systems were highly cost-effective, and could achieve removal efficiencies of ninety-five percent which is near the ninety-eight to ninety-nine percent removal efficiencies of newly-installed scrubber systems.[42] In fact, as EPA notes in its 2017 Regional Haze Rule revision, EPA disapproved Texas' four-factor analysis in part because "it did not include scrubber upgrades that would achieve highly cost-effective emission reductions that would lead to significant visibility improvements."[43] Consequently, EPA's blanket guidance that examination of potential upgrades to recently installed post-combustion controls is unlikely necessary is demonstrably false. Even if, considering the entire universe of potential post-combustion control upgrades, the vast majority cannot be cost-effectively upgraded to result in significant visibility benefits, which is unlikely, there is no justification in the Regional Haze Rule to skip an examination of the remaining units.

EPA goes on to present examples of pollutant-specific controls that have been installed due to a requirement outside of the regional haze program for which it "believes it may be reasonable for a state not to select a particular source for further analysis."[44] This list includes new source performance standard ("NSPS") controls installed since July 31, 2013; best available control technology ("BACT") or lowest achievable emission rate ("LAER") controls installed since July 31, 2013; power plants with FGD controls that meet the 2012 model attainment test systems ("MATS") standard; particulate matter ("PM") controls under National Emission

[44] Final Guidance at 23.

Standards for Hazardous Air Pollutants ("NESHAP") since July 31, 2013; boilers that have installed an FGD or SCR system that operates year round and has a total efficiency of ninety percent; and any BART-eligible unit that has installed BART controls.[45] EPA reasons that due to their recent installation and the similarity of the requirements for those programs, it is unlikely that a four-factor analysis will result in additional cost-effective controls.[46] But, as EPA notes in its 2005 BART revision to the Regional Haze Rule, it reviewed some of these standards and concluded they may not be the most stringent available.[47] Furthermore, the 2017 revision to the Regional Haze Rule warned states that "we anticipate that a number of BART-eligible sources that installed only moderately effective controls (or no controls at all) *will need to be reassessed*. Under the 1999 [Regional Haze Rule and] 40 CFR 51.308(e)(5), BART-eligible sources are subject to the requirements of 40 CFR 51.308(d), which addresses regional haze SIP requirements for the first implementation period, in the same manner as other sources going forward."[48] This is in contrast to EPA's Final Guidance statement that "if a source installed and is currently operating controls to meet BART emission limits, it may be unlikely that there will be further available reasonable controls for such sources."[49] Therefore, a state must first subject a source to a four-factor analysis under section 51.308(f)(2)(i) before it is able to determine whether there are no emission reducing options available (including upgrades to existing controls).

Regarding which control measures states should consider in assessing reasonable progress, EPA states "there is no statutory or regulatory requirement to consider all technically feasible measures or any particular measures. A range of technically feasible measures available to reduce emissions would be one way to justify a reasonable set."[50] This conflicts with past guidance and with the Regional Haze Rule. Although there is no requirement that controls required under the reasonable progress requirements of the Regional Haze Rule uniformly be the most stringent available, not considering this level of control bypasses section 51.308(f)(2)(i), which requires that the state perform a four-factor analysis. A state cannot consider "the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment" unless it considers all feasible controls available, including upgrades to existing controls.

EPA acknowledged that a range of controls should be evaluated in a four-factor analysis in its Draft Guidance:

> In order to define a control measure with sufficient specificity to assess its cost and potential for emission reductions, the state should specify and consider the range of control efficiencies that the measure is capable of achieving. For example, when

[49] Final Guidance at 25.
[50] *Id.* at 29.

> evaluating a flue gas desulfurization system to reduce SO_2 emissions, the state should consider both a system capable of achieving a 90 percent reduction in SO_2 emissions as well as a more advanced system capable of achieving a 97 or 98 percent reduction. The state should not limit its analysis to either an unrealistically high and prohibitively expensive control efficiency or to a control efficiency that is substantially lower than has been achieved at other sources.[51]

Furthermore, EPA does not require that states secure the operation of controls with this level of efficiency through an enforceable commitment.

Just because a source has the most effective or highly effective control technology does not mean that it is required to be operated to a level reflective of its maximum pollution reduction capability. Thus, states should not be screening such sources out of review during the second implementation period. By allowing states to "screen out" and choose not to select such sources for a full four-factor analysis, EPA may be allowing states to ignore very cost-effective emission reducing options like simply requiring sources with highly effective controls to operate those controls in the most effective manner to reduce air pollutants. EPA should revise the Final Guidance to recommend that sources with existing pollution control technology evaluate options that could improve the emissions reduced through more effective use of that control technology. This could include requiring year-round operation of controls, reducing capacity, imposing more effective percent reduction requirements, requiring sources to meet more stringent emission limits, or requiring that emission limits apply on shorter averaging times to ensure continuous levels of emission reduction.

F. States should ensure that modeled emissions are tied to enforceable limits for sources with appropriate averaging times that reflect year-round abilities of existing controls or operation.

EPA should revise the Final Guidance to recommend that wherever possible, whether they are screened in or out, states should make sure that the emissions relied upon in the state's RPG demonstration are enforceable, and also that they reflect the lowest emission rates feasible at the facility given its existing configuration. This is particularly true for major sources that are screened out on the basis of emissions that reflect unenforceable conditions.

However, this is also true for sources that are screened out on the basis of emissions that do not reflect their full capacity for emission reductions. For example, if a source is screened out with emissions that reflect using its controls only seventy-five percent of the time, the state should nevertheless require year-round operation of the control. Requirements reflecting existing capacity for emission reductions are inherently reasonable, and represent low hanging fruit necessitating reduced resource expenditure for potentially large gain. Moreover, states routinely rely on actual emissions in assessing current visibility and using that assessment as a jumping off point to determine if additional reductions are necessary. Where a state is to rely on operational

[51] Draft Guidance at 87.

realities, such reliance must be justified by enforceable emission limits. Indeed, failing to take advantage of such reasonable progress measures is an example of one of the pitfalls of using this type of a screening process in the first place. EPA should recommend that states assure reasonable progress by requiring that sources have enforceable limits or conditions reflecting their full emission reduction capacity if they are to be screened out.

G. States must include both "dominant" and "non-dominant" pollutants in their analyses of controls.

In Section II.B.3.a of the Final Guidance, EPA advises states that they can skip analyses of controls for sources with "non-dominant" pollutants. Specifically, EPA states:

> When selecting sources for analysis of control measures, a state may focus on the PM species that dominate visibility impairment at the Class I areas affected by emissions from the state and then select only sources with emissions of those dominant pollutants and their precursors. Also, it may be reasonable for a state to not consider measures for control of the remaining pollutants from sources that have been selected on the basis of their emissions of the dominant pollutants.[52]

This position, absent from the Draft Guidance, directs states to produce deficient regional haze SIPs and is in conflict with the Regional Haze Rule's requirements and preamble language in the 2017 Regional Haze Rule revision.

The preamble specifically states that a "reasonable progress analysis must consider a meaningful set of sources and controls that impact visibility. If a state's analysis fails to do so, for example, by . . . *failing to include cost-effective controls at sources with significant visibility impacts*, then the EPA has the authority to disapprove the state's unreasoned analysis and promulgate a FIP.[53] This provision in the Guidance would allow states to arbitrarily determine that because one pollutant has a greater impact on visibility at a Class I area(s), the state may simply ignore other visibility impacting pollutants for one or all sources in the state emitting the non-dominant pollutants, despite the availability of cost-effective controls under reasonable progress criteria. It would also allow states to conclude that when examining a source that emits multiple pollutants that contribute to haze (e.g., SO_2, Nitrogen Oxide ("NOx")), potential reductions for the non-dominant pollutant can be summarily ignored. Furthermore, EPA does not provide any metric for what it considers a "dominant" pollutant.[54] For instance, if a state has determined that fifty-one percent of the visibility impact at a Class I area is due to SO_2, forty

[52] Final Guidance at 11.
[53] 82 Fed. Reg. at 3088. EPA states elsewhere in its 2017 Regional Haze Rule revision, that "A state may refer to its own experience, past EPA actions, the preamble to this rule as proposed and this final rule preamble, and existing guidance documents for direction on what constitutes a reasoned determination." 82 Fed. Reg. at 3099.
[54] Merriam-Webster defines dominant as "(a) commanding, controlling, or prevailing over all others," or as "(b) very important, powerful, or successful."

percent is due to NOx, and nine percent is due to PM, would SO_2 be considered dominant (and consequently the only analyzed pollutant), or must its share of the visibility impact be greater?

This provision in the Final Guidance has potentially far-reaching negative impacts on the Regional Haze Rule's requirements that states make reasonable progress, as many large sources emit multiple types of visibility impacting pollutants. Still other sources may emit significant levels of non-dominant emissions for which emission reducing control or measures may be well within the framework of the four-factor analysis. If this is not corrected, a state could assume it would be justified in concluding that state-wide, SO_2 is its "dominant" pollutant and forego control analysis of a large gas-fired power plant emitting thousands of tons of NOx which could also significantly impact visibility at one or more Class I areas.

The Final Guidance also directly conflicts with multiple sections of the Regional Haze Rule. For instance, a state following the guidance would not be able to determine if it was even subject to section 51.308(f)(3)(ii)(B), because by arbitrarily excluding pollutants or entire sources from review it could not determine if it "reasonably [was] anticipated to contribute to visibility impairment in a mandatory Class I Federal area in another State." Nor could that state "demonstrate that there are no additional emission reduction measures for anthropogenic sources or groups of sources in the State that may reasonably be anticipated to contribute to visibility impairment in the Class I area." Similarly, if that state's RPG was above its URP, it could not satisfy section 51.308(f)(3)(ii)(A), which requires the same demonstration. Such a state would also not be able to reasonably satisfy its state-to-state consultation requirements under section 51.308(f)(2)(i), which requires it to "evaluate and determine the emission reduction measures that are necessary to make reasonable progress" and "include in its implementation plan a description of the criteria it used to determine which sources or groups of sources it evaluated and how the four factors were taken into consideration in selecting the measures for inclusion in its long-term strategy." By severely compromising the entire foundation of a state's technical demonstration, EPA is directing states to submit deficient SIPs. For these reasons, EPA should delete the above-quoted language from the Final Guidance.

H. States cannot eliminate VOCs and ammonia emissions from consideration.

In Section II.B.3.a. of the Final Guidance, EPA also advises states that irrespective of their particular state emissions inventories or the acknowledged potential impacts of VOCs and ammonia on Class I areas, they can completely disregard these pollutants. Specifically, EPA states:

> In the first implementation period, many states eliminated VOC and ammonia emissions from consideration based on the expectation that anthropogenic VOC emissions make only a small contribution to visibility impairment and that formation of nitrate and sulfate PM is most effectively reduced by reducing emissions of NOx and SO_2 rather than by anthropogenic emissions of ammonia. EPA believes that, in general, this

> would also be a reasonable approach for the second implementation period.[55]

This position is completely absent from EPA's regulations and was not present in the Draft Guidance.

VOCs are organic chemicals emitted by products or industrial processes that when released into the atmosphere can react with sunlight and NOx to form tropospheric ("ground-level") ozone. In addition, VOCs are important precursor of Secondary Aerosol Formation ("SOA"). SOA comprises a large fraction of atmospheric aerosol mass and can have significant effects on atmospheric chemistry, visibility, human health, and climate.[56] A major source of VOCs in the United States is the oil and gas industry, which includes wells, gas gatherings and processing facilities, storage, and transmission and distribution pipelines. According to data from EPA and the Energy Information Agency ("EIA"), more than 20 million tons of VOCs are emitted from point and non-point sources in the oil and gas industry every year. Studies on oil and gas emissions have indicated that VOC source signatures associated with oil and gas operations can be clearly differentiated from urban sources dominated by vehicular exhaust emissions.[5758] According to a recent air quality study by the National Park Service ("NPS") in Carlsbad Caverns National Park, high levels of light alkanes such as ethane, propane, butane, and, pentane compounds were consistent with oil and gas emissions. However, high alkanes ("$>C_8$") and aromatics are assumed to contribute more significantly to SOA formation.[59]

In California alone, statewide agricultural operations produce an average of 272.12 tons per day ("tpd") of ammonia ("NH_3") emissions.[60] Of those 272.12 tpd, 158.50 tpd is attributed to "agricultural waste" specifically from dairy cattle.[61] In regions such as California's heavily polluted San Joaquin Valley, ammonia concentrations are found to be much higher than NOx

[61] *Id.*

concentrations.[62] When mixed with the region's NOx emissions (primarily from mobile sources), this excess ammonia helps form high levels of haze causing ammonium nitrate, which accounts for the majority of PM2.5 emissions found in the San Joaquin Valley.[63]

The San Joaquin Valley is home to multiple communities such as Bakersfield, Fresno, and Visalia that rank amongst the very topmost polluted cities for both annual and twenty-four hour PM2.5 pollution. [64] The entire air basin is also listed as being in extreme nonattainment with the 1997 and 2006 PM2.5 NAAQS standards.[65] As it relates to regional haze pollution, the San Joaquin Valley is located directly adjacent to the Southern Sierra Nevada Mountains, home to heavily polluted Class 1 areas like Sequoia and Kings Canyon National Parks—both of which fall within the jurisdiction of the San Joaquin Valley Air District.

Despite ammonia being a major precursor to PM2.5 pollution in the region, its emissions are currently not controlled in the San Joaquin Valley under the state's various PM2.5 SIPs.[66] Beyond ammonia, agricultural sources in California also produce and average of 145.90 tpd of direct PM10 and 21.79 tpd of direct PM2.5 emissions.[67]

In its 2005 BART amendments to the Regional Haze Rule, EPA left it to the states to individually determine if these two pollutants, which EPA acknowledges can potentially impact visibility, should be addressed.[68] In the Draft Guidance, EPA acknowledged that much of its guidance on BART remained applicable to the second round of SIPs and included an entire appendix devoted to identifying which portions of the BART guidance remained applicable.[69] This appendix has been deleted in EPA's Final Guidance. By arbitrarily excluding potential visibility-impairing pollutants from review, EPA's guidance conflicts with the same sections of the Regional Haze Rule as described *supra* section III.G, primarily preamble language to the 2017 Regional Haze Rule revision and sections 51.308((f)(3)(ii)(A), 51.308((f)(3)(ii)(B), and 51.308(f)(2)(i). EPA should revise the Final Guidance to direct states to inventory and evaluate potential visibility-impairing pollutants including VOCs and ammonia and determine associated control measures necessary to make reasonable progress. .

[69] Draft Guidance at Appendix D.

I. Light extinction thresholds should be tailored to Class I areas and low enough to bring in most sources of visibility-impairing pollution.

States choosing light extinction as a metric for visibility impacts should use Class I-specific figures to identify sources for a four-factor analysis. If a threshold is applied, states must ensure that the threshold is low enough to bring in most sources harming a Class I area. In the Final Guidance, EPA recommends visibility metrics and thresholds in terms of inverse megameters of light extinction.[70] Although light extinction may be acceptable as a metric, states should not use a generic extinction threshold for selecting sources for consideration of pollution controls for each of the Class I areas evaluated in their regional haze SIPs. If a light extinction threshold is too high, it can significantly limit the amount of sources a state evaluates for controls to make reasonable progress.

States must make clear how each source's visibility impacts are to be determined. States must explain whether the sources' potential emissions were modeled, what visibility-impairing pollutants were modeled for each source, whether all units were modeled for all sources, whether sources were modeled for impacts on the twenty percent worst days or some other timeframe, and identify and allow public review of and comment on the technical approach that the state employed to determine source-specific visibility extinction, pursuant to 40 C.F.R. § 51.308(f)(2). Any proposed extinction threshold for defining sources to target for controls is only as good as the underlying technical analysis to define if a source exceeds the extinction threshold. States must address these requirements and justify any and all extinction thresholds that they rely on for each Class I area impacted by states' sources.

For any souces that exceed an extinction threshold but are not subject to reduction requirements, states should provide a thorough four-factor analysis of controls or provide justification as to why a four-factor analysis would not likely lead to a determination that additional controls are needed to make reasonable progress. For any sources that a state claims already has adequate controls or justifies for other reasons that a four-factor analysis of controls would not result in additional controls, the state must document in its regional haze SIP why it makes this finding. To the extent such justification is relying on other regulatory or permit requirements, the state must document those regulatory or permit requirements in detail and indicate whether such requirements are already or will be submitted to EPA as part of the SIP

J. State's using the Q/d metric should include all visibility-impairing pollutants when calculating a source's annual emissions.

In Section II.B.3.b of the Final Guidance, EPA discusses the use of a source's annual emissions in tons divided by distance in kilometers between the source and the nearest Class I area (often referred to as Q/d) as a surrogate for source visibility impacts, along with a reasonably selected threshold for this metric.[71] As EPA notes, although Q/d is the least

[70] Final Guidance at 19.
[71] Final Guidance at 13.

complicated technique, it should "be limited to source selection for the purpose of developing a list of sources for which a state may conduct a four-factor analysis" because the metric is a less reliable indicator of actual visibility impact.[72]

EPA should revise the Final Guidance to require states using the Q/d metric to include all visibility-impairing pollutants when determining the annual emissions being used to obtain a source or source category's estimated visibility impacts. As discussed further *supra* section III.H, states cannot eliminate certain emissions, such as VOCs and ammonia emissions, from consideration. Additionally, EPA should recommend that states using the Q/d metric not use the Q/d threshold from the first implementation period for the second implementation period. Rather, the Q/d threshold should be lower in order to address more sources, including sources that are lower emitting and sources that are further in distance than the sources addressed in the first implementation period.

IV. Determination of affected Class I areas in other states

A. States must use methods permitted by statute and regulation to identify its sources that impact visibility at Class I areas in other states, not merely any "reasonable method."

In Section II.B.2 of the Final Guidance, EPA inserts a blanket statement that jeopardizes making progress towards the Clean Air Act Class I visibility goal and obfuscates the Regional Haze Rule's requirements regarding how a state should identify its sources that impact the visibility at Class I areas in other states: "As an initial matter, a state has the flexibility to use any reasonable method for quantifying the impacts of its own emissions on out-of-state Class I areas, and it may use any reasonable assessment for this determination."[73]

EPA does not provide any explanation or examples of what it considers "reasonable." Thus, this statement would allow a state to use any methodology, regardless of its scientific rigor, to identify those sources. Furthermore, once having identified these sources, however loosely, the state can then "assess" those sources any way it wishes. Confusingly, EPA seems to distinguish between quantifying the impacts of these sources and assessing these impacts. This single statement would serve to hand a state seemingly unlimited discretion over a key step in preparing its SIP, in marked contrast to what it proposed.

As EPA states in its 2017 Regional Haze Rule revision:

> On July 8, 2016, we released Draft Guidance that discusses how states can determine which Class I areas they ''may affect'' and therefore must consider when selecting sources for inclusion in a four-factor analysis. The Draft Guidance discusses various approaches that states used during the first implementation

[72] *Id.*
[73] Final Guidance at 8.

> period, provides states with the flexibility to choose from among these approaches in the second implementation period, and recommends that states adopt ‘‘a conservative . . . approach to determining whether their sources may affect visibility at out-of-state Class I areas.[74]

Indeed, EPA's Draft Guidance did provide actual guidance to the states on this issue:

> Once contributions by sources, groups of sources or geographic areas have been quantified in some manner, the EPA recommends that states adopt a conservative (more protective approach of visibility) approach to determining whether their sources may affect visibility at out-of-state Class I areas. For example, states could consider all Class I areas for which the state contributes at least one percent to anthropogenic light extinction from all U.S. sources on any day within the 20 percent most impaired days. States may choose a different threshold to determine which out-of-state Class I areas may be affected by the States sources, but must provide an adequate explanation of why the threshold is sufficiently protective of visibility.[75]

EPA followed this statement with more than twelve pages of highly technical guidance detailing approaches it deemed acceptable.[76] The Final Guidance deletes most of this and provides a summary approach void of technical rigor or analytical teeth. The Regional Haze Rule makes plain that a state's long-term strategy, including its application of the four statutory factors, be comprised of a robust initial step—the assessment of the state's emission sources on downwind states' Class I areas. However, by diminishing actual guidance and inventing this undefined and ambiguous standard, EPA creates confusion and ambiguity for states, leaving states to determine reasonability on a SIP-by-SIP basis. EPA should restore the discussion and directives to states from the Draft Guidance.

B. Application of a threshold for cumulative impacts to multiple Class I areas.

EPA should reconsider and revise the Final Guidance to recommend that states quantitatively document the results of the screening process for each Class I area rather than presenting only the impacts at the most affected or nearest Class I area. This allows the public to know the scope of the source's impacts and assures that the SIP comports with the letter and spirit of the regional haze program, a program grounded in the fact that regional haze is a regional problem and that Class I area impacts are felt typically by a multitude of sources' pollution that defy state boundaries.

EPA should also make clear that states must consider cumulative impacts of sources or groups of sources to all affected Class I areas. A source's cumulative impacts across Class I

[74] 82 Fed. Reg. at 3094.
[75] Draft Guidance at 58.
[76] Draft Guidance at 58-70.

areas provides a valuable screen to identify sources for further analysis. As EPA conceded and the court found in *Nat'l Parks Conservation Ass'n v. EPA*, in considering the visibility improvement expected from the use of controls, states must take into account the visibility impacts at all impacted Class I areas rather than focusing solely on the benefits at the most impacted areas.[77] This must include sources that have relatively small impacts in isolation but larger cumulative impacts either in the aggregate or across Class I areas.

V. Ambient data analysis

A. States must prioritize emissions within their borders to achieve reasonable progress.

International emissions contribute to visibility impacts. Rather than encouraging states to pursue an adjustment to the end goal of natural visiblity due to international emissions, EPA should be directing states to focus on the emissions within their borders for which requirements would help achieve reasonable progress. We encourage EPA to work with states, FLMs, stakeholders, and other countries to develop emissions inventories for cross-border pollution as well as scientifically valid methods for assessing long range emissions transport. However, the development of accurate accounting and modeling should not come with the expense of postponing or ignoring domestic emission-reducing measures. EPA's updated 2028 modeling[78] attempts to incorporate international emissions, but the agency itself makes clear that the science upon which the modeling rests is questionable.[79] EPA should reconsider and revise its Guidance to clarify that assessing international emissions is a work in progress and opportunity for partnership across a broad set of stakeholders, but the mandate of the Clean Air Act compels states to take measures to make reasonable progress by reducing emissions in their borders, not look to analysis to excuse doing so because other nations also contribute to regional haze.

We also urge EPA to revise the Final Guidance to clarify that affected states also have an obligation to take appropriate action to address international emissions.[80] Although EPA and the states are not required to "compensate" for international emissions, it is well within EPA and the states' rights and obligations to formally request reductions from international sources where appropriate, or to take permitting actions in the United States that will lead to emission reductions in other countries.

For example, Mexico's Carbon I and II power plants, which are less than twenty miles from the Texas border, are responsible for significant levels of pollution across several of the border states. Despite noting the significant impact of Mexican sources on its Class I areas, and

[79] *Id.* at 67.
[80] 64 Fed. Reg. 35,714, 35,755 (July 1, 1999) ("The States retain a duty to work with EPA in helping the Federal government use appropriate means to address international pollution transport concerns.").

requesting federal efforts to reduce impacts from international emissions,[81] Texas approved water discharge and mining permits for a coal mine in Maverick County. Rejecting these permits instead would have prevented the Mexican company Dos Republicas from mining high-sulfur coal that is transported and burned at the Carbon I & II facilities. EPA should remove its false implication that international emissions are entirely "uncontrollable" and should instead make clear that states must demonstrate that they are doing what is within their control to address international emissions—both generally and in particular.

EPA also discusses an "adjustment" to the URP for prescribed wildland fires. Wildfires, particularly in the West, have grown hotter, bigger, and more frequent with climate change. We recognize the role of prescribed fire in both managing fire size due to climate impacts and in restoration of natural ecosystems—which can, if effective, reduce the size and scale of fires later. There are, as a result of increased prescribed fire, potential benefits to both short- and long-term air quality. In planning for prescribed wildland fires, states should consider effects on visibility, alongside health and other concerns, including potential control measures and the potential benefits. A State cannot adjust a URP based on prescribed fires unless these fires actually result in visbility impairment on the "most-impaired" days. The Final Guidance should be clear that analysis of and planning for prescribed wildland fires need to be tailored to the planning period basis and would not automatically apply to the next planning period.

VI. Characterization of factors for emission control measures

A. States should identify and consider the best available emission control measures in the four-factor reasonable progress analysis.

In Section II.B.4.a of the Final Guidance, EPA advises states that they have the flexibility to reasonably determine which control measures to evaluate, and the agency lists examples of types of emission control measures states may consider.[82] EPA should reconsider its approach to ensure that the best controls for a source or source category are identified, evaluated, and the appropriate option determined. Identification of all available control measures is an important first step to ensure the best controls or emission reduction measures emerge from a four-factor analysis. However, EPA should revise the Final Guidance to ensure evaluation of the best control options.

1. EPA should reiterate and expand upon Step 1 of the BART-Guidelines regarding the identification of all available emission control techniques.

EPA should encourage states to consider various sources of information and types of emissions control techniques in developing its long-term strategy. Specifically, EPA should make clear that states must look to new source review control technology determinations, including major source BACT and LAER determinations, as well as state minor source BACT

[81] Texas Revisions to the State Implementation Plan (SIP) Concerning Regional Haze, at ES-2 (Feb. 25, 2009).
[82] Final Guidance at 29-30.

determinations. EPA should also recommend that states evaluate technologies that were considered in applicable new source performance standards, as well as those emission controls that were required in applicable new source performance standards.[83] EPA should also recommend that states consider the control techniques evaluated and required for similar source BART determinations.

In addition, EPA should recommend that states consider BACT determinations and other new source control requirements that states have adopted in minor new source review permits. Several states have minor source BACT provisions which may provide useful information for control technology considerations, and/or states have adopted targeted emission control requirements for source categories that do not have parallel federal requirements.[84]

Further, EPA should recommend that states investigate controls for source categories evaluated in reasonably available control measures ("RACM")/ reasonably available control technology ("RACT") and best available control measures ("BACM")/BACT determinations for nonattainment areas, a good starting point for information for control techniques available for a particular source category. States should also be encouraged to consult vendors or vendor groups such as the Institute of Clean Air Companies for control techniques for sources or source categories.

States should consider inherently lower-emitting processes, by themselves, and in combination with add-on controls. A state should not reject a combination of control measures altogether when the control measures could also be applied independently, unless the state is instead focusing on a control measure that is more effective at reducing emissions than the individual control measures.

In general, EPA should provide flexibility for states to consider innovative technologies tied to quantifiable and enforceable emission reduction requirements and to consider control techniques that some could view as "redefining the source" such as a change in fuel form. The BART Guidelines seemed to limit such controls from consideration for BART. Setting aside whether this was appropriate for BART determinations, States should not be constrained when evaluating measures to consider for the long-term strategy to make reasonable progress towards the national visibility goal.

In evaluating measures for the long-term strategy, states may need to address sources that were constructed many decades ago and/or sources to which pollution controls have not typically

[83] As EPA acknowledges in the BART guidelines, the NSPS standards do not always require the most stringent level of available control technology for a source category. 40 C.F.R. Part 51, Appendix Y, Section IV.D.2. In some cases, EPA evaluates more stringent controls in an NSPS proposed rulemaking, but ultimately requires a less stringent control to set the NSPS standard. EPA should make clear that NSPS standards are likely insufficient for purposes of reasonable progress determinations because the standards will not be reflective of the reduction measures available and otherwise meeting the four factors as SIPs are being advanced.

[84] *See, e.g.*, Colorado Regulation No. 7 – Control of Ozone via Ozone Precursors and Control of Hydrocarbon via Oil and Gas Emissions, https://www.sos.state.co.us/CCR/GenerateRulePdf.do?ruleVersionId=8546&fileName=5%20CCR%201001-9.

been applied. There may be little experience with applying pollution controls to such sources. However, the lack of information on "available" control technologies should not be used as a justification to eliminate a source from consideration of controls (or to only evaluate less effective controls). In such cases, States should be encouraged to consider innovative technologies, technologies that may not have historically been applied to the source type but could be transferred to the source type, emission unit replacement with more energy efficient/less polluting technology, and other such measures in evaluating how to best reduce haze-forming pollution from the source or source type.

2. EPA should advise states how to determine "available" and "technically feasible" control techniques for long-term strategy measures.

EPA should elaborate on how to determine whether a control technique is considered "available" or "technically feasible" for a source or source category. Section IV(D)(1) of the BART Guidelines[85] states in part that that "available retrofit control options are those with a practical potential for application to the emissions unit . . ." and "technologies which have not yet been applied to (or permitted for) full scale operations need not be considered available; we do not expect the source owner to purchase or construct a process or control device that has not already been demonstrated in practice." EPA should recommend that states take a broader view in determining what control strategies are "available" for a source or source category, especially if traditional pollution controls had not been historically applied to that source category. In such cases, states may need to examine more innovative options for pollution control at such sources or source categories, including the consideration of promising pollution control options that have not already been demonstrated in practice but which offer quantifiable emission reductions.

Section IV(D)(1) of the BART Guidelines includes provisions to determine whether a control option is "technically feasible." Those provisions, as well as the discussion on available technologies, generally track guidance on evaluations for BACT determinations set out in EPA's New Source Review Workshop Manual.[86]

Sources often make availability or technical infeasibility arguments to avoid having to consider a pollution control, pointing out that that the control has not been used on the specific type of coal the source utilizes or on the particular size plant. Given that states may be having to determine controls for sources or source categories that have not been traditionally controlled in the long-term strategies, EPA should encourage states in such situations to fully evaluate controls that can be transferred from other source categories or that can be altered to accommodate the specific source or source category in question. EPA should recommend in such situations that states consult with, for example, environmental consultants, research technical journals, or air pollution control conference articles. States should also consider technologies demonstrated outside of the United States. EPA's New Source Review Workshop Manual describes how to

[85] 40 C.F.R. § Pt. 51, App. Y.
[86] U.S. EPA, New Source Review Workshop Manual, at B.17-B.21 (Draft Oct. 1990).

identify all control options "with potential application to the source and pollutant under evaluation."[87]

In summary, EPA should reconsider and revise the Final Guidance to elaborate on how states should evaluate available and technically feasible control techniques with the goal of ensuring that all potential controls with a practical application to a source or source category are considered in the development of the long-term strategy.

B. Cost analyses for the long-term strategy.

1. States must adhere to the accounting principles of the Control Cost Manual.

EPA should require states to follow the accounting principles and generic factors of EPA's Control Cost Manual because states and EPA have historically determined whether the costs of control measures are "reasonable" based on the costs that other similar sources determined in other regulatory actions including permits. [88] If EPA does not require all states to use the same accounting principles, it will be extremely difficult to compare costs of control between sources to evaluate whether the controls are cost effective.

2. States should compile and make publicly available the documentation for generic cost estimates.

EPA's Final Guidance suggests that states may reduce time and effort in determining control costs by using generic cost estimates or estimation algorithms, such as the Control Strategy Tool.[89] However, we request that EPA require the documentation for such generic cost estimates to be compiled and made publicly available. As stated in Sierra Club and National Parks Conservation Association's comments on EPA's proposed revisions to the Control Cost Manual, the Integrated Planning Model's SCR cost database is based on Sargent & Lundy's confidential database and the underlying data and methods used to develop the regression equations have not been publicly reviewed and analyzed.[90] Given that the cost estimates may be a primary basis for rejecting a control measure, the underlying data for such cost estimates must be publicly available.

C. EPA should reconsider and revise the Final Guidance regarding how to address energy and non-air quality environmental impacts of control measures.

EPA should state that the third factor of energy and non-air quality environmental impacts should generally be based on the same methodology laid out in the BART Guidelines. Section 8.1.1 of the BART Guidelines indicates that states must consider the energy and non-air quality environmental impacts as part of the cost analyses. With respect to taking into account non-air quality environmental impacts, we agree in general to take into account such impacts in

[87] *Id.* at B.10-B.11.
[88] Final Guidance at 31.
[89] *Id.* at 32.
[90] *See* September 10, 2015 Comment Letter from Sierra Club and National Parks Conservation Association to U.S. EPA, Docket ID No. EPA-HQ-OAR-2015-0341, at 8.

the cost analysis if the costs can be quantified. Otherwise, such impacts may need to be discussed qualitatively and weighed in the four-factor analysis.

EPA should also revise the Final Guidance and recommend that states analyze the climate and environmental justice impacts of regional haze SIPs. Although the Regional Haze Rule does not define "non-air quality environmental impacts," the BART Guidelines, which inform a state's reasonable progress analysis, explain that the term should be interpreted broadly.[91] Climate change[92] and environmental justice[93] impacts are the types of non-air quality impacts that states should consider when they determine reasonable progress measures for specific sources. Incorporating climate change and environmental justice impacts into the regional haze analysis will further states' climate and environmental justice policy goals, and it will also help states ensure that their actions related to regional haze planning support their other work on climate and environmental justice issues. Most of the same sectors and sources implicated under the regional haze program are also implicated in climate and environmental justice initiatives. As a result, when states determine "the emissions reduction measures that are necessary to make reasonable progress," they should assess how those measures will either reduce or exacerbate greenhouse gas emissions and/or environmental justice impacts on nearby disproportionately burdened communities.

VII. Decisions on what control measures are necessary to make reasonable progress

A. States cannot allow sources to discontinue the use of currently operating controls.

In Section II.B.5.e of the Final Guidance, EPA advises states how currently controlled sources may be able to discontinue those controls under reasonable progress:

> It is also possible that a source may be operating an emission control device but could remain in compliance with applicable emission limits if it stopped operation of the device. The state may reasonably consider based on appropriate factors whether continued operation of that device is necessary to make reasonable progress, such that the regional haze SIP submission for the second implementation period must make such operation of the device (or attainment of an equivalent level of emission control) enforceable.[94]

Suggesting to states that they may discontinue the use of controls that are already operating is antithetical to the regional haze program. Rather, EPA should revise the Final Guidance to require states to evaluate more effective operation of existing controls, including year-round

[94] Final Guidance at 43.

operation requirements. Further, the Clean Air Act is clear that visibility is not a factor in determining reasonable progress measures required at a source.

In evaluating controls for a source that already had a control installed, such as a wet or dry scrubber for SO_2 or SCR or selective non-catalytic reduction ("SNCR") for NOx, states must be required to evaluate whether these controls can be more effectively operated. Companies tend to operate their air pollution control systems to the level needed to ensure compliance with applicable emission limits rather than to the maximum emission reduction capability of the pollution control technology. For example, there are electrical generating units ("EGUs") that are only operating their installed SCR or SNCR systems during the ozone season to meet limits under the Cross State Air Pollution Rule ("CSAPR"). Indeed, in projecting operations and emissions scenarios for evaluating the CSAPR program, EPA included assumptions for dispatchable SCR, SNCR, and also scrubbers, which reflected the fact that no emission limits or consent decrees required continuous operation of the pollution controls installed at many EGUs. EPA should thus recommend that states, at a minimum, require year-round operation of existing scrubbers, SCRs, SNCRs, or other controls as one of the control options considered.

Additionally, there are numerous examples of scrubbers, SCRs, and SNCRs that, when operated, are not operated to achieve the maximum emission reductions that could be accommodated within the existing control technology at a particular unit, primarily because the applicable emission limitation does not require operation of those pollution controls to achieve the maximum emission reductions. As mentioned *supra* section III.E, states should consider sources that already have in place the most stringent controls available for additional control in the development of the long-term strategy during the second implementation period.

EPA should revise the Final Guidance to recommend that sources with existing pollution control technology evaluate options that could improve the emissions reduced through more effective use of that control technology. This could include requiring year-round operation of controls, imposing more effective percent reduction requirements, requiring sources to meet more stringent emission limits, and requiring that emission limits apply on shorter averaging times to ensure continuous levels of emission reduction.

VIII. Regional scale modeling of the long-term strategy to set the RPGs for 2028

A. States should use regional scale modeling to support their regional haze SIPs.

In Section II.B.6 of the Final Guidance, EPA advises states that they are not required to use regional scale modeling to support their regional haze SIPs. Specifically, under Step 6, EPA states that a state must:

> Determine the visibility conditions in 2028 that will result from implementation of the LTS and other enforceable measures to set the RPGs for 2028. Typically, a state will do

> this through regional scale modeling, *although the Regional Haze Rule does not explicitly require regional scale modeling*.[95]

Were a state to forego estimating source or source categories emitting visibility-impairing pollutants, as the guidance provides, it would not be able to satisfy a number of basic requirements of the Regional Haze Rule. Estimating the visibility impacts from a collection of sources is a prerequisite of establishing a state's RPG. As EPA explains in its 2017 Regional Haze Rule revision, this is a key first step in a state setting its RPG: "the 2007 guidance clearly describes the goal-setting process as starting with the evaluation of control measures. First, we recommended that states '[i]dentify the key pollutants and sources and/or source categories that are contributing to visibility impairment at each Class I area.'"[96] If a state did not estimate the visibility impacts from source or source categories, it could not satisfy the requirement in Section 51.308(f)(3)(ii)(A) that it demonstrate, "there are no additional emission reduction measures for anthropogenic sources or groups of sources in the State that may reasonably be anticipated to contribute to visibility impairment in the Class I area." Indeed, this misplaced advice is not even internally consistent with other sections of the Final Guidance, which cover many techniques for estimating the visibility impacts of sources or source categories. Estimating the collective visibility impacts of sources or source categories to determine the RPG is a fundamental requirement of the regional haze program.

In fact, there is no known substitute for the use of photochemical air quality models to project the visibility impact from thousands of individual sources, influenced by complex meteorological fields and atmospheric chemical interactions at a Class I area, ten years into the future, as EPA makes clear in Appendix W to Part 51.[97] The use of air quality models has been a cornerstone of the technical demonstration of the regional haze program (and many other air programs) since its inception. Almost every EPA Regional Haze Rule revision and guidance either discusses the use of air quality models or assumes their use. In fact, EPA recently updated its modeling guidance for regional haze.[98] The very first sentence of the section specifically devoted to regional haze is: "[t]his section focuses on the modeling analysis needed to set RPGs that reflect the enforceable emission limitations, compliance schedules, and other measures included in the long-term strategy of a regional haze SIP."[99] Part 51 makes it clear that air quality

---

[95] Final Guidance, Table 1, at 6 (emphasis added).
[96] *See* 82 Fed. Reg. at 3092-93. Notably, EPA does not abandon its 2007 Guidance and in fact refers to in several places in its rule revision.
[97] *See* 40 C.F.R. Pt. 51; App. W, Section 2.0 (a), "Guideline on Air Quality Models," ("Increasing reliance has been placed on concentration estimates from air quality models as the primary basis for regulatory decisions concerning source permits and emission control requirements. In many situations, such as review of a proposed new source, no practical alternative exists."); *see also id.* at Section 1.0 (b), ("The impacts of new sources that do not yet exist, and modifications to existing sources that have yet to be implemented, can only be determined through modeling.") This is precisely the challenge of setting RPGs – accounting for modifications to potentially dozens of existing sources (e.g., installation of controls).
[98] Modeling Guidance for Demonstrating Air Quality Goals for Ozone, PM2.s and Regional Haze, EPA 454/R-18-009, (Nov. 2018).
[99] *Id.* at 143.

modeling is a necessary tool in the setting of RPGs and EPA should not imply otherwise in its guidance.

Instead of guiding states on modeling, EPA repeatedly informs states that they can use "surrogates" to estimate visibility impacts of a body of sources. Specifically, EPA states that "the Regional Haze Rule does not require states to develop estimates of individual source or source category visibility impacts, or to use an air quality model to do so. Reasonable surrogate metrics of visibility impact may be used instead."[100] EPA lists a number of surrogates that can be used for this purpose, including Q/d, wind trajectories, and daily light extinctions budgets and states that states can use "other reasonable techniques."[101] However, although more strongly worded in its Draft Guidance,[102] EPA does state in its Final Guidance, "[s]urrogate metric here refers to a quantitative metric that is correlated to some degree with visibility impacts as they would be estimated via air quality modeling."[103] Consequently, although EPA tells states that modeling is unnecessary and that surrogate measures can be used, modeling is required in order to check the validity of visibility surrogates. EPA should reconsider this provision, and clarify that modeling is needed to assess the collective visibility impacts of sources or source categories to establish RPGs.

IX. Progress, degradation, and URP glidepath checks

A. If a state's RPG is above the URP, the state's "robust demonstration" must include a consideration of specific items identified by EPA.

In section II.B.7.c of the Final Guidance, EPA discusses what could constitute a "robust demonstration," required under section 51.308(f)(3)(ii)(A) when a state's RPG is above the URP.[104] EPA states that a simple "narrative explanation of how the state has already conducted the source selection and control measures analyses in such a manner that addresses the requirements of 51.308(f)(3)(ii)" may suffice.[105] EPA then goes on to note that such a state *may* consider a long list of additional items, including reconsideration of its visibility threshold, acceptable cost threshold, additional technically feasible controls, how its determination criteria compares to that of other states, etc.[106]

In contrast, EPA's Draft Guidance did not state that a simple narrative would suffice. The Draft Guidance stated that such a demonstration *should* include consideration of a similar listing

[100] Final Guidance at 12.
[101] *Id.* at 13.
[102] Draft Guidance at 76 ("Before relying on Q/d as a surrogate for screening purposes, a state should investigate how well Q/d relates to visibility impacts for the 20 percent most impaired and 20 percent clearest days, in terms of both the central tendency of the relationship (e.g., the regression line) and the variability of the relationship (e.g., the error of the regression). This understanding should be developed through relevant modeling of some actual cases or model plant scenarios, or another appropriate approach.")
[103] Final Guidance at 10 n.25.
[104] *Id.* at 50.
[105] *Id.*
[106] *Id.* at 50-51.

of items. EPA's pivot from *should* consider to *may* consider substantially misinterprets and is directly at odds with what the robust demonstration required under section 51.308(f)(3)(ii)(A) should contain.

Moreover, states should not rely on EPA's Updated 2028 Modeling[107] to determine which Class I areas are projected to be at or below the URP. Projected conditions for 2028 are tied to the 2064 natural conditions endpoint adjustments to account for international anthropogenic contributions, as well as wildfires. By EPA's own admission as discussed *supra* section V.A, these adjustments lack scientific validation and should not be relied on to determine whether a Class I area is on track to meet its URP in 2028.[108] The result of the updated modeling adjustments reduced the number of Interagency Monitoring of Protected Visual Environments ("IMPROVE") sites projected to be above the glidepath from forty-seven to eight. IMPROVE monitors are not the same as Class I areas, however many Class I areas share monitors; only ninety-nine monitoring sites (representing 142 Class I areas) were evaluated.[109] EPA must reconsider and revise the Final Guidance to specify what a "robust demonstration" under section 51.308(f)(3)(ii)(A) requires and that a state's demonstration should include consideration of the specific list of items identified by the agency.

X. Additional requirements for regional haze SIPs

A. States must submit to EPA the emission inventory used in a regional haze SIP.

In section II.B.8.c of the Final Guidance, regarding section 51.308(f)(6)(v) which covers the requirements for the state's emissions inventory, EPA states that "[t]he emission inventories themselves are not required SIP elements and so are not required to be submitted according [sic] the procedures for SIP revisions. The emission inventories themselves are not subject to EPA review."[110] This conflicts with the Regional Haze Rule, is internally inconsistent with the rule and other state requirements, and is impracticable. First, EPA's statement conflicts with several sections of the Regional Haze Rule. For instance, section 51.308(f)(2)(iii) requires that the state must document the following:

> [T]he technical basis, including modeling, monitoring, cost, engineering, and emissions information, on which the State is relying to determine the emission reduction measures that are necessary to make reasonable progress in each mandatory Class I Federal area it affects. . . . The emissions information must include, but need not be limited to, information on emissions in a year at least as recent as the most recent year for which the State has submitted emission inventory information to

[107] *See* Updated 2028 Modeling.
[108] *Id.* at 67.
[109] *Id.* at 3 n.6.
[110] Final Guidance at 55.

> the Administrator in compliance with the triennial reporting requirements of subpart A of this part.

Here, it is clear that a state is required to document the technical basis of all aspects of its regional haze demonstration. A state's emission inventory is a foundational aspect of its technical demonstration. In fact, EPA specifically calls out "emissions information," and clarifies that the emissions information must include "information on emissions in a year at least as recent as the most recent year for which the State has submitted emission inventory information to the Administrator."[111]

Plainly, a state is required to submit the emission inventory it is using as part of its technical demonstration to EPA, and that inventory must include certain specified elements. Because states are already required to submit specified emission inventories to EPA as part of other requirements ("Part A"), EPA clarifies that a state may refer to that submission instead of physically including it in its SIP. However, the mere fact that EPA specifies a state may use an already prepared work product does not shield it from a review of its suitability for the task at hand. [112] For instance, EPA has frequently stated that states may use the technical work of RPOs in their SIPs. That position has never been interpreted to mean information is shielded from EPA review.[113] Indeed, EPA has a duty to review that inventory in the context of the state's regional haze SIP submission.[114] Thus, a state's emission inventory is an inseverable part of its regional haze SIP and subject to EPA's review.

Despite this, EPA appears to imply in its guidance that it cannot bring to the state's attention potential faults in the emission inventory a state used to support its regional haze SIP, nor even examine that inventory in the context of its review of the state's regional haze SIP. EPA should revise the Final Guidance to advise states that a state's emission inventory is a part of the state's SIP and subject to EPA's review.

---

[111] *Id.*

[112] *See* EPA's "Emissions Inventory Guidance for Implementation of Ozone and Particulate Matter National Ambient Air Quality Standards (NAAQS) and Regional Haze Regulations," EPA-454/B-17-002, at 11 (May 2017), ("[Inventory information provided to EPA] will allow the EPA to make a determination whether the emissions information used in Regional Haze analysis is sufficient for the purposes of the SIP.")

[113] For instance, in the Texas FIP, EPA observed that under the current regulation each state "must document the technical basis, including modeling, monitoring and emissions information, on which the State is relying to determine its apportionment of emission reduction obligations necessary for achieving *reasonable progress* in each mandatory Class I Federal area it affects." 79 Fed. Reg. 74,818, 74,829 (Dec. 16, 2014) (emphasis in original). While the current regulations provide that, "[s]tates may meet this requirement by relying on technical analyses developed by the regional planning organization and approved by all State participants," 40 C.F.R. § 51.308(d)(3)(iii), the Texas haze rule clarified that in situations "where a regional planning organization's analyses are limited, incomplete *or do not adequately assess the four factors*, however, then states must fill in any remaining gaps to meet this requirement." *Id.* (emphasis added).

[114] In the 2017 Regional Haze Rule revision, EPA makes it a point to review a number of circuit court opinions that affirm EPA's review authority, including the Eight Circuit's conclusion that EPA "must 'review the substantive content of the . . . determination." 82 Fed. Reg. at 3090 (quoting *Ariz. el rel. Darwin v. EPA*, 815 F.3d 519, 531 (9th Cir. 2016).

B. States must ensure that FLM opinions and concerns are made transparent to the public, considered by the state and addressed in the SIP.

In Section II.B.8.a of the Final Guidance, EPA provides guidance to the states regarding the FLM consultation requirements in the Regional Haze Rule, 40 C.F.R. § 51.308. Although EPA reiterates that states are required to consult with FLMs, EPA should reconsider and revise the Final Guidance to ensure that states give credence to the opinions and concerns expressed by FLMs. FLMs have affirmative duties under section 169A(a) and (d) of the Clean Air Act as well as mandates to protect and manage public lands under the Wilderness Act[115] and the Organics Act[116]. Therefore, EPA should revise the Final Guidance to direct states that to work collaboratively with FLM to develop regional haze SIPs that satisfy federal agency duties and public resource protections.

XI. Overarching recommendations

A. EPA should emphasize that the end result must be reasonable progress.

EPA should make clear in a revised Final Guidance that the end result of any state's implementation plan must be real, reasonable progress. Consequently, each new plan must require that states actually reduce their emissions that contribute to visibility impairment. The statute requires each haze plan to contain "emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress . . . ."[117] Therefore, any interpretation of the Regional Haze Rule via guidance should direct a state's long-term strategy to be more than just a hand waving exercise—each plan must require adequate emission limits and other enforceable measures to make reasonable progress.[118] EPA should revise the Final Guidance to explicitly provide that actually requiring emission reductions which constitute reasonable progress must be the outcome of the four-factor analysis to meet the applicable requirements; deliberation, no matter how well documented, is not enough. Emission reductions recognized through the four-factor analysis must result in emission reduction measures enforceable through a state or federal regional haze plan.

B. Decisions on which controls to require as part of the long-term strategy cannot merely ratify past determinations.

EPA must also revise the Final Guidance to clarify that decisions on which controls to require as part of long-term strategy cannot rest solely on controls required by past SIPs and state rules. Although EPA stated in the Draft Guidance that decisions on whether controls for a source or source category are cost-effective or provide sufficient visibility improvement cannot rely solely on past decisions evaluating controls for similar sources[119], that language is completely absent from the Final Guidance. EPA must revise the Final Guidance to state this point. For

[115] 16 U.S.C. §§ 1131-1136.
[116] 54 U.S.C. § 100101.
[117] 42 U.S.C. § 7491(b)(2).
[118] *See id.*
[119] Draft Guidance at 97, 103.

example, costs or technologies which were previously considered unreasonable or infeasible at a later date may become more common and may nevertheless be necessary in the second or future planning periods to make reasonable progress. Likewise, making reasonable progress in the current and future planning periods will require the implementation of controls that individually account for smaller visibility impacts than those contemplated in the first planning period and in other past emission reducing rules and permits. Therefore, EPA must revise the Final Guidance to direct states to conduct new source-specific, four-factor emission reduction analyses.

C. EPA must ensure that long-term strategies include appropriate measures to prevent future as well as remedy existing impairment of visibility.

The Clean Air Act not only requires that existing visibility impairment be remedied, but that future impairment be prevented. 42 U.S.C. § 7491(a)(1). As such, it is imperative that each state's long-term strategy be required to include measures to prevent regional haze visibility impairment and that such plans take into account the effect of new sources, as well as existing sources of visibility impairment. EPA must revise its Guidance to comport with this requirement.

EPA has historically relied on the prevention of significant deterioration ("PSD") permitting program and the visibility new source review ("NSR") requirements mandated by 40 C.F.R. § 51.307[120] to address this requirement of the national visibility goal.[121] These provisions essentially mandate that new and modified major sources that are subject to major source permitting requirements do not adversely impact visibility in any Class I area. However, much has changed in the PSD and NSR permitting programs since 1980. The current PSD rules, as well as the major source nonattainment NSR rules, now exempt many modifications at existing major sources that were previously subject to PSD review. As a result, the PSD and visibility NSR rules do not provide as comprehensive Class I areas protections as they previously did, due to impacts from modified sources. Further, there have been significant increases in emissions near some Class I areas due to oil and gas emissions and other activities that are not adequately addressed by the PSD permitting program.

EPA must revise its Final Guidance to ensure that states prevent future impairment by analyzing new and modified emission sources and by requiring mitigation of the cumulative visibility-impairing emissions. As we discuss below, it is especially important for EPA to articulate that states consider minor, area, and other new growth, or modification of stationary sources that are not subject to the Class I area protections of the PSD permitting and visibility NSR requirements.

[120] 40 C.F.R. §51.307(b)(2) and (c) provides that the PSD requirements of 40 C.F.R. §51.166(o), (p)(1) through (2), and (q) apply to new and modified major proposing to locate in nonattainment areas that may have an impact on visibility in a mandatory Class I area.
[121] *See* 45 Fed. Reg. 80,089 (Dec. 2, 1980).

1. The 2002 PSD and nonattainment NSR Rule revisions exempt many modifications from PSD permitting that could result in large, visibility-impairing emission increases from existing major sources.

EPA has historically relied on the PSD and nonattainment/visibility NSR permitting programs to meet the requirement of preventing future impairment of visibility. The PSD permitting requirements specifically provide for ensuring that a new or modified major source will not adversely impact visibility in a Class I area[122], and the EPA's visibility NSR rules in 40 C.F.R. §51.307(c) require new and modified major sources proposing to locate in nonattainment areas that may impact visibility in a Class I area to meet these same requirements of the PSD program.[123] However, the December 2002 revisions to the PSD and nonattainment NSR permitting requirements significantly reduced the scope of modifications that would trigger PSD or nonattainment NSR as major modifications by drastically changing the methodology for determining whether a significant emission increase would occur as a result of a modification.[124]

Despite these significant regulatory changes which reduced the scope of modified sources subject to PSD and nonattainment NSR permitting, EPA has never re-evaluated its reliance on the major source permitting programs as sufficient to prevent future impairment of visibility. However, these rules, as revised in recent years, will likely allow significant increases[125] in actual emissions from existing sources to occur without any evaluation of the impacts on visibility and without even applying BACT or LAER, due to being exempt from PSD or nonattainment NSR permitting.

In summary, the PSD and nonattainment NSR rules as revised in 1992 and 2002 now exempt many modifications that would have previously been subject to major source permitting, including the visibility requirements of the PSD program and visibility NSR rules. Thus, while the rules still include vital provisions for the prevention of future visibility impairment, the PSD and visibility NSR rules are no longer adequate by themselves to ensure the prevention of future visibility impairment. In light of this, EPA should revise the Final Guidance to clarify that states may not solely rely on the PSD and visibility NSR programs to prevent future impairment of visibility. EPA must ensure that states specify requirements in their SIPs to prevent future visibility impairment from the new source growth in any state that may increase visibility-impairing pollution and thus affect Class I area visibility.

2. Minor, area, mobile, and other source emissions must be evaluated to prevent future, as well as remedy existing, impairment of visibility.

---

[124] 67 Fed. Reg. 80,185, 80,186-89 (Dec 31, 2002) (also known as "NSR Reform" Rule).
[125] *See* Joseph Goffman, et al., EPA's Attack on New Source Review and Other Air Quality Protection Tools (Nov. 1, 2019), http://eelp.law.harvard.edu/wp-content/uploads/NSR-paper-EELP.pdf.

Although the Final Guidance mentions minor, area, mobile, and other emission sources, most of the discussion addresses major stationary sources. EPA should be more explicit in its expectation that states evaluate sources and source categories that are not major stationary sources as well, including the potential for growth in emissions from these sources. For example, given the increases in emissions from oil and gas development over the last 10 years,[126] it is clear that the existing SIPs and FIPs do not currently include adequate mechanisms for preventing visibility impairment from these sources as production ebbs and flows with economic conditions and other factors, such as deregulation and technology. EPA must revise the Final Guidance to clarify that states need to address these sources in the aggregate, rather than source-by-source.

There are several examples of rules and programs that may be necessary in a long-term strategy to prevent future impairment of visibility in Class I areas. EPA should revise the Final Guidance to direct states to consider these examples and include them where appropriate in SIPs.

a. Methods to address visibility-impairing emissions from oil and gas development

EPA should revise the Final Guidance to explicitly note that it expects states to review area sources like oil and gas, and should provide additional guidance on how to do so. Undoubtedly, this should begin with requiring states to collect better data on the emissions from oil and gas.

In many states, emissions from oil and gas development are a significant threat to visibility and air quality in Class I areas. Such development often occurs on federal lands that are near to or abut Class I areas For example, oil and gas development contributes to visibility impairment in public lands in Utah and Colorado where the NPS found that oil and gas development and leasing in the two states would "cause visibility impairment" at Dinosaur National Monument.[127] Additionally, NPS recently found impacts from oil and gas emissions at Carlsbad Caverns and San Pedro Parks Wilderness Class I areas, among others, based on 2008 emissions inventories—which do not capture more recent growth—and include only a portion of emissions from the production process.[128] Examples of Class I areas currently or potentially

[126] "The U.S. Energy Information Administration ("EIA") reports that oil production growth in the United States has risen by about 3 million barrels per day (from 5.8 to 8.72 MMb/d) from January 2001 to July 2014 (EIA, 2014a). Natural gas production has increased from 53.74 to 70.46 billion cubic feet per day within this time period (EIA, 2014a). The trend is expected to continue with the number of oil and gas wells in the lower 48 states projected to increase by 84 percent between 2013 and 2040 (EIA, 2014b)." impacted by oil and gas emissions include: Theodore Roosevelt and Lostwoods (Bakken Shale in eastern Montana and North Dakota); Wind Cave and Badlands (Powder River Basin in northeast Wyoming); Bridger and Fitzpatrick Wilderness Areas (Pinedale Anticline and Jonah Fields in western Wyoming); Mesa Verde (North and South San Juan Basin); Carlsbad Caverns and Guadalupe Mountains (Permian Basin in southeastern New Mexico and western Texas); and Canyonlands and Arches (Uintah, Paradox, and Piceance Basins in Utah and Colorado).

Significant information is available to enable states and EPA to develop strategies to reduce visibility-impairing emissions from this significant source category. However, these prior analyses do not substitute for meaningful consideration of oil and gas emissions reductions sufficient to meet the Regional Haze Rule's "reasonable progress" mandate. NPCA's recent report, "Oil and Gas Sector Reasonable Progress Four-Factor Analysis for Five Source Categories" assesses emissions controls for the five primary sources of visibility-impairing (and health harming) pollution in the sector: gas-fired reciprocating internal combustion engines ("RICE"); diesel-fired RICE; gas-fired combustion turbines; gas-fired heater, boilers, and reboilers; and flaring and thermal incineration of excess gas and waste gas.[129] The controls and practices included in this document represent various requirements for sources across the country and should be considered by states with emissions from the oil and gas sector.

Resource Management Plans ("RMPs") or land use plans issued by federal agencies explain how the agency will manage areas of public land over a period of time, usually ten to fifteen years. RMPs and amendments to those plans are required to go through a public review process under the National Environmental Policy Act ("NEPA"), which must include an analysis of projected impacts to all resources, including air quality. Such plans would include projections of oil and gas development, among other land use projections, on federal lands. Unfortunately, numerous RMPs have not been revised for decades, and only a few consider the effect of emissions from the planning area. EPA should revise the Final Guidance to require that states consider RMPs and other land use plans in determining the appropriate measures to prevent future impairment of visibility to include in regional haze SIPs. However, if RMPs are outdated or fail to consider the effects of visibility-impairing pollution from development, EPA must also indicate that those RMPs not be relied upon.

Recent NEPA analyses conducted for projected oil and gas development in RMPs can be useful tools for obtaining data regarding anticipated growth in such emissions. However, neither NEPA assessments nor RMPs are tools for preventing future impairment from oil and gas development. First, if adverse impacts are projected, the federal agency may make recommendations on mitigation methods to avoid adverse impacts, but neither the federal agency nor the local or state air permitting agency are under any obligation to implement such mitigation measures. Second, the federal agency is often making projections of expected amounts of development and in the types and emission rates of emissions units utilized. Those projections do

[129] Vicki Stamper & Megan Williams, Nat'l Parks Conservation Ass'n, Oil and Gas Sector Reasonable Progress Four-Factor Analysis for Five Source Categories: Natural Gas-Fired Engines, Natural Gas-Fired Turbines, Diesel-Fired Engines, Natural Gas-Fired Heaters and Boilers, Flaring and Incineration (Mar. 6, 2020) ("NPCA Report").

not always reflect the level of development that actually occurs, or the specific emission units and emission rates that are utilized. The Colorado Air Resources Management Modeling Study is one example of the type of information which can be developed in conjunction with the RMP process.[130]

In developing long-term strategies, EPA should direct states to use available information such as county-level reported emissions data and RMP and site-specific NEPA analyses, and request additional information to round out and make inventories accurate. To aid in this data gathering, EPA should direct industry to produce emissions inventories and submit them to states alongside an evaluation of emissions-reduction strategies and control technologies for this significant source of visibility impairment. Further, EPA should revise the Final Guidance to explicitly advise states on creating and making publicly available oil and gas emissions data.

States with significant oil and/or gas development should be required to consider the adoption of emission control regulations for the oil and gas development industry to reduce visibility-impairing emissions from such development.[131] Many states already require measures to reduce emissions from the sector. For example, California has enacted extensive air pollution requirements for oil and gas production, processing, and storage.[132] Colorado has also adopted emission requirements for the oil and gas industry.[133] Pennsylvania has also revised the state's oil and gas drilling regulations.[134] While these regulations may not be sufficient as to visibility impairment from the sector's emissions, the regulations provide relevant examples of states' decisions to address threats to air quality that are not covered by federal major source permitting requirements. EPA should identify the source types and associated emission-reducing measures available in the sector and use them to develop guidance to specify EPA's expectations of states in assessing these sources and requiring emission reduction measures from them. EPA must reconsider and revise the Final Guidance to require states to apply these and other control measures in their regional haze SIPs.

b. Minor New Source Review permitting programs

A state's minor NSR permitting program can be a useful tool to impose emission limitations and otherwise ensure that new source growth occurs in a manner consistent with making reasonable progress towards the national visibility goal. EPA should revise the Final Guidance to direct states to model new or modified minor NSR sources for their impacts on visibility in Class I areas. States could thus determine if the source's emissions would be consistent with making reasonable progress towards the national visibility goal, similar to the requirement in 40 C.F.R. §51.307(c) of the visibility NSR rules. Such a provision would also be

[133] Colo. Regulation No. 7, Section XII, https://www.colorado.gov/pacific/cdphe/air/oil-and-gas-compliance.
[134] *See* Environmental Protection Performance Standards at Oil and Gas Well Sites, 46 Pa. B. 6431 (Oct. 8, 2016), http://www.pacodeandbulletin.gov/Display/pabull?file=/secure/pabulletin/data/vol46/46-41/1757.html.

consistent with section 7410(a)(2)(D)(i)(II) of the Clean Air Act, which requires SIPs to include adequate provisions prohibiting any source type from emitting any air pollutant which will interfere with measures to protect visibility. States could include criteria to ensure that the sources most likely to interfere with making reasonable progress are addressed, based on total emissions of visibility-impairing pollutants, distance to Class I areas, and/or other criteria focused on modifications at existing major sources that avoid PSD or nonattainment NSR review. EPA should instruct states to add such provisions to their minor NSR programs as necessary to ensure that their long-term strategies adequately prevent future impairment to visibility. Such provisions should also be incorporated and made enforceable through regional haze SIPs relying on such emission reductions to make reasonable progress.

States that decide to rely on minor NSR programs to prevent future impairment should be required to examine the relevant definitions and exemptions that exist in their programs to ensure that the types of sources that need to be addressed to prevent future impairment are indeed subject to the states' minor NSR programs. A state's minor NSR program also may need to be revised to include emissions from emitting units not typically covered under PSD permitting requirements, such as fugitive emissions.

Applicability at minor NSR sources should be based on projected changes in allowable or actual emissions from a baseline reflective of recent emissions. If a state is intending to rely on its minor NSR program to prevent future impairment of visibility, then the minor NSR program must be written in a manner to truly accomplish that intention. As other Clean Air Act programs fail to adequately integrate limits for new or modified sources, regional haze SIPs should be used directly for this purpose.

c. Provisions for other potential threats to visibility impairment

There are a number of source types other than those covered by a minor NSR permit program or oil and gas development that could potentially impair visibility. In recognition of this, EPA should revise its Final Guidance to recommend that states specifically include the analyses of these potential sources in their long-term strategies, and if necessary, adopt provisions to address them. For instance, if construction activities threaten future impairment, states should adopt control measures to mitigate air pollution at construction sites. As an example, the Sacramento Metropolitan Air Quality Management District applies air emissions requirements to construction sites.[135] California also has stricter mobile source emissions requirements (including for non-road engines) that apply under federal rules, and states with significant mobile source growth threatening future impairment could consider adopting such standards as their own.[136] EPA should encourage states to consider various measures to address

[135] *See* Sacramento Metro. Air Quality Management Dist., CEQA Guide, Ch. 3: Construction-Generated Criteria Air Pollutant and Precursor Emissions (April 2019), http://www.airquality.org/LandUseTransportation/Documents/Ch3ConstructionFinal4-2019.pdf.

[136] Congress preempted states from setting emission standards for mobile sources, except that California could set its own standards with EPA's permission and other states could opt into the stricter California standards (generally for ozone SIP purposes). 42 U.S.C. § 7543(e)(2)(B)(i)-(ii).

potential future Class I visibility impairment, based on the recent or planned growth in new source emissions expected for the state, that could threaten future impairment of visibility in any Class I area.

Additionally, to the extent that states have limited information on such sources, EPA should require that states collect and submit actual emissions increase data on minor modifications at existing sources in order to gather more information on the extent of minor source growth and on new minor, area, and other source growth.

Visibility-impairing emissions need to be inventoried and modeled from many sectors in order to properly inform the next round of haze plans. Several states have started collecting and submitting oil and gas emissions data to be inventoried and modeled for purposes of regional haze. For instance, the Western Regional Air Partnership has started collecting from its oil and gas producing states emissions for their modeling inventory.[137] However, there are several states not in the western region of the country, such as Pennsylvania and Virginia, which are significant producers of oil and gas, and should also be collecting and submitting oil and gas emissions data.[138] Furthermore, as noted *supra* section III.H, there is no inventory of emissions from the agricultural sector; states should develop such inventories and submit them with their regional haze SIPs.

Emissions data from wood burning devices should be modeled. As EPA has explained, the smoke from these devices "contains harmful particle pollution, also known as fine particulate matter or PM2.5, along with other pollutants including carbon monoxide, volatile organic compounds (VOCs), black carbon, and air toxics such as benzene."[139] EPA has also confirmed that residential wood combustion "accounts for 44 percent of total stationary and mobile polycyclic organic matter (POM) emissions, nearly 25 percent of all area source air toxic cancer risks and 15 percent of noncancer respiratory effects."[140] Furthermore, wood burning devices are a significant source of heating for many communities near Class I areas that struggle with regional haze pollution problems. Wood burning devices materially contribute to the significant proportion of particulate matter (fine and course) and VOC emissions that come from residential wood combustion in Arizona, Massachusetts, Minnesota, Nevada, Washington and other states, adding to regional haze visibility problems in Class I areas around the country.

While the collection and evaluation of much of this data should inform the next round of haze plans, we note that for the oil and gas sector, this data is sufficiently available such that regulation of the sector is appropriate and much needed in this second round of regional haze

planning. EPA should specify that in order for a state to satisfy the requirements of proposed 40 C.F.R. § 51.308(f), states must consider the cumulative impacts from minor and other source growth that may affect future visibility impairment. With this information, states can determine the number and types of new source growth and magnitude of emissions that may threaten future visibility impairment, which can then assist states in developing targeted measures to prevent future visibility impairment and address regional haze from these source types. Such measures should be required to be part of the long-term strategy of the regional haze SIP.

In summary, EPA must revise the Final Guidance to require long-term strategies to include measures to ensure the prevention of future visibility impairment, as well as the remedying of existing visibility impairment in Class I areas, in accordance with the national visibility goal of the Clean Air Act. While the PSD and visibility NSR programs have some effective provisions for ensuring that new and modified sources subject to those permitting requirements do not threaten future visibility impairment, those programs are not sufficient to fully address the statutory requirement of preventing future impairment to visibility. EPA should require states to evaluate the threats to future impairment to visibility in any Class I area and to adopt provisions within regional haze SIPs to minimize emissions from such sources, and otherwise ensure that new source growth occurs in a manner consistent with making reasonable progress towards the national visibility goal.

XII. Conclusion

The Conservation Organizations respectfully ask that EPA reconsider and revise the Final Guidance as mentioned above.

Sincerely,

Stephanie Kodish

Re: Comments responding to 4-factor analysis submittals from identified oil & gas operators

Dear Ms. Ely, Mr. Baca, Mr. Jones, and Mr. Singleton,

We applaud the New Mexico Environment Department for welcoming public input and engagement throughout the development of its Regional Haze State Implementation Plan (SIP). We encourage the agency to require robust measures in its forthcoming SIP that will result in clearer skies and better air quality in our state and region's Class 1 Airsheds and communities.

We submit the attached expert comments on the four-factor analyses submitted by oil and gas facilities in New Mexico prepared by consultants Megan Williams and Vicki Stamper.

The report identifies numerous errors in operators' 4-factor analyses, including overestimation of interest rate and underestimation of life of controls, high capital estimates, failure to annualize costs in some cases, failure to provide emissions data that reflect a reasonable estimate of current and future actual operations, failure to document sources of emissions data and/or claims made regarding feasibility of controls, and failure to analyze available control options, including electrification.

We value NMED's inclusion of the 20 oil and gas facilities in the state's four-factor list and encourage the state to consider the contents of the attached report. We also request NMED assess control options applicable to source categories within the oil and gas sector from facilities that were excluded from its four-factor list. We urge the state to pursue electrification across the sector and in the alternative ask the state to apply category-wide requirements that would result in effective reductions in visibility-impairing pollution.[1]

We re-emphasize our request that NMED require electrification of engines as an overarching control option. As detailed in our May 22, 2020 cover letter accompanying a report on SCR feasibility at Lean Burn engines, electrification is ultimately the best option for reducing or eliminating emissions of NOx and all other air pollutants from gas-fired engines, thereby better reducing visibility and public health-harming emissions while helping New Mexico achieve its climate goals.

NPCA, Western Environmental Law Center, and other allies across the state are committed to working with the agency, operators, and utilities to identify solutions to overcome spatial and regulatory questions regarding oilfield electrification. We believe a harmonized framework is within reach to aggregate emissions and load, and generate power as a collective instead of operating as a dispersed set of points. Acknowledging the structural questions of oilfield electrification, we urge NMED to move forward on a parallel track with emission-limiting requirements necessitating electrification. Public lands and our communities deserve no less than a forward-looking regional haze plan that will effectively curb existing burdens and mitigate future impacts to air quality.

[1] We refer NMED back to the March 2020 NCPA Oil and Gas Four-Factor Report for consideration of effective control options for oil and gas source categories.

Notwithstanding the above, we offer the following summary takeaways from the attached assessment.

Summary of Effective Controls for Emission Units at New Mexico Oil and Gas Facilities

Combustion Turbines: Based on the revised and additional cost analyses provided in the report, SCR is cost effective for most combustion turbines at the New Mexico Gas Plants evaluated, with the few exceptions potentially being units that limit operating hours (for example, Kutz Canyon Unit 4 appears not to operate much based on its reported NOx emissions in 2016, should limited operations be enforceable, SCR would not be considered cost effective). While several operators summarily dismissed SCR as a feasible pollution control, they failed to support their claims, failing to provide site details or vendor proposals for claims of site constraints or other claimed retrofit difficulties. Although the attached report did not evaluate SCR cost effectiveness for the turbines at Kutz Canyon, Indian Basin or South Carlsbad due to lack of the needed inputs to utilize EPA's SCR cost spreadsheet, based on the other SCR cost analyses that are provided in the report for several similar combustion turbines, SCR should be considered the most cost effective, and most effective in terms of NOx reductions, for all combustion turbines operating more than ~1,000 hours per year. Beyond superior emission-reducing capabilities, SCR is also preferable as water use is not an adverse impact from use of the technology. We further note that SCR combined with SoLoNOx or other dry low-NOx combustion techniques may be the more fitting control option at some units because it would achieve the greatest reduction in NOx emissions.

Lean Burn Engines: As found in NPCA's March 2020 Oil and Gas Four-Factor Report, LEC has been required for retrofit controls—and has been deemed cost effective—for Lean Burn RICE units of a wide size range (e.g., down to 50 hp).[1] In many cases when considering LEC as a potential control, operators failed to specify achievable emission rates, often greatly underestimating the reductions that might be achieved and therefore underestimating the cost effectiveness of the technology. In the accompanying comments on four-factor analyses for oil and gas facilities in New Mexico, LEC is shown to be cost effective for most engines except for those that consistently operate a limited number of hours per year. However, it's important to note that, for some engines, operation may be limited in one year but that may not hold true for the same unit for other years. For example, Targa indicated that "[w]ith regards to the engine usage, Targa attempts to use its engines uniformly but this does not mean equally on a calendar year basis."[2] So, when looking at the cost effectiveness of LEC control for RICE it's important to consider how the engine will be used, on average, over the life of controls rather than just looking at one year that may or may not be representative of that engine's usage in other years. Generally, LEC is cost effective for the specific engine models analyzed operating over 1,000 per year and can achieve 80–90% NOx reduction and reduce NOx emission rates to 2 g/hp-hr and lower. In addition, SCR is shown to be cost effective for Lean Burn engines at the two plants that evaluated SCR for such engines (Roswell Compressor Station No. 9 and Jal No. 3 Gas Plant). Based on those cost analyses as revised in the attached report, SCR should also be considered a cost effective control, with the capability to achieve 90% NOx reduction and reduce NOx emission rates to 1 g/hp-hr.

Rich Burn Engines: As with Lean Burn RICE, control of NOx emissions from Rich Burn RICE has been widely required for retrofit controls—and deemed exceedingly cost effective—for a wide range of units (e.g., down to 50 hp). Specifically, the Rich Burn RICE units at Targa's Saunders Gas Plant NSCR was shown to be extremely cost effective—at under $300 per ton of NOx reduced—based on Targa's own analysis. No other New Mexico facilities submitted cost analyses for Rich Burn RICE but, given that NSCR is often extraordinarily cost effective, NMED should assess the Rich Burn units at the facilities that submitted four-factor analyses, even if those units have NOx emissions that fall below NMED's original cutoffs of 10 lb/hr or 5 tpy; cumulatively, control of NOx emissions from these emissions units using NSCR would be a very cost effective way to achieve additional, meaningful NOx reductions.

Amine Units/Acid Gas Flaring: For amine units and associated acid gas flares at gas sweetening plants, an acid gas injection well with a backup electric acid gas compressor is the minimum level of control of SO2

that should be required. In fact, NMED has required this suite of controls in some settlement agreements, according to information provided in the Targa Eunice Gas Plant and Monument Gas Plant four-factor analyses. For those locations at which an acid gas injection well may not work effectively, then a sulfur recovery unit (SRU) along with an incinerator *and* acid gas scrubber should be used to most effectively control SO2 emissions. Alternatively, a facility could employ both an acid gas injection well and a sulfur recovery unit, as is implemented at the Jal No. 3 amine unit, although improvements should be made at that facility, such as adding an acid gas scrubber to the SRU or routing the acid gas stream from the SRU to the acid gas injection well. Any maintenance or upset that requires the flaring of the acid gas stream from an amine unit can be a significant source of SO2 emissions and thus redundancy of controls is key for reducing/eliminating SO2 emissions associated with amine units at gas sweetening plants.

In a 2018 presentation from the Air Resources Division of the National Parks Service, entitled "Source Attribution Using Volatile Organic Compound Measurements to Assess Air Quality Impacts at Five National Parks in the Western US," data is shown confirming that Carlsbad is impacted by VOCs from oil and gas activity in the Permian. This further warrants the implementation of the strongest suites of controls at amine units and associated gas flares.

NOx is a visibility-impairing pollutant of interest: We urge the agency to dispel the claim made by several operators that SO_2, not NOx, is the contaminant of interest for visibility impairment in various Class 1 Airsheds. Both pollutants contribute to visibility impairment and emissions of nitrogen oxides must be mitigated to make reasonable progress toward the national goal of restoring natural air quality conditions. Some operators claim that NOx emissions from these pieces of equipment are inconsequential for regional haze purposes, while numerous federal agencies and groups have maintained that reducing NOx is necessary for best reducing visibility-reducing haze.

Colorado State's IMPROVE website makes available a Particulate Matter and Haze Composition Browser (available at http://vista.cira.colostate.edu/Improve/pm-and-haze-composition/), in which there is a map of all Class I areas, with associated 2018 data of PM composition by day. The recent data found in this IMPROVE resource reinforces the importance of controlling NOx in improving visibility in Class 1 airsheds impacted by oil and gas – particularly as this industrial activity has been accelerating greatly in the past several years. As shown in the data for 2018 for Carlsbad Caverns (Figure 1), nitrates are a significant contributor to PM in the winter months.

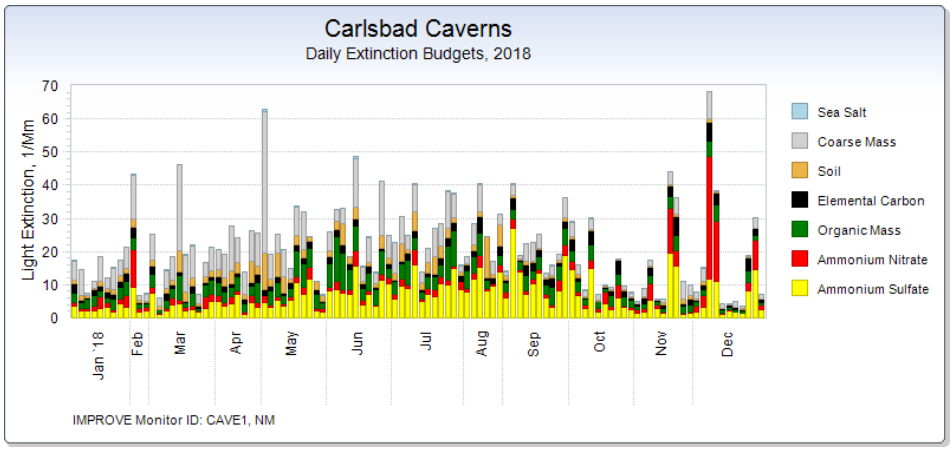

Figure 1.

Moreover, EPA's 2019 Regional Haze Guidance specifies that a state may use a number of screening tools and New Mexico's Q/d approach is a recognized screening methodology that reflects emissions of both SO2 and NOx.

Additional facilities that warrant reduction requirements: The agency's 10 lb/hr and 5 tpy criteria leaves out a wide array of facilities and equipment which contribute significantly to regional haze. In some cases, the agency did not require four-factor analysis for all units at a plant that had PTE greater than these thresholds (such as Units 7 and 8 at Kutz Canyon Gas Plant) - even though the company submitted other four-factor analyses for other units at the same facility.

NPCA has analyzed facilities not identified by NMED as being required to submit four-factor analyses (Figure 2). We have detailed the findings below, including the number of like sources and emissions and emission rate equivalents. In all, we assessed 62 additional facilities, with NOx emissions greater than 50 tpy. The NOx emissions from these 62 additional facilities total 10,711 tons per year according to the 2019 emissions NMED data. Within these 62 facilities, are 209 Lean Burn RICE units (Figure 3):

- 134 Lean Burn RICE units have NOx limits that equate to values greater than 1.0 gr/hp-hr.
- 69 Lean Burn RICE units have NOx limits that equate to values greater than 1.5 gr/hp-hr.
- 17 Lean Burn RICE units have NOx limits that equate to values greater than 2.0 gr/hp-hr.

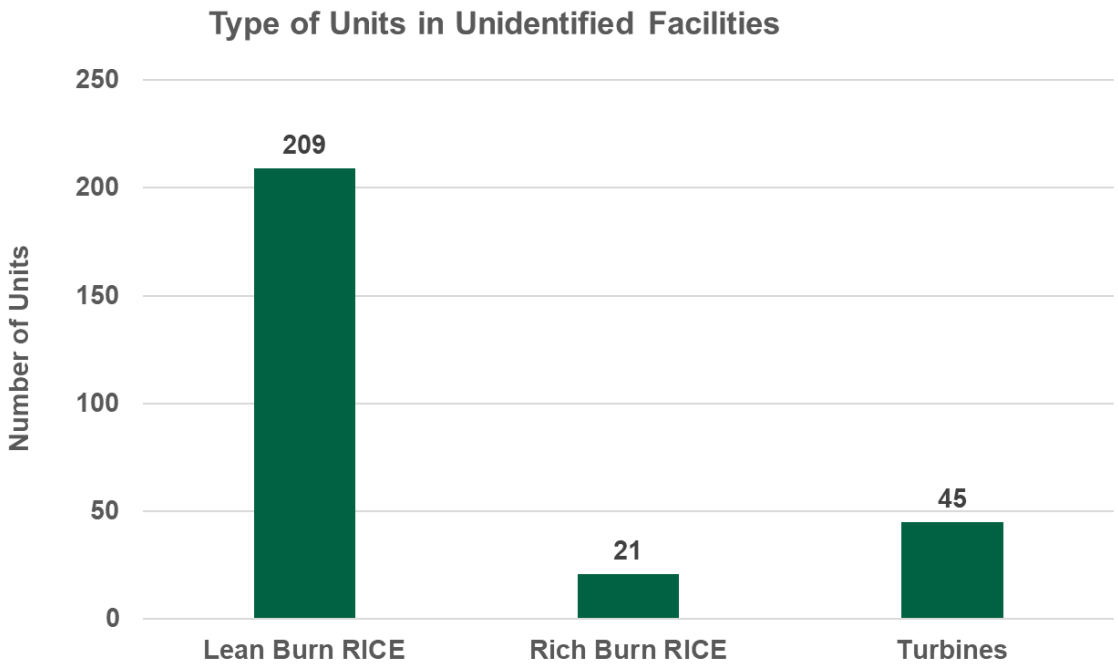

Figure 2.

As discussed above, emission reduction controls such as LEC and SCR are cost effective controls and can be used at these units to achieve NOx limits that equate to 0.15 to 2 g/hp-hr. with a NOx removal efficiency ranging from 87% to 95%. NPCA recommends NMED require a four-factor analysis of any Lean Burn RICE with equivalent NOx emission rates greater than 1.0 gr/hp-hr.

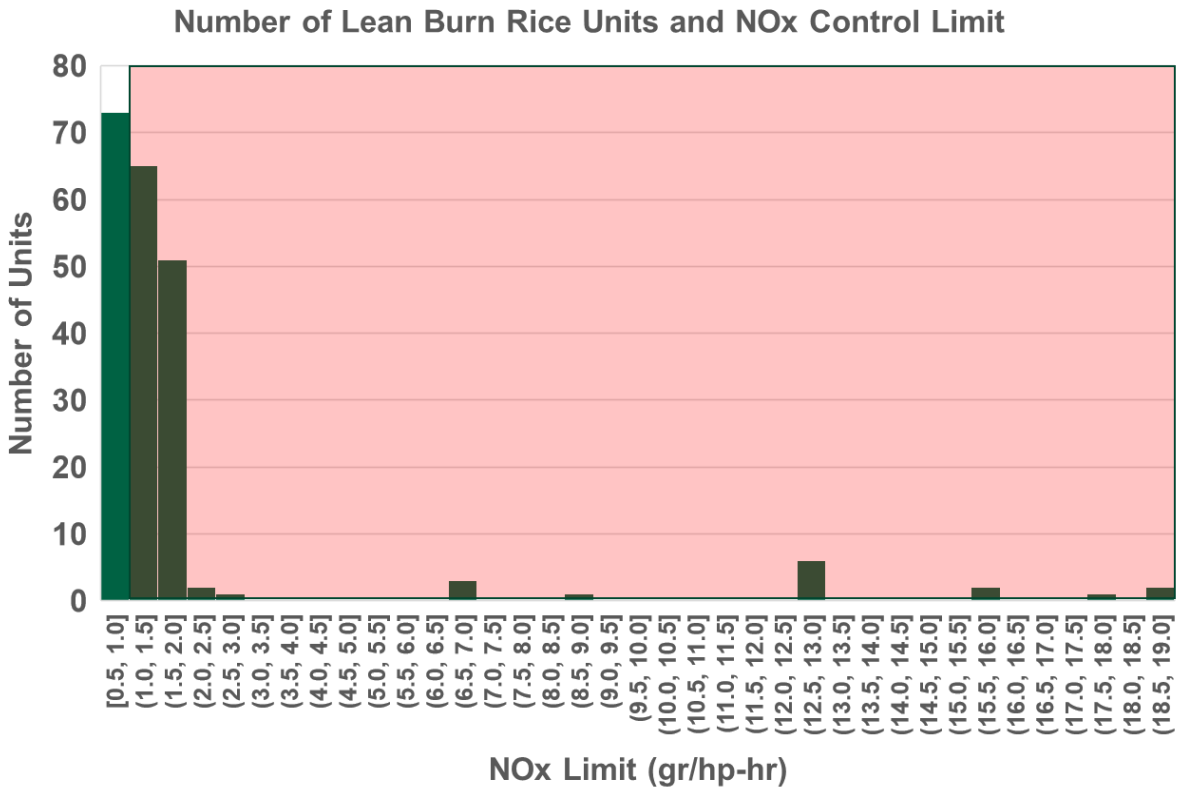

Figure 3.

In addition, we identified 21 Rich Burn RICE units at the 62 facilities not selected by NMED for a four-factor analysis. Of these Rich Burn RICE units, 17 have NOx limits that equate to 1.0 gr/hp-hr (Figure 4). Controlled NOx emission rates from 0.3 to 1.6 g/hp-hr. can be achieved using NSCR with a NOx removal efficiency ranging from 90% to 98%. Given the extremely favorable cost effectiveness of NSCR, NPCA recommends NMED require a four-factor analysis for any Rich Burn RICE with equivalent NOx emission rates greater than 1.0 gr/hp-hr.

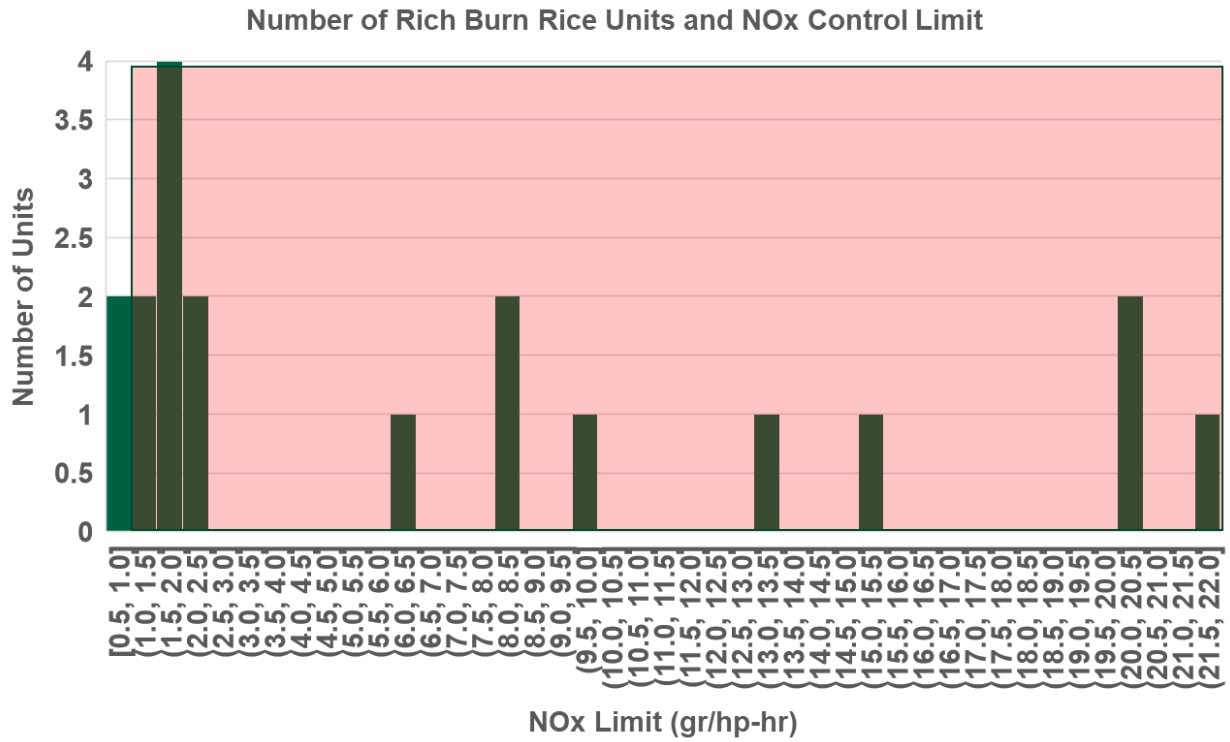

Figure 4.

Lastly, NPCA identified 45 turbines at compressor stations not selected for a four-factor analysis by NMED. Of them, 43 turbines have NOx limits higher than 15 parts per million (ppm) (~0.06 lb/MMBtu) (Figure 5), which reflects a controlled NOx emissions rate achievable with Dry Low NOx Combustors (DLNC) such as SoLoNOx or with SCR. NPCA recommends NMED require a four-factor analysis of these 45 gas turbines with equivalent NOx emission rates greater than 15 ppm.

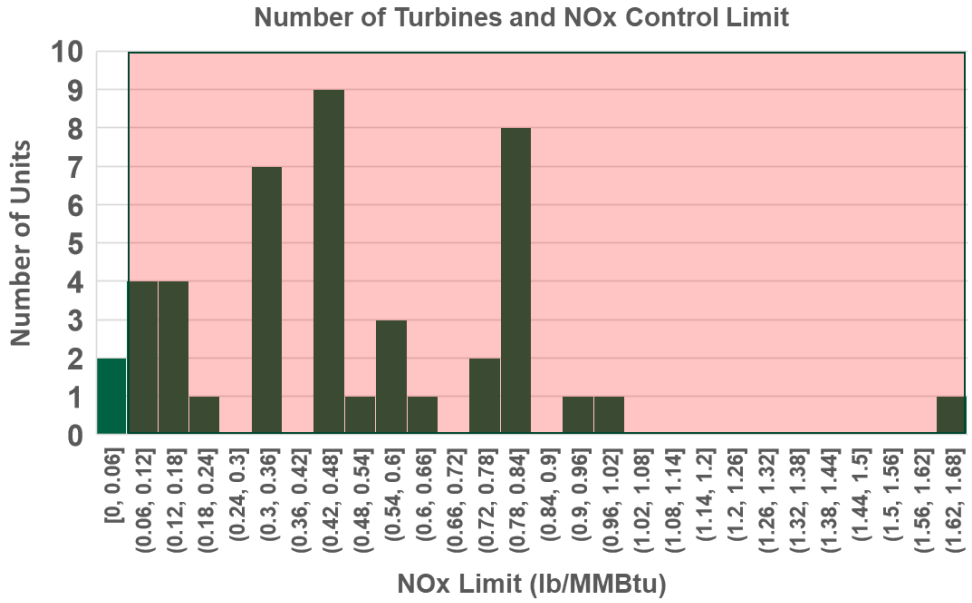

Figure 5.

In closing, we greatly appreciate the opportunity to work with New Mexico Environment Department, and welcome any questions and discussion regarding the attached comments and next steps to ensure the New Mexico Regional Haze Plan results in significant improvements to the visibility at our treasured Class I landscapes and across our communities.

Assessment of Cost Effectiveness Analyses for Controls Evaluated Four – Factor Analyses for Oil and Gas Facilities For the New Mexico Environment Department's Regional Haze Plan for the Second Implementation Period

July 2, 2020

Prepared for National Parks Conservation Organization

Prepared by:

Vicki Stamper & Megan Williams

Executive Summary

In a March 2020 report on reasonable progress controls for several sources in the oil and gas sector, the authors provided general four-factor analyses of regional haze pollution control options for five source categories in the oil and gas industry, including natural gas-fired engines, combustion turbines, boilers, heaters, diesel-fired engines, and flaring and incineration.[1] That report identified regional haze pollution control options that are cost-effective and have been required by state and local air pollution control agencies through adaptation of emission limitations requiring retrofit of pollution controls for most of these source categories. For example, the report showed that, for natural gas-fired reciprocating internal combustion engines (RICE), cost effective controls include replacing engines with electric compressors, use of nonselective catalytic reduction (NSCR) at rich burn RICE, and use of low emissions combustion (LEC) or selective catalytic reduction (SCR) at lean burn RICE.[2] For natural gas-fired combustion turbines, the report found that the installation of dry low NOx combustion or the use of SCR (or in combination with dry low NOx combustion) is cost effective.[3] And for natural gas-fired heaters and boilers, the use of ultra-low NOx burners and/or SCR were found to be cost effective.[4] We refer the New Mexico Environment Department (NMED) to the March 2020 NCPA Oil and Gas Four-Factor Report for consideration in deciding the pollution controls to require of the New Mexico oil and gas sources for which NMED requested four-factor analyses.

In this document, we provide more specific comments on the cost of controls in the four-factor analyses submitted by oil and gas companies to NMED. The document is organized to provide comments on the facilities' four-factor analyses in order of magnitude of each facilities' "Q/d" value based on 2014 emissions. In the last sections of this document, we provide comments on two additional sources for which NMED did not request four-factor analyses but for which NPCA requested that NMED evaluate based on the facilities' Q/d—the Corona Compressor Station and the Empire Abo Gas Plant. And in the very last section, we provide comments on the four-factor analyses and control options for SO_2 emissions from amine units and flaring including startup, shutdown, malfunction emissions. Specifically, this report provides comments on the company cost analyses and/or provides cost analyses on the listed emission units at the following gas compressor stations and gas processing plants in New Mexico.

RICE Notes: 2SLB: Two-Stroke Lean Burn; 4SLB: Four-Stroke Lean-Burn; 4SRB: Four-Stroke Rich-Burn

In general, the facilities' four-factor analyses are addressed in the order given in the above table, except that amine units and acid gas flares are addressed collectively in Section XXIII at the end of this report.

One overarching control option that NMED should give serious consideration to for lean burn RICE is the electrification of these engines. As was demonstrated in the March 2020 NCPA Oil and Gas Four-Factor Report, electrification of RICE units used for gas compression can be very cost effective just considering the NOx removal benefits, in the range of $1,200-$2,800/ton of NOx removed.[5] And several other pollution control benefits would occur with electrification of engines. From the regional haze perspective, replacing fossil fuel-fired RICE with electric engines would also reduce other visibility-impairing pollutants formed by the engines including volatile organic compounds (VOCs) and, for diesel-fired engines, particulate matter and sulfur dioxide (SO_2). Further, there would be reduced emissions of VOCs from compressor blowdowns. In addition, electric engines would require less maintenance time and have fewer upsets, which would not only reduce high NOx emissions that occur due to startups, shutdowns, and malfunctions, but would also reduce flaring of gas during compressor engine downtime which will reduce VOCs, NOx and, if the gas is sour gas, SO_2. And, of course, the additional significant co-benefit of the reduction in fossil fuel-firing and the reduction in upsets/less maintenance is that greenhouse gases will be greatly reduced. As stated in the NPCA Oil and Gas Report, replacing five RICE engines at a compressor station with electric compressors could eliminate approximately 16,000,000 cubic feet per year of fugitive methane emissions, which along with the greenhouse gas reductions from not burning natural gas in the engines would reflect a reduction of about 12,000 tons per year of carbon dioxide (CO_2) equivalent emissions.[6]

While the analysis of the costs to electrify units in the March 2020 NCPA Oil and Gas Four-Factor Report did not include any costs to upgrade electricity to a facility if needed, there are options that NMED should consider to reduce costs of power upgrades. For example, if more than one facility is located nearby each other, the facilities could partner to bring and/or upgrade electricity to the facilities. In a review of permits for midstream oil and gas facilities on NMED's Emissions Analysis Tool website,[7] there are at least five natural gas processing plants with electric engines in the New Mexico portion of the Permian Basin: 1) Targa -Eunice Gas Processing Plant, 2) Transwestern - Roswell Compressor No. 9, 3) Occidental- South Hobbs Reinjection Compression Facility, 4) DCP – Zia II Gas Plant, and 5) Durango Midstream – Maljammer Gas Plant. NMED should explore whether there are options for these plants to either electrify more engines and/or partner with nearby facilities to enable any necessary electric utility upgrades to electrify currently gas-fired engines. In the northwest part of New Mexico, there are three facilities that are co-located and are actually considered to be one source for Title V purposes despite having different owners: Blanco A Compressor Station,

[5] *Id.* at 44.
[6] *Id.* at 45-46.
[7] https://eatool.air.net.env.nm.gov/aqbeatool/.

Blanco C&D Compressor Station, and San Juan Gas Plant.[8] These facilities are about 1 mile from the city of Bloomfield, so they are not very remote. There are several lean burn RICE that could be replaced with electric engines at these facilities. Given the significant regional haze benefits that could be realized with electrification of engines, NMED should consider these and other options to facilitate implementation of this highly effective control measure.

With respect to other, albeit less effective than electrification control measures that should be considered cost effective for the emission units in the above table, the revised and supplemental cost effectiveness analyses provided herein support the findings of the March 2020 NCPA Oil and Gas Four-Factor Report. First, nonselective catalytic reduction (NSCR) is extremely cost effective for rich burn RICE. Given how cost effective NSCR is and how effective the control is for reducing NOx emissions, NMED should request analyses for all rich burn RICE at the facilities that submitted four-factor analyses, even if those units have NOx emissions that fall below NMED's emission thresholds of 10 pounds per hour (lb/hr) or 5 tons per year (tpy). Installation of NSCR could be a very cost effective way to achieve additional, meaningful NOx reductions at midstream facilities in New Mexico.

With respect to lean burn RICE, low emissions combustion (LEC) and, where evaluated, selective catalytic reduction (SCR), is generally cost effective for lean burn RICE that are operated greater than 500-1,000 hours per year. While several of the four-factor submittals to NMED had very high cost effectiveness values for LEC, those cost effectiveness analyses were often improperly inflated for the reasons discussed herein, including the assumption of low baseline emissions by focusing on a single year of baseline emissions. A single year of operational data of a lean burn engine used in a gas processing facility may not reflect how the unit will operate on average over its lifetime. For example, Targa, indicated that "[w]ith regards to the engine usage, Targa attempts to use its engines uniformly but this does not mean equally on a calendar year basis."[9] If an engine operates less than 1,000 hours per year—consistently, from year to year—LEC may not be cost effective. However, generally, LEC is cost effective for the specific engine models analyzed and can achieve 80–90% NOx reduction and reduce NOx emission rates to 2 g/hp-hr and lower. In addition, SCR is also shown below to be cost effective for lean burn engines at the two plants that evaluated SCR for such engines (Roswell Compressor Station No. 9 and Jal No. 3 Gas Plant). Based on those cost analyses provided herein, SCR should also be considered a cost effective control for lean burn engines, with the capability to achieve 90% NOx reduction and NOx emission rates of 1 g/hp-hr. With respect to claims made about whether SCR can be effectively used at lean burn engines, we refer NMED to the May 21, 2020 report "Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines" that NPCA provided to NMED via a May 22, 2020 letter.

[9] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 6.

For gas-fired combustion turbines, combustion controls and SCR have been required as best available control technology for new gas-fired turbines that power compressors at compressor stations.[10] In addition, combustion controls and SCR have been retrofit to numerous combustion turbines in numerous instances, primarily at electric utility combustion turbines. In revised and supplemental cost analyses presented herein, SCR is shown to be cost effective for most of the combustion turbine evaluated. While several companies made claims of space constraints and retrofit difficulty for SCR, the fact that SCR has been retrofit to numerous existing combustion turbines, coal-fired boilers, refineries, and other emissions sources that were not originally designed with space for SCR indicates that retrofit difficulties can and have been overcome. NMED should not allow a company to ignore evaluation of SCR based on purported retrofit difficulty claims without getting a vendor analysis of retrofit options for this highly effective control. The revised and supplemental cost effectiveness analyses provided herein show that SCR is cost effective for most of the combustion turbines evaluated in the New Mexico oil and gas facility four-factor analyses, unless the turbine has consistently low levels of operation and a low level of baseline emissions (in which case NMED should consider capping operations or emissions as a regional haze control).

For amine units and associated acid gas incineration or flaring, an acid gas injection well with, at the minimum, a backup electric acid gas compressor is the minimum level of control of SO2 that should be required. In fact, NMED has required this suite of controls in some settlement agreements, according to information provided in the Targa Eunice Gas Plant and Monument Gas Plant four-factor analyses. For those locations at which an acid gas injection well may not work effectively, then a sulfur recovery unit along with an incinerator and acid gas scrubber should be used to most effectively control SO2 emissions. Any maintenance or upset that requires the flaring of the acid gas stream from an amine unit can be a significant source of SO2 emissions and thus redundancy of controls is key for reducing/eliminating SO2 emissions associated with amine units at gas sweetening plants.

Below, we provide comments on the cost analyses in the company submittals made to NMED and provide revised and/or supplement cost analyses for the emission units analyzed.

E. Summary 162

I. Enterprise Field Services Chaco Gas Plant

The Enterprise Field Services (Enterprise) Chaco Gas Plant is a natural gas processing plant. NMED has described the plant process as follows:

> The function of the facility is to receive field natural gas, process the gas through removal of water, then extraction/separation of natural gas liquids (NGL) through a cryogenic process. NGL recovered are then treated to remove carbon dioxide and hydrogen sulfide. Recovered NGL is delivered to a pipeline for transport to fractionation facilities downstream. The facility compresses/pumps residue and sales natural gas for distribution through mainline natural gas pipelines.

3/1/2019 Statement of Basis for Title V Permit Significant Modification (Permit Nos. 1555-M6 (revisions through M6R2) and P116-R2M1 at 1.

According to the permit, the plant includes several 2-stroke and 4-stroke lean-burn RICE, several natural gas-fired turbines, a diesel generator, flares, and a heater.[11] In Enterprise's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- General Electric (GE) Frame 5 Turbines: Units 17 and 18
- Solar Mars T-15000 Turbines: Units 35, 36, and 37
- Clark TLA-10 2SLB SI-RICE Engines: Units 12, 13, and 14.[12]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tons per year (tpy), which is the criteria established by NMED to identify sources subject to four-factor analyses.[13] The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

Enterprise used an 8.38% interest rate in the cost analyses for all the controls evaluated in its 4-factor analyses.[14] This is an unreasonably high interest rate for cost effectiveness analyses. EPA's Control Cost Manual indicates that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[15] The current bank prime rate is 3.25%.[16] The highest

[13] *Id.*
[14] *Id.* at Section 8.0 Supporting Documentation.
[15] EPA, Control Cost Manual, Section 1, Chapter 2 (November 2016) at 16, available at:

the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[17] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. However, in a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[18] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. Enterprise's use of an 8.38% interest rate is unreasonably high and overstates the cost effectiveness of pollution controls evaluated in the four-factor analyses.

B. GE Frame 5 Turbines: Units 17 and 18.

Units 17 and 18 at the Chaco Gas Plant are 19,500 horsepower natural gas-fired turbines that were constructed in 1970 and 1971.[19] The units each have a NOx emissions limit of 78.5 lb/hr and 344 tpy.[20] For these units, Enterprise identified water or steam injection as viable combustion controls for NOx but claimed that dry low NOx combustors were not available for retrofit to these types of gas turbines.[21] Enterprise claimed that SCR installation was not possible for these gas turbines, due to the size estimates of the SCR.[22] Presumably, Enterprise is claiming issues of retrofit difficulty. There is no question that SCR is technically feasible for natural gas-fired combustion turbines, including those used at compressor stations.

1. Evaluation of Baseline NOx Emissions.

According to the company's cost analysis for water/steam injection, Unit 17 has an actual NOx emission rate of 29.15 lb/hr (54.7 ppm) and Unit 18 has an actual NOx emission rate of 29.15 lb/hr (48.7 ppm) based on 2016 stack test data.[23] These actual emission rates are much lower than the units' 78.5 lb/hr allowable NOx emission rates, so either the 2016 stack test data was not performed while the engines were operating at maximum capacity, or the allowable NOx

[22] *Id.* at 2-4.
[23] November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 82- to 8-3.

emission rates have been set unreasonably high. NMED should present information on the 2016 stack test data so the circumstances of the stack tests can be reviewed. In addition, NMED and Enterprise should review other stack tests for these units to ensure that the actual emission rates can be considered to truly reflect actual emissions over the lifetime of the controls being evaluated. For example, in the November 2007 Title V renewal application for the Chaco Gas Plant, the actual emission test results were listed for Unit 17 as 49.22 lb/hr when the unit was operating at 83% load and was listed for Unit 18 as 69.8 lb/hr when the unit was operated at 89% load.[24] In addition, test data from 1995 was also included in the November 2007 permit application which shows Unit 17 with a NOx emission rate of 78.7 ppm @15% oxygen (O_2) and 90.6 ppm @ 15% O_2 and Unit 18 with a NOx emission rate of 93.4 ppm @ 15% O_2 and 109.5 ppm @15% O_2.[25] Clearly, these actual emission rates from Enterprise's 2007 Title V permit application are significantly higher than the 29.15 lb/hr (48.7-54.7 ppm) NOx emission rates that the company's four-factor cost effectiveness analysis is based upon. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on an estimate of emissions expected in 2028 pursuant to EPA's regional haze guidance for the second implementation period.[26]

2. Evaluation of Water Injection and Steam Injection for NOx Control

As a result of assuming what appears to be unreasonably low NOx emission rates for current emissions from the GE Frame 5 turbines, Enterprise also assumed an unreasonably low level of NOx reduction in its cost effectiveness analysis of water injection and steam injection. Specifically, Enterprise only assumed a 15% NOx reduction from water or steam injection.[27] While Enterprise cites EPA's AP-42 emission factor documentation for the 15% control with water or steam injection, EPA's AP-42 states that such controls can achieve 60% or higher NOx removal.[28] EPA's 1993 Alternative Control Techniques Document (ACT) for NOx emissions from Stationary Gas Turbines, cited in EPA's AP-42 emission factor documentation, states that NOx rates in the range of 25 to 42 ppmv can be achieved with water or steam injection as gas-fired combustion turbines.[29] For the Frame 5 turbines installed at the Chaco Gas Plant which, based on the 1978 year of manufacture indicated in the Title V permit, were presumably Model MS5001P,[30] EPA's 1993 Gas Turbine ACT listed the uncontrolled NOx emissions as 142 ppmv, dry, at 15% O_2.[31] Thus, a reduction to 25-42 ppm with water or steam injection would equate

[28] EPA, AP-42 Emission Factor Documentation, at 3.1-6.
[29] *See* EPA. Alternative Control Techniques Document – NOx Emissions form Stationary Gas Turbines, EPA-453/R-93-007, January 1993, at 2-5 [hereinafter EPA 1993 Gas Turbine ACT].
[30] *See* https://www.ccj-online.com/3q-2012/special-report-the-venerable-frame-5-gas-turbine/.
[31] *See* EPA. Alternative Control Techniques Document – NOx Emissions form Stationary Gas Turbines, EPA-453/R-93-007, January 1993, at 2-3.

to a 70% to 82% reduction in NOx emissions with water or steam injection from EPA's listed uncontrolled NOx rate of 142 ppmv. If the uncontrolled emissions of Units 17 and 18 are truly in the range of 48.7 to 54.7 ppm as indicated in Enterprise's 4-Factor analyses (assuming this is parts per million by volume at 15% oxygen, which NMED should confirm) and that is a reasonable projection of NOx emission rates into 2028 despite prior emission tests that were much higher than these levels, it seems very likely that the water or steam injection could reduce NOx down to at least 25 ppmv @ 15% O_2, which would be a reduction in emissions of 56% at Unit 17 and of 50.7% at Unit 18. Thus, NMED must require that Enterprise evaluate water or steam injection for Units 17 and 18 assuming a 25 ppmv @ 15% O_2 NOx rate could be achieved.

With respect to the life assumed of water or steam injection, Enterprise only assumed a 15-year life of these controls.[32] Enterprise did not provide any justification for assuming such a short life of water or steam injection. As discussed in NPCA's March 2020 report, the life of water or steam injection should be the life of the combustion turbines. In NPCA's March 2020 report, we assumed a 25-year life of water or steam injection.[33]

In terms of Enterprise's costs for water injection or steam injection, the company's capital costs seem very high for the size turbines, based on a comparison to the 1999 Department of Energy (DOE) report entitled "Cost Analyses of NOx Control Alternatives for Stationary Gas Turbines," which is cited in several EPA and State documents on the costs of NOx controls at gas turbines.[34] In that 1999 DOE report, the costs of water or steam injection for a slightly larger gas turbine, a GE LM2500 turbine which is of 22.7 megawatt capacity or about 30,400 hp, the capital cost in 1999 dollars of water injection was estimated to be $1,083,175.[35] Although EPA's Control Cost Manual advises against escalating costs more than five years because it can lead to inaccuracies in price estimation,[36] just using the Chemical Engineering Plant Cost Indices between 1999 and 2018, the DOE's 1999 costs of water injection for a larger GE LM2500 gas turbine would increase to $1.67 million.[37] Using a different cost index specific to oil refineries, the Nelson-Farrar index, the 1999 costs of water injection increase from $1.0 million to $1.88 million as of 2016 (the most recent annual Nelson-Farrer cost index found online).[38] Yet,

[35] *Id.*, Appendix A at A-4.
[36] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017.
[37] Based on multiplying the 1999 cost estimate for water injection from the 1999 DOE report by the ratio of the CEPCI indices for 2018 to 1999 (603.1/390.6).
[38] Based on multiplying the 1999 cost estimate for water injection from the 1999 DOE report by the ratio of Nelson-Farrar indices for 2016 to 1999 (2598.7/1497.2).

Enterprise's capital cost estimate for water injection at Units 17 and 18 was $6.6 million, more than three times the escalated capital costs from the 1999 DOE report based on either the CEPCI index or the Nelson-Farrar index. Thus, Enterprise's capital cost estimate of water injection for a smaller capacity gas turbine at Units 17 and 18 seems very high. Further, the inspection and operating costs of water injection, which Enterprise stated would be $1,238,327 per year,[39] are not explained or documented and seem unreasonably high. NMED must request more details and support for these cost estimates of water injection and steam injection at Units 17 and 18.

We addressed just some of these issues to revise Enterprise's cost effectiveness analyses to reflect 1) a 4.7% interest rate (instead of 8.38%), 2) a 25-year life of water or steam injection (instead of an assumed 15-year life), 3) a controlled NOx rate with water or steam injection of 25 ppmvd at 15% O_2, and 4) revising Enterprise's baseline emissions to reflect EPA's NOx rate for uncontrolled GE Frame 5 gas turbines of 142 ppmvd[40] and a controlled NOx rate of 42 ppmvd. With the revisions listed in items 1 through 3 above, Enterprise's cost effectiveness of water or steam injection reduction from approximately $107,000 to $149,000/ton of NOx removed to $24,500- $38,692/ton, and it is important to note that no changes were made to Enterprise's own seemingly high estimates for capital and operating costs of water or steam injection. Revising Enterprise's cost estimates to use EPA's uncontrolled NOx rate for the turbine models of 142 ppmvd and a controlled NOx rate of 42 ppmvd with water or steam injection (the least stringent NOx emission rate that EPA indicates can be met with the control), reduces cost effectiveness of these controls to $7,300-$10,500/ton. Again, these revisions do not reflect any changes to Enterprise's seemingly high capital and operating costs for water or steam injection.

In its identification of energy and non-air quality environmental impacts of compliance, Enterprise did not list water use as an adverse environmental impact, but it is an issue to be concerned with for water injection.[41] That is why dry low NOx combustion, if available (which Enterprise claims is not available for the Unit 17 and 18 turbine models) or SCR are more preferable choices for NOx control from gas-fired turbines in New Mexico.

3. Evaluation of SCR for Units 17 and 18 Gas Turbines.

Enterprise did not evaluate SCR for the Units 17 and 18 gas turbines, stating that it was "not possible to install these units at the Chaco facility" due to "the amount of buffer space needed to maintain accessibility to equipment and to avoid compromising worker safety."[42] While the facility and gas turbines may not have been originally designed to have space to accommodate SCR, that is typically the case with most SCR retrofits. As such, there have been numerous SCR retrofits installations at various industrial facilities that have had to overcome space constraints. For example, for many large coal-fired power plants, SCR reactors have been elevated above the air preheaters. Indeed, a report about SCR retrofits at GE LM2500 turbines at Chevron's Eastridge Cogeneration plant in California showed that some significant changes to the facility had to be made to accommodate SCR, including cutting the duct between economizers and moving the stack and one economizer onto new foundations to make way for the SCR reactor.[43] Thus, before NMED accepts a very brief claim of retrofit difficulty of SCR at any emissions unit being evaluated for reasonable progress controls, it is imperative that NMED ask Enterprise for a site plan and photos that show whatever space constraints are being claimed, and that NMED asks Enterprise to consult with SCR vendors for options for SCR installation at the gas turbines of Units 17 and 18. For Unit 18, a schematic of the unit provided in the 2007 Title V permit application shows an oil heat recovery unit labeled as "out of commission."[44] Perhaps extracting that heat recovery unit out of the unit would enable for the relocation of the stack and space for the SCR. Unit 17 is also shown as being equipped with a heat recovery unit[45] and it is not clear if that is still operating or whether it could also be removed to make room for an SCR installation. In addition, there may be other options for the location of the SCR system. Depending on the proximity of the gas turbines, it is possible that one SCR reactor could be used by both Units 17 and 18, which would reduce costs and potentially be easier to install at the site. NMED must require all possibilities for SCR installation be evaluated and documented by Enterprise. The state must not simply discount this highly effective NOx control based on a claim of some retrofit difficulty.

In terms of the costs of SCR control, NPCA's March 2020 Oil and Gas Four-Factor Report showed the cost effectiveness in 1999 dollars for SCR achieving about 90% NOx reductions would range from $2,000/ton to $3,400/ton for a 5 MW combustion turbine (~6800 hp engine) depending on the operating capacity factor, and costs decrease for larger turbines like Units 17 and 19 which are approximately 19,500 hp engines.[46] For much larger combustion turbines of 75 MW

generating capacity (~100,500 hp), cost effectiveness of SCR was significantly lower in the range of $560-$850/ton depending on operating capacity factor.[47]

To get an idea of the costs for SCR at Units 17 and 18 in current dollars, one can use EPA's SCR cost spreadsheet made available as part of EPA's Control Cost Manual.[48] While the EPA SCR cost spreadsheet was not specifically designed for simple cycle gas combustion turbines, it can be modified to estimate SCR cost for gas-fired combustion turbines. It seems likely that this EPA cost spreadsheet for boilers will overestimate the cost of SCR for natural gas-fired combustion turbines. This is because gas turbines, particularly those used in power generation, are routinely equipped with SCR systems, and for simple cycle gas turbines, the SCR systems are typically placed in an enclosure attached to the combustion turbine exhaust.[49] Boilers are not as commonly equipped with SCR compared to natural gas combustion turbines, and the SCR placement is more complicated with its placement usually between the economizer and air preheater and upstream of pollution control equipment. This EPA SCR cost spreadsheet is based on cost assumptions from the Integrated Planning Model (IPM) and those costs are, in turn, based on actual SCR retrofit costs for boilers.[50] Because SCR systems are more commonly applied at gas combustion turbines, especially those used in power generation (including simple cycle turbines) and because SCR installation at a simple cycle combustion turbine is often more straightforward than at a boiler, the EPA SCR cost spreadsheet likely overestimates the cost of SCR for a natural gas-fired combustion turbine. Thus, to generate a more current cost estimate of SCR for the natural gas-fired combustion turbines of Units 17 and 18 at the Chaco Gas Plant, EPA's SCR cost spreadsheet was also used to estimate SCR cost effectiveness.

For this analysis, Enterprise's claimed baseline NOx emission rates of 54.7 ppm and 48.7 ppm for Units 17 and 18, respectively, were used. These are assumed to be reflective of ppm by dry volume at 15% oxygen. As previously discussed, NMED should ensure that this 2016 test data reflects operations at maximum operating capacity and ensure that these emission rates are a reasonable projection of NOx emissions as of 2028, especially given that past NOx emission rates have been identified as significantly higher than these NOx rates. The company's actual NOx rates were converted to lb/MMBtu emission rates using a conversion formula from EPA's

[47] *Id.*

[48] While this spreadsheet was not identified to be used with natural gas-fired combustion turbines, as EPA states that its use is for boilers fired by coal, fuel oil, or natural gas with heat input greater than 250 MMBtu/hr or generating capacity greater than or equal to 25 MW, the spreadsheet can be used to estimate SCR capital and operations costs for any fossil fuel-fired unit as long as the necessary input data is available. In fact, it has been utilized by several oil and gas facilities in their four-factor analyses to NMED.

[49] *See*, e.g., Managing the Catalysts of a Combustion Turbine Fleet, Power, April 30, 2012, under 2. Typical simple cycle SCR. Available at https://www.powermag.com/managing-the-catalysts-of-a-combustion-turbine-fleet/.

[50] *See* Sargent & Lundy, IPM Model – Updates to Cost and Performance for APC Technologies, SCR Cost Development Methodology, January 2017, at 1, available at https://www.epa.gov/airmarkets/ipm-v6-emission-control-technologies-attachment-5-3-scr-cost-development-methodology.

1993 Gas Turbine ACT.[51] Enterprise's ppm NOx baseline rates thus were converted to 0.22 lb/MMBtu for Unit 17 and 0.20 lb/MMBtu for Unit 18. With this data, the authors input unit-specific information into EPA's SCR cost spreadsheet to estimate cost effectiveness of SCR at Units 17 and 18, including the altitude of the site listed in the 2007 Title V permit application of 6,020 feet and the exhaust gas temperature of 766 degrees Fahrenheit.[52] Two different SCR control levels were assumed: approximately 70% control to achieve a 15 ppmvd NOx rate and a 90% control efficiency to achieve approximately a 5 ppmvd NOx emission rate. In an analysis of SCR cost effectiveness from an uncontrolled gas turbine, NESCAUM estimated that a 15 ppmvd NOx rate reflective of 90% NOx control (from uncontrolled NOx rates) could be achieved with SCR.[53] As stated above, the 2016 baseline emission rates assumed by Enterprise are much lower than worse case NOx rates, and a 15 ppmvd limit only reflects 70% control across the SCR, when such controls can achieve 90% or greater NOx reduction. Thus, two levels of NOx emission reduction were assumed to reflect a low and a high level of NOx reduction with the SCR. The heat value of the fuel and hourly heat input for Units 17 and 18 identified in Part 3 of Enterprise's 2007 Title V permit application (i.e., 1,245 Btu/standard cubic feet and 181 MMBtu/hr)[54] were assumed to reflect current operations at the units. With Enterprise's 2016 actual annual NOx emissions and its reported ppm NOx emissions and the reported heat value of the fuel, actual annual gas consumption rates were estimated for each unit for input into the SCR cost spreadsheet. Capital costs were annualized applying a cost recovery factor using a 4.7% interest rate and a 25-year life which EPA has identified as typical for SCR systems used at industrial boilers.[55] Last, two different reagent types were evaluated: 29% aqueous ammonia and 50% urea solution. Urea was evaluated due to concerns raised by Enterprise in the use of ammonia as a reagent because, with urea used as a reagent, the concerns from hazards of using pressurized ammonia do not apply. The results of these analyses are provided in Table 1 below.

Table 1. Cost Effectiveness of SCR at Chaco Gas Plant Units 17 and 18 GE Frame 5 Gas Combustion Turbines, Using EPA's SCR Cost Calculation Spreadsheet for Boilers

Unit	Assumed NOx Removal Efficiency with SCR	Capital Cost of SCR (2018 $)	Annual O&M Costs with 29% Ammonia	Annual O&M Costs with Urea	NOx Removed from 2016 Baseline, tpy	Cost Effectiveness of SCR with Ammonia (2018 $), $/ton	Cost Effectiveness of SCR with Urea (2018 $), $/ton
17	72%	$5,725,135	$95,677	$125,129	79	$6,264	$6,638
17	90%	$5,725,135	$100,385	$137,200	98	$5,059	$5,433
18	70%	$5,725,135	$110,586	$144,582	91	$5,591	$5,965
18	90%	$5,725,135	$116,197	$159,905	117	$4,396	$4,771

The cost estimates of SCR based on EPA's boiler SCR cost spreadsheet project costs for SCR that are significantly lower than Enterprise's water or steam injection capital cost estimates, which were projected to range from $6.6 to $8.7 million, as well as the company's annual operating cost estimates, which ranged from $1.2 to $1.8 million per year.[56] Given that SCR can achieve much higher levels of control at much lower costs than water or steam injection, NMED must require Enterprise to more fully evaluate the ability to install SCR at Unit 17 and/or 18. Ninety percent control should be readily achievable with SCR at these units to meet a NOx emission rate of 5 ppmvd (0.02 lb/MMBtu). Before allowing Enterprise to dismiss SCR due to claims that it is not feasible to locate one or more SCR reactors at Units 17 and 18, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at Units 17 and 18, including any potential options for a shared SCR system between Units 17 and 18 if such options exist. SCR can be a very effective method for reducing NOx emissions from the Units 17 and 18 gas turbines and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for Units 17 and 18 at the Chaco Gas Plant.

C. Solar Mars T-15000 Turbines

Units 35, 36, and 37 at the Chaco Gas Plant are 15,000 horsepower natural gas-fired Solar Mars T-15000 combustion turbines that were constructed in 1996.[57] The units each have a NOx emissions limit of 76.2 lb/hr and 333.6 tpy.[58] For these units, Enterprise identified dry low NOx combustors made by the turbine manufacturer ("SoLoNOx") as a viable control technology, but claimed that SCR was not possible for these turbines due to retrofit difficulty; namely, due to the size estimates of the SCR.[59] As previously discussed, there is no question that SCR is

[56] November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 8-1 to 8-3.
[57] Title V Operating Permit P116-R2M1 for Chaco Natural Gas Processing Plant at A7.
[58] *Id.* at A11.
[59] November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 2-4.

technically feasible for natural gas-fired combustion turbines, including those used at compressor stations.

1. SoLoNOx at Units 35, 36, and 37

Enterprise evaluated SoLoNOx for the Solar Mars turbines of Units 35, 36, and 37, stating that it could reduce NOx concentrations down to 15 ppmv which reflects 85-88% NOx reduction efficiency from the 2016 stack test data that Enterprise assumed as baseline emissions.[60] NMED must ensure that the 2016 stack test data reflect actual emissions from the units and expected actual emissions from the units in 2028.

Enterprise's cost estimates for SoLoNOx at Units 35, 36, and 37 are based on vendor quotes from Solar Turbines.[61] Enterprise then determined cost effectiveness of SoLoNOx controls to meet a 15 ppmv NOx emissions rate, using an interest rate of 8.38% and an assumed life of controls of 20 years.[62] As previously discussed, a 4.7% interest rate is more reflective of current and likely near future interest rates. In terms of the life of SoLoNOx controls, the combustors should last the life of a combustion turbine, which is at least 25 years. Thus, to more accurately reflect cost effectiveness for the SoLoNOx controls at Units 35, 36, and 37, Enterprise's cost effectiveness calculations were revised to reflect a 4.7% interest rate and a 25-year life of controls. The revised costs are reflected in Table 2.

Table 2. Revised Cost Effectiveness of SoLoNOx at Units 35, 36, and 37 of the Chaco Gas Plant, to Reflect a 4.7% Interest Rate and a 25 Year Life

Unit	Enterprise's Total Annual Costs of SoLoNOx (at 8.38% Interest and 20-Year Life)	Enterprise's Cost Effectiveness at 8.38% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25-Year Life
35	$715,215	$6,800/ton	$512,744	$4,875/ton
36	$688,967	$6,668/ton	$495,494	$4,796/ton
37	$693,345	$9,434/ton	$498,371	$6,781/ton

Thus, SoLoNOx at Units 35, 36, and 37 should be considered much more cost effective than reflected in Enterprise's cost analysis.

[60] *Id.* at 2-2.
[61] *Id.* at 3-2.
[62] *Id.* at 8-4 through 8-6.

2. SCR at Units 35, 36, and 37

As with Units 17 and 18, Enterprise did not evaluate SCR for Units 35, 36, and 37, claiming it was "not possibly to install these units at the Chaco facility" due to "the amount of buffer space needed to maintain accessibility to equipment and to avoid compromising worker safety."[63] For the reasons discussed above in Section I.B.3, NMED must request more information and documentation before allowing Enterprise to dismiss SCR due to claims that it is not feasible to locate one or more SCR reactors at Units 35, 36, and 37. NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at Units 35, 36, and 37, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions from the Units 35-37 gas turbines and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for Units 35-37 at the Chaco Gas Plant.

There are two options for the evaluation of cost effectiveness of SCR at Units 35, 36 and 37: One is to consider SCR as a control option without SoLoNOx installed. A second option is to consider SoLoNOx plus SCR as the maximum achievable reductions in NOx emissions. As discussed in the NPCA March 2020 Oil and Gas Four-Factor Report, SCR has recently been proposed to be installed at several compressor stations.[64] Once such compressor station is the Buckingham Compressor station to be located in Virginia. That compressor station was proposed to be constructed with Solar Mars combustion turbines equipped with SoLoNOx and SCR to achieve a NOx emission rate of 3.75 ppmv @ 15% oxygen.[65] SCR installed along with the SoLoNOx combustion control could achieve 96 to 97% reduction in NOx emissions from Units 35, 36, and 37. However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as best available control technology (BACT) or Lowest Achievable Emission Rate (LAER) for such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15% oxygen.[66]

To get an idea of the costs for SCR at Units 35, 36, and 37 in more current dollars, we used EPA's SCR cost spreadsheet made available as part of EPA's Control Cost Manual. Two different costs analyses were completed for these comments: 1) SCR plus SoLoNOx to achieve a 3.75 ppmv NOx rate and 2) SCR by itself to achieve 15 ppmv. The costs analyses were based on the

use of a 50% urea solution as the reagent. As shown in Table 1 above, if a 29% aqueous ammonia reagent is used, the cost effectiveness will be lower than if urea is used – thus, these cost estimates reflect a worst case estimate. The company's actual NOx rates and the emission limits evaluated were converted to lb/MMBtu emission rates for input into EPA's SCR spreadsheet using a conversion formula from EPA's 1993 ACT for Gas Turbines.[67] With this data, unit-specific information was input into EPA's SCR cost spreadsheet to estimate cost effectiveness of SCR at Units 35-37, including the altitude of the site listed in the 2007 Title V permit application of 6,020 feet and the exhaust gas temperature of the turbines of 907 degrees Fahrenheit.[68] The heat value of the fuel and hourly heat input for Units 35-37 identified in Part 3 of Enterprise's 2007 Title V permit application (i.e., 900 Btu/standard cubic feet[69] and 91.2 MMBtu/hr)[70] were assumed to reflect current operations at the units. With Enterprise's 2016 actual annual NOx emissions and its reported ppm NOx emissions and the reported heat value of the fuel, actual annual gas consumption rates were estimated for each unit for input into the SCR cost spreadsheet. Capital costs were annualized applying a cost recovery factor using a 4.7% interest rate and a 25-year life which EPA has identified as typical for SCR systems used at industrial boilers.[71] To determine cost effectiveness of SoLoNOx plus SCR, the revised annualized costs of SoLoNOx at a 4.7% interest rate and a 25 year life were added to the costs of SCR to reduce NOx emissions from 15 ppmv to 3.75 ppmv. The results of these analyses are provided in Table 3 below.

Table 3. Cost Effectiveness of SCR Plus SoLoNOx at Chaco Gas Plant Units 35, 36, and 37 Solar Mars T15000 Turbines to Reduce NOx to 3.75 ppmv, Using EPA's SCR Cost Calculation Spreadsheet with Urea Reagent (2018 $)

Unit	Revised Total Annual Costs of SoLoNOx (at 4.7% Interest and 25-Year Life)	Capital Cost of SCR to Reduce NOx from 15 ppmv to 3.75 ppmv	Annual O&M Costs of SCR	Total Annual Costs of SCR	Total Annual Costs of SoLoNOx Plus SCR	NOx Reduced with SoLoNOx and SCR, tpy	Cost Effectiveness of SoLoNOx plus SCR, $/ton
35	$512,744	$3,666,834	$53,222	$308,349	$821,093	115.9	$7,082/ton
36	$495,494	$3,666,834	$53,361	$308,488	$803,982	114.2	$7,039/ton
37	$498,371	$3,666,834	$50,409	$305,536	$803,907	82.8	$9,704/ton

[67] *See* EPA, Alternative Control Techniques Document – NOx Emissions from Stationary Gas Turbines, EPA-453/R-93-007, January 1993, Appendix A which has conversion equations for natural gas-fired combustion turbines.
[68] November 2007 Title V Permit Application for Chaco Gas Plant, Part 3 at pdf page 24.
[69] Note that it is not clear that this reflects the high heating value of the fuel used at Units 35-37, especially given that the heat value of the fuel used at Units 17 and 18 was tested as having a much higher heat value of 1,245 Btu/scf. However, it is the heat value listed in the 2007 Title V permit application as specific to these units, so it is used here.
[70] November 2007 Title V Permit Application for Chaco Gas Plant, Part 3 at pdf page 24.
[71] *See* EPA Control Cost Manual, Section 4, Chapter 2, at pdf page 80.

Table 4. Cost Effectiveness of SCR at Chaco Gas Plant Units 35, 36, and 37 Solar Mars T15000 Turbines to Reduce NOx to 15 ppmv, Using EPA's SCR Cost Calculation Spreadsheet with Urea Reagent (2018 $)

Unit	Capital Cost of SCR	Annual O&M Costs	Total Annualized Costs of SCR	NOx Removed from 2016 Baseline, tpy	Cost Effectiveness of SCR, $/ton
35	$3,666,834	$104,172	$359,298	105.2	$3,416/ton
36	$3,666,834	$103,345	$358,472	103.4	$3,468/ton
37	$3,666,834	$85,814	$340,940	73.5	$4,642/ton

As shown by a comparison of Table 4 to Table 2, the costs of SCR to achieve the same level of NOx reduction as SoLoNOx at Units 35-37 is lower than the cost of SoLoNOx. As previously stated, costs were only provided for urea-based SCR. If aqueous ammonia was used as the reagent, the costs of SCR would be lower.

Clearly, SCR alone appears to be a more cost effective method to reduce NOx emissions from Units 35-37 by 85-88% control compared to SoLoNOx. Further, SCR used in combination with SoLoNOx can achieve the greatest reductions in NOx at these units. Thus, NMED must require further evaluation of the feasibility of installing SCR at Units 35, 36, and 37, including asking Enterprise to obtain vendor analyses of the site and feasibility of SCR retrofits.

D. Units 12, 13, and 14: Clark TLA-10 2-Stroke Lean Burn RICE

Units 12, 13, and 14 are two-stroke lean-burn RICE that were constructed in 1996, each with a capacity of 3,400 hp.[72] The units each have an hourly NOx limit of 49.7 lb/hr and an annual NOx limit of 218 tpy.[73] Enterprise states in its four-factor analysis that the NOx emissions from these units are calculated from stack test data from 4/18/1995.[74] This date seems possibly incorrect, or the permit is incorrect as it identifies the units as being constructed in 1/1/1996. Enterprise further states that the maximum hourly emission rate corresponds to a NOx exhaust concentration of 1,032 ppmv.[75] That is the extent of information provided on the actual NOx emissions from these units. NMED should request more information on the units' current hours of operation and actual NOx emissions.

[75] *Id.*

1. Use of Low Emission Combustion Technology

Enterprise claims that the Clark TLA-10 engines are currently operating with "Clean Burn Technology (CBT)."[76] Yet, the stated maximum hourly NOx rate of 1,032 ppmv does not reflect the levels of NOx emissions typically expected with such low emission combustion (LEC) technology. This NOx concentration is equivalent to 14 grams per horsepower-hour (g/hp-hr).[77] Note, the hourly NOx permit limits for these units of 49.7 lb/hr, corresponding to a NOx limit of 7 g/hp-hr for each 3,400 hp engine.[78] And, in fact, the information provided as part of permit applications for the source, in 2007 and in 2016, indicate that these three units were initially retrofitted with the Controlled Rapid Burn (CRB™) systems from Diesel Supply Company, guaranteeing NOx emission rates of 7 g/hp-hr.[79] But even this controlled NOx emission level does not reflect the levels of NO_x emissions achievable with LEC technology. In order to effectively evaluate a company's assessment of LEC, a more precise definition of LEC technologies and associated achievable emission rates is needed.

EPA has examined source test data from large natural gas-fired lean burn engines and has affirmed that these data support an uncontrolled emission rate from these engines, generally, of 16.8 g/hp-hr.[80] More specifically, these source test data include individual data for three Clark TLA-10 engines with uncontrolled emission rates of 16 g/hp-hr and two Clark TLA-10 engines with uncontrolled emission rates of 7 g/hp-hr.[81] Even the permitted NOx limit of 7 g/hp-hr for the engines at the Chaco Gas Plant could therefore reflect an uncontrolled emission rate, although it appears these engines were retrofit with certain combustion modifications to reduce NOx emissions by 50% (i.e., CRB™ technology to reduce NOx emissions from 14 g/hp-hr to 7 g/hp-hr). Controlled NOx emission rates with LEC are typically much lower. NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable

[76] *Id.* at 2-7.
[77] Using the following EPA conversion factors for uncontrolled lean burn engines (73 ppmv = 1 g/bhp-hr) and lean-burn engines controlled with LEC technology (73 ppmv = 1 g/bhp-hr), NOx emission rates would be 13.8 g/bhp-hr (assuming LEC control) or 14.1 g/bhp-hr (uncontrolled). *See* EPA-457/R-00-001 *Stationary Reciprocating Internal Combustion Engines Updated Information on NOx Emissions and Control Techniques,* September 2000, p. 2-1, *available at*: https://nepis.epa.gov/Exe/ZyPDF.cgi/P100V343.PDF?Dockey=P100V343.PDF [hereinafter referred to as "EPA 2000 RICE Update"]. NOTE: this emission rate of 14 g/hp-hr appears to represent the uncontrolled emission rate, prior to retrofits to the units that reduced NOx emission by 50% and reflected in the permitted 49.7 lb/hr limit for these 3,400 hp engines (14 g/hp-hr * 3,400 hp / 453.6 g/lb = 100 lb/hr; 7 g/hp-hr * 3,400 hp / 453.6 g/lb = 50 lb/hr).

[81] *Id*. at 6 and 7.

with LEC technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).[82]

For reference, the following additional sources of information regarding NOx emission rates specific to Clark TLA model engines – both uncontrolled and with LEC technology – are provided here:

- EPA's 2000 RICE Update includes NOx emissions test data for specific engines, including Clark Model TLA-6, 2-stroke, lean-burn, 2,000 hp RICE retrofitted with LEC. According to EPA, six engines retrofitted by a third-party vendor had NOx emission rates ranging from 0.8–1.4 g/bhp-hr, with a mean of 1.0 g/bhp-hr.[83]

- An evaluation by a technical group for the Pipeline Research Council International looked at three of the most representative make / models of 2-stroke lean-burn compressor engines: (1) 2,250 hp Cooper GMVH-10; (2) 2,000 hp Clark TLA-6; and (3) 2,500 hp Cooper GMW-10. According to a technical report by the Ozone Transport Commission (OTC) describing this evaluation, "[t]he evaluation concluded that there were no technology gaps and that each of the three makes/models evaluated were capable of attaining a NOx emissions limitation of 0.5 g/bhp-hr using a combination of improvements and retrofits related to air supply, fuel supply, ignition, electronic controls, and engine monitoring."[84]

- In 2002, EPA collected data on emission rates of lean burn engines that have been retrofitted with LEC, including data from several state agencies for specific engine models.[85] Test results for 20 Clark TLA engines ranged from 0.4 to 2.9 g/hp-hr, with an average controlled NOx rate of 1.5 g/hp-hr.[86]

More generally, the 2012 OTC Report suggests that, "combustion related modifications have the potential to achieve from 60% to 90% reduction in NOx emissions [or, "an approximate range of NOx emissions rate of 3.0 g/bhp-hr to 0.5 b/bhp-hr"] from two-stroke lean-burn spark ignited reciprocating engines, depending upon the make/model configuration of the engine." Specifically, the 2012 OTC Report discusses the use of "layered combustion controls"

[82] March 6, 2020 NPCA Oil and Gas Four-Factor Report at 28.
[83] EPA 2000 RICE Update at 4-8.
[84] Ozone Transport Commission, Technical Information, Oil and Gas Sector, Significant Stationary Sources of NOx Emissions, Final, October 17, 2012, p. 24, *available at*: https://otcair.org/upload/Documents/Meeting%20Materials/Final%20Oil%20%20Gas%20Sector%20TSD%2010-17-12.pdf [hereinafter referred to as "2012 OTC Report"].

[86] *Id.* Table 4.

in order to achieve emission rates at the lower end of this range, that include: improved airflow, improved fuel-air mixing, improved ignition, and upgraded controls.[87] According to the 2012 OTC Report, the higher emission rates in this range would tend to be more representative of situations where layered combustion controls packages have not been commercialized.[88]

More recently, EPA describes layered combustion (LC) as demonstrated control techniques for 2-stroke lean-burn engines, achieving a NOx emission rate of 0.5 g/hp-hr.[89] Specifically, EPA described LC as consisting of multiple combustion modifications, including: (1) high pressure fuel injection; (2) turbocharging; (3) a precombustion chamber; and (4) cylinder head modifications.[90]

Also, recently, EPA described LEC retrofit kits designed to achieve extremely lean air-to-fuel ratios – in order to minimize NOx emissions – as encompassing the following similar retrofit technologies:

- Redesign of cylinder head and pistons to improve mixing (on smaller engines)
- Precombustion chamber (on larger engines)
- Turbocharger
- High energy ignition system
- Aftercooler
- Air-to-fuel ration controller (AFRC)[91]

It is not entirely clear what specific combustion and LEC technologies are employed for the Clark TLA-10 engines at the Chaco Gas Plant. Enterprise states that these engines are currently operating with "Clean Burn Technology" and discusses that to generally mean the use of high energy ignition system, turbocharger, and AFRC technologies.[92] The Controlled Rapid Burn (CRB™) retrofit kits originally installed on Units 12–14 appear to include pre-chambers and high

[92] November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 2-7.

flow fuel valves.[93] However, the controls at these units are not achieving NOx emission levels commensurate with LEC.

EPA noted, in its 2000 Updated Information on NOx Emissions and Control Techniques for RICE, that "CleanBurn" is a trademark of Cooper Energy Systems, and that industry comments on its draft AP-42 emission factors for stationary internal combustion engines objected to a "clean burn" designation for that reason.[94] EPA's 1997 draft AP-42 section for stationary internal combustion sources defined "clean burn" engines as separate engine families (*i.e.*, distinct from other 2-stroke and 4-stroke lean-burn engines), equipped with "LEC precombustion chamber technology" and identified the following NOx emission factors for these distinct LEC-equipped "engine families":

> (1) 1.1 g/bhp-hr (2-stroke clean-burn engines); and
>
> (2) 0.5 g/bhp-hr (4-stroke clean-burn engines).[95]

EPA's 2000 RICE Update notes that, "[t]oday, many engine manufacturers refer to their engines equipped with precombustion chambers simply as "lean-burn engines"."[96] And EPA's final AP-42 section on natural gas-fired reciprocating engines clarified the term, as follows:

> Some lean-burn engines are characterized as clean-burn engines. The term "clean-burn" technology is a registered trademark of Cooper Energy Systems and refers to engines designed to reduce NOx by operating at high air-to-fuel ratios.[97]

A recent Interstate Natural Gas Association of America (INGAA) Report provides some information on Clark TLA engine stock components and retrofit modification / upgrade options.[98] Examples from this report include: upgrading stock turbocharger and stock intercooler systems; upgrading stock low pressure direct fuel systems to high pressure fuel injection and control systems; and upgrading controls for the stock fuel system.[99] Based on the

[98] INGAA, Report No. 2016-6, *Potential Impacts of the Ozone and Particulate Matter NAAQS on Retrofit NOx Control for Natural Gas Transmission and Storage Compressor Drivers* (December 2017), *available at:* https://www.ingaa.org/File.aspx?id=33789.
[99] *Id. See, e.g.,* Table 6 at 18.

information in this report, Clark TLA model engines come equipped with a single turbo, an intercooler system, and a low pressure direct fuel system. The INGAA report evaluated controls for various regulatory scenarios that would achieve NOx emission levels in the 1–3 g/hp-hr range.[100]

LEC retrofit costs specific to Clark TLA model engines are reported in the INGAA report, ranging from $300–$600 per hp, for upgrades to the scavenging, intercooler, and fuel systems.[101] The INGAA report doesn't specify what year the cost data are from so we assume it reflects the timeframe of the report, or 2017$. Using these cost data, we can estimate the cost effectiveness of retrofitting Units 12, 13, and 14 at the Chaco Gas Plant. Retrofit costs for each 3,400 hp unit using INGAA's cost data would range from $1.02–$2.04 million, in 2017$. Using the Chemical Engineering Plant Cost Indices, these costs could increase to $1.08–$2.17 million, in 2018$.[102] It's not clear if operating costs are included in these estimates; to be conservative, annual operating costs of the LEC controls are assumed to be 15% of capital costs.[103]

The cost effectiveness of retrofitting these engines with LEC to meet a 2 g/hp-hr NOx emissions rate, based on the units' uncontrolled emission rate, is presented in the table below. The original retrofits to these units resulted in controlled NOx emission rates of 7 g/hp-hr possibly employing some of the upgrades associated with LEC. This analysis shows the cost effectiveness of an LEC retrofit that can achieve an emission level between 1–3 g/hp-hr based on current technologies and costs. The operating schedule for these engines at the Chaco Gas Plant is unknown but we present cost effectiveness for 8,000 operating hours per year since annual facility NOx emissions indicate that the units operated near capacity in 2016.[104] Note, this analysis uses an interest rate of 4.7%, reflective of current and likely near future interest rates.[105] Further note, the LEC controls are assumed to last 25 years, consistent with other cost effectiveness analyses submitted to NMED for LEC controls.[106]

[100] *Id.* at 23.
[101] *Id.*
[102] Based on multiplying the cost estimate from the 2017 INGAA report by the ratio of the CEPCI indices for 2018 to 2017 (603.1/567.5).
[103] This assumption is consistent with cost data provided for the October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9, however it results in much higher O&M costs than those used in Targa's (Eunice, Monument, and Saunders Gas Plants) and Harvest Four Corners' (Kutz Canyon Gas Plant) four-factor analyses—which ranged from $40,000/yr to $100,000/yr—and than those used for ETC Texas Pipeline's Jal No. 3 Gas Plant, which assumed O&M costs would be 13% of capital costs.
[104] *See* NMED's Emissions Analysis tool, which reports 2016 NOx emissions of 2,258.9 tons per year, compared to total annual NOx PTE for the units evaluated in Enterprise's four-factor analysis for the Chaco Gas Plant of 2,342.8 tons per year (*see* Table 1 of the November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 1-1).
[105] As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.
[106] *See* 2019 Four-Factor Analyses for Roswell Compressor No. 9 and Jal No. 3..

Table 5. Cost Effectiveness of LEC at Uncontrolled Chaco Gas Plant Units 12, 13, and 14 to Reduce NO_x Levels to 2 g/hp-hr, Assuming a 4.7% Interest Rate and a 25-Year Life, 2018 $

Unit	Capital Cost of LEC to Reduce NOx from the Uncontrolled rate of 14 g/hp-hr	Annual O&M Costs (assume 15% of Capital Costs)	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (~85% NOx Reduction)	NOx Removed, tpy operating 8,000 hr/yr	Cost Effectiveness of LEC operating 8,000 hr/yr, $/ton
12	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	360	$659/ton–$1,319/ton
13	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	360	$659/ton–$1,319/ton
14	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	350	$659/ton–$1,319/ton

LEC at Units 12, 13, and 14 would be even more cost effective than what is shown if retrofits at these engines could meet even lower NOx emission levels, less than 2 g/hp-hr. Note, an analysis of individual upgrades at the units at the Chaco Gas Plant is not possible without knowing which specific LEC technologies are already employed to meet the permitted emission rate of 7 g/hp-hr and which additional possible upgrades could be installed to achieve even greater emissions reductions. NMED must ask for a list of specific LEC technologies employed at Units 12–14 and an evaluation of additional applicable LEC technologies for these units. NMED should require additional LEC retrofit techniques be evaluated in order to assess the cost effectiveness of further reducing NOx emissions from these engines to a level more in line with current LEC technology – i.e., emission levels in the 0.5–2 g/hp-hr range.

2. Use of SCR.

Enterprise did not evaluate SCR for Units 12, 13, and 14, primarily because it claimed that it was not possible to install SCR at these units due to space limitations.[107] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at Units 12, 13, and 14, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for Units 12-14

[107] November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 2-6.

at the Chaco Gas Plant, particularly because Enterprise has not evaluated any other NOx reduction strategy for these units.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[108]

If Clean Burn or other low emissions technology is not a viable or cost-effective control for lean burn engines, SCR could possibly be a more cost-effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[109] In Section XX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[110] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

II. DCP Midstream – Eunice Gas Plant

The DCP Midstream Eunice Gas Plant is a natural gas processing plant located in Lea County, New Mexico. A NMED Statement of Basis for the plant's Title V permit describes the plant as follows: "The Eunice plant consists of an Inlet Receiving System, Amine Treater, Sulfur Recovery Plant, Inlet Compression, Dehydration, Cryogenic/Turbo Expansion Plant with External Propane Refrigeration, and product sales for Residue Gas, NGLs, and Condensate. Supporting systems and operations at the plant include Fuel Gas Systems, Instrument and Starting Air Systems, a Heat Medium (Hot Oil) System, Cooling Towers, Process Flare, Acid Gas Flare, and Drain Systems. Processing operations at the plant include chemical reaction processes, thermodynamic processes, and physical processes."[111] The plant separates heavier hydrocarbons that can be condensed into liquids (called "Natural gas liquids or NGLs" and removes impurities from the natural gas such as water, hydrogen sulfide (H2S) gas, and carbon dioxide gas.[112]

[108] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[109] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.
[110] Available at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution.
[111] NMED Statement of Basis – Narrative, Title V Permit, for Permit Nos. 0044-M-10-M10R6 and P086-R3, at 1.
[112] *Id.*

According to the permit, the plant includes several four-stroke lean-burn RICE, several natural gas-fired turbines, boilers, a heater, gas sweetening equipment (amine unit, sulfur recovery unit (SRU) incinerator, acid gas and SRU flares), and other emission units.[113] In DCP Midstream's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Solar Centaur Turbines: Units 17A, 18B, 19A, 25A, and 26A
- Amine Unit controlled by SRU Incinerator: Unit 31
- Startup, Shutdown, Malfunction (SSM).[114]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[115] The following provides a review of the company's four-factor analyses for the turbines. The analysis for the amine unit and SSM emissions is addressed in Section XXIII. below.

A. Interest Rate Used in Cost Analyses.

DCP Midstream used a 5.5% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[116] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. This is the same interest rate that EPA has used in its cost spreadsheet for SCR, but EPA also states that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[117] The current bank prime rate is 3.25%.[118] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[119] In a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[120] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable

progress controls. For these reasons, in the cost effectiveness calculations provided herein, a 4.7% interest rate is used rather than a 5.5% interest rate.

B. Solar Centaur Natural Gas-Fired Combustion Turbines (Units 17A, 18B, 19A, 25A, and 26A).

The combustion turbines evaluated at the Eunice Gas Plant are Solar combustion turbines, model T-4002 of 3329 hp capacity (Units 17A, 25A, and 26A) and model T-4502 (Units 18B and 19A) of 3372 hp capacity.[121] These units were constructed between 1974 and 1986.[122] Units 18A and 19A are subject to a NOx emission limit of 165.85 ppmv at 15% O_2 and Units 25A and 26A are subject to a NOx limit of 158.76 ppmv at 15% O_2, pursuant to 40 C.F.R. Part 60, Subpart GG.[123] Under the terms of the permit, the units are also subject to the following hourly and annual emission limits of NOx.

Table 6. Limits from DCP Midstream Title V Permit for the Eunice Gas Plant Combustion Turbines[124]

Combustion Turbine Unit ID	NOx limit, lb/hr	NOx limit, tpy
17A	18.5	81.0
18B	23.0	100.9
19A	23.0	100.9
25A	18.5	81
26A	18.5	81

DCP Midstream evaluated two control options for these combustion turbines: Solar's SoLoNOx combustion system and SCR.

1. Baseline Emissions for Units 17A, 18B, 19A, 25A, and 26A.

DCP Midstream did not provide any specific data on actual emissions for the Solar Centaur combustion turbines in its four-factor analysis of controls. The company did state that its cost effectiveness analyses for SoLoNOx and SCR were based on 2016 turbine operating hours multiplied by the permitted potential to emit rate (lb/hr).[125] However, the company did not provide the operating hours or this calculation of 2016 emissions in its four-factor analysis. The company also provided analyses of cost effectiveness of controls "[u]sing the actual emissions testing data (NSPS KKKK) for these turbines, rather than [potential to emit]."[126] Yet, the company provided no data in its four-factor analyses as to what the actual emission testing results were. Further confusing the matter is that, based on a review of the permit, the turbines are not subject to NSPS KKKK. Instead, all of the units except Unit 17A are subject to

[121] Title V Operating Permit P086-R3 for DCP Eunice Gas Plant at A6 to A7.
[122] *Id.*
[123] *Id.* at A10.
[124] *Id.* at A9.
[125] November 2019 Regional Haze Four-Factor Analysis for DCP Midstream Eunice Gas Plant at 3-10, fn 13.
[126] *Id.*

NSPS Subpart GG, and the Title V permit does not identify Unit 17A as subject to either NSPS Subpart GG or Subpart KKKK.[127] A review of Title V permit application data for the Eunice Gas Plant on the NMED's Emissions Analysis Tool did not find any other emissions testing data available for these units.[128]

NMED must make available whatever test data is being relied on to reflect actual emissions of these five combustion turbines if NMED intends to rely on the cost effectiveness analyses provided in a footnote of DCP Midstream's four-factor analysis. NMED should present information on the test data so the circumstances of the stack tests can be reviewed. According to DCP Midstream's four-factor analysis, its 2016 emission inventory is based on its actual operating hours multiplied by its hourly NOx emission limit.[129] Given that this is how DCP Midstream reports actual emissions for the combustion turbines to NMED and in the absence of testing documentation to ensure that the test data DCP relies on for its alternative baseline analysis reflects actual emissions at all levels of operation of the combustion turbines, it seems most appropriate to use the data that DCP has been using for its emission inventory. NMED should require that DCP identify the operating hours of each unit that it has assumed for the combustion turbines.

2. Evaluation of SoLoNOx for Turbines at Units 17A, 18B, 19A, 25A, and 26A.

DCP Midstream states that SoLoNOx can achieve an "overall reduction efficiency of 70-80%...for the turbines located at this facility using this technology in comparison to permitted [potential to emit]."[130] NMED should request that DCP Midstream identify the NOx rate that Solar Turbines guarantees for each of the five turbines at Eunice Gas Plant. Specifying a NOx emission rate that can be met with SoLoNOx also would provide for a clear benchmark for comparison to SCR.

Based on assuming 70 to 80% reduction with SoLoNOx from the permitted ppmv NOx emission limits, it appears that DCP Midstream evaluated SoLoNOx to achieve NOx emission rates in the range of 31 ppmv to 50 pppmv at 15% O_2 at Units 17A, 18B, 19A, 25A, and 26A.[131] These seem like high emission rates expected with SoLoNOx, based on a review of emission limit data for combustion turbines in the EPA's RACT/BACT/LAER Clearinghouse which indicates SoLoNOx limits in the range of 15-25 ppmv. As another comparison, Enterprise evaluated SoLoNOx for the Solar Mars turbines at the Chaco Gas Plant and stated that SoLoNOx could reduce NOx concentrations down to 15 ppmv. Although Section 8.0 of DCP Midstream's four-factor analysis

[127] Title V Operating Permit P086-R3 for DCP Eunice Gas Plant at A5, Table 103.A.
[128] While Section 8.0 of the four-factor analysis for the Eunice Gas Plant has specific baseline NOx emission rates for the Linam Ranch Gas Plant combustion turbines, it does not have baseline NOx rates for the Eunice Gas Plant combustion turbines.
[129] *Id.* at 3-11.
[130] *Id.* at 2-4.
[131] This range of controlled ppmv NOx emission rates is based on assuming 70 to 80% reduction from the 158.76 ppmv NOx emission limit that Units 17A, 25A, and 26A and from the 165.85 ppmv NOx limit that Units 18B and 19A are subject to.

has cost data sheets for SoLoNOx indicating a NOx guarantee from Solar of 15 ppm, those cost data sheets pertain to the Linam Ranch Gas Plant rather than for the combustion turbines at the Eunice Gas Plant. For these reasons as well as completeness of the four-factor analysis of emissions controls for these units, NMED must collect more specific information on the NOx emission rates that DCP Midstream used in its SoLoNOx cost effectiveness analysis for the combustion turbines.

In terms of the life of SoLoNOx controls in the cost effectiveness analyses, DCP's analysis assumed a 20-year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[132] In the table below, we revised DCP Midstream's cost effectiveness analyses of SoLoNOx to take into account a longer lifetime of controls and a lower 4.7% interest rate.

Table 7. Revised Cost Effectiveness of SoLoNOx at Units 17A, 18B, 19A, 25A, and 26A of the DCP Midstream Eunice Gas Plant

Unit	DCP's Total Annual Costs of SoLoNOx (at 5.5% Interest and 20-Year Life)	DCP's Cost Effectiveness at 5.5% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25-Year Life
17A	$264,731	$4,909/ton	$244,277	$4,530/ton
18B	$264,154	$3,578/ton	$243,700	$3,301/ton
19A	$264,154	$3,618/ton	$243,700	$3,338/ton
25A	$264,731	$5,186/ton	$244,277	$4,785/ton
26A	$264,731	$6,005/ton	$244,277	$5,542/ton

Thus, the cost effectiveness of SoLoNOx at Units 17A, 18B, 19A, 25A, and 26A are in the range of $3,300/ton to $5,542/ton to achieve 70-80% NOx reduction. However, if SoLoNOx can achieve 15-25 ppmv NOx emission rates at these units as has been permitted for other Solar turbine units with SoLoNOx, and as has been proposed in several four-factor analyses before NMED, then the NOx removal expected with SoLoNOx would be 84 to 91% and the controls would be even more cost effective than shown in the above table. The table below provides an estimate of the cost effectiveness of SoLoNOx if the controls could achieve 25 ppmv (~85% control) and 15 ppmv (~90% control).

[132] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.

Table 8. Estimated Cost Effectiveness of SoLoNOx at Units 17A, 18B, 19A, 25A, and 26A of the DCP Midstream Eunice Gas Plant to Meet 25 ppmv NOx Rates and to Meet 15 ppmv NOx Rates.

Unit	Revised Total Annual Costs of SoLoNOx	Estimated NOx Reduced to Achieve 25 ppmv NOx Rate (~85% Reduction), tpy	Estimated NOx Reduced to Achieve 55 ppmv NOx Rate (~90% Reduction), tpy	Cost Effectiveness to Meet 15 to 25 ppmv NOx limit, $/ton
17A	$244,277	68.8	72.9	$3,352 - $3,549/ton
18B	$243,700	85.7	90.8	$2,684 - $2,842/ton
19A	$243,700	84.8	89.8	$2,714 - $2,874/ton
25A	$244,277	65.2	69.0	$3,541 - $3,749/ton
26A	$244,277	56.3	59.6	$4,100 - $4,341/ton

If SoLoNOx at Units 17A, 18B, 19A, 25A, and 26A of the DCP Midstream Eunice Gas Plant could meet more typical NOx limits with SoLoNOx of 15-25 ppmv, then the SoLoNOx controls would be even more cost effective than shown in DCP Midstream's four-factor analysis.

3. Evaluation of SCR for Units 17A, 18B, 19A, 25A, and 26A of the DCP Midstream Eunice Gas Plant.

Unlike Enterprise in its four-factor analysis of controls for the combustion turbines at the Chaco Gas Plant, DCP Midstream evaluated SCR as a technically feasible control option for the Solar Centaur gas combustion turbines of Units 17A, 18B, 19A, 25A, and 26A of the DCP Midstream Eunice Gas Plant. DCP Midstream used EPA's SCR cost spreadsheet made available with EPA's Control Cost Manual.[133] While the company presented printouts of the EPA SCR cost spreadsheet in Section 8.0 of its four-factor analysis, the printouts appear to be for the Linam Ranch Gas Plant and not the Eunice Gas Plant. NMED should request a printout of the pages of the SCR cost spreadsheet for Units 17A, 18B, 19A, 25A, and 26A of the Eunice Gas Plant so the inputs to the spreadsheet can be reviewed.

DCP Midstream only assumed 70% control could be achieved with SCR at Units 17A, 18B, 19A, 25A, and 26A, even though the company indicated that SCR could achieve up to 90% control.[134] As presented NPCA's Oil and Gas Four-Factor Report, NESCAUM assumed 90% control with SCR in its 2000 Status Report to control small gas turbines down to 15 ppmv.[135] Analyses of EPA's SCR cost spreadsheet for combustion turbines of similar size to Units 17A, 18B, 19A, 25A, and 26A shows that the spreadsheet's calculation of capital cost does not vary based on the NOx control efficiency assumed for the SCR, but that the direct operational expenses increase by

[133] November 2019 Regional Haze Four-Factor Analysis for DCP Midstream Eunice Gas Plant at 3-11.
[134] *Id.* at 2-6.
[135] NPCA March 2020 Oil and Gas Four-Factor Report at 74-75. *See also* NESCAUM, December 2000, Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, Internal Combustion Engines, Technologies & Cost Effectiveness at III-21 through III-24 and at III-40 (see referenced 11, 16, 9, 14, and 15), available at http://www.nescaum.org/documents/nox-2000.pdf/view.

about 17.7%. Using this assumption, we revised DCP Midstream's SCR cost estimate to reflect the costs to achieve 90% NOx reduction, reflective of approximately a 15 ppmv NOx emission rate, along with using a longer life of the SCR of 25-years[136] and a 4.7% interest rate (instead of DCP's assumed 20-year life of SCR and 5.5% interest rate). The table below provides an estimated cost effectiveness of SCR to achieve 90% control at Units 17A, 18B, 19A, 25A, and 26A of the DCP Midstream Eunice Gas Plant.

Table 9. Estimated Cost Effectiveness of SCR to Achieve 90% Reduction (~15 ppmv NOx Rate) at Units 17A, 18B, 19A, 25A, and 26A (at 4.7% interest rate and 25-year life)

Eunice Gas Plant Unit #	DCP's Capital Cost of SCR	DCP's Annual Operational Costs of SCR[137]	Estimate of Revised DCP Annual Operational Costs of SCR to Reflect 90% Control[138]	Revised Annual Cost of SCR to Achieve 90% Control	NOx Emission Reductions at 90% Control, tpy	Cost Effectiveness of SCR to Achieve 90% Control
17A	$1,500,000	$149,435	$136,663	$239,914	72.87	$3,292/ton
18B	$1,500,000	$148,858	$138,195	$241,446	90.78	$2,660/ton
19A	$1,500,000	$148,858	$137,979	$241,230	89.79	$2,686/ton
25A	$1,500,000	$149,435	$135,696	$238,947	68.99	$3,463/ton
26A	$1,500,000	$149,435	$123,938	$227,189	59.58	$3,813/ton

A comparison of Table 9 to Tables 7 and 8 above shows that SCR at the Eunice Gas Plant Units 17A, 18B, 19A, 25A, and 26A is actually more cost effective than SoLoNOx at DCP's assumed 70-80% control or even assuming SoLoNOx can achieve 15 ppmv. SCR could be even more cost effective if there are opportunities to share an SCR between two or more combustion turbines. Moreover, SCR combined with SoLoNOx, which is commonly required to meet BACT for gas turbines, could reduce NOx by 97% or more. As discussed in Section I.C.2 of this report, this combination of NOx controls has been permitted for the Buckingham Compressor Station to achieve a NOx emission rates of 3.75 ppmv @ 15% oxygen.[139] However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as BACT or LAER for such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15%

[136] EPA's Control Cost Manual indicates that SCR at industrial units has a life of 25-years. *See* EPA Control Cost Manual, Section 4, Chapter 2, at pdf page 80.
[137] This was calculated from DCP Midstream's Total Annual Cost of SCR by subtracting the product of DCP's capital cost of SCR and a cost recovery factor reflective of DCP's assumed 5.5% interest rate and 20-year life.
[138] Estimated by multiplying DCP's annual operational costs of SCR by a factor of 1.177.
[139] See January 9, 2019 Registration No. 21599, available at: https://www.deq.virginia.gov/Portals/0/DEQ/Air/BuckinghamCompressorStation/21599_Signed_Permit.pdf. Note that this permit was recently vacated by the Courts, see https://www.cbs19news.com/story/41533113/permit-forbuckingham-county-compressor-station-vacated.

oxygen.[140] NMED should require DCP Midstream to evaluate the cost effectiveness of the combination of SoLoNOx and SCR to achieve the greatest level of NOx reduction.

III. IACX Roswell – Bitter Lake Compressor Station

The IACX Roswell, LLC Bitter Lake Compressor Station is located 13 miles northeast of Roswell, New Mexico and identified by NMED as contributing to regional haze at the Salt Creek WA Class I area.[141] NMED has described the facility processes as follows:

> The function of the facility is to compress and dehydrate field natural gas for transport in underground pipelines, to extract natural gas liquids, and to recover helium.[142]

According to the permit, the plant includes two Cooper-Bessemer 2-stroke lean-burn RICE, a glycol dehydrator with two associated reboilers, a refrigeration unit, and three tanks.[143] In IACX's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Cooper-Bessemer 2SLB RICE GMVH-10C: Units C-891 and C-893.[144]

The selection of these two engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[145] The following provides a review of the company's four-factor analyses.

A. Units C-891 and C-893: Cooper-Bessemer GMVH-10C 2-Stroke Lean Burn RICE

Units C-891 and C-893 are two-stroke lean-burn RICE that were constructed in the 1980s, each with a capacity of 2,250 hp.[146] The units each have an hourly NOx limit of 20 lb/hr and an annual NOx limit of 87.6 tpy.[147] That is the extent of information provided on the actual NOx emissions from these units. NMED should request more information on the units' current hours of operation and actual NOx emissions.

[147] *Id.* at A8.

1. Use of Low Emission Combustion Technology

IACX claims that the Cooper-Bessemer GMVH-10C engines are currently operating with turbochargers and efficient combustion air intercoolers and describes these as "Clean Burn Technology (CBT)."[148] And IACX states that, "[b]ased on manufacturer guidance, the addition of these clean burn technologies allows the engines to range from 1.74 to 3.04 g/hp-hr, which allows for 25% to 57% reduction in NOx emissions; thus, no further assessment of these control practices is included in this report."[149] Yet, the permitted maximum hourly NOx emission rate of 20 lb/hr does not reflect the levels of NOx emissions claimed by IACX in its four-factor analysis. This hourly NOx emission rate is equivalent to 4 g/hp-hr for a 2,250 hp engine. A recent permit application supplied an uncontrolled NOx emission rate of 4 g/hp-hr, based on "engine manufacturer data."[150] This NOx emission level does not reflect the levels of NOx emissions achievable with LEC technology. In order to effectively evaluate a company's assessment of LEC a more precise definition of LEC technologies, and associated achievable emission rates, is needed.

NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable with LEC technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).

For reference, the following additional sources of information regarding NOx emission rates specific to Cooper-Bessemer GMV model engines – both uncontrolled and with LEC technology – are provided here:

- EPA's 2000 RICE Update includes NOx emissions test data for specific engines, including Cooper-Bessemer GMV-10C, 2-stroke, lean-burn, 1,100 hp RICE retrofitted with LEC. Tested at 0.61 g/bhp-hr.[151]

- An evaluation by a technical group for the Pipeline Research Council International looked at three of the most representative make / models of 2-stroke lean-burn compressor engines: (1) 2,250 hp Cooper GMVH-10; (2) 2,000 hp Clark TLA-6; and (3) 2,500 hp Cooper GMW-10. According to a technical report by the OTC describing this evaluation, "[t]he evaluation concluded that there were no technology gaps and that each of the three makes/models evaluated were capable of attaining a NOx emissions limitation of 0.5 g/bhp-hr using a combination of improvements and retrofits related to air supply, fuel supply, ignition, electronic controls, and engine monitoring."[152]

[148] November 2019 Regional Haze Four-Factor Analysis for IACX Roswell, LLC Bitter Lake Compressor Station at 7.
[149] *Id.*
[150] Bitter Lake Compressor Station permit application P047R3 (8/17/2016) Section 6, Page 2.
[151] EPA 2000 RICE Update at 4-8.
[152] Ozone Transport Commission, Technical Information, Oil and Gas Sector, Significant Stationary Sources of NOx Emissions, Final, October 17, 2012, p. 24, *available at*: https://otcair.org/upload/Documents/Meeting%20Materials/Final%20Oil%20%20Gas%20Sector%20TSD%2010-17-12.pdf [hereinafter referred to as "2012 OTC Report"].

EPA describes LEC retrofit kits designed to achieve extremely lean air-to-fuel ratios – in order to minimize NOx emissions – as encompassing the following retrofit technologies:

- Redesign of cylinder head and pistons to improve mixing (on smaller engines)
- Precombustion chamber (on larger engines)
- Turbocharger
- High energy ignition system
- Aftercooler
- Air-to-fuel ration controller (AFRC)[153]

So, in addition to the turbochargers and upgraded intercooler systems already employed at these Cooper-Bessemer engines, NMED should request that the company evaluate the cost effectiveness of retrofitting these engines with additional LEC technologies – e.g., precombustion chambers, high energy ignition systems, AFRCs, etc. – to further reduce NOx emissions from these engines– e.g., to achieve emission levels as low as 0.5 g/hp-hr. Without data on actual NOx emissions from these engines it's not possible to know if, in fact, the current "clean burn technologies" employed at these units are achieving the emission levels of 1.74 to 3.04 g/hp-hr (that are based on manufacturer guidance) identified in the company's four-factor analysis. NMED should ask for test data reflective of actual operations at maximum operating capacity and ensure that these emission rates are a reasonable projection of NOx emissions in 2028.

2. Use of SCR

IACX did not evaluate SCR for Units C-891 and C-893, primarily because it claimed that the two engines run on ongoing variable loads and an SCR system may not function effectively at variable loads.[154] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines, particularly if it could achieve greater NOx emissions reductions from these units cost effectively.

[153] EPA, Final Technical Support Document for the Cross-State Air Pollution Rule for the 2008 Ozone NAAQS, Docket ID EPA-HQ-OAR-2015-0500-0508, Assessment of Non-EGU NOx Emission Controls, Cost of Controls, and Time for Compliance, August 2016, Appendix A at 5-3, *available at:* https://www.regulations.gov/document?D=EPA-HQ-OAR-2015-0500-0508 [hereinafter referred to as "2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls"].
November 2019 Regional Haze Four-Factor Analysis for IACX Roswell, LLC Bitter Lake Compressor Station at 7.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[155]

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[156] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[157] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

IV. Targa Eunice Gas Processing Plant

The Targa Midstream Services, LLC Eunice Gas Plant is a natural gas processing plant identified by NMED as potentially contributing to regional haze at the Carlsbad Caverns National Park Class I area.[158] NMED has described the facility processes as follows:

> The function of the facility is to receive field natural gas, perform dehydration and removal of carbon dioxide and hydrogen sulfide, and separate natural gas liquids (NGL). The products (natural gas and NGL) are compressed or pumped to sales pipelines for distribution.[159]

According to the permit, the plant includes 21 reciprocating internal combustion engines (RICE), two boilers, an amine still, three electric compressors, backup diesel generators, flares, glycol dehydrator sources, heaters, and storage tanks.[160] In Targa's four-factor submittal, the company evaluated air pollution controls for the following emission units:

- Clark 2SLB RICE BA-8: Units C-01, C-02, C-03, C-04, C-05, C-06, C-07, C-09

[155] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[156] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.
[157] Available at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution.
[158] November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant at 1-1.
[159] Title V Operating Permit P109-R3 for Eunice Gas Processing Plant at A3.
[160] *Id.* at A7-A9.

- Clark 2SLB RICE HBA-8: Units C-10, C-11, C-12
- Clark 2SLB RICE HBA-T8: Unit C-13
- Wickes/Type A Boiler: Units B-01, B-02.[161]

The selection of these sources for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hr or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[162] The following provides a review of the company's four-factor analyses.

A. Units C-01 through C-07, C-09 through C-13: Clark Natural Gas-Fired 2-Stroke Lean-Burn RICE

Units C-01 through C-07 and C-09 are Clark BA-8 two-stroke lean-burn RICE that were constructed in 1984, each with a capacity of 1,200 hp.[163] Units C-01 through C-07 each have an hourly NOx limit of 53.6 lb/hr and an annual NOx limit of 234.8 tpy.[164] Unit C-09 is restricted to 500 hours per year operation and has an hourly NOx limit of 53.6 lb/hr and an annual NOx limit of 13.4 tpy.[165]

Units C-10 through C-12 are Clark HBA-8 two-stroke lean-burn RICE that were constructed in 1984, each with a capacity of 1,600 hp.[166] The units each have an hourly NOx limit of 77.2 lb/hr and an annual NOx limit of 19.3 tpy.[167] These units are restricted to 500 hr/yr operation.[168] Unit C-13 is a Clark HBA-T-8 two-stroke lean-burn RICE that was constructed in 1984, with a capacity of 2,050 hp.[169] This unit has an hourly NOx limit of 61.1 lb/hr and an annual NOx limit of 267.5 tpy.[170]

1. Evaluation of Baseline NOx Emissions

Targa's four-factor submittal includes unit-specific operating hours based on 2016 emission inventory calculations or based on permit limits of 500 hr/yr for some units (C-09 through C-12). Uncontrolled NOx emission rates (g/hp-hr) in Targa's original four-factor analysis are, for all but one unit, based on a single performance test conducted in July 2015. The NOx emission rate for the one unit without performance test data, Unit C-03, is noted as, "from client."[171] Targa's February 2020 Addendum includes a corrected uncontrolled NO_x emission rate for C-03,

based on a 2015 performance test, of 14.192 g/hp-hr.[172] The actual emission rates for these units, based on the July 2015 testing, and the allowable NOx emission rates are shown in the table below.[173]

Table 10. Targa Eunice Gas Processing Plant 2SLB RICE Unit NOx Emission Rates

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Permit Limit [g/hp-hr]	NOx Actual Emissions from April 2015 Test Data [g/hp-hr]
C-01	1,200	53.6	20.3	13.165
C-02	1,200	53.6	20.3	9.226
C-03	1,200	53.6	20.3	14.192
C-04	1,200	53.6	20.3	11.742
C-05	1,200	53.6	20.3	9.285
C-06	1,200	53.6	20.3	13.261
C-07	1,200	53.6	20.3	13.787
C-09	1,200	53.6	20.3	17.249
C-10	1,600	77.2	21.9	11.401
C-11	1,600	77.2	21.9	16.265
C-12	1,600	77.2	21.9	9.838
C-13	2,050	61.1	13.5	13.654

As shown, the actual emission rates for most of these units—with the exception of unit C-13—are lower than these units' allowable NOx emission rates, with some less than 50% of allowable levels. So, either the 2015 performance test data was not conducted while the engines were operating at maximum capacity or the allowable NOx emission rates have been set unreasonably high. NMED should present information on the 2015 test data so the circumstances of the tests can be reviewed. Targa's February 2020 Addendum included the results from portable
analyzer testing conducted over a few days in August 2016 for the engines at the Saunders Gas Plant, which presumably are the tests used in determining baseline emissions for the four-factor analysis for that source.[174] NMED and Targa should review performance tests based on EPA Reference Methods for the Eunice Gas Plant to ensure that the actual emission rates can be considered to truly reflect actual emissions over the lifetime of the controls being evaluated. Citing variability in test data, Targa admits that these data are only a snapshot in time and only provide potential emissions based on that snapshot.[175] If testing is only done sporadically and is not done using EPA Reference Methods then it is questionable that such test data truly

[175] *Id.* at pdf page 6.

reflect an accurate projection of emissions expected over the lifetime of the controls being evaluated.

According to the source's Title V permit application, the allowable NOx emissions for these units are based on performance test data. Specifically, in the April 2018 Title V renewal application for the Eunice Gas Processing Plant, permitted rates for units C-01 through C-07 and C-09 of 53.6 lb/hr (equivalent to 20 g/hp-hr) are based on "stack data."[176] Note, stack test-based emissions are included for units C-09 through C-11, which are from the 2008 Title V renewal application, and are more in line with the emission rates used in the four-factor analysis (i.e., the Title V application lists "stack test-based emissions" for unit C-09 of 44.6 lb/hr (16.9 g/hp-hr) and for units C-10 and C-11 of 60 lb/hr (17.0 g/hp-hr), compared to the emission rates in the four-factor analysis of 17.249, 11.401, and 16.265 g/hp-hr for units C-09, C-10, and C-11, respectively).[177] However, the "current permitted rates (based on stack data)" for Units C-01 through C-07 that are listed in Targa's 2018 Title V permit application are equivalent to 20 g/hp-hr and are significantly higher than the NOx emission rates that the company's four-factor cost effectiveness analysis is based upon, meaning NOx reductions estimates for the various control options considered may be underestimated. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on a more comprehensive estimate of emissions expected in 2028.

2. Use of Low Emission Combustion Technology

Targa describes the LEC control technologies for these 2SLB engines as "Clean Burn Technology (CBT)."[178] Targa determined that this LEC technology is a technically feasible option for the 2SLB RICE units at the Eunice Gas Plant and the cost analysis provided in its four-factor analysis indicates this control is cost effective, especially for the engines that operate without restriction (i.e., Units C-01 through C-07 and C-13). Despite this, Targa concludes these retrofits would be uneconomical.[179]

The cost analysis in Targa's four-factor submittal doesn't support this claim, and the cost effectiveness of controls may be even more favorable than what is presented by Targa.

In its original November 2019 submittal, Targa presents cost effectiveness of controls for units C-01 through C-07 and for unit C-13 that range from $900–$6,000 per ton. The capital cost estimates are based on "manufacturer specification" and the annual operating and maintenance costs were provided by Targa.[180] Note, these annual operating and maintenance costs are higher than what was provided by other companies for LEC retrofits for similar

[177] *Id.* at 47 and 48.
[178] November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant at 2-9.
[179] *Id.* at 7-1.
[180] *Id.* Appendix B. Note, Targa stated, on pdf page 8 of its February 2020 Addendum, that "the O&M cost included in the analyses were based on Targa's experience operating similar control devices at other sites for expected maintenance and repair."

engines.[181] Targa's February 2020 Addendum included a revised control cost analysis, with costs effectiveness ranging from $3,331–$121,892 per ton, based on much higher cost estimates, and based on higher controlled NOx emission rates.[182] The capital investment for the Clean Burn Technology in the original submittal totaled just under $1 million per engine, compared to over $5 million in the Addendum.[183] The original capital cost estimates are in line with other capital cost estimates for LEC controls at other similar engines, at less than $140/hp,[184] whereas the capital cost estimates in Targa's Addendum are significantly higher, at up to $400/hp. It appears that the revised costs include $3 million—per engine—for electrical power, which Targa indicated in its original submittal could cost between $1–$3 million but would require an engineering assessment in order to know the full cost of this upgrade.[185] Note, even without these electrical upgrades, the other capital costs reach over $200/hp which is still significantly higher than the Targa's original estimates of less than $140/hp.

In its original submittal Targa stated that the Clean Burn Technology upgrades would either include turbochargers or externally driven blowers, with the electrical upgrades only necessary if blowers are used.[186] Even assuming the need for blowers and the highest cost estimate for upgrading the electrical substation (i.e., $3 million instead of $1 million), the cost effectiveness of these LEC controls is as low as $3,300—$5,600/ton for frequently-operating engines.[187] Assuming the electrical upgrades would cost $1 million instead of $3 million or that electrical upgrades aren't needed would obviously result in much more favorable cost effectiveness of these controls.

Note that Targa's submittal for the Saunders Gas Plant includes an analysis of the exact same LEC controls for the 2SLB RICE at that facility—e.g., requiring turbochargers or externally driven blowers—and the capital costs for that analysis are in line with the original cost estimates for the Eunice Gas Plant, at <$140/hp. And Targa's February 2020 Addendum for the Eunice, Monument, and Saunders gas plants did not include higher cost estimates for increased electricity needs at the Saunders Gas Plant. It's true that there are on-site electrical generation capabilities at the Saunders Gas Plant (e.g., units G-01 through G-04) but Targa's analysis for this facility does not appear to reflect a measurable increase in capital cost expenditures

[181] *See, e.g.,* November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant, which assumed O&M costs of $40,000/yr for Clark HRA-8 engines.
[182] *See* February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf pages 7 and 83—95.
[183] Note, these original capital cost estimates are in line with other company analyses for similar engines, e.g., Harvest Four Corners Kutz Canyon Gas Processing Plant's analysis for Clark HBA-8 engines used capital cost estimates of $1,000,000. Also, EPA's 2000 RICE Update (p. 5-2) included capital cost estimates for third-party retrofit of a Clark Model HSRA, 2SLB 1,000 hp 8-cylindar engine at a pipeline station of $710,000.
[184] *See, e.g.*, November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant cost data for Clark engines at just under $140/hp.
[185] November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant at 2-10 and 3-2.
[186] *Id.*
[187] E.g., cost effectiveness of C-13 at 7,560 hr/yr is $3,331/ton, C-06 at 8,123 hr/yr is $5,465/ton, C-03 at 7,275 hr/yr is $5,430/ton, C-01 at 8,009 hr/yr is $5,600/ton.

associated with the externally driven blowers that may be required at this site for LEC controls at the 2SLB RICE. And at any rate, any cost analysis associated with upgrades to a power substation that serves the Eunice Gas Plant should be considered separately, as part of a facility-wide assessment of the cost effectiveness of electrifying additional sources that could further reduce NOx emissions from the plant (e.g., electrification of additional engines).

In Targa's original submittal, its cost effectiveness analysis assumes controlled NOx emission rates of 2 g/hp-hr based on "information provided by the engine control vendor."[188] The corresponding NOx emissions reductions in Targa's original four-factor analysis for these units range from 61% to 88%.[189] Note, greater emissions reductions would result from control of units that are operating at levels closer to permitted levels (which are, again, based on test data for the units according to the source's Title V permit application) would mean that the LEC controls would be even more cost effective than what is shown in the original four-factor analysis. Targa specifically describes the control technology for these engines as able to reduce NOx emissions between 70% and 90%.[190] Subsequently, Targa's Addendum includes a new analysis of the cost effectiveness of reducing NOx emissions to levels of 4 g/hp-hr and 5 g/hp-hr, reflecting NOx emissions reductions of only 46–77%.[191]

In addition, as a result of assuming what could be unreasonably low NOx emission rates for current uncontrolled emissions from some of the 2SLB engines, i.e., emission rates based on performance test data that show much lower rates than the permitted limits for these units (that, according to Targa's Title V permit application, are based on stack data),[192] Targa then also potentially further underestimates the magnitude of potential NOx reductions for these units in its cost effectiveness analysis. The permitted hourly NOx emission rates, based on stack test data, are as follows: 20 g/hp-hr (units C-01 through C-07 and C-09); 23 g/hp-hr (units C-10 through C-12); and 14 g/hp-hr (unit C-13).[193] The permitted rate for unit C-13 is in line with the performance test data from 2015 used in the four-factor analysis but the other units' emission rates are significantly lower in the four-factor analysis than the stack test based rates in the source's Title V permit application. Therefore, the potential emissions reductions achieved by retrofitting units C-01 through C-07 and C-09 through C-12 could be much greater than what the four-factor analysis shows for these units. For uncontrolled permitted emission rates around 20 g/hp-hr, controlled rates of 2 g/hp-hr would achieve 90% reduction in NOx emissions.

With respect to the life assumed for LEC control, Targa assumed a 20-year period.[194] Targa appears to base this on EPA's guidance default for SCR.[195] It's possible that LEC controls can last 25 years, as stated in other cost effectiveness analyses submitted to NMED for LEC controls.[196]
Also, Targa uses an interest rate of 5.5% which is likely high and therefore underestimates annualized costs of control for these engines. As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.

Revising Targa's cost effectiveness analyses to address some of these issues, including assuming: 1) a 4.7% interest rate (instead of 5.5%), 2) a 25-year life of LEC (instead of an assumed 20-year life), and 3) emissions reductions of 90% based on potential operation at permitted levels (based on stack test data), improves the cost effectiveness of these controls even further, as shown in the table below. Note, this revised analysis uses Targa's original capital investment costs, since these are more in line with the cost analysis for its Saunders Gas Plant and with other capital cost estimates for LEC technology for similar engines; additional capital investments related to electrical capacity upgrades at the facility should be assessed, in more detail, as a separate broader analysis. Further note, this revised analysis assumes a slightly lower NOx emissions reductions estimate for unit C-13 of 85%, based on this unit's actual emission rate, since this emission rate is in line with permitted emissions for this unit.

Table 11. Cost Effectiveness of LEC at Uncontrolled Eunice Gas Plant Units C-01 through C-07 and C-09 through C-13 to Reduce NO_x Levels to 2 g/hp-hr, Assuming 90% Reductions in NOx Emissions, at 4.7% Interest Rate, and a 25-Year Life of Controls, 2019 $

Unit	Size [hp]	Capital Cost of LEC to Reduce NOx from the Uncontrolled rate of 20 g/hp-hr	Annual O&M Costs	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (90% NOx Reduction)	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of LEC, $/ton
C-01	1,200	$950,000	$100,000	$165,392	8,009	191	$867/ton
C-02	1,200	$950,000	$100,000	$165,392	4,271	102	$1,626/ton
C-03	1,200	$950,000	$100,000	$165,392	7,275	173	$955/ton
C-04	1,200	$950,000	$100,000	$165,392	5,996	143	$1,159/ton
C-05	1,200	$950,000	$100,000	$165,392	7,684	183	$904/ton
C-06	1,200	$950,000	$100,000	$165,392	8,123	193	$855/ton
C-07	1,200	$950,000	$100,000	$165,392	6,476	154	$1,073/ton
C-09	1,200	$950,000	$100,000	$165,392	500*	12	$13,893/ton
C-10	1,600	$950,000	$100,000	$165,392	500*	16	$10,420/ton
C-11	1,600	$950,000	$100,000	$165,392	500*	16	$10,420/ton
C-12	1,600	$950,000	$100,000	$165,392	500*	16	$10,420/ton
C-13	2,050	$950,000	$100,000	$165,392	7,560	203**	$814/ton

* These units are limited to 500 hr/yr operation in NSR Permits 067-M8R1 and 067-M7.

** Emissions reductions for Unit C-13 are based on controlling NOx emissions from the unit's actual emission rate of 14 g/hp-hr to 2 g/hp-hr (i.e., assuming NOx emissions reductions of 85%, instead of the 90% reduction assumed for all other units).

In Targa's original submittal it specifically describes the LEC modifications for these engines as including pre-combustion chambers and fuel systems to significantly lean the combustion mixture.[197] And Targa notes that the modifications will, "need turbochargers or externally driven blowers added as well."[198] Regarding the possibility of externally driven blowers, Targa points out the following:

> If a 2SLB engine does need an externally driven blower, this will be an electric blower and require electricity to operate. At this time, Eunice Gas Plant would have to significantly upgrade the power substation at the plant to operate blowers associated with these controls. The cost provided in Section 3 of this report does not include the cost to upgrade the electrical substation at the facility. An engineering design assessment would need to be completed before a total cost for the upgrade can be provided but is estimated at $1 million to $3 million.

[197] November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant at 2-9.
[198] *Id.* at 2-10.

> Even with the power concerns, Targa has determined that this method of NOX control is feasible for the 2SLB engines at the facility.[199]

In Targa's Addendum, it more specifically describes the technologies included in its updated analysis, including adding a pre-combustion chamber with power cylinder heads, modifications to the fuel system, adding a turbocharger system, and various upgrades to the intercooler system.[200]

As Targa acknowledges, it's not clear to what degree – and at what cost – additional upgrades to the power substation would be required. And Targa has stated that these LEC controls are feasible regardless of power concerns. So any claim that electrical power upgrades would render this control infeasible must be more carefully evaluated based on more specific data (e.g., energy needs in kW and the costs of those energy needs) in order to be able to assess the cost effectiveness of the additional electricity usage that would be required to power any blowers, or any other potential electrified sources, as determined from a full engineering assessment.

3. Use of SCR.

Targa did not evaluate SCR for these units, primarily because it claimed that, "most 2SLB engines have a poor air-to-fuel ratio that will not support the SCR control."[201] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines, particularly because Targa does not consider LEC to be economical.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[202]

[200] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 7.
[201] November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant at 2-11.
[202] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[203] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[204] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

B. Natural Gas-Fired Boilers (Units B-01 and B-02)

Targa also evaluated controls for the Units B-01 and B-02 natural gas-fired boilers. These boilers are Wickes Type A boilers, each with a permitted capacity of 100 MMBtu/hr that were manufactured in 1972.[205] The units each are subject to allowable NOx emission limits of 20.6 lb/hr and 90.0 tpy.[206]

Targa states that the two boilers already are using good combustion practices and have low NOx burners. Targa states that ultra-low NOx burners are available but would be technically infeasible at times for the Eunice Gas Processing Plant boilers because of the age of the boilers and the vendors' concerns with the higher Btu content of the fuel.[207] Targa also found SCR to be technically infeasible for the boiler claiming the significant power requirements would require the power at the plant to be significantly upgraded and redesigned. In addition, Targa found the selective non-catalytic reduction (SNCR) was not technically feasible due to concerns about how low loads will impact the temperature profile and optimal operating temperature of the control. Targa's dismissal of all three of these controls as technically infeasible only provides brief claims of technical infeasibility with no details specific to the Unit B-01 and B-02 boilers design or operation that make the particular control technically infeasible for the units. Further, issues of cost do not make a control technically infeasible. Instead, the costs of any requirements to alter a boiler to be able to operate with ultra-low NOx burners or to upgrade electricity to power SCR needs to be costed out and considered in the cost effectiveness analysis. NMED must require more information from Targa to exclude these controls as technically infeasible, particularly ultra-low NOx burners and SCR, especially given that Targa's

[205] 11/29/2019 Title V Operating Permit For Targa Eunice Gas Processing Plant at A7.
[206] *Id.* at A11.
[207] November 2019 Four-Factor Analysis for Targa Eunice Gas Processing Plant at 2-13.

research of RACT/BACT/LAER Clearinghouse entries shows that these controls are commonly required for natural gas-fired industrial boilers.[208]

The only NOx control evaluated by Targa for the boilers is flue gas recirculation (FGR). Targa assumed that FGR would reduce NOx to 45 ppm, which would be 50% control from the base NOx emissions rate of 90 ppm.[209] At least one boiler manufacturer, Cleaver Brooks, states that FGR is one of the more commonly used methods to reduce NOx emissions and that it can achieve up to 80% NOx reduction.[210] However, the cost effectiveness of the control was calculated by Targa to be between $16,000 to $19,000/ton.[211] Part of the reason for the high cost effectiveness is that Targa assumed only a 20 year life of controls and a 5.5% interest rate. FGR consists of recycling a portion of the flue gas from the stack to the burner windbox. The NOx reduction occurs due to the recirculated flue gas reducing combustion temperatures and because of lowering the oxygen content in the flame zone.[212] The life of FGR should be the same as the life of the boiler. Targa did not identify the remaining useful life of boilers B-01 and B-02, but the boilers have been in operation since 1972 or 47 years. The lifetime of a boiler is typically thought to be at least 30 years, and Targa did not give any indication of any end of life for the boilers. Thus, Targa should have assumed a 30-year life of FGR. Also, as previously discussed, a lower interest rate should have been used, no higher than 4.7%.

However, the other reason the cost effectiveness of FGR appears to be so high at Units B-01 and B-02 is because the 2016 annual baseline emissions relied on by Targa are very low compared to the units' allowable emissions (8.08 and 6.73 tpy compared to 90 tpy allowable emissions each for Units B-01 and B-02). Yet, a review of the 2016 hourly emissions of NOx compared to the annual emissions of NOx indicates that the boilers operate very close to 8,760 hours per year. If the boilers' NOx emissions are expected to continue to be as low as indicated by the 2016 emission inventory, it seems questionable that the emission limits applicable to these units are reflective of the existing good combustion practices and low NOx burners. NMED should reduce the emission limits to reflect the current NOx controls on the boilers. If the boiler NOx emissions in 2016 are anomalous and not reflective of future operations of the boilers in 2028, then NMED should require a revised cost effectiveness analysis based on a more realistic estimate of annual NOx emissions.

V. Targa Monument Gas Plant

The Targa Midstream Services, LLC Monument Gas Plant is a natural gas processing plant identified by NMED as potentially contributing to regional haze at the Carlsbad Caverns National Park Class I area.[213] NMED has described the facility processes as follows:

> The function of the facility is to process natural gas through inlet separation, an amine system for acid gas removal (carbon dioxide and hydrogen sulfide), dehydration for water removal, and the separation of methane from natural gas liquids (NGL). The natural gas is delivered to sales pipelines, propane is transported offsite with pressurized tank trunks, and the separated condensate is loaded into tank trucks for transport offsite.[214]

According to the permit, the plant includes seven RICE units, a steam boiler, heaters, gas turbines, storage tanks, vapor recovery units, an amine unit, and flares.[215]

In Targa's four-factor submittal, the company evaluated air pollution controls for the following emission units:

- Clark 2SLB RICE RA-8 (800 hp): Units C-01, C-02
- Clark 2SLB RICE RA-6 (600 hp): Units C-04, C-05, C-06
- Clark 2SLB RICE HRA-8 (880 hp): Unit C-24
- Cooper-Bessemer GMVA-8 (1,100 hp): Unit C-28
- Amine Gas Treating Unit / Flare: Unit AM-01 / F-03.[216]

The selection of these sources for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hr or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[217] The following provides a review of the company's four-factor analyses for the engines listed above. The Amine Gas Treating Unit/Flare is addressed in Section XXIII further below.

A. Units C-01, C-02, C-04 through C-06, C-24, and C-28: Natural Gas-Fired 2-Stroke Lean-Burn RICE

Units C-01 and C-02 are Clark RA-8 two-stroke lean-burn compressor engines that were constructed in 1956, each with a capacity of 800 hp.[218] These units each have an hourly NOx limit of 27.8 lb/hr and an annual NOx limit of 121.8 tpy.[219]

Units C-04 through C-06 are Clark RA-6 two-stroke lean-burn compressor engines that were also constructed in 1956, each with a capacity of 600 hp.[220] The three units each have an hourly NOx limit of 25.1 lb/hr and an annual NOx limit of 109.9 tpy.[221]

Unit C-24 is a Clark HRA-8 two-stroke lean-burn compressor engine that was constructed in 1969, with a capacity of 880 hp.[222] This unit has an hourly NOx limit of 41.9 lb/hr and an annual NOx limit of 183.5 tpy.[223]
Unit C-28 is a Cooper-Bessemer GMVA-8 two-stroke lean-burn compressor engine that was constructed in 1977, with a capacity of 1,100 hp.[224] This unit has an hourly NOx limit of 16.6 lb/hr and an annual NOx limit of 72.7 tpy.[225]

1. Evaluation of Baseline NOx Emissions

Targa's four-factor submittal includes unit-specific operating hours based on 2016 emission inventory calculations. Uncontrolled NOx emission rates (g/hp-hr) in Targa's original four-factor analysis are based on a single performance test conducted for each engine in April 2015. The actual emission rates for these units, based on this April 2015 testing, and the allowable NOx emission rates are shown in the table below.[226]

Table 12. Targa Monument Gas Plant 2SLB RICE Unit NOx Emission Rates

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Permit Limit [g/hp-hr]	NOx Actual Emissions from April 2015 Test Data [g/hp-hr]
C-01	800	27.8	15.8	11.9
C-02	800	27.8	15.8	9.8
C-04	600	25.1	19.0	9.9
C-05	600	25.1	19.0	8.4
C-06	600	25.1	19.0	11.4

[226] November 2019 Regional Haze Four-Factor Analysis for Targa – Monument Gas Plant Appendix B.

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Permit Limit [g/hp-hr]	NOx Actual Emissions from April 2015 Test Data [g/hp-hr]
C-24	880	41.9	21.6	18.2
C-28	1,100	16.6	6.8	6.3

As shown, the actual emission rates for all units, with the exception of C-28, are much lower than the units' allowable hourly NOx emission rates so, either the 2015 test data for these units was not conducted while the engines were operating at maximum capacity or the allowable NOx emission rates for these units have been set unreasonably high. NMED should present information on the 2015 test data so the circumstances of the tests can be reviewed. Targa's February 2020 Addendum included the results from portable analyzer testing conducted over a few days in August 2016 for the engines at the Saunders Gas Plant, which presumably are the tests used in determining baseline emissions for the four-factor analysis for that source.[227] NMED and Targa should review performance tests at the Monument Gas Plant, that are based on EPA Reference Methods, to ensure that the actual emission rates can be considered to truly reflect actual emissions over the lifetime of the controls being evaluated. Citing variability in test data, Targa admits that these data are only a snapshot in time and only provide potential emissions based on that snapshot.[228] If testing is only done sporadically and is not done using EPA Reference Methods then it is questionable that such test data truly reflect an accurate projection of emissions expected over the lifetime of the controls being evaluated.

According to the August 2018 Title V renewal application for the Monument Gas Plant, NOx emissions were determined, "based on stack test data with a safety factor..."[229] The permitted rates for these units (with the exception of unit C-28)—that are based on stack test data—are significantly higher than the NOx emission rates that the company's four-factor cost effectiveness analysis is based upon, meaning NOx reductions estimates for the various control options considered may be underestimated. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on a more comprehensive estimate of emissions expected in 2028.

2. Use of Low Emission Combustion Technology

Targa describes the LEC control technologies for these 2SLB engines as "Clean Burn Technology (CBT)."[230] According to EPA, "[t]he term "clean-burn" technology is a registered trademark of Cooper Energy Systems and refers to engines designed to reduce NOx by operating at high air-to-fuel ratios."[231] In Targa's original submittal it specifically describes the LEC modifications for

[231] EPA AP-42 Chapter 3, Section 3.2 (July 2000) at 3.2-2.

these engines as including pre-combustion chambers and fuel systems to significantly lean the combustion mixture.[232] And Targa notes that the modifications will, "need turbochargers or externally driven blowers added as well."[233] In Targa's February 2020 Addendum, it more specifically describes the technologies included in its updated analysis, including adding a pre-combustion chamber with power cylinder heads, modifications to the fuel system, adding a turbocharger system, and various upgrades to the intercooler system.[234]

Targa determined that this LEC technology is a technically feasible option for the 2SLB RICE units at the Monument Gas Plant and the cost analysis provided in its four-factor analysis indicates this control could be cost effective for some of these units (e.g., Unit C-24). Despite this, Targa concludes the following:

> However, retrofitting with these technologies would require Targa to spend significant amounts of time (for design and installation) and capital. In addition, based on the predominant wind direction and that SO_2, not NOx, is the contaminant of interest for visibility impairment in Carlsbad Caverns, NOx emissions from these pieces of equipment are inconsequential for regional haze purposes. Thus, retrofitting the Monument Gas Plant engines would be uneconomical and unnecessary for improving visibility.[235]

In terms of being uneconomical, the cost analysis in Targa's four-factor submittal doesn't necessarily support this claim for all engines, and more importantly, the cost effectiveness of controls may be even more favorable than what is presented by Targa.

In its original November 2019 submittal, Targa presents cost effectiveness of controls for these units that range from $1,688–$33,892 per ton. The capital cost estimates are based on "manufacturer specification" and the annual operating and maintenance costs were provided by Targa.[236] Note, these annual operating and maintenance costs are higher than what was provided by other companies for LEC retrofits for similar engines.[237] Targa's February 2020 Addendum included a revised control cost analysis, with costs effectiveness ranging from $6,398–$155,568 per ton, based on much higher cost estimates, and based on higher controlled NOx emission rates.[238] The capital investment for the Clean Burn Technology in the original submittal totaled $900,000 per engine, compared to over $5 million in the

[232] November 2019 Regional Haze Four-Factor Analysis for Targa – Monument Gas Plant at 2-4.
[233] *Id*.
[234] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 7.
[235] November 2019 Regional Haze Four-Factor Analysis for Targa – Monument Gas Plant at 7-1.
[236] *Id.* Appendix B. Note, Targa stated, on pdf page 8 of its February 2020 Addendum, that "the O&M cost included in the analyses were based on Targa's experience operating similar control devices at other sites for expected maintenance and repair."
[237] *See, e.g.,* November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant, which assumed O&M costs of $40,000/yr for Clark HRA-8 engines.
[238] *See* February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf pages 7 and 96–102.

Addendum.[239] The original capital cost estimates are high, at $150—$270/hp, compared to other capital cost estimates for LEC controls at other similar engines.[240] The capital cost estimates in Targa's Addendum are significantly higher, at over $750/hp for some units (e.g., C-04 through C-06). It appears that the revised costs include $3 million for electrical power, which Targa indicated in its original submittal could cost between $1–$3 million but would require an engineering assessment in order to know the full cost of this upgrade.[241] Note, even without these electrical upgrades, the other capital costs come in at over $400/hp for some units, which is still significantly higher than the $/hp figures in Targa's original submittal.

In its original submittal, Targa stated that the Clean Burn Technology upgrades would either include turbochargers or externally driven blowers, with the electrical upgrades only necessary if blowers are used.[242] Even assuming the need for blowers and the highest cost estimate for upgrading the electrical substation (i.e., $3 million instead of $1 million), the cost effectiveness of these LEC controls is as low as $6,398/ton for unit C-24.[243] Assuming the electrical upgrades would cost $1 million instead of $3 million, or that electrical upgrades aren't needed would obviously result in much more favorable cost effectiveness of these controls.

Note that, Targa's submittal for the Saunders Gas Plant includes an analysis of the exact same LEC controls for the 2SLB RICE at that facility—e.g., requiring turbochargers or externally driven blowers—and the capital costs for that analysis are, generally, less than $140/hp. And Targa's February 2020 Addendum for the Eunice, Monument, and Saunders gas plants did not include higher cost estimates for increased electricity needs at the Saunders Gas Plant. It's true that there are on-site electrical generation capabilities at the Saunders Gas Plant (e.g., units G-01 through G-04) but Targa's analysis for this facility does not appear to reflect a measurable increase in capital cost expenditures associated with the externally driven blowers that may be required at this site for LEC controls at the 2SLB RICE. And at any rate, any cost analysis associated with upgrades to a power substation that serves the Monument Gas Plant should be considered separately, as part of a facility-wide assessment of the cost effectiveness of electrifying additional sources that could further reduce NOx emissions from the plant (e.g., electrification of engines).

[239] Note, these original capital cost estimates are in line with other company analyses for similar engines, e.g., Harvest Four Corners Kutz Canyon Gas Processing Plant's analysis for Clark HBA-8 engines used capital cost estimates of $1,000,000. Also, EPA's 2000 RICE Update (p. 5-2) included capital cost estimates for third-party retrofit of a Clark Model HSRA, 2SLB 1,000 hp 8-cylindar engine at a pipeline station of $710,000.

[240] *See, e.g.,* Four-Factor analyses for Chaco Gas Plant (Clark 2SLB RICE at $140/hp), Saunders Gas Plant (Cooper-Bessemer 2SLB RICE at $90-$138/hp), Roswell Compressor Station No. 9 (Cooper-Bessemer 4SLB RICE at $90/hp), Jal No. 3 (Cooper-Bessemer 2SLB RICE at $123/hp).

[242] *Id.*

[243] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 101.

The annual hours of operation for these engines varies significantly. According to Targa's submittal, the annual hours of operation used in the four-factor analysis are based on 2016 emission inventory data, as shown in the table below:

Table 13. Targa Monument Gas Plant 2SLB RICE Units Annual Operation

Unit	Size [hp]	Hours of Operation From 2016 EI Calculations [hr/yr]
C-01	800	2,357
C-02	800	4,069
C-04	600	990
C-05	600	2,035
C-06	600	3,938
C-24	880	6,610
C-28	1,100	573
AVERAGE		2,939

In Targa's Addendum, it indicated that annual hours of operation depend on various factors—e.g., including whether units are working, when they require maintenance, etc. —and will vary each year from engine to engine but, overall, are generally uniform.[244] According to Targa, "each year the engines will operate with different hours of operation and fuel usage."[245] NMED should request operation data for additional years for these units in order to be able to better assess the cost effectiveness of controls for operating schedules that reflect the full range of usage for these engines.

In Targa's original submittal, its cost effectiveness analysis assumes controlled NOx emission rates of 2 g/hp-hr based on "information provided by the engine control vendor."[246] The corresponding NOx emissions reductions in Targa's original four-factor analysis for these units range from 68.3% to 89%.[247] Note, greater emissions reductions would result from control of units that are operating at levels closer to permitted levels (which are, again, based on test data for the units according to the source's Title V permit application) would mean that the LEC controls would be even more cost effective than what is shown in the original four-factor analysis. Targa specifically describes the control technology for these engines as able to reduce NOx emissions between 70% and 90%.[248] Subsequently, Targa's Addendum includes a new analysis of the cost effectiveness of reducing NOx emissions to levels of 4 g/hp-hr and 5 g/hp-hr, reflecting NOx emissions reductions of only 37–78%.[249]

[244] *Id.* at 6.
[245] *Id.* at 6.

[247] *Id.* at Appendix B.
[248] *Id.*at 2-4.
[249] *See* February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf pages 96—102.

In addition, as a result of assuming what could be unreasonably low NOx emission rates for current uncontrolled emissions from some of the 2SLB engines, i.e., emission rates based on performance test data that show much lower rates than the permitted limits for these units (that, according to Targa's Title V permit application, are based on stack data), Targa then also potentially further underestimates the magnitude of potential NOx reductions for these units in its cost effectiveness analysis. The permitted hourly NOx emission rates, based on stack test data, are notably higher than the actual emission rates used in the four-factor analysis for all but unit C-28, as shown in the table in the previous section.[250] Therefore, the potential emissions reductions achieved by retrofitting these units could be much greater than what the four-factor analysis shows due to potential underestimated baseline emissions, hours of operation, and emissions reductions. For uncontrolled permitted emission rates ranging from 15.8—21.6 g/hp-hr, controlled rates of 2 g/hp-hr would achieve 87—91% reduction in NOx emissions.

With respect to the life assumed for LEC control, Targa assumed a 20-year period.[251] Targa appears to base this on EPA's guidance default for SCR.[252] It's possible that LEC controls can last 25 years, as stated in other cost effectiveness analyses submitted to NMED for LEC controls.[253]
Also, Targa uses an interest rate of 5.5% which is likely high and therefore underestimates annualized costs of control for these engines. As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.

Revising Targa's cost effectiveness analyses to address some of these issues, including assuming 1) a 4.7% interest rate (instead of 5.5%), 2) a 25-year life of LEC (instead of an assumed 20-year life), and 3) emissions reductions of 87—91% based on potential operation at permitted levels (based on stack test data), improves cost effectiveness of these controls even further, as shown in the table below. Note, this revised analysis uses Targa's original capital investment costs, since these are more in line with the cost analysis for its Saunders Gas Plant and with other capital cost estimates for LEC technology for similar engines; additional capital investments related to electrical capacity upgrades at the facility should be assessed, in more detail, as a separate broader analysis. Further note, this revised analysis assumes a NOx emissions reduction estimate for unit C-28 of just over 70%, based on this unit's actual emission rate, since this emission rate is in line with permitted emissions for this unit.

[250] *Also see* August 2018 Title V Permit Application for Monument Gas Plant at pdf pages 44–47.
[251] November 2019 Regional Haze Four-Factor Analysis for Targa – Monument Gas Plant Appendix B.
[252] *Id.*
[253] See 2019 Four-Factor submittals for Roswell Compressor Station and Jal No. 3 which both assume 25-year life of controls for LEC.

Table 14. Cost Effectiveness of LEC at Uncontrolled Monument Gas Plant Units C-01, C-02, C-04 through C-06, C-24, and C-28 to Reduce NO_x Levels to 2 g/hp-hr, Assuming 87—91% Reductions in NOx Emissions, a 4.7% Interest Rate, and a 25-Year Life of Controls

Unit	Size [hp]	Capital Cost of LEC to Reduce NOx from an Uncontrolled Rate [2019$]	Annual O&M Costs [2019$]	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (87—91% NOx Reduction) [2019$]	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of LEC [2019$], $/ton
C-01	800	$900,000	$100,000	$161,951	2,357	29	$5,661/ton
C-02	800	$900,000	$100,000	$161,951	4,069	49	$3,279/ton
C-04	600	$900,000	$100,000	$161,951	990	11	$14,570/ton
C-05	600	$900,000	$100,000	$161,951	2,035	23	$7,088/ton
C-06	600	$900,000	$100,000	$161,951	3,938	44	$3,663/ton
C-24	880	$900,000	$100,000	$161,951	6,610	126	$1,289/ton
C-28	1,100	$850,000	$100,000	$158,509	573	3	$47,086/ton*

* Emissions reductions for Unit C-28 are based on controlling NOx emissions from the unit's actual emission rate of 6.8 g/hp-hr to 2 g/hp-hr (i.e., assuming NOx emissions reductions of just over 70%), since this uncontrolled emission rate is in line with permitted emissions for this unit.
Capital costs for C-28 are listed as $850,000 based on manufacturer specification.

The cost effectiveness of LEC control could be significantly lower than what is shown above for engines that operate more frequently than in 2016. Targa stated, in its February 2020 Addendum, that "[w]ith regards to the engine usage, Targa attempts to use its engines uniformly but this does not mean equally on a calendar year basis."[254] An analysis that assumes each engine operates at the average annual operation of all engines in 2016, which is roughly 3,000 hours per year, e.g., would lower the cost effectiveness of Unit C-01 to $5,080/ton, units C-04 and C-05 to $5,491/ton each, and unit C-28 to $10,226/ton.

Regarding the possibility of externally driven blowers that would require electrical upgrades, Targa points out the following:

> If a 2SLB engine does need an externally driven blower, this will be an electric blower and require electricity to operate. At this time, Eunice Gas Plant would have to significantly upgrade the power substation at the plant to operate blowers associated with these controls. The cost provided in Section 3 of this report does not include the cost to upgrade the electrical substation at the facility. An engineering design assessment would need to be completed before a total cost for the upgrade can be provided but is estimated at $1 million to $3 million.

[254] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 6.

> Even with the power concerns, Targa has determined that this method of NOX control is feasible for the 2SLB engines at the facility.[255]

As Targa acknowledges, it's not clear to what degree – and at what cost – additional upgrades to the power substation would be required. And Targa has stated that these LEC controls are feasible regardless of power concerns. So any claim that electrical power upgrades would render this control infeasible must be more carefully evaluated based on more-specific data (e.g., energy needs in kW and the costs of those energy needs) in order to be able to assess the cost effectiveness of the additional electricity usage that would be required to power any blowers, or any other potential electrified sources, as determined from a full engineering assessment.

3. Use of SCR.

Targa did not evaluate SCR for these units, primarily because it claimed that, "most 2SLB engines have a poor air-to-fuel ratio that will not support the SCR control."[256] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines, particularly because Targa does not consider LEC to be economical.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[257]

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[258] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost

[255] *Id.*
[256] November 2019 Regional Haze Four-Factor Analysis for Targa – Monument Gas Plant at 2-5.
[257] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[258] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.

Manual[259] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

VI. Targa Saunders Gas Plant

The Targa Midstream Services, LLC Saunders Gas Plant is a natural gas processing plant identified by NMED as potentially contributing to regional haze at the Salt Creek Wilderness Area Class I area.[260] NMED has described the facility processes as follows:

> The function of the facility is to process natural gas, including dehydration and sweetening sour natural gas (removing sulfur and CO_2), and also remove lighter hydrocarbons (such as ethane and methane) from the inlet gas stream. The facility is capable of processing approximately 100 MMscf/d of gas.[261]

According to the permit, the plant includes nine two-stroke reciprocating internal combustion engines (RICE) used for compression, four 4-stroke generator RICE, an emergency generator, heaters, sulfur recovery unit and incinerator, storage tanks, an amine unit, and flares.[262] In Targa's four-factor submittal, the company evaluated air pollution controls for the following emission units:

- Cooper-Bessemer 2SLB RICE GMVA-10 (1,350 hp): Units C-01 through C-06
- Cooper-Bessemer 2SLB RICE GMV-10 (1,195 hp): Units C-07 and C-08
- Cooper-Bessemer GMVC-10 (1,800 hp): Unit C-09
- Ingersoll-Rand 4SRB RICE PKVG-8 (780 hp): Units G-01, G-02, G-03
- Amine Gas Treating Unit with Sulfur Recovery Unit and Incinerator: Unit AM-01 / I-01.[263]

The selection of these sources for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hr or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[264] The following provides a review of the company's

[259] Available at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution.

[264] *Id.* at 1-3.

four-factor analyses for the engines listed above. Comments on the four-factor analysis for the amine gas treating unit are provided in Section XXIII further below.

A. Units C-01 through C-09: Natural Gas-Fired 2-Stroke Lean-Burn RICE

Units C-01 through C-06 are Cooper-Bessemer GMVA-10 2-stroke lean-burn compressor engines that were constructed in 1953, each with a capacity of 1,350 hp.[265] These units each have an hourly NOx limit of 32.6 lb/hr and an annual NOx limit of 142.8 tpy.[266]

Units C-07 and C-08 are Cooper-Bessemer GMV-10 2-stroke lean-burn compressor engines that were also constructed in 1953, each with a permitted capacity of 1,195 hp.[267] The two units each have an hourly NOx limit of 28.7 lb/hr and an annual NOx limit of 125.6 tpy.[268]

Unit C-09 is a Cooper-Bessemer GMVC-10 2-stroke lean-burn compressor engine that was constructed in 1953, with a capacity of 1,800 hp.[269] This unit has an hourly NOx limit of 43.2 lb/hr and an annual NOx limit of 189.2 tpy.[270]

1. Evaluation of Baseline NOx Emissions

Targa's four-factor submittal includes unit-specific operating hours based on 2016 emission inventory calculations. Uncontrolled NOx emission rates (g/hp-hr) in Targa's original four-factor analysis are based on a single performance test conducted for each engine in August 2016. The actual emission rates for these units, based on this August 2016 testing, and the allowable NOx emission rates are shown in the table below.[271]

Table 15. Targa Saunders Gas Plant 2SLB RICE Unit NOx Emission Rates

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Permit Limit [g/hp-hr]	NOx Actual Emissions from August 2016 Test Data [g/hp-hr]
C-01	1,350	32.6	11.0	2.05
C-02	1,350	32.6	11.0	10.78
C-03	1,350	32.6	11.0	4.99
C-04	1,350	32.6	11.0	3.87
C-05	1,350	32.6	11.0	7.21
C-06	1,350	32.6	11.0	8.3

[266] *Id.* at A9.
[267] *Id.* at A7. Note, Unit C-08 has a maximum capacity of 1,350 hp and a permitted capacity of 1,195 hp.
[268] *Id.* at A9.
[269] *Id.* at A7.
[270] *Id.* at A9.
[271] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant Appendix B.

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Permit Limit [g/hp-hr]	NOx Actual Emissions from August 2016 Test Data [g/hp-hr]
C-07	1,195	28.7	10.9	7.35
C-08	1,195	28.7	10.9	9.13
C-09	1,800	43.2	10.9	5.54

As shown, the actual emission rates for most units, with the exception of C-02 and a few others, are much lower than the units' allowable hourly NOx emission rates, so either the 2016 testing for these units was not conducted while the engines were operating at maximum capacity or the allowable NOx emission rates for these units have been set unreasonably high. Targa's February 2020 Addendum included the results from portable analyzer testing conducted over a few days in August 2016 for the engines at the Saunders Gas Plant, which presumable are the tests used in determining baseline emissions for the four-factor analysis.[272] NMED and Targa should review other performance tests, that are based on EPA Reference Methods, for these units to ensure that the actual emission rates can be considered to truly reflect actual emissions over the lifetime of the controls being evaluated. Citing variability in test data, Targa admits that these data are only a snapshot in time and only provide potential emissions based on that snapshot.[273] If testing is only done sporadically and is not done using EPA Reference Methods then it is questionable that such test data truly reflect an accurate projection of emissions expected over the lifetime of the controls being evaluated.

According to the September 2018 Title V renewal application for the Saunders Gas Plant, NOx emissions for units C-01 through C-07 were," calculated using stack test data from 2/22/1994 with a 20% safety factor."[274] Note, permitted emission rates for units C-08 and C-09 were calculated using EPA AP-42 emission factors (Table 3.2-2).[275] The permitted rates for these units (with the exception of unit C-02, but especially for units C-01, C-03, and C-04)—that are based on stack test data—are significantly higher than the NOx emission rates that the company's four-factor cost effectiveness analysis is based upon, even considering the 20% "safety factor", meaning NOx reductions estimates for the various control options considered for these units may be underestimated. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on a more comprehensive estimate of emissions expected in 2028.

1. Use of Low Emission Combustion Technology

Targa describes the LEC control technologies for these 2SLB engines as "Clean Burn Technology (CBT)."[276] In Targa's original submittal it specifically describes the LEC modifications for these

[276] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant at 2-7.

engines as including pre-combustion chambers and fuel systems to significantly lean the combustion mixture.[277] And Targa notes that the modifications will, "need turbochargers or externally driven blowers added as well."[278] In Targa's February 2020 Addendum, it more specifically describes the technologies included in its updated analysis, including adding a pre-combustion chamber with power cylinder heads, modifications to the fuel system, adding a turbocharger system, and various upgrades to the intercooler system.[279]

Targa determined that this LEC technology is a technically feasible option for the 2SLB RICE units at the Saunders Gas Plant and the cost analysis provided in its four-factor analysis indicates this control could be cost effective for these units, depending on the baseline emission rates and operating schedules. Despite this, Targa concludes these retrofits would be uneconomical.[280]

The cost analysis in Targa's four-factor submittal doesn't necessarily support this claim for these engines, and more importantly, the cost effectiveness of controls may be even more favorable than what is presented by Targa.

In its original November 2019 submittal, Targa presents cost effectiveness of controls for these units that range from $2,754–$277,724 per ton.[281] The capital cost estimates are based on "manufacturer specification" and the annual operating and maintenance costs were provided by Targa.[282] Targa's February 2020 Addendum included an additional control cost analysis based on higher controlled NOx emission rates; Targa also specified that the capital control cost estimates include engineering costs (e.g., equipment / installation, structural, drawings, etc.).[283] The capital cost estimates are similar, at $80—$138 per hp, compared to other capital cost estimates for LEC controls at other similar engines.[284]

The annual hours of operation for these engines varies quite a bit. According to Targa's submittal, the annual hours of operation used in the four-factor analysis are based on 2016 emission inventory data, as shown in the table below:

[278] *Id*.
[279] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 7.
[280] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant at 7-1.
[281] *Id.* at 3-2. Note, the $277,724/ton figure for unit C-01 represents the cost effectiveness of reducing NOx emissions from a baseline level for this unit (based on a single performance test from 2016) of 2.04 g/hp-hr to a controlled emission rate of 2 g/hp-hr; if this unit were operating at its permitted emission rate (that is also based on performance testing, from 1994) the cost effectiveness of this control would be *significantly* lower (i.e., <$2,000/ton).
[282] *Id.* Appendix B. Note, Targa stated, on pdf page 8 of its February 2020 Addendum, that "the O&M cost included in the analyses were based on Targa's experience operating similar control devices at other sites for expected maintenance and repair."
[283] *See* February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf pages 7 and 114–122.
[284] *See, e.g.,* Four-Factor analyses for Roswell Compressor Station No. 9 (Cooper-Bessemer 4SLB RICE at $90/hp) and Jal No. 3 (Cooper-Bessemer 2SLB RICE at $123/hp).

Table 16. Targa Saunders Gas Plant 2SLB RICE Units
Annual Operation

Unit	Size [hp]	Hours of Operation From 2016 EI Calculations [hr/yr]
C-01	1,350	8,656
C-02	1,350	4,971
C-03	1,350	5,321
C-04	1,350	7,770
C-05	1,350	5,431
C-06	1,350	1,910
C-07	1,195	5,622
C-08	1,195	2,948
C-09	1,800	5,989

In Targa's Addendum, it indicated that annual hours of operation depend on various factors—e.g., including whether units are working, when they require maintenance, etc.—and will vary each year. According to Targa, "each year the engines will operate with different hours of operation and fuel usage."[285] NMED should request operation data for additional years for these units in order to be able to better assess the cost effectiveness of controls for operating schedules that reflect the full range of usage for these engines.

In Targa's original submittal, its cost effectiveness analysis assumes controlled NOx emission rates of 2 g/hp-hr based on "information provided by the engine control vendor."[286] The corresponding NOx emissions reductions in Targa's four-factor analysis for these units range from 2.4% to 81.4%.[287] Note, greater emissions reductions would result from control of units that are operating at levels closer to permitted levels (which are, again, based on test data for Units C-01 through C-07 according to the source's Title V permit application) would mean that the LEC controls would be even more cost effective than what is shown in the original four-factor analysis. And, in fact, Targa states that "[t]he Clean Burn technology will reduce NOx emissions by 81%."[288] For uncontrolled permitted emission rates of 11 g/hp-hr, controlled rates of 2 g/hp-hr would achieve an 81% reduction in NOx emissions, which is exactly what the Clean Burn technology is promising to achieve for all of these units.

As a result of assuming what could be unreasonably low NOx emission rates for baseline uncontrolled emissions from some of the 2SLB engines, i.e., emission rates based on performance test data that show much lower rates than the permitted limits for these units

[285] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 6.
[286] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant at 3-2.
[287] *Id.* at Appendix B.
[288] *Id.*at 2-7.

(that, according to Targa's Title V permit application, are based on stack data for all units but C-08 and C-09), Targa then also potentially further underestimates the magnitude of potential NOx reductions for these units in its cost effectiveness analysis. Therefore, the potential emissions reductions achieved by retrofitting these units could be much greater than what the four-factor analysis shows due to potential underestimated baseline emissions, hours of operation, and emissions reductions.

With respect to the life assumed for LEC control, Targa assumed a 20-year period.[289] Targa appears to base this on EPA's guidance default for SCR.[290] It's possible that LEC controls can last 25 years, as stated in other cost effectiveness analyses submitted to NMED for LEC controls.[291]
Also, Targa uses an interest rate of 5.5% which is likely high and therefore underestimates annualized costs of control for these engines. As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.

Revising Targa's cost effectiveness analyses to address some of these issues, including assuming 1) a 4.7% interest rate (instead of 5.5%), 2) a 25-year life of LEC (instead of an assumed 20-year life), and 3) emissions reductions of 81% based on potential operation at permitted levels (largely based on stack test data), improves cost effectiveness of these controls even further, as shown in the table below. Note, this revised analysis reflects the large range in operating hours, based on 2016 data, which may not be representative of individual engine usage in other years.

Table 17. Cost Effectiveness of LEC at Uncontrolled Saunders Gas Plant Units C-01 through C-09 to Reduce NO_x Levels to 2 g/hp-hr, Assuming 81% Reductions in NOx Emissions, a 4.7% Interest Rate, and a 25-Year Life of Controls, 2019 $

Unit	Size [hp]	Capital Cost of LEC to Reduce NOx from a Permitted Rate of 11 g/hp-hr	Annual O&M Costs	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (81% NOx Reduction)	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of LEC, $/ton
C-01	1,350	$942,500	$100,000	$164,876	8,656	116	$1,422
C-02	1,350	$942,500	$100,000	$164,876	4,971	67	$2,476
C-03	1,350	$942,500	$100,000	$164,876	5,321	71	$2,314
C-04	1,350	$942,500	$100,000	$164,876	7,770	104	$1,584
C-05	1,350	$942,500	$100,000	$164,876	5,431	73	$2,267

[289] *Id.* at Appendix B.
[290] *Id.*
[291] See 2019 Four-Factor submittals for Roswell Compressor Station and Jal No. 3 which both assume 25-year life of controls for LEC.

Unit	Size [hp]	Capital Cost of LEC to Reduce NOx from a Permitted Rate of 11 g/hp-hr	Annual O&M Costs	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (81% NOx Reduction)	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of LEC, $/ton
C-06	1,350	$942,500	$100,000	$164,876	1,910	26	$6,445
C-07	1,195	$945,000	$100,000	$165,048	5,622	66	$2,504
C-08	1,195	$945,000	$100,000	$165,048	2,948	35	$4,776
C-09	1,800	$615,500	$100,000	$142,367	5,989	106	$1,346

The cost effectiveness of LEC control could be significantly lower than what is shown above for engines that operate more frequently than in 2016. Targa stated, in its Addendum, that "[w]ith regards to the engine usage, Targa attempts to use its engines uniformly but this does not mean equally on a calendar year basis."[292] An analysis that assumes each engine operates at the average annual operation across all engines in 2016, which is roughly 5,400 hours per year, would result in cost effectiveness estimates as low as $2,279/ton for unit C-06 and $2,606/ton for unit C-08.

2. Use of SCR.

Targa did not evaluate SCR for these units, primarily because it claimed that, "most 2SLB engines have a poor air-to-fuel ratio that will not support the SCR control."[293] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines, particularly because Targa does not consider LEC to be economical.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[294]

[292] February 2020 Regional Haze Four-Factor Analysis Addendum for Targa Midstream Services, LLC – Eunice Gas Plant, Monument Gas Plant, Saunders Gas Plant at pdf page 13.
[293] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant at 2-8.
[294] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[295] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[296] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

B. Units G-01, G,02, and G-03: Natural Gas-Fired 4-Stroke Rich-Burn RICE

Units G-01 through C-03 are Ingersoll-Rand PKVG-8 4-stroke rich-burn generator engines that were constructed in 1953, each with a capacity of 780 hp.[297] These units each have an hourly NOx limit of 34.2 lb/hr and an annual NOx limit of 149.8 tpy.[298]

1. Evaluation of Baseline NOx Emissions

Targa's four-factor submittal includes baseline unit-specific NOx emission rates in hours per year and tons per year, based on 2016 emission inventory calculations.[299] Operating hours can be calculated based on these data. These baseline NOx emission rates and the allowable NOx emission rates from the source's Title V permit are shown in the table below.[300]

Table 18. Targa Saunders Gas Plant 4SRB RICE Unit NOx Emission Rates

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Baseline Emissions [lb/hr]
G-01	780	34.2	19.81
G-02			21.63
G-03			17.4

As shown, the baseline emission rates for all three units are significantly lower than the units' allowable hourly NOx emission rates so, either the baseline emissions for these units is not reflective of operation at maximum capacity or the allowable NOx emission rates for these units

[295] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.

[299] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant Appendix B.
[300] *Id*.

have been set unreasonably high. NMED and Targa should review performance tests for these units to ensure that the actual emission rates can be considered to truly reflect baseline emissions over the lifetime of the controls being evaluated.

According to the September 2018 Title V renewal application for the Saunders Gas Plant, NOx emissions for units G-01 through G-03 were," calculated using stack test data from 2/22/1994 with a 20% safety factor."[301] The permitted rates for these units—that are based on stack test data—are significantly higher than the baseline NOx emission rates that the company's four-factor cost effectiveness analysis is based upon, even considering the 20% "safety factor", meaning NOx reductions estimates for the various control options considered for these units may be underestimated. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on a more comprehensive estimate of emissions expected in 2028.

2. Use of Non-Selective Catalytic Reduction

Targa determined that non-selective catalytic reduction (NSCR) is a technically feasible option for the 4SRB RICE units at the Saunders Gas Plant and the cost analysis provided in its four-factor analysis indicates this control could be very cost effective for these units.[302] Despite this, Targa concludes these retrofits would be uneconomical.[303]

The cost analysis in Targa's four-factor submittal doesn't support this claim for these engines, and the cost effectiveness of controls may be even more favorable than what is presented by Targa.

In its November 2019 submittal, Targa presents cost effectiveness of controls for G-01, G-02, and G-03 of $259/ton, $231/ton, and $287/ton, respectively.[304] The capital cost estimates are based on "information received from engine control vendors or knowledge on the particular equipment."[305] Targa's February 2020 Addendum did not include any revisions to these cost estimates.

The annual hours of operation for these engines is around 7,000 hours per year, based on the pound per hour and ton per year emission rates provided in Targa's submittal:

[301] *See* September 2018 Title V Permit Application for Saunders Gas Plant at pdf page 37.
[302] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant at 2-6 and 3-2.
[303] *Id.* at 7-1.
[304] *Id.* at 3-2.
[305] *Id.* at B-1.

Table 19. Targa Saunders Gas Plant 4SRB RICE Units Annual Operation Based on 2016 EI Calculations

Unit	Size [hp]	NOx Baseline Emissions [lb/hr]	NOx Baseline Emissions [tpy]	Hours of Operation [hr/yr]
C-01	780	19.81	69.47	7,014
C-02	780	21.63	77.28	7,146
C-03	780	17.14	63.52	7,412

NMED should request operation data for additional years for these units in order to be able to better assess the cost effectiveness of controls for operating schedules that reflect greater usage of these engines, as allowed by current permit limits, e.g., if increased usage would be more representative of typical operation in 2028.

In Targa's submittal, its cost effectiveness analysis assumes controlled NOx emission rates of 0.986 g/hp-hr, based on "a similar unit at the site which is controlled by NSCR."[306] The corresponding NOx emissions reductions in Targa's four-factor analysis for units G-01, G-02, and G-03 are 91.9%, 92.6%, and 90.7% respectively.[307] Note, greater emissions reductions would result from control of these units if they operate at levels closer to permitted levels (which are, again, based on test data), meaning NSCR would be even more cost effective than what is shown in Targa's four-factor analysis. Targa states that, "NSCR controls are typically 90% or greater."[308] For uncontrolled permitted emission rates of 34.2 g/hp-hr, controlled rates of 0.986 g/hp-hr would achieve 97% reduction in NOx emissions. According to EPA's Alternative Control Techniques document for RICE, NSCR vendors quote NOx emission reduction efficiencies of 90 to 98%, resulting in an expected range of controlled NOx emissions from 0.3-1.6 g/hp-hr.[309]

As a result of assuming what could be low NOx emission rates for baseline uncontrolled emissions from these 4SRB RICE, i.e., emission rates based on performance test data that show lower rates than the permitted limits for these units (that, according to Targa's Title V permit application, are also based on stack data), Targa then also potentially further underestimates the magnitude of potential NOx reductions for these units in its cost effectiveness analysis. Therefore, the potential emissions reductions achieved by retrofitting these units could be much greater than what the four-factor analysis shows due to potential underestimated baseline emissions, hours of operation, and emissions reductions.

With respect to the life assumed for LEC control, Targa assumed a 10-year period.[310] Targa does not provide any justification for this assumption for the life of controls. In the NPCA

[306] *Id*. at 3-1.
[307] *Id.* Appendix B.
[308] *Id.*at 2-6.
[309] EPA 1993 Alternative Control Techniques Document for RICE at 2-10 to 2-11.
[310] November 2019 Regional Haze Four-Factor Analysis for Targa – Saunders Gas Plant Appendix B.

March 2020 Oil and Gas Four-Factor Report, we assumed a 15-year life of controls in determining the cost effectiveness of NSCR control for 4SRB RICE.[311]

Also, Targa uses an interest rate of 8.25% which is high and therefore underestimates annualized costs of control for these engines. As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.

Revising Targa's cost effectiveness analyses to address some of these issues, including assuming 1) a 4.7% interest rate (instead of 8.25%), 2) a 15-year life of NSCR (instead of an assumed 10-year life), and 3) emissions reductions of 97% based on potential operation at permitted levels (largely based on stack test data), improves cost effectiveness of these controls even further, as shown in the table below.

Table 20. Cost Effectiveness of NSCR at Uncontrolled Saunders Gas Plant Units G-01, G-02, and G-03 to Reduce NO_x Levels to 0.986 g/hp-hr, Assuming 97% Reductions in NOx Emissions, a 4.7% Interest Rate, and a 15-Year Life of Controls

Unit	Size [hp]	Capital Cost of NSCR to Reduce NOx from a Permitted Rate [2019$]	Annual O&M Costs [2019$]	Total Annualized Costs of LEC to Reduce NOx to 0.986 g/hp-hr (97% NOx Reduction) [2019$]	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of NSCR [2019$], $/ton
C-01	780	$8,206	$15,308	$16,083	7,014	116	$138/ton
C-02	780	$8,206	$15,308	$16,083	7,146	119	$136/ton
C-03	780	$8,206	$15,308	$16,083	7,412	123	$131/ton

Based on this analysis, it is *extremely* cost effectiveness to retrofit these 4SRB RICE with NSCR and would result in the removal of over 350 tons per year of NOx.

VII. DCP Artesia Gas Plant

The Artesia Gas Plant is a natural gas processing plant that removes condensate, H_2S and CO_2 in an amine unit, and separates natural gas liquids.[312] The plant is located about 15 miles east-southeast of Artesia, New Mexico. It is owned/operated by DCP Midstream. The plant consists of numerous natural gas-fired four-stroke rich-burn RICE units, natural gas-fired four-stroke lean-burn RICE, boilers, amine contactor, flares, and other emissions sources.[313] Of all of those sources of emissions, NMED apparently only requested a four-factor analysis for the flares at

[311] *See* NPCA March 2020 Oil and Gas Four-Factor Report at 20.
[312] 6/27/2017 Title V Permit No. P095-R3 for Artesia Gas Plant at A3.
[313] *Id.* at A6 to A8.

the plant. Notably, all of the four-stroke rich-burn RICE are equipped with nonselective catalytic reduction for NOx control. In Section XXIII further below, we provide comments on the four-factor analysis for the flares associated with the amine unit.

VIII. Harvest Four Corners – Kutz Canyon Gas Plant

Kutz Canyon Gas Plant is a natural gas processing plant that removes ethane and heavier hydrocarbons from natural gas. It is operated by Harvest Four Corners, LLC. The facility is located in San Juan County, about 3.1 miles south of Bloomfield, New Mexico. According to NMED's Statement of Basis for a New Source Review (NSR) permit for the facility, "The Kutz I Plant removes heavier hydrocarbons using a refrigerated lean oil absorption process and was built in 1936. The Kutz II Plant removes heavier hydrocarbons using a cryogenic process and was added to the facility much later, in 1975. The facility operates 8760 hours per year."[314] The Title V operating permit for the facility indicates that the plant includes several natural gas-fired turbines, boilers, several natural gas-fired RICE, heaters, boilers, and flares.[315] In Harvest Four Corner's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Solar Centaur 40 combustion turbines (Units 1-6 and Units 19 and 20)
- Clark HRA-8 two-stroke lean burn RICE (Units 16, 17, and 18)[316]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tons per year (tpy), which is the criteria established by NMED to identify sources subject to four-factor analyses.[317] The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

Harvest Four Corners used a 5.5% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[318] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. This is the same interest rate that EPA has used in its cost spreadsheet for SCR, but EPA also states that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[319] The current bank prime rate is 3.25%.[320] The highest the bank

[315] Title V Operating Permit P097-R3 for Kutz Canyon Processing Plant at A6 to A8.
[316] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 1-2.
[317] *Id.*
[318] *Id.* at Section 8.0 Supporting Documentation.
[319] EPA, Control Cost Manual, Section 1, Chapter 2 (November 2016) at 16, available at: https://www.epa.gov/sites/production/files/2017-12/documents/epaccmcostestimationmethodchapter_7thedition_2017.pdf.
[320] https://www.federalreserve.gov/releases/h15/.

prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[321] In a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[322] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. For these reasons, in the cost effectiveness calculations provided herein, a 4.7% interest rate is used rather than a 5.5% interest rate.

B. Solar Centaur Natural Gas-Fired Combustion Turbines (Units 1-8 and 19 and 20) at the Kutz Canyon Gas Plant.

The combustion turbines evaluated at the Kutz Canyon Gas Plant are Solar combustion turbines, model Centaur 40 of 3830 hp capacity (Units 1-6) and of 3016 hp capacity (Units 19 and 20).[323] These units were manufactured between 1975 and 1981.[324] Under the terms of the permit, the units are subject to the following hourly and annual emission limits of NOx.

Table 21. Limits from Kutz Canyon Gas Plant Title V Permit for the Units 1-8 and 19-20 Combustion Turbines[325]

Combustion Turbine Unit ID	NOx limit, lb/hr	NOx limit, tpy
1	15.5	67.9
2	15.5	67.9
3	15.5	67.9
4	15.5	67.9
5	15.5	67.9
6	15.5	67.9
19	15.5	67.9
20	15.5	67.9

Units 19 and 20 are also subject to NOx limits of 161.91 ppmv at 15% O_2, pursuant to 40 C.F.R. Part 60, Subpart GG.[326]

Harvest Four Corners evaluated one control option for these combustion turbines: Solar's SoLoNOx combustion system. The company did not evaluate SCR, claiming that it would not operate effectively at the units and that there was not space available for SCR or power

[325] *Id.* at A9-A10.
[326] *Id.* at A26.

capabilities for such SCR systems.[327] For reasons previously discussed above and in the NPCA Oil and Gas Four-Factor Report, SCR should have been considered as a technically feasible control for these natural gas-fired combustion turbines.

1. Baseline Emissions for the Units 1 – 6 and 19-20 Combustion Turbines.

Harvest Four Corners states that its cost effectiveness analyses for SoLoNOx were based on the 2016 emission inventory submittal.[328] In its cost data sheets in Section 8.0 of its four-factor analysis, the company provided the 2016 emission inventory calculations for the combustion turbines evaluated, but the company did not specify the actual 2016 operating hours for each unit.[329] This is inconsistent with most other four-factor analyses submitted to NMED. Submittal of operating hours is very important for understanding the operating capacity factor of the units, and NMED must require that more specific operational data be made public for the units as part of the four-factor analyses of controls. The company also provided the NOx ppm rate, but it was "converted from 2016 [emission inventory] calculations and data."[330]

Specifically, the company's cost data sheets indicate that the NOx ppm rate for each unit is 67.61 ppm.[331] That NOx concentration was then compared to the NOx emission rate guarantee from SoLoNOx of 25 ppm to determine the percent NOx reduction which was then multiplied by 2016 tpy emissions to determine the NOx removed for the cost effectiveness analysis of SoLoNOx. NMED must require Harvest Four Corners to provide more specific data on how the NOx ppm rate was calculated. Further, each of the units is subject to emission testing requirements of the Title V permit.[332] Such actual emissions tests should be evaluated as well (including the circumstances of the test data) to ensure that the baseline emissions inventory and emission rates are reflective of current actual emissions and emissions expected from the units in 2028. A review of Title V permit application data for the Kutz Canyon Gas Plant on the NMED's Emissions Analysis Tool did not find any other emissions testing data available for these units.

Units 19 and 20 are also subject to NOx limits of 161.91 ppmv at 15% O_2, pursuant to 40 C.F.R. Part 60, Subpart GG as discussed above. This is 2.4 times higher than the 67.61 ppm base NOx rate relied upon by Harvest Four Corners to determine the tons per year of NOx removed due to SoLoNOx. In addition, Units 19 and 20 are different Solar Centaur models than Units 1-6 (T4001 versus T4002). Further, Units 19 and 20 have a lower horsepower rating than Units 1-6. Yet, all eight units were assumed to have the same uncontrolled NOx baseline emission rate. The discrepancies between these two NOx rates need to be addressed by NMED to ensure that

[332] Title V Operating Permit P097-R3 for Kutz Canyon Processing Plant at A25.

baseline emissions are based on a valid analysis of actual emissions that are projected to occur in 2028.

2. Evaluation of SoLoNOx for the Combustion Turbines at Units 1-6 and 19-20.

Harvest Four Corners indicates that SoLoNOx can achieve a NOx rate of 25 ppm, which it claims is a reduction of 63% "based on the currently permitted hourly emission rate and turbine stack parameters."[333] This makes clear that Harvest Four Corners is using the 67.71 ppm NOx rate identified in its SoLoNOx cost data sheets along with the 25 ppm NOx rate expected from SoLoNOx to calculate the tons per year NOx reductions expected with SoLoNOx.[334] This statement implies that the NOx baseline emission rate of 67.71 ppm that Harvest Four Corners cites in its SoLoNOx cost data sheets is based on the allowable pound per hour emission limits applicable to each unit. However, in the cost data sheets of Section 8.0 of the Kutz Canyon Gas Plant four-factor analysis, it is stated that the 67.71 ppmv was calculated from the 2016 emission inventory data. Given that this baseline rate forms the basis of the company's claimed NOx removal efficiency with SoLoNOx, NMED must disclose the basis for this base concentration.

In terms of the life of SoLoNOx controls in the cost effectiveness analyses, Harvest Four Corners' analysis assumed a 20-year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[335] In the table below, Harvest Four Corners' cost effectiveness analyses of SoLoNOx were revised to take into account a longer lifetime of controls and a lower 4.7% interest rate.

[333] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 2-3.
[334] A 25 ppm NOx rate reflects 63% NOx reduction from a 67.71 ppm NOx rate.
[335] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.

Table 22. Revised Cost Effectiveness of SoLoNOx at Units 1-6 and 19-20 of the Kutz Canyon Gas Plant, to Reflect a 4.7% Interest Rate and a 25 Year Life

Unit	Harvest Four Corners' Total Annual Costs of SoLoNOx (at 5.5% Interest and 20-Year Life)	Harvest Four Corners' Cost Effectiveness at 5.5% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25 Year Life
1	$61,603	$2,246/ton	$54,666	$1,993/ton
2	$61,603	$2,412/ton	$54,666	$2,141/ton
3	$61,603	$1,983/ton	$54,666	$1,760/ton
4	$78,339	$23,111/ton	$68,433	$20,183/ton
5	$78,339	$2,145/ton	$68,433	$1,873/ton
6	$78,339	$1,910/ton	$68,433	$1,668/ton
19	$61,603	$4,779/ton	$54,666	$4,242/ton
20	$61,603	$2,043/ton	$54,666	$1,813/ton

It must be noted that, for some unexplained reason, the capital cost to install SoLoNOx at Units 4, 5, and 6 was $200,000 higher than the capital cost to install SoLoNOx at the other combustion turbine units. Yet, Units 4, 5, and 6 are the same turbine model as Units 1, 2, and 3 (Model T4002).[336] NMED should evaluate the reason for the higher capital cost of SoLoNOx at Units 4, 5, and 6.

For Unit 4, the unit had very low NOx emissions in 2016 of 5.38 tpy, and thus the cost effectiveness of SoLoNOx was very high at this unit. NMED must ensure that these low NOx emissions at Unit 4 are not anomalous and that the company's baseline emissions for the unit are reflective of expected operations in 2028. With the exception of Unit 4, the cost effectiveness of SoLoNOx at these combustion turbines are in the range of $1760/ton to $4,242/ton to achieve 63% NOx reduction, which is very cost effective.

3. SCR at Units 1-6 and 19-20 at Kutz Canyon Gas Plant

As discussed above, Harvest Four Corners did not evaluate SCR for any of the combustion turbine units, claiming that the exhaust temperatures of the turbines is 1,271 degrees Fahrenheit which the company claims would negatively impact SCR operation, and also that there are site-specific space limitations for installation of SCR. With respect to space limitations, as discussed in Section I.B.3. above, most SCR retrofits have space limitations, because the facility was not likely designed to have space to accommodate SCR. There have been numerous SCR retrofits installations at various industrial facilities that have had to overcome space constraints. For example, for many large coal-fired power plants, SCR reactors

[336] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at Section 8.0.

have been elevated above the air preheaters. Indeed, a report about SCR retrofits at GE LM2500 turbines at Chevron's Eastridge Cogeneration plant in California showed that some significant changes to the facility had to be made to accommodate SCR, including cutting the duct between economizers and moving the stack and one economizer onto new foundations to make way for the SCR reactor.[337] Thus, before NMED accepts a very brief claim of retrofit difficulty of SCR at any emissions unit being evaluated for reasonable progress controls, it is imperative that NMED ask Harvest Four Corners for a site plan and photos that shows whatever space constraints are being claimed, and that NMED ask the company to consult with SCR vendors for options for SCR installation at the gas turbines.

Depending on the proximity of the gas turbines, it is possible that one SCR reactor could be used by more than one combustion turbine. This would reduce costs and potentially be easier to install at the site. NMED should require all possibilities for SCR installation to be evaluated and documented by Enterprise. The state must not simply discount this highly effective NOx control based on a claim of some retrofit difficulty.

Regarding the company's stated exhaust temperature of 1,271 degrees Fahrenheit, NMED should determine if this is the sustained temperature of the gas turbines or the maximum temperature of the exhaust expected from the Units 1-6 and Unit 19-20 gas turbines. There are options for dealing with high exhaust temperatures of simple cycle turbines to enable the use of SCR. The Buckingham Compressor Station which is proposed to be constructed in Virginia would be equipped with Solar turbines with SoLoNOx, SCR, and cooling air skids.[338] Essentially, this provides for the injection of tempering air at the turbine discharge (upstream of the SCR) to cool the exhaust temperature to the optimal temperature of the SCR catalyst.[339]

Further, these high exhaust temperatures are another reason why NMED should investigate routing more than one combustion turbine exhaust to a common SCR. The routing of the turbine exhausts from multiple turbines to one SCR reactor will allow for some cooling of the exhaust before it enters the SCR. Salt River Project (SRP) is planning to route the flue gas from one boiler at the Coronado Generating Station in Arizona to an existing SCR reactor that had previously been constructed at Coronado Unit 2.[340] It will be a shared SCR system, although it must be noted that the Coronado Unit 1 SCR was designed as a split (two towers within one

reactor) SCR system. So, according to SRP, each unit will have its own SCR within one reactor. Such an approach seems like it could be a viable, more cost effective control option for co-located combustion turbines at compressor stations.

One further reason that Harvest Four Corners identified for SCR not being feasible was due to the electricity needs of the SCR. Harvest Four Corners states that it "does not anticipate that the current electricity availability at Kutz will be sufficient to support the substantial energy burden associated with SCR control" and that "[i]nstallation of this control will require the facility to expand its current power generation."[341] The site has two onsite combustion turbine generators in Units 19 and 20. The Title V Permit states that each of these two generators cannot exceed 2400 kilowatts, and also states that only one unit can operate at any given time.[342] This condition was apparently imposed pursuant to a NSR Permit 0301M9. If this condition was imposed to allow a project to net out of PSD review, then the operational limits cannot be relaxed without the units obtaining a permit as though construction had not yet commenced.[343] But if the units install BACT level controls (SoLoNOx plus SCR), then the burden of obtaining a PSD permit for the units in order to allow both units to produce the needed electricity to operate SCRs may not be substantial. According to EPA's cost spreadsheet for the similar size units to Units 1-6 and 19-20 of the Kutz Canyon Gas Plant, the electricity usage for SCR at the turbines operating at maximum capacity would be approximately 20 kW per hour. Assuming very conservatively that the power for a cooling air skid might double these power needs to 40 kW per hour, the total electricity need for 8 SCR systems (if all combustion turbines being evaluated in this four-factor analysis were equipped with SCR) would very conservatively be 320 kW. If 2400 kW is the maximum capacity of each of Units 19 and 20, this power need reflects 13% of one of the Units 19 or 20 generating units. Given that both generating units are currently not allowed to operate simultaneously under the terms of the permit, it appears that the plant currently has the generating capacity to address worst case electricity needs of SCR systems on each of the eight combustion turbines if the permit was revised to allow for simultaneous operation of both Units 19 and 20.[344]

For all of the reasons discussed above, SCR should not have been excluded from review as a possible NOx control option for Units 1-6 and Units 19-20 at the Kutz Canyon Gas Plant, both by itself and in combination with SoLoNOx.

As discussed above, an SCR installation by itself should be able to reduce emissions to at least 15 ppmv at 15% O_2.[345] That NOx rate reflects a 40% reduction in NOx emissions compared to

[341] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 2-5.
[342] Title V Operating Permit P097-R3 for Kutz Canyon Processing Plant at A26, Condition A205.C.
[343] *See* 40 C.F.R. 52.21(r)(4).
[344] As previously stated, the ability to allow both Units 19 and 20 to operate simultaneously Depends on the reasons that these operational limitations were imposed at Units 19 and 20. If imposed as "synthetic minor" limits or to allow other projects at the facility to net out review, relaxations in those operational restrictions can be allowed if all regulatory requirements including PSD permitting requirements are addressed.
[345] *See* March 2020 NPCA Oil and Gas Four-Factor Report at 75.

the 25 ppm expected NOx rate with SoLoNOx at Units 1-6 and Units 19-20. Further, a 15 ppmv NOx rate reflects a 78% reduction in NOx from Harvest Four Corners' claimed baseline NOx rate for each unit of 67.61 ppm. Based on the fact that the combustion turbines at the Eunice Gas Plant (Units 17A, 18B, 19A, 25A, and 26A) evaluated for SCR by DCP Midstream are of similar size as the Kutz Canyon Units 1-6 and 19-20 combustion turbines, one would expect SCR to have a similar cost effectiveness. As shown in Table 9 above, the cost effectiveness SCR at the DCP Eunice Gas Plant turbines ranged from $2,600/ton to $3,800/ton (assuming a 4.7% interest rate and 25-year life). Thus, one would expect the similar (or same) model turbine and similar size units at Kutz Canyon to have a similar cost effectiveness of SCR to achieve 15 ppmv at 15% O_2, with the exception of units that are not operated at similar levels as the Eunice turbines such as Kutz Canyon Unit 4.

Moreover, SCR combined with SoLoNOx, which is commonly required to meet BACT for gas turbines, could reduce NOx by 97% or more. As discussed in Section I.C.2 of this report, this combination of NOx controls has been permitted for the Buckingham Compressor Station to achieve a NOx emission rates of 3.75 ppmv @ 15% oxygen.[346] However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as BACT or LAER for such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15% oxygen.[347] NMED should require Harvest Four Corners to evaluate the cost effectiveness of the combination of SoLoNOx and SCR to achieve the greatest level of NOx reduction.

C. Clark HRA-8 Two-Stroke Lean-Burn RICE (Units 16-18) of Kutz Canyon Gas Plant

Units 16, 17, and 18 are Clark HRA-8 two-stroke lean-burn refrigerant compressor engines that were constructed in prior to 1973, each with a nameplate capacity of 830 hp and a site-rated capacity of 723 hp.[348] These units each have an hourly NOx limit of 37.1 lb/hr and an annual NOx limit of 162.0 tpy.[349]

1. Evaluation of Baseline NOx Emissions

Harvest Four Corners' four-factor submittal includes baseline NOx emissions (in tpy) based on 2016 emission inventory calculations; no information is provided on operating hours for these engines. NMED should request more information on the units' current hours of operation and

[346] See January 9, 2019 Registration No. 21599, available at: https://www.deq.virginia.gov/Portals/0/DEQ/Air/BuckinghamCompressorStation/21599_Signed_Permit.pdf. Note that this permit was recently vacated by the Courts, see https://www.cbs19news.com/story/41533113/permit-forbuckingham-county-compressor-station-vacated.
[347] *See*, e.g., Chupka, Mark, The Brattle Group, and Anthony Licata, Licata Energy & Environmental Consulting, Inc., Independent Evaluation of SCR Systems for Frame-Type Combustion Turbines, Report for ICAP Demand and Curve Reset, at 9.
[348] Title V Operating Permit P1097-R3 for Kutz Canyon Processing Plant at A6-A7.
[349] *Id.* at A9.

actual NOx emissions. The baseline emission rates for these units, based on 2016 emission inventory calculations, and the allowable NOx emission rates are shown in the table below.[350]

Table 23 Harvest Four Corners Kutz Canyon Processing Plant 2SLB RICE Unit NOx Emission Rates

Unit	Size [hp]	NOx Permit Limit [tpy]	NOx Baseline Emissions [tpy]
16	723	162.0	151.37
17	723	162.0	89.63
18	723	162.0	87.5

Without information on operating hours it's not possible to know if baseline NOx emissions from units 17 and 18 are lower than permitted rates because these units operated fewer hours in 2016 or if their hourly emission rates were lower.

According to the May 2019 permit application for the Kutz Canyon Processing Plant, NOx emissions for these units were determined, "using stack test and manufacturer's data."[351] The permitted rates for units 17 and 18—that are based on stack test and manufacturer data—are significantly higher than the NOx emission rates that the company's four-factor cost effectiveness analysis is based upon, meaning NOx reductions estimates for the various control options considered may be underestimated if 2016 operation is not reflective of operation in current and future years. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on a more comprehensive estimate of operating hours and emission rates (e.g., in g/hp-hr or hr/yr) expected in 2028.

2. Use of Low Emission Combustion Technology

Harvest Four Corners describes the LEC control technologies for these 2SLB Clark engines as "Clean Burn Technology (CBT)."[352] According to EPA, "[t]he term "clean-burn" technology is a registered trademark of Cooper Energy Systems and refers to engines designed to reduce NOx by operating at high air-to-fuel ratios."[353] It's not entirely clear what specific technologies are being proposed for the Clark engines at the Kutz Canyon Gas Processing Plant. Harvest Four Corners' submittal discusses, generally, the use of high energy ignition system, turbocharger, and AFRC technologies.[354] EPA described LEC retrofit kits designed to achieve extremely lean

[350] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant Appendix B.
[351] *See* May 2019 Permit Revision Application to NSR Permit 0301-M10 for Kutz Canyon Processing Plant, Section 6 Page 2.
[352] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 2-6.
[353] EPA AP-42 Chapter 3, Section 3.2 (July 2000) at 3.2-2.
[354] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 2-7.

air-to-fuel ratios – in order to minimize NOx emissions – as encompassing the following specific retrofit technologies:

- Redesign of cylinder head and pistons to improve mixing (on smaller engines)
- Precombustion chamber (on larger engines)
- Turbocharger
- High energy ignition system
- Aftercooler
- Air-to-fuel ration controller (AFRC)[355]

In order to effectively evaluate a company's assessment of LEC a more precise description of LEC technologies, and associated achievable emission rates is needed. Harvest Four Corners states that Clean Burn Technology is estimated to achieve an 80 to 93% reduction in NOx emissions, depending on engine and loading.[356] Harvest Four Corners assumes an 80% NOx reduction in its four-factor analysis for these engines.

The allowable NOx emission rate for these 723 hp engines, at 37.1 lb/hr, is equivalent to 23.3 g/hp-hr. An 80% reduction in NOx emissions would achieve a NOx level of over 4 g/hp-hr. NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable with LEC technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).[357]

For reference, the following sources of information regarding NOx emission rates specific to Clark engines – both uncontrolled and with LEC technology – are provided here:

- EPA's 2000 RICE Update includes NOx emissions test data for specific engines, including Clark Model TLA-6, 2-stroke, lean-burn, 2,000 hp RICE retrofitted with LEC. According to EPA, six engines retrofitted by a third-party vendor had NOx emission rates ranging from 0.8–1.4 g/bhp-hr, with a mean of 1.0 g/bhp-hr.[358]

- An evaluation by a technical group for the Pipeline Research Council International looked at three of the most representative make / models of 2-stroke lean burn compressor engines: (1) 2,250 hp Cooper GMVH-10; (2) 2,000 hp Clark TLA-6; and (3) 2,500 hp Cooper GMW-10. According to a technical report by the Ozone Transport Commission (OTC) describing this evaluation, "[t]he evaluation concluded that there

[355] EPA, Final Technical Support Document for the Cross-State Air Pollution Rule for the 2008 Ozone NAAQS, Docket ID EPA-HQ-OAR-2015-0500-0508, Assessment of Non-EGU NOx Emission Controls, Cost of Controls, and Time for Compliance, August 2016, Appendix A at 5-3, *available at:* https://www.regulations.gov/document?D=EPA-HQ-OAR-2015-0500-0508 [hereinafter referred to as "2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls"].
[356] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 2-7, citing EPA's 1993 Alternative Control Techniques document for RICE.
[357] March 6, 2020 NPCA Oil and Gas Four-Factor Report at 28.
[358] EPA 2000 RICE Update at 4-8.

were no technology gaps and that each of the three makes/models evaluated were capable of attaining a NOx emissions limitation of 0.5 g/bhp-hr using a combination of improvements and retrofits related to air supply, fuel supply, ignition, electronic controls, and engine monitoring."[359]

For the units at the Kutz Canyon Processing Plant, a controlled NOx emission rate of 2 g/hp-hr from the uncontrolled allowable NOx emission rate (that is based on stack test and manufacturer data) represents a 91% emissions reduction, which is in the range presented in Harvest Four Corners' four-factor submittal of 80 to 93%.

Harvest Four Corners presents cost effectiveness of LEC controls for these units that range from $1,021–$1,767 per ton.[360] The capital cost estimates of $1 million and annual operating and maintenance cost estimates of $40,000 per year are provided by Harvest Four Corners.[361] These capital cost estimates are a little higher, at $186/hp, compared to other capital cost estimates for LEC controls at other similar engines.[362]

Harvest Four Corners assumes NOx emissions reductions of 80% despite stating that the Clean Burn technologies it would employ are capable of reducing NOx emissions up to 93%.[363] And achieving NOx emission rates of 2 g/hp-hr—as shown by other companies in their four-factor analyses for similar engines at similar costs—would correspond to 91% NOx reductions.[364] These greater emissions reductions would result from control of units that are operating at levels closer to permitted levels (which are, again, based on stack test and manufacturer data) and would mean that the LEC controls would be even more cost effective than what is shown in Harvest Four Corners' original four-factor analysis.

[359] Ozone Transport Commission, Technical Information, Oil and Gas Sector, Significant Stationary Sources of NOx Emissions, Final, October 17, 2012, p. 24, *available at*: https://otcair.org/upload/Documents/Meeting%20Materials/Final%20Oil%20%20Gas%20Sector%20TSD%2010-17-12.pdf [hereinafter referred to as "2012 OTC Report"].

[360] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 3-2.

[361] *Id.* Appendix B. Note, these capital cost estimates are in line with other company analyses for similar engines, e.g., Targa's original Four-Factor analysis for Clark HBA-8 engines used capital cost estimates of $950,000. Also, EPA's 2000 RICE Update (p. 5-2) included capital cost estimates for third-party retrofit of a Clark Model HSRA, 2SLB 1,000 hp 8-cylindar engine at a pipeline station of $710,000

[362] *See, e.g.*, November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant cost data for Clark engines at just under $140/hp. *See also* November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant cost data for Clark engines, also under $140/hp.

[363] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Processing Plant at 2-7.

[364] *See* November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Eunice Gas Plant at 3-3 and November 2019 Regional Haze Four-Factor Analysis for Targa Midstream Services, LLC – Monument Gas Plant at 3-2, assuming controlled NOx rates of 2 g/hp-hr for Clark engines.

With respect to the life assumed for LEC control, Harvest Four Corners assumed a 20-year period.[365] This assumption appears to be based on EPA's guidance default for SCR.[366] It's possible that LEC controls can last 25 years, as stated in other cost effectiveness analyses submitted to NMED for LEC controls.[367]

Also, Harvest Four Corners uses an interest rate of 5.5% which is likely high and therefore underestimates annualized costs of control for these engines.[368] As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. Revising Harvest Four Corners cost effectiveness analyses to address some of these issues, including assuming 1) a 4.7% interest rate (instead of 5.5%), 2) a 25-year life of LEC (instead of an assumed 20-year life), and 3) emissions reductions of 91% from baseline emissions, improves cost effectiveness of these controls even further, as shown in the table below.

Table 24. Cost Effectiveness of LEC at Uncontrolled Kutz Canyon Gas Processing Plant Units 16, 17, and 18 to Reduce NO_x Levels to 2 g/hp-hr, Assuming 91% Reductions in NOx Emissions, a 4.7% Interest Rate, and a 25-Year Life of Controls, 2019 $

Unit	Size [hp]	Capital Cost of LEC to Reduce NOx from Baseline Emissions	Annual O&M Costs [2019$]	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (91% NOx Reduction)	Annual Baseline Emissions, tpy	NOx Removed, tpy	Cost Effectiveness of LEC, $/ton
16	723	$1,000,000	$40,000	$134,399	151	138	$790/ton
17	723	$1,000,000	$40,000	$134,399	90	82	$1,334/ton
18	723	$1,000,000	$40,000	$134,399	88	80	$1,367/ton

Harvest Four Corners determined that LEC technology is a technically feasible option for the 2SLB RICE units at the Kutz Canyon Gas Processing Plant and the cost analysis provided in its four-factor analysis, and revised here, confirms this control would be very cost effective. Harvest Four Corners expresses concern that the addition of these controls may be "operationally detrimental" due to the need for a third-party installation. However, no additional specific examples of operational impacts are identified or explained that would necessarily preclude retrofit of these engines. Just because there may be operational issues to

overcome does not mean that the technology is not feasible or that the resulting emissions reductions are not warranted.

3. Use of SCR

Harvest Four Corners did not evaluate SCR for Units 16, 17, and 18 primarily because it claimed that it was not technically feasible for these engines.[369] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[370]

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[371] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[372] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

IX. El Paso Natural Gas Company LLC - Pecos River Compressor Station

The Pecos River Compressor Station is a natural gas compressor station located approximately 12 miles south/southeast of Malaga, New Mexico in Eddy County. It is owned/operated by El

[369] *Id.* at 2-8.
[370] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[371] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.

Paso Natural Gas Company (EPNG). The facility consists of three GE Frame 3 Regenerative Cycle Turbines that each have a capacity of 7,150 hp.[373]

In EPNG's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Natural Gas-Fired Regenerative Cycle Turbine (Units A-01, A-02, and A-03)[374]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[375] The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

EPNG used a 5.5% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[376] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. This is the same interest rate that EPA has used in its cost spreadsheet for SCR, but EPA also states that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[377] The current bank prime rate is 3.25%.[378] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[379] In a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[380] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. For these reasons, in the cost effectiveness calculations provided herein, a 4.7% interest rate is used rather than a 5.5% interest rate.

B. GE Regenerative Cycle Turbines (Units A-01, A-02, and A-03) of Pecos River Compressor Station

As stated above, the three turbines evaluated for controls are GE Frame 3 Regenerative Cycle Turbines with capacity of 7,150 hp. These units were all manufactured in 1953.[381] Under the terms of the permit, the units are each subject to the following hourly and annual emission limits of NOx: 53.1 lb/hr and 232.6 tpy.[382]

EPNG evaluated one control option for these turbines aside from the good combustion practices which the company indicated were currently being utilized at the units. The other combustion control type of controls considered by EPNG included a Lean Head End (LHE) combustion liner, dry low NOx combustors, water/steam injection, but El Paso claimed that based on communications with GE, none of these controls were an option for the Pecos River Compressor Station turbines.[383] Thus, the company only evaluated SCR for the turbines. The following provides comments on the company's four-factor analysis of SCR.

1. Baseline Emissions for the Units A-01, A-02, and A-03 Combustion Turbines.

EPNG states that its cost effectiveness analyses for SCR were based on actual emissions using 2016 stack test data and actual hours of operation from the 2016 emission inventory submittal.[384] In its cost data sheets in Section 8.0 of its four-factor analysis, the company provided summaries of the 2016 test data and the 2016 annual NOx tons per year from each unit, from which the actual operating hours could then be calculated.[385] NMED and EPNG should review other stack tests for these units to ensure that the actual emission rates can be considered to truly reflect actual emissions over the lifetime of the controls being evaluated. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on an estimate of emissions expected in 2028.

2. Evaluation of SCR for the Regenerative Cycle Turbines at Pecos River Compressor Station

EPNG evaluated SCR to achieve 70% reduction in NOx emissions, assuming a 20-year life of SCR.[386] With respect to the lifetime of an SCR, EPA's Control Cost Manual indicates that the life of an SCR at a gas turbine used in an industrial setting like a compressor station.[387] Thus, to be consistent with EPA's current Control Cost Manual chapter on SCR, a 25-year life of SCR should have been assumed.

EPNG only assumed 70% control with SCR at Units A-01, A-02, and A-03 and cites to an older EPA Fact Sheet on SCR.[388] A review of that EPA fact sheet, which appears to be from 2003, shows that EPA assumed SCR could achieve 70-90% NOx control, and EPA assumed 85% control in its example cost effectiveness analysis of the 2003 Fact Sheet. In EPA's June 2019 updated chapter on selective catalytic reduction in its Control Cost Manual, EPA states that "[t]heoretically, SCR systems can be designed for NOx removal efficiencies [of] close to 100 percent. In practice, commercial coal-, oil-, and natural gas-fired SCR systems are often designed to meet control targets of over 90 percent."[389] EPNG did not provide any other justification for assuming only 70% control with SCR at the Pecos River Compressor station turbines. Indeed, ninety percent control has been the benchmark of SCR NOx removal efficiency expected with SCR including at natural gas-fired combustion turbines.[390] As discussed in NPCA's Oil and Gas Four-Factor Report, in a 2000 analysis of SCR cost effectiveness from an uncontrolled gas turbine, NESCAUM estimated that a 15 ppmvd NOx rate reflective of 90% NOx control (from uncontrolled NOx rates) could be achieved with SCR.[391]

EPNG used the SCR cost spreadsheet that EPA has made available with the Control Cost Manual to estimate SCR costs for its combustion turbines.[392] However, EPNG stated that the exhaust system would require significant modifications to install the catalyst, requiring the stack to be moved and additional ducting.[393] EPNG also states that it believes there is insufficient room within the existing building that houses the turbines, and thus has included costs to modify the turbine housing in the cost analysis.[394] Presumably, to account for some of this, EPNG applied a 1.5 retrofit factor in EPA's SCR cost spreadsheet, and also EPNG also included an additional $2.5 million would be required per combustion turbine for building modifications. However, as previously stated above, there have been numerous SCR retrofits installations at various industrial facilities that have had to overcome space constraints and retrofit difficulties. Indeed, a report about SCR retrofits at GE LM2500 turbines at Chevron's Eastridge Cogeneration plant in California showed that some significant changes to the facility had to be made to accommodate SCR, including cutting the duct between economizers and moving the stack and one economizer onto new foundations to make way for the SCR reactor.[395] EPA's SCR cost spreadsheet has an option to indicate whether the SCR installation is a new installation or a retrofit, and SPNG selected "retrofit." EPA's SCR chapter in its Control Cost Manual already provides for a 25% increase in cost above the cost of SCR at a new greenfield coal-fired boiler,

which is reflected in EPA's SCR cost spreadsheet, because EPA's spreadsheet calls for use of a "0.8" retrofit factor for an SCR installation at a new facility and a "1" retrofit factor for an average SCR retrofit.[396] Further, given that most gas turbines that have retrofitted an SCR reactor likely were not planned or designed for an SCR reactor to be installed, the average retrofit costs that EPA's SCR cost spreadsheet calculates likely take into account some of the difficulties like the need to move the exhaust stack to install the SCR, which would be required for most if into all SCR retrofits to gas turbines.[397] Thus, EPNG was not justified in using both a 1.5 retrofit factor in the SCR cost spreadsheet and also adding $2.5 million in capital costs per unit for compressor building modifications.

With respect to the compressor building modifications, there is one entry made by EPNG into the EPA cost spreadsheet that ultimately defines the size of the SCR reactor, and that is the "base case fuel gas volumetric flow rate factor" which is in terms of ft^3/min-MMBtu/hr. EPNG used a fuel gas volumetric flow rate factor of 35,103.70 ft^3/min-MMBtu/hr for Unit A-01, 50,483.81 ft^3/min-MMBtu/hr for Unit A-02, and 45,807.42 ft^3/min-MMBtu/hr for Unit A-03, which they state is "[c]alculated based on the estimated actual annual fuel consumption and maximum heat input rate."[398] These numbers seem very high in comparison to the values EPA uses for coal-fired boilers for which EPA defines as a constant for fuel type regardless of unit size or actual gas throughput.[399] EPNG's fuel gas volumetric flow rate factors for each combustion turbine are roughly a factor of 100 higher than the fuel gas volumetric flow rate factors used by EPA in its SCR cost spreadsheet for coal-fired boilers. Given that the fuel gas volumetric flow rate factor is used to determine the size of SCR reactor required, it is imperative that NMED ensure that an accurate fuel gas volumetric flow rate factor for natural gas-fired combustion turbines is used in the SCR cost spreadsheet. Presumably, EPNG relied on the reactor size calculations of the spreadsheet to estimate the cost of $2.5 million per SCR installation for modifying the compressor building.

With respect to the cost to modify the compressor building, it appears that EPNG included the $2.5 million per SCR to modify the compressor building with the capital costs of SCR in determining total annual costs of the control.[400] This reflects a 65% increase in the capital cost of SCR that was calculated using a 1.5 retrofit factor. However, while the life of the SCR might be only 25 years, the life of the modifications to the compressor building would likely last as long as the compressor station is in operation, which has been 65 years so far "without any significant deterioration in operating efficiency [of the combustion turbines],[401] and EPNG anticipates that the life of the turbines will be longer than the SCR. Thus, EPNG's approach significantly increases the capital cost and thus the cost effectiveness of SCR for building

[401] *Id.* at 5-2.

modifications that will have a useful life much longer than the 25 years that EPA assumes for SCRs at industrial facilities.

To attempt to address some of these issues, as well as to revise the cost effectiveness to reflect a 4.7% interest rate and a 25-year life, EPA's SCR cost spreadsheets were used to calculate SCR cost to meet a NOx emission rate of 15 ppmv (reflective of 82 to 86% NOx removal at the Pecos River turbines)[402] assuming a 25-year life and a 4.7% interest rate. No retrofit factor was used in EPA's cost spreadsheets for the reasons previously described, but an analysis was done adding in the company's projected $2.5 million capital cost to the total SCR capital costs. Although the life of the modified compressor building would be much longer than 25 years, the $2.5 million was amortized at the same 25-year life as the SCR. No other changes were made to any of EPNG's inputs to the SCR spreadsheet. The results of these analyses are provided below.

Table 25. Cost Effectiveness of SCR at Pecos River Compressor Station Units A-01, A-02, and A-03 Combustion Turbines, Using a 25-year Life, 4.7% Interest Rate, Retrofit Factor of 1, and EPNG's Assumptions for all Other Inputs

Unit	Assumed NOx Removal Efficiency to meet 15 ppm NOx rate	Capital Cost of SCR (2018 $)	Annual O&M Costs	NOx Removed from 2016 Baseline, tpy	Cost Effectiveness of SCR (2018 $), $/ton	Cost Effectiveness of SCR with Building Modifications (2018 $), $/ton
A-01	82%	$2,535,199	$33,780	42	$5,007/ton	$9,104/ton
A-02	86%	$2,535,199	$43,109	82	$2,676/ton	$4,775/ton
A-03	86%	$2,535,199	$48,533	101	$2,230/ton	$3,934/ton

The above table provides cost effectiveness for SCR by itself at Units A-01, A-02, and A-03 as well as SCR plus the EPNG's estimated $2.5 million capital cost per SCR to modify the compressor building. As the table shows, including EPNG's estimated cost to modify the compressor building for each SCR installation significantly increases the cost effectiveness of SCR. For the reasons stated above, it is imperative that NMED ensure that the costs to modify the compressor building were appropriately estimated. Regardless, for at least Units A-02 and A-03 which operated more than Unit A-01 in 2016, SCR should still be considered cost effective even with $2.5 million in costs per SCR to modify the building. And if 2016 operating hours were lower than typical operation for Unit A-03, SCR should be considered cost effective for that unit as well.

[402] This was determined by converting EPNG's stated uncontrolled lb/MMBtu NOx rates to ppm NOx rates using the conversions of EPA's 1993 ACT for Gas Turbines (*See* EPA, 1993 ACTfor Gas Turbines at Appendix A which has conversion equations for natural gas-fired combustion turbines) and determining the percent NOx reduction efficiency to achieve a 15 ppmv NOx limit (equivalent to ~0.060 lb/MMBtu).

EPNG expressed concerns with the ammonia reagent used in an SCR system.[403] As discussed in the NPCA Oil and Gas Four-Factor Report, the primary concerns with ammonia releases are when anhydrous ammonia is used for the reagent.[404] EPNG assumed 29% aqueous ammonia in its SCR analyses.[405] When aqueous ammonia, or urea, is used, the hazards from transporting and storing pressurized ammonia don't apply. SCR has been installed at numerous industrial facilities across the U.S. There are well-established protocols and procedures for safely transporting, storing, and using anhydrous ammonia at facilities that use that reagent in their SCR systems.

X. DCP Midstream - Linam Ranch Gas Plant

The Linam Ranch Gas Plant is a natural gas processing plant located about seven miles west of Hobbs, New Mexico in Lea County. The plant is owned/operated by DCP Midstream LP. According to the Title V permit for the plant, the facility processes natural gas by removing hydrogen sulfide, water, and carbon dioxide from field gas and separates natural gas liquids from the field gas stream.[406] NMED's Statement of Basis for the plant's Title V permit describes the plant as follows: "The plant consists of an Inlet Receiving System, Amine Treater, Acid Gas Injection Well, Inlet Compression and Dehydration System, Cryogenic/Turbo Expander Plant with external Propane Refrigeration, Residual Compression, and Product Sales for Residue Gas, NGL Liquids, Stabilized Oil, Slop Oil, and Molten Liquid Sulfur."[407] The plant include Fuel Gas Systems, Instrument and Starting Air Systems, a Heat Medium (Hot Oil) System, Cooling Towers, Process Flare, Acid Gas Flare, and Drain Systems. Processing operations at the plant include chemical reaction processes, thermodynamic processes, and physical processes."[408]

According to the Title V permit, the Linam Ranch Gas Plant includes several 2-stroke lean burn RICE, several natural gas-fired turbines, boilers, a heater, gas sweetening equipment (amine unit, sulfur recovery unit (SRU) incinerator, acid gas and SRU flares), and other emission units.[409] In DCP Midstream's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Clark TLA-6 2-stroke lean-burn RICE: Units 6-11
- Solar Centaur Turbines: Units 29, 30, 31, and 32B.[410]

[406] Title V Operating Permit P094-R2 for Linam Ranch Gas Plant at 3.
[407] NMED Statement of Basis – Narrative, Title V Permit, Linam Ranch Gas Plant, March 2015, at 1.
[408] NMED Statement of Basis – Narrative, Title V Permit, for Permit Nos. 0044-M-10-M10R6 and P086-R3, at 1.
[409] Title V Operating Permit P094-R2 for Linam Ranch Gas Plant at 7-8.
[410] November 2019 Regional Haze Four-Factor Analysis for DCP Midstream Linam Ranch Gas Plant at 1-2.

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[411] The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

DCP Midstream used a 5.5% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[412] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. This is the same interest rate that EPA has used in its cost spreadsheet for SCR, but EPA also states that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[413] The current bank prime rate is 3.25%.[414] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[415] In a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[416] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. For these reasons, in the cost effectiveness calculations provided herein, a 4.7% interest rate is used rather than a 5.5% interest rate.

B. Clark TLA Two-Stroke Lean Burn RICE (Units 6-11) of the Linam Ranch Gas Plant

Units 6 and 7 are Clark TLA-6 two-stroke lean-burn RICE that were constructed in 1974, each with a capacity of 2,000 hp.[417] Units 6 and 7 each have an hourly NOx limit of 39.3 lb/hr; units 6-11 have a combined annual NOx limit of 566 tpy.[418]

Units 8 through 11 are Clark HBA-6 two-stroke lean-burn RICE that were constructed in 1951, each with a capacity of 1,267 hp.[419] Units 8 through 11 each have an hourly NOx limit of 47.5 lb/hr; units 6-11 have a combined annual NOx limit of 566 tpy.[420]

1. Use of Low Emission Combustion Technology

DCP Midstream determined that, "…clean burn technology retrofits are physically possible yet deemed technically infeasible for the engines at Linam. The aforementioned available clean burn control technologies are incapable of being retrofit on the existing 70-year-old engines on site."[421] It's true that Units 8 through 11 are 69 years old but units 6 and 7 are newer units and, in fact, units of similar ages to all of these units at Linam Ranch have demonstrated LEC retrofit technology to reduce NOx emissions. For example, Targa's Eunice and Monument gas plants operate Clark engines of similar vintage to the ones at Linam Ranch and submitted four-factor analyses to NMED for Clean Burn technology retrofits, which Targa deemed to be feasible control options.[422]

More generally, the following additional information regarding NOx emission rates specific to Clark TLA model engines – both uncontrolled and with LEC technology – are provided here:

- EPA's 2000 RICE Update includes NOx emissions test data for specific engines, including Clark Model TLA-6, 2-stroke, lean-burn, 2,000 hp RICE retrofitted with LEC. According to EPA, six engines retrofitted by a third-party vendor had NOx emission rates ranging from 0.8–1.4 g/bhp-hr, with a mean of 1.0 g/bhp-hr.[423]

- An evaluation by a technical group for the Pipeline Research Council International looked at three of the most representative make / models of 2-stroke lean burn compressor engines: (1) 2,250 hp Cooper GMVH-10; (2) 2,000 hp Clark TLA-6; and (3) 2,500 hp Cooper GMW-10. According to a technical report by the Ozone Transport Commission (OTC) describing this evaluation, "[t]he evaluation concluded that there were no technology gaps and that each of the three makes/models evaluated were capable of attaining a NOx emissions limitation of 0.5 g/bhp-hr using a combination of improvements and retrofits related to air supply, fuel supply, ignition, electronic controls, and engine monitoring."[424]

- In 2002, EPA collected data on emission rates of lean burn engines that have been retrofitted with LEC, including data from several state agencies for specific engine

[422] Targa's Eunice Gas Plant operates several Clark BA-6 and HBA-T8 2SLB RICE constructed in 1984 and capable of being retrofit with LEC technology. Targa's Monument Gas Plant operates several Clark RA-6, RA-8, and HRA-8 2SLB RICE constructed in 1956 and 1969 and capable of being retrofit with LEC technology.
[423] EPA 2000 RICE Update at 4-8.
[424] Ozone Transport Commission, Technical Information, Oil and Gas Sector, Significant Stationary Sources of NOx Emissions, Final, October 17, 2012, p. 24, *available at*: https://otcair.org/upload/Documents/Meeting%20Materials/Final%20Oil%20%20Gas%20Sector%20TSD%2010-17-12.pdf [hereinafter referred to as "2012 OTC Report"].

models.[425] Test results for 20 Clark TLA engines ranged from 0.4 to 2.9 g/hp-hr, with an average controlled NOx rate of 1.5 g/hp-hr.[426]

The above references don't specify the age of the engines retrofit with LEC technology but NMED should require DCP Midstream to further explore additional third-party vendor options for retrofitting these units.

A recent Interstate Natural Gas Association of America (INGAA) Report provides some information on Clark TLA engine stock components and retrofit modification / upgrade options.[427] Examples from this report include: upgrading stock turbocharger and stock intercooler systems; upgrading stock low pressure direct fuel systems to high pressure fuel injection and control systems; and upgrading controls for the stock fuel system.[428] Based on the information in this report, Clark TLA model engines come equipped with a single turbo, an intercooler system, and a low pressure direct fuel system. The INGAA report evaluated controls for various regulatory scenarios that would achieve NOx emission levels in the 1–3 g/hp-hr range.[429]

LEC retrofit costs specific to Clark TLA model engines are reported in the INGAA report, ranging from $300–$600 per hp, for upgrades to the scavenging, intercooler, and fuel systems.[430] The INGAA report doesn't specify what year the cost data are from so we assume it reflects the timeframe of the report, or 2017$. Using these cost data, we can estimate the cost effectiveness of retrofitting Units 6 through 11 at the Linam Gas Plant. Retrofit cost estimates using INGAA's cost estimate would range from $600,000–$1,200,000 for the 2,000 hp units 6 and 7 and $380,000–$760,200 for the 1,267 hp units 8 through 11, in 2017$. Using the Chemical Engineering Plant Cost Indices, these costs would increase to $640,000–$1,275,000 and $400,000–$800,000, in 2018$.[431] It's not clear if operating costs are included in these INGAA cost estimates; to be conservative, annual operating costs of the LEC controls are assumed to be 15% of capital costs.[432]

[429] *Id.* at 23.

[430] *Id.*

[431] Based on multiplying the cost estimate from the 2017 INGAA report by the ratio of the CEPCI indices for 2018 to 2017 (603.1/567.5).

[432] This assumption is consistent with cost data provided for the October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9, however it results in much higher O&M costs than those used in Targa's (Eunice, Monument, and Saunders Gas Plants) and Harvest Four Corners' (Kutz Canyon Gas Plant) four-factor analyses—which ranged from $40,000/yr to $100,000/yr—and than those used for ETC Texas Pipeline's Jal No. 3 Gas Plant, which assumed O&M costs would be 13% of capital costs.

EPA has examined source test data from large natural gas-fired lean burn engines and has affirmed that these data support an uncontrolled emission rate from these engines, generally, of 16.8 g/hp-hr.[433] More specifically, these source test data include individual data for three Clark TLA engines with uncontrolled emission rates of 16 g/hp-hr and two Clark TLA-10 engines with uncontrolled emission rates of 7 g/hp-hr.[434] The allowable hourly NOx emission rates for the units at Linam Ranch are equivalent to 9 g/hp-hr (for units 6 and 7) and 17 g/hp-hr for units 8 through 11. NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable with LEC technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).[435] Retrofitting LEC technology on the units at Linam Ranch to achieve a controlled NOx rate of 2 g/hp-hr reflects a 78-88% emissions reduction from the sources' allowable NOx rates. Baseline NOx emissions for these units at Linam Ranch were not provided in DCP Midstream's four-factor submittal.
The cost effectiveness of retrofitting these engines with LEC to meet a 2 g/hp-hr NOx emissions rate, based on uncontrolled emission rates (no higher than what is permitted for this source), is presented in the table below. Since the operating schedule for these engines at the Linam Gas Plant is unknown we present cost effectiveness for 2,000 and 4,000 operating hours per year; the permitted annual NOx emission rate cap for these units of 566 tons per year indicates that the units likely wouldn't operate much more than 4,000 hours per year, on average. Note, this analysis uses an interest rate of 4.7%, reflective of current and likely near future interest rates.[436] Further note, the LEC controls are assumed to last 25 years, consistent with other cost effectiveness analyses submitted to NMED for LEC controls.[437]

[433] *See* EPA Stationary Reciprocating Internal Combustion Engines Technical Support Document for NOx SIP Call (October 2003) at 5, *available at:* http://www.valleyair.org/workshops/postings/2011/8-18-11-rule4702/R4702%20APPF.pdf.
[434] *Id*. at 6 and 7.
[435] March 6, 2020 NPCA Oil and Gas Four-Factor Report at 28.
[436] As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.
[437] See 2019 Four-Factor submittals for Roswell Compressor Station and Jal No. 3 which both assume 25-year life of controls for LEC.

Table 26. Cost Effectiveness of LEC at Uncontrolled Linam Gas Plant Units 6 through 11 to Reduce NO_x Levels to 2 g/hp-hr, Assuming a 4.7% Interest Rate and a 25-Year Life, 2018$

Unit	Capital Cost of LEC to Reduce NOx from Uncontrolled Rate	Annual O&M Costs (assume 15% of Capital Costs)	Total Annualized Costs of LEC to Reduce NOx to 2 g/hp-hr (78-88% NOx Reduction)	NOx Removed, tpy operating 2,000 hr/yr	Cost Effectiveness of LEC operating 2,000 hr/yr, $/ton	NOx Removed, tpy operating 4,000 hr/yr	Cost Effectiveness of LEC operating 4,000 hr/yr, $/ton
6	$640,000–$1,275,000	$96,000–$191,000	$140,000–$280,000	31	$4,521/ton—$9,042/ton	62	$2,260/ton–$4,521/ton
7	$640,000–$1,275,000	$96,000–$191,000	$140,000–$280,000	31	$4,521/ton—$9,042/ton	62	$2,260/ton–$4,521/ton
8	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	41	$2,138/ton—$4,277/ton	83	$1,069/ton–$2,138/ton
9	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	41	$2,138/ton—$4,277/ton	83	$1,069/ton–$2,138/ton
10	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	41	$2,138/ton—$4,277/ton	83	$1,069/ton–$2,138/ton
11	$1,083,986–$2,167,972	$162,598–$325,196	$237,213–$474,426	41	$2,138/ton—$4,277/ton	83	$1,069/ton–$2,138/ton

LEC at these units would be even more cost effective than what is shown if retrofits at these engines could meet even lower NOx emission levels, less than 2 g/hp-hr. DCP Midstream indicated that retrofitting engines at the Linam Gas Plant is physically possible and NMED should require that the company solicit specific vendor quotes in order to assess the cost effectiveness of reducing NOx emissions from these engines, as has been done by other companies in New Mexico with similar engines.

2. Use of SCR

DCP Midstream did not evaluate SCR for Units 6 through 11 primarily because it claimed that it was not technically feasible for these engines.[438] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be

[438] November 2019 Regional Haze Four-Factor Analysis for DCP Midstream Linam Ranch Gas Plant at 2-9.

summarily dismissed as not feasible for these engines, particularly because DCP Midstream has not found LEC to be a cost effective NOx reduction strategy for these units.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[439]

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[440] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[441] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

C. Solar Centaur Natural Gas-Fired Combustion Turbines (Units 29, 30, 31, and 32B) of the Linam Ranch Gas Plant.

The combustion turbines evaluated at the Linam Ranch Gas Plant are Solar combustion turbines of the following models, horsepower capacities, and manufacture date:[442]

Unit 29	Solar T-70	77.6 MMBtu/hr	1995
Unit 30	Solar Taurus T-70	73.95 MMBtu/hr	1995
Unit 31	Solar T4700	36.8 MMBtu/hr	1995
Unit 32B	Solar T4000	36.2 MMBtu/hr	1979

The units are all subject to NOx limits in 40 C.F.R. Part 60, Subpart GG, but those specific limits are not detailed in the Title V permit.[443] Under the terms of the permit, the units are also subject to the following hourly and annual emission limits of NOx.

[439] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[440] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.
[441] Available at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution.
[442] *See* Title V Operating Permit P094-R2 for Linam Ranch Gas Plant at 8.
[443] *Id.* at 10.

Table 27. Limits from DCP Midstream Title V Permit for the Linam Ranch Plant Combustion Turbines[444]

Combustion Turbine Unit ID	NOx limit, lb/hr	NOx limit, tpy
29	11.8	51.8
30	11.3	49.3
31	26.0	114
32B	23.7	103.9

DCP Midstream evaluated two control options for these combustion turbines: Solar's SoLoNOx combustion system and SCR.

1. Baseline Emissions for Units 29, 30, 31, and 32B.

DCP Midstream states that its cost effectiveness analyses for SoLoNOx and SCR were based on 2016 turbine operating hours multiplied by the permitted potential to emit rate (lb/hr).[445] However, the company did not provide the operating hours or this calculation of 2016 emissions in its four-factor analysis. The company also provided analyses of cost effectiveness of controls "[u]sing the actual emissions testing data (NSPS KKKK) for these turbines, rather than [potential to emit]."[446] However, the company provided no data in its four-factor analyses as to what the actual emission testing results were. Further confusing the matter is that, based on a review of the permit, the turbines are not subject to NSPS KKKK. Instead, all of the units are subject to NSPS Subpart GG.[447] A review of Title V permit application data for the Linam Ranch Gas Plant on the NMED's Emissions Analysis Tool did not find any other emissions testing data available for these units. NMED must make available whatever test data is being relied on to reflect actual emissions of these five combustion turbines if NMED intends to rely on the cost effectiveness analyses provided in a footnote of DCP Midstream's four-factor analysis. NMED should present information on the test data so the circumstances of the stack tests can be reviewed.

According to DCP Midstream's four-factor analysis, its 2016 emission inventory is based on its actual operating hours multiplied by its hourly NOx emission limit.[448] Given that this is how DCP Midstream reports actual emissions for the combustion turbines to NMED and in the absence of testing documentation to ensure that the test data DCP relies on for its alternative baseline analysis reflects actual emissions at all levels of operation of the combustion turbines, it seems most appropriate to use the data that DCP has been using for its emission inventory. NMED should require that DCP identify the operating hours of each unit that it has assumed for the combustion turbines.

[446] *Id.*
[447] Title V Operating Permit P094-R2 for DCP Midstream Linam Ranch Gas Plant at 6, Table 103.A.
[448] *Id.* at 3-11.

2. Evaluation of SoLoNOx for the Combustion Turbines at 29, 30, 31, and 32B.

DCP Midstream states that SoLoNOx can achieve an "overall reduction efficiency of 55%-80%...for the turbines located at this facility using this technology in comparison to permitted [potential to emit]."[449] Specifically, DCP Midstream evaluated SoLoNOx to meet a 15 ppm NOx rate at Units 29 and 30 and a 25 ppm NOx rate at Units 31 and 32B.[450]

In terms of the life of SoLoNOx controls in the cost effectiveness analyses, DCP's analysis assumed a 20 year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[451] In the table below, DCP Midstream's cost effectiveness analyses of SoLoNOx were revised to take into account a longer lifetime of controls and a lower 4.7% interest rate.

Table 28. Revised Cost Effectiveness of SoLoNOx at Units 29, 30, 31 and 32B of the DCP Midstream Linam Ranch Gas Plant, to Reflect a 4.7% Interest Rate and a 25 Year Life

Unit	DCP's Total Annual Costs of SoLoNOx (at 5.5% Interest and 20-Year Life)	DCP's Cost Effectiveness at 5.5% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25 Year Life
29	$605,743	$21,278/ton	$602,950	$20,642/ton
30	$618,799	$23,829/ton	$616,006	$23,720/ton
31	$269,048	$3,100/ton	$248,594	$2,865/ton
32B	$268,805	$12,765/ton	$248,151	$11,794/ton

The cost effectiveness of SoLoNOx at Units 29 and 30 are very high, because according to DCP Midstream's four-factor submittal, the units' current NOx rates are 33-35 ppm, and thus SoLoNOx to reduce the units' NOx emissions to 15 ppm will only reduce emissions by 55-57%. For Unit 31, SoLoNOx is much more cost effective at $2,865/ton, as the company's four-factor submittal shows that SoLoNOx at Unit 31 would reduce NOx by 78%. For Unit 32B, the cost effectiveness is higher despite SoLoNOx being projected to reduce NOx by 76% because the unit had low actual emissions in 2016 (which appears to be due to low operating hours). NMED should ensure that the 2016 emissions and operational data that is being relied on for the cost effectiveness analyses is reflective of historical operations and projected operations in 2028 before discounting a highly effective control as not cost effective.

[451] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.

3. Evaluation of SCR for Units 29, 30, 31, and 32B of the DCP Midstream Linam Ranch Gas Plant.

DCP Midstream evaluated SCR as a technically feasible control option for the Solar Centaur gas combustion turbines of Units 29, 30, 31, and 32B of the DCP Midstream Linam Ranch Gas Plant. DCP Midstream used EPA's SCR cost spreadsheet made available with EPA's Control Cost Manual.[452]

DCP Midstream only assumed 70% control could be achieved with SCR at Units 29, 30, 31, and 32B, even though the company indicated that SCR could achieve up to 90% control.[453] As presented NPCA's Oil and Gas Four-Factor Report, NESCAUM assumed 90% control with SCR in its 2000 Status Report to control small gas turbines down to 15 ppmv.[454] However, for Units 29 and 30, a 15 ppm NOx rate with SCR only reflects 55-57% control. As discussed in Section I.C.2 above, NOx rates as low as 3.75 ppm have been permitted for gas turbines with SoLoNOx and SCR.[455] Thus, to reflect the capabilities of SCR at Units 29 and 30, a much lower NOx emissions rate should have been evaluated for these units. For this report, the EPA's SCR cost spreadsheet was thus used with almost all of the same data inputs as used by DCP Midstream, but assuming a NOx rate equivalent to about an 85% NOx reduction would be met at the units (approximately a 5 ppm NOx emission rate at Units 29 and 30 and 15 ppmv NOx emission rate at Units 31 and 32B). The only other changes made to DCP's SCR spreadsheet inputs were to assume a longer life of the SCR of 25-years[456] and a 4.7% interest rate (instead of DCP's assumed 20-year life of SCR and 5.5% interest rate). The table below provide the estimated cost effectiveness of SCR to achieve 85-87% control at Units 29, 30, 31, and 32B of the DCP Midstream Linam Ranch Gas Plant.

[452] November 2019 Regional Haze Four-Factor Analysis for DCP Midstream Linam Ranch Gas Plant at 3-12.
[453] *Id.* at 2-6.
[454] NPCA March 2020 Oil and Gas Four-Factor Report at 74-75. *See also* NESCAUM, December 2000, Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, Internal Combustion Engines, Technologies & Cost Effectiveness at III-21 through III-24 and at III-40 (see referenced 11, 16, 9, 14, and 15), available at http://www.nescaum.org/documents/nox-2000.pdf/view.
[455] See January 9, 2019 Registration No. 21599, available at: https://www.deq.virginia.gov/Portals/0/DEQ/Air/BuckinghamCompressorStation/21599_Signed_Permit.pdf. Note that this permit was recently vacated by the Courts, see https://www.cbs19news.com/story/41533113/permit-forbuckingham-county-compressor-station-vacated.
[456] EPA's Control Cost Manual indicates that SCR at industrial units has a life of 25-years. *See* EPA Control Cost Manual, Section 4, Chapter 2, at pdf page 80.

Table 29. Cost Effectiveness of SCR to Achieve ~85% NOx Reduction (5 ppmv at Units 19 and 20 and 15 ppmv at Units 21 and 22B) at the Linam Ranch Gas Plant, Assuming a 25-Year Life of SCR and a 4.7% Interest Rate

Linam Ranch Unit #	Capital Cost of SCR	Annual Operational and Maintenance Costs of SCR	Annualized Cost of SCR to Achieve 85-87% NOx control	NOx Emission Reductions, tpy	Cost Effectiveness of SCR to Achieve 85-87% Control (at 4.5% interest rate and 25 year life)
19	$3,029,516	$50,364	$261,605	44	$5,991/ton
20	$2,935,376	$47,267	$252,025	39	$6,395/ton
21	$1,864,898	$34,660	$165,705	97	$1,706/ton
22B	$1,845,408	$18,703	$148,406	24	$6,195/ton

As shown by a comparison of Table 29 to Table 28 above, SCR at the Linam Ranch Gas Plant Units 19, 20, 21, and 22B is actually more cost effective than SoLoNOx at the units and SCR can achieve greater levels of NOx reductions. SCR could be even more cost effective if there are opportunities to share an SCR between two or more combustion turbines.
Moreover, SCR combined with SoLoNOx, which is commonly required to meet BACT for gas turbines, could reduce NOx by 97% or more. As discussed in Section I.C.2 of this report, this combination of NOx controls has been permitted for the Buckingham Compressor Station to achieve a NOx emission rates of 3.75 ppmv @ 15% oxygen.[457] However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as BACT or LAER for such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15% oxygen.[458] NMED should require DCP Midstream to evaluate the cost effectiveness of the combination of SoLoNOx and SCR to achieve the greatest level of NOx reduction.

XI. ETC Texas Pipeline – Jal No. 3 Gas Plant

The ETC Texas Pipeline, Ltd. Jal No. 3 Gas Plant is located in Lea County. NMED has described the facility processes as follows:

> The function of the facility is to treat and process natural gas. The facility consists of natural gas compression units, amine-sweetening units, a sulfur unit, an acid

[457] See January 9, 2019 Registration No. 21599, available at: https://www.deq.virginia.gov/Portals/0/DEQ/Air/BuckinghamCompressorStation/21599_Signed_Permit.pdf. Note that this permit was recently vacated by the Courts, see https://www.cbs19news.com/story/41533113/permit-forbuckingham-county-compressor-station-vacated.
[458] *See*, e.g., Chupka, Mark, The Brattle Group, and Anthony Licata, Licata Energy & Environmental Consulting, Inc., Independent Evaluation of SCR Systems for Frame-Type Combustion Turbines, Report for ICAP Demand and Curve Reset, at 9.

gas reinjection system, various storage tanks, fugitive emissions, and three flares.[459]

According to the permit, the plant includes several 2-stroke and 4-stroke lean-burn reciprocating internal combustion engines (RICE), boilers, heaters, amine sweetening units, vapor recover unit and thermal oxidizer, flares, and tanks.[460] In ETC Texas Pipeline's four-factor submittal, the company evaluated air pollution controls for the following emission units:

- Cooper-Bessemer 2SLB RICE GMV-10T5: Units 4A and 5A.[461]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[462] The following provides a review of the company's four-factor analyses.

A. Units 4A and 5A: Cooper-Bessemer GMV-10T5 2-Stroke Lean-Burn RICE

Units 4A and 5A are two-stroke lean-burn RICE that were constructed in 1948, each with a capacity of 1,100 hp.[463] The units each have an hourly NOx limit of 27.9 lb/hr and an annual NOx limit of 122.0 tpy.[464] The operating hours for these units, based on 2016 emissions inventory data are 560 hours per year for unit 4A and 4,290 hours per year for units 5A.[465]

1. Use of Low Emission Combustion Technology

ETC Texas Pipeline describes units 1A, 2A, and 3A as the same Cooper-Bessemer GMV-10T5 engines but currently operating with low emission control technology.[466] These engines were retrofit in 2007 by Cameron Compression Systems including new power cylinder heads, gas ignitors, a high efficiency turbocharger, and guaranteeing a controlled NOx emission rate of 2 g/hp-hr.[467]

ETC Texas Pipeline assumes a controlled NOx emission rate from LEC retrofits on units 4A and 5A of 1 g/hp-hr and estimates this represents an 81–89% reduction from baseline NOx emission rates that are based on the 2016 emissions inventory.[468] The permitted maximum hourly NOx emission rate of 27.9 lb/hr for these units is significantly higher than the 2016 emissions

[468] *Id.* at 5.

inventory data used for baseline emissions, especially for unit 5A. The allowable hourly NOx emission rate is equivalent to 11.5 g/hp-hr for these 1,100 hp engines. The source's Title V renewal application provided details on the basis for the uncontrolled NOx emission rate as stack test data, with data provided for all five Cooper-Bessemer GMV-10TF engines. The stack test data for units 4A and 5A are shown in the table below, along with the baseline emissions used in the four-factor analysis (that are based on 2016 emissions inventory calculations):

Table 30. ETC Texas Pipeline Jal No. 3 Gas Plant 2SLB RICE Unit NOx Emission Rates

Unit	Size [hp]	NOx Permit Limit [lb/hr]	NOx Permit Limit [g/hp-hr]	NOx Stack Test Data from Title V Permit Application [g/hp-hr]	NOx Baseline Emissions from August 2016 EI [g/hp-hr]
A4	1,100	27.9	11.5	6.2–6.8	9.4
A5	1,100	27.9	11.5	7.2–8.2	5.1

Assuming a controlled NOx emission rate for LEC of 1 g/hp-hr, emissions reductions range from 84–89% for unit A4 and from 81–88% for units A5. ETC Texas Pipeline assumed 89% control for unit A4 and 81% control for unit A5. If unit A5 operates at a higher emission rate than in 2016—one that is more reflective of the emission rate from the stack testing completed for the source's Title V Renewal Application—then the emissions reductions would be greater than what was assumed in the four-factor analysis.

It's possible that the controlled emission rate with LEC for these specific engines could be even lower that 1 g/hp-hr. For reference, the following additional sources of information regarding NOx emission rates specific to Cooper-Bessemer GMV model engines – both uncontrolled and with LEC technology – are provided here:

- EPA's 2000 RICE Update includes NOx emissions test data for specific engines, including Cooper-Bessemer GMV-10C, 2-stroke, lean-burn, 1,100 hp RICE retrofitted with LEC. Tested at 0.61 g/bhp-hr.[469]

- An evaluation by a technical group for the Pipeline Research Council International looked at three of the most representative make / models of 2-stroke lean burn compressor engines: (1) 2,250 hp Cooper GMVH-10; (2) 2,000 hp Clark TLA-6; and (3) 2,500 hp Cooper GMW-10. According to a technical report by the Ozone Transport Commission (OTC) describing this evaluation, "[t]he evaluation concluded that there were no technology gaps and that each of the three makes/models evaluated were capable of attaining a NOx emissions limitation of 0.5 g/bhp-hr using a combination of improvements and retrofits related to air supply, fuel supply, ignition, electronic controls, and engine monitoring."[470]

[469] EPA 2000 RICE Update at 4-8.
[470] 2012 OTC Report at p. 24.

LEC controls at unit 5A would be even more cost effective if the baseline emission rate is more in line with the stack test data provided in the source's Title V Renewal Application (i.e., reflective of 88% control).

ETC Texas Pipeline states that units 4A and 5A are backup engines that operate, on average, 25-50% of the time each year.[471] The four-factor analysis is based on operating hours from the 2016 emissions inventory of 560 hours for unit 4A and 4,290 hours for unit 5A, or 6% and 50% operation, respectively. Therefore, the cost effectiveness of LEC controls at unit 4A would be more favorable than what is shown in the four-factor analysis for operation between 25-50%. Revising ETC Texas Pipeline's cost effectiveness analyses to address some of these issues, including assuming 1) 88% control of NOx at unit 5A, and 2) unit 4A operating 50% of the year, results in more favorable cost effectiveness of these controls, as shown in the table below.

Table 31. Cost Effectiveness of LEC at Uncontrolled Jal No. 3 Gas Plant Units 4A and 5A to Reduce NO_x Levels to 1 g/hp-hr, Assuming 89% Control (Unit 4A) and 88% Control (Unit 5A) and Unit 4A Operating 50% of the Year, 2019 $

Unit	Size [hp]	Capital Cost of LEC (vendor quote)	Annual O&M Costs (13% of Capital Costs)	Total Annualized Costs of LEC to Reduce NOx to 1 g/hp-hr (88-89% NOx Reduction)	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of LEC, $/ton
4A	1,100	$798,355	$103,786	$135,720	4,380	45	$3,042/ton
5A	1,100	$798,355	$103,786	$135,720	4,290	37	$3,624/ton

Note, the cost effectiveness of LEC controls would be more favorable for both units if they were able to meet controlled emission rates below 1 g/hp-hr, which, as discussed earlier, has been demonstrated for other LEC retrofits for similar engines.

2. Use of SCR

ETC Texas Pipeline also evaluated SCR as a control for the two-stroke lean burn engines at Jal No. 3. The company did identify concerns with applicability of SCR to the two-stroke lean burn units including reagent injection control, exhaust temperature requirements, variations in the exhaust NO/NO_2 ratio, and engine oil carryover harming the SCR catalyst.[472] In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by

[471] October 2019 Regional Haze Four-Factor Analysis for ETC Texas Pipeline, Ltd. Jal No. 3 Gas Plant at 2.
[472] *Id.* at 4.

reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[473]

Irrespective of the company's concerns with applicability of SCR to the lean burn engines, ETC Texas Pipeline did conduct a cost effectiveness evaluation for SCR at Units 4A and 5A assuming a target NOx emission rate of 1 g/hp-hr.[474] Specifically, the company estimated the cost effectiveness of SCR at Unit 4A, which in its base emissions only operated 560 hours per year, as $28,561/ton, and at Unit 5A, which operated 4290 hours in its base emissions, at $7,517/ton.[475]

ETC Texas Pipeline appears to have used a 2000 NESCAUM Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, and Internal Combustion Engines to estimate capital costs for SCR.[476] Specifically, the NESCAUM formula which was based on only one case study for a RICE unit to "approximate" SCR capita costs for lean burn RICE is as follows:

$310,000 + ($72.7 x hp)[477]

This NESCAUM equation is twenty years old and is likely based on cost data from the 1990's. SCR has been implemented on numerous source types over the past twenty years, and the much wider-scale implementation and innovation in catalyst design has lowered the cost of SCR.[478] Yet, ETC Texas Pipeline's analysis escalated the capital costs developed with the above equation from the 2000 NESCAUM report by assuming the NESCAUM cost equation was based on 1994 costs and escalating to 2019, using the differences in the Consumer Price Index between 1994 and 2019.[479] EPA's Control Cost Manual cautions against escalating costs more than five years due to the potential for significant inaccuracies in price estimates.[480]
EPA currently has a spreadsheet available to estimate the capital and operating costs for SCR. While the spreadsheet was developed for fossil fueled fired boilers, it can be used as an estimate for SCR at other natural gas-fired sources and, in fact, has been used oil and gas companies for several four-factor analyses submitted to NMED. Unfortunately, ETC Texas Pipeline did not include the necessary information to use the EPA SCR cost spreadsheet to estimate SCR costs for the Units 4A and 5A engines. NMED should ask the company to use the EPA spreadsheet rather than the NESCAUM formula and escalate the cost 25 years to current dollars.

[473] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[474] October 2019 Regional Haze Four-Factor Analysis for ETC Texas Pipeline, Ltd. Jal No. 3 Gas Plant at 2.
[475] *Id.* at Appendix B.
[476] *Id.* at 8. *See also* December 2000 NESCAUM Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, and Internal Combustion Engines at III-30.
[477] *Id*.
[478] See EPA, Combined Heat and Power Partnership, Catalog of CHP Technologies, Section 3. Technology Characterization-Combustion Turbines, March 2015, at 3-18.
[479] October 2019 Regional Haze Four-Factor Analysis for ETC Texas Pipeline, Ltd. Jal No. 3 Gas Plant at Appendix B.
[480] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017.

In addition, the company's assumed annual operations and maintenance cost, estimated to be 20% of the total capital cost, is arbitrary and unjustified. In particular, ETC Texas Pipeline's annual operations and maintenance costs have no connection to the operating capacity of Units 4A and 5A. As a comparison, in Section XIX.A.2. below, we provide an SCR cost estimate using the EPA cost spreadsheet for the Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[481] For the two units at Roswell Compressor No. 9, that are 4500 hp each and that operate at 11% to 41% of available hours, the operation and maintenance costs to achieve 90% NOx reduction were roughly $26,000/year. See Table 46 in Section XIX.A.2. below.

If we assume that the operation and maintenance expense at Units 4A and 5A are the same as the larger units at Roswell Compressor No. 9 – i.e., $26,000 per year rather than ETC Texas Pipeline's assumed $134,973 per year, the cost effectiveness of SCR at Units 4A and 5A at Jal No. 3 decrease to $10,191/ton at Unit 4 A and $2,459/ton at Unit 5A. Thus, a more appropriate annual operations and maintenance cost make SCR very cost effective particularly at Unit 5A which operates more than Unit 4A.

For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal. NMED should request that ETC Texas Pipeline submit a refined analysis of SCR cost effectiveness using the EPA SCR cost spreadsheet.

B. SO2 Emissions from Thermal Oxidizer

ETC Texas Pipeline also evaluated controls for thermal oxidizer which combust the acid gas stream from its amine units.[482] We address that analysis in Section XXIII of this report.

XII. Davis Gas Processing Denton Gas Plant

The Denton Gas Plant is a natural gas processing plant in which the H2S is removed from the natural gas in an amine unit and then the gas is processed through a cryogenic unit to condense natural gas liquids.[483] The plant is located about 11 miles east of Lovington, New Mexico in Lea County. It is owned/operated by Davis Gas Processing. The plant consists of an amine unit, dehydrator regenerator, four-stroke rich burn RICE units, heaters, and tanks, but SO2 emissions from flaring of acid gases are the primary source of air emissions from the plant.[484] Thus, the four-factor analysis for this facility focused on the amine unit and the acid gas flare (Unit No. 007)Amine unit and flare.[485] Comments on the company's four-factor analysis are provided in Section XXIII further below, in comments on amine units and flaring emissions.

XIII. El Paso Natural Gas Company – Washington Ranch Storage Facility

The El Paso Natural Gas Company, LLC. (EPNG) Washington Ranch Storage Facility is located in Eddy County and was identified by NMED as one of the sources contributing to regional haze at Carlsbad Caverns National Park Class I area.[486] NMED has described the facility processes as follows:

> The function of the facility is to compress and inject pipeline quality natural gas into underground storage wells and withdraw the gas for delivery into the pipeline.[487]

According to the permit, the plant includes two 2-stroke lean-burn reciprocating internal combustion engines (RICE), a 4-stroke rich-burn auxiliary engine, a glycol dehydrator and reboiler, a heater, a flare, and a diesel water pump engine.[488] In EPNG's four-factor submittal, the company evaluated air pollution controls for the following emission units:

- Cooper-Bessemer 2SLB RICE 12Q155HC2: Units A-01 and B-02.[489]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[490] The following provides a review of the company's four-factor analyses.

A. Units A-01 and B-02: Cooper-Bessemer 12Q155HC2 2-Stroke Lean-Burn Compressor Engines

Units A-01 and B-02 are 2-stroke lean-burn RICE that were constructed in 1982, each with a capacity of 4,500 hp.[491] The units each have an hourly NOx limit of 27.3 lb/hr and an annual NOx limit of 119.5 tpy.[492]

1. Use of Low Emission Combustion Technology

EPNG describes a "layered approach" strategy for Clean Burn technology applied to the two engines reviewed in its four-factor analysis, A-01 and B-02.[493] Specifically, EPNG states that these units are already equipped with a turbocharger, advanced ignition system, pre-combustion chambers, high pressure fuel injection systems, and an Automatic Balancing Platform.[494] According to EPNG these Clean Burn technologies, based on manufacturer guidance, result in NOx emission rates of 0.5–2.75 g/hp-hr, or 27–82% reduction in NOx emissions.[495] Based on the information provided on the different Clean Burn technologies available for these engines it's possible that there are additional technologies that could be employed to ensure the NOx emission rates are closer to 0.5 g/hp-hr. For example, it's not clear if the pre-combustion chamber installed on units A-01 and B-02 is a "closed loop ePCC," which corresponds to emission rates of 0.5 g/hp-hr.[496] And it's also not clear if the Automatic Balancing Platform is considered "Advanced TER Control" or "Transient Control," the latter of which would result in emission rates around 0.5 g/hp-hr.[497] In EPA's Alternative Control Techniques document for RICE it reports achievable emission levels for retrofit low-emission designs for a Cooper-Bessemer 16Q155HC engine of 1.8 g/hp-hr.[498] And more recently, EPA has described layered combustion as demonstrated control techniques for 2-stroke lean-burn engines, achieving a NOx emission rate of 0.5 g/hp-hr.[499]

Units A-01 and B-02 have an allowable NOx emission rate of 27.3 lb/hr, or 2.75 g/hp-hr for these 4,500 hp units. And the source's Title V Permit Renewal Application specifies that these permit limits are based on the design for the low emission conversion.[500] NMED should require additional LEC retrofit techniques be evaluated in order to assess the cost effectiveness of further reducing NOx emissions from these engines to a level closer to 0.5 g/hp-hr. Reducing emissions to this level would achieve an additional 82% reduction in NOx emissions from these compressor engines. If these engines operate frequently it could be cost effective to update the Clean Burn technology on these engines, resulting in potentially significant NOx emissions

[500] September 2013 Title V Permit Renewal Application El Paso Natural Gas Company, LLC Washington Ranch Storage Facility Section 6, Page 2.

reductions. At continuous operation these units have the potential to emit 120 tons per year of NOx each; an 82% reduction using layered combustion to meet a 0.5 g/hp-hr NOx emission rate would prevent almost 200 tons per year of NOx emissions from both units, when operating continuously.

2. Use of SCR

EPNG did not evaluate SCR for Units A-01 and B-02 primarily because it claimed that it was not technically feasible for variable load engines of this type.[501] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines, particularly because EPNG has not found LEC to be a cost effective NOx reduction strategy for these units.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[502]

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[503] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[504] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

XIV. Enterprise Blanco Compressor C & D

The Blanco C & D Compressor Station is a natural gas compressor station located about one mile northeast of Bloomfield, New Mexico in San Juan County.[505] It is owned/operated by Enterprise Field Services LLC.

The Title V operating permit for the facility indicates that the plant includes several natural gas-fired turbines, flares, and tanks.[506] In Enterprise's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- GE 5221W combustion turbines (Units T-C01 and T-C02)
- GE M5322B combustion turbine (Unit T-D01)[507]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[508] The following provides a review of the company's four-factor analyses. The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

Enterprise used an 8.38% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[509] This is an unreasonably high interest rate for cost effectiveness analyses. EPA's Control Cost Manual indicates that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[510] The current bank prime rate is 3.25%.[511] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[512] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. However, in a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[513] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate

(and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. Enterprise's use of an 8.38% interest rate is unreasonably high and overstates the cost effectiveness of pollution controls evaluated in the four-factor analyses.

B. GE Combustion Turbines: Units T-C01 and T-C02 and T-D01

Units T-C01 and T-C02 at the Blanco C&D Compressor Station are each 22,280 hp natural gas-fired turbines that are listed in the Title V permit as constructed before June 1989.[514] The units each have a NOx emissions limit of 80.0 lb/hr and 350.4 tpy.[515] For these units, Enterprise identified water or steam injection as viable combustion controls for NOx but claimed that dry low NOx combustors were not available for retrofit to these types of gas turbines.[516] Unit T-D01 is a GE M5322B combustion turbine of 32,550 hp capacity that is identified in the Title V permit as being constructed before October 1987.[517] Unit T-D01 has NOx limits of 143.3 lb/hr and 628 tpy.[518] For this unit, Enterprise identified water or steam injection or dry low NOx combustors as feasible controls.[519] Enterprise claimed that SCR installation was not possible for any of these gas turbines, due to the size estimates of the SCR.[520] Presumably, Enterprise is claiming issues of retrofit difficulty. There is no question that SCR is technically feasible for natural gas-fired combustion turbines, including those used at compressor stations.

1. Evaluation of Baseline NOx Emissions.

According to the company's cost analysis for water/steam injection, Unit T-C01 has an actual NOx emission rate of 36.92 lb/hr (57.7 ppm), Unit T-C02 has an actual NOx emission rate of 51.56 lb/hr (83.2 ppm), and Unit T-D01 has an actual NOx emission rate of 49.32 lb/hr (65.0 ppm) based on 2016 stack test data.[521] These actual emission rates are much lower than the units' allowable NOx emission rates so, either the 2016 stack test data was not performed while the engines were operating at maximum capacity or the allowable NOx emission rates have been set unreasonably high. In addition, while both Units T-C01 and T-C02 are the same model and same horsepower, one unit's NOx rate (T-C01) is listed by Enterprise as 31% lower than the NOx rate of T-C02. That does not make sense, if such emission rates are reflective of test data at maximum or close to maximum capacity. NMED should present information on the 2016 stack test data so the circumstances of the stack tests can be reviewed. In addition, NMED and Enterprise should review other stack tests for these units to ensure that the actual emission rates can be considered to truly reflect actual emissions over the lifetime of the controls being evaluated. If testing is only done sporadically, such as once every five years, then it is

[520] *Id.* at 2-4.
[521] November 2019 Regional Haze Four-Factor Analysis for Enterprise Blanco C&D Compressor Station at Section 8.0.

questionable that such stack test data truly reflect an accurate projection of emissions expected over the lifetime of the controls being evaluated, especially given that the emission rates are so much lower than the units' allowable pound per hour emission rates. NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on an estimate of emissions expected in 2028.

2. Evaluation of Water Injection and Steam Injection for NOx Control

Enterprise only assumed 15% NOx reduction from water or steam injection.[522] While Enterprise cites to EPA's AP-42 emission factor documentation for the 15% control with water or steam injection, EPA's AP-42 states that such controls can achieve 60% or higher NOx removal.[523] EPA's 1993 Alternative Control Techniques Document for NOx emissions from Stationary Gas Turbines, which EPA's AP-42 documentation cites to, states that NOx rates in the range of 25 to 42 ppmv can be achieved with water or steam injection as gas-fired combustion turbines.[524] If the uncontrolled emissions of Units T-C01, T-C02, and T-D01 are truly in the range of 57.7 to 83.2 ppm as indicated in Enterprise's four-Factor analyses (assuming this is parts per million by volume at 15% oxygen, which NMED should confirm), water injection to meet a NOx rate of 25-42 ppm reflects 27% to 70% NOx removal. NMED must require that Enterprise evaluate water or steam injection for these units reflective of the NOx rates that have historically been achieved with water or steam injection.

With respect to the life assumed of water or steam injection, Enterprise only assumed a 15-year life of these controls.[525] Enterprise did not provide any justification for assuming such a short life of water or steam injection. As discussed in NPCA's March 2020 report, the life of water or steam injection should be the life of the combustion turbines. In NPCA's March 2020 report, we assumed a 25-year life of water or steam injection.[526]

In terms of Enterprise's costs for water injection or steam injection, the company's capital costs seem very high for the size turbines, based on a comparison to the 1999 Department of Energy report entitled "Cost Analyses of NOx Control Alternatives for Stationary Gas Turbines," which is cited in several EPA and State documents on the costs of NOx controls at gas turbines.[527] In that 1999 DOE report, the costs of water or steam injection for a gas turbine that is larger than Units T-C01 and T-C02 and slightly smaller than T-D01, a GE LM2500 turbine which is of 22.7 megawatt capacity or about 30,400 hp, the capital cost in 1999 dollars of water injection was

[527] Bill Major, ONSITE SYCOM Energy Corporation, and Bill Powers, Powers Engineering, Cost Analysis of NOx Control Alternatives for Stationary Gas Turbines, prepared for U.S. Department of Energy, November 5, 1999, available at: https://www.energy.gov/sites/prod/files/2013/11/f4/gas_turbines_nox_cost_analysis.pdf [hereinafter "1999 DOE Report"].

estimated to be $1,083,175.[528] Although EPA's Control Cost Manual advises against escalating costs more than five years because it can lead to inaccuracies in price estimation,[529] just using the Chemical Engineering Plant Cost Indices between 1999 and 2018, the DOE's 1999 costs of water injection for a larger GE LM2500 gas turbine would increase to $1.67 million.[530] Using a different cost index specific to oil refineries, the Nelson-Farrar index, the 1999 costs of water injection increase from $1.0 million to $1.88 million as of 2016 (the most recent annual Nelson-Farrer cost index found online).[531] Yet, Enterprise's capital cost estimate for water injection at T-C01 and T-C02 was $6.1 million, more than three times the escalated capital costs from the 1999 DOE report based on either the CEPCI index or the Nelson-Farrar index. Thus, Enterprise's capital cost estimate of water injection for a smaller capacity gas turbine at these units seem very high, and its capital costs for steam injection are $2 million higher than its costs for water injection. Further, the inspection and operating costs of water injection, which Enterprise stated would be $1,238,327 per year,[532] are not explained or documented and seem unreasonably high. NMED must request more details and support for these cost estimates of water injection and of steam injection at these units.

We addressed just some of these issues to revise Enterprise's cost effectiveness analyses to reflect 1) a 4.7% interest rate (instead of 8.38%), 2) a 25-year life of water or steam injection (instead of an assumed 15-year life), 3) a controlled NOx rate with water or steam injection of 25 ppmvd at 15% O_2. With the revisions listed in items 1 through 3 above, Enterprise's cost effectiveness of water or steam injection reduced from approximately $57,000 to $110,000/ton of NOx removed to $14,000 to $51,000/ton, and it is important to note that no changes were made to Enterprise's apparently inflated capital and operating costs of water or steam injection.

In its identification of energy and non-air quality environmental impacts of compliance, Enterprise did not list water use as an adverse environmental impact, but it is an issue to be concerned with for water injection.[533] That is why dry low NOx combustion, if available (which Enterprise claims is not available for the Units T-C01 and T-C02 turbine models) or selective catalytic reduction (SCR) are more preferable choices for NOx control from gas-fired turbines in New Mexico.

3. Evaluation of Dry Low NOx Combustion at Unit T-D01

Enterprise did evaluate dry low NOx combustors for the GE M5322B unit (Unit T-D01), but claimed that dry low NOx combustors could only achieve a NOx rate of 35 ppmv at this unit, or

[528] *Id.*, Appendix A at A-4.

[531] Based on multiplying the 1999 cost estimate for water injection from the 1999 DOE report by the ratio of Nelson-Farrar indices for 2016 to 1999 (2598.7/1497.2).
[532] November 2019 Regional Haze Four-Factor Analysis for Enterprise Chaco Gas Plant at 8-2 to 8-3.
[533] *See* March 6, 2020 NPCA Oil and Gas Four-Factor Report at 67-68.

a NOx reduction efficiency of 46%. This is a high NOx rate and a low NOx removal efficiency to assume with dry low NOx combustors. As discussed in NPCA's March 2020 Oil and Gas Four-Factor Report, such controls can achieve NOx removal efficiencies of 80-95% with typical NOx emission rates in the range of 9-15 ppm.[534] In a 1999 Department of Energy Report on the costs of NOx controls for gas combustion turbines, the highest NOx emission rate evaluated with dry low NOx combustors was 25 ppm.[535] Thus, Enterprise's cost effectiveness analysis for dry low NOx combustors assumed an unreasonable low level of NOx reduction with this control.

In terms of the life of dry low NOx combustion controls in the cost effectiveness analyses, Enterprise's analysis assumed a 20-year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[536]

In the table below, Enterprise's cost effectiveness analyses of dry low NOx combustors were revised to take into account a longer lifetime of controls and a lower 4.7% interest rate. In addition, two lower NOx rates were evaluated: 25 ppm and 15 ppm.

Table 32. Revised Cost Effectiveness of Dry Low NOx Combustors at Unit T-D01 of the Blanco C&D Compressor Station, to Reflect a 4.7% Interest Rate and a 25 Year Life[537]

NOx Emission Rate Evaluated, ppm	NOx Removal Efficiency Evaluated	Annual Cost of Dry Low NOx Combustors (at 4.7% interest and 25 Year Life)	NOx Emissions Reduced, tpy	Cost Effectiveness
35[538]	46%	$609,798	91.04	$6,694/ton
25	62%	$609,798	121.46	$5,021/ton
15	77%	$609,798	151.82	$4,017/ton

Dry low NOx combustors at Unit T-D01 are much more cost effective than water or steam injection and, based on historical assumed NOx emission rates with these controls which range between 15 to 25 ppm (or even as low as 9 ppm), such controls should be able to reduce NOx emissions at Unit T-D01 by 62 to 77% or maybe more.

[534] March 2020 NPCA Oil and Gas Four-Factor Report at 69.
[535] *Id.* *See also* Bill Major, ONSITE SYCOM Energy Corporation, and Bill Powers, Powers Engineering, Cost Analysis of NOx Control Alternatives for Stationary Gas Turbines, prepared for U.S. Department of Energy, November 5, 1999, 2-10, available at: https://www.energy.gov/sites/prod/files/2013/11/f4/gas_turbines_nox_cost_analysis.pdf.
[536] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.
[537] The company's capital and operational and maintenance costs were not revised for this analysis. Only the interest rate was reduced from 8.38% to 4.7% and the life of controls was revised from 20 to 25 years.
[538] This in the NOx rate evaluated by Enterprise for dry low NOx combustors at Unit T-D01.

4. Evaluation of SCR for the Gas Turbines at Blanco C&D Compressor Station

Enterprise did not evaluate SCR for the gas turbines at the Blanco C&D Compressor Station, stating that it was "not possible to install these units at the Blanco facility" due to "the amount of buffer space needed to maintain accessibility to equipment and to avoid compromising worker safety."[539] While the facility and gas turbines may not have been originally designed to have space to accommodate SCR, that is typically the case with most SCR retrofits. As such, there have been numerous SCR retrofits installations at various industrial facilities that have had to overcome space constraints. For example, for many large coal-fired power plants, SCR reactors have been elevated above the air preheaters. Indeed, a report about SCR retrofits at GE LM2500 turbines at Chevron's Eastridge Cogeneration plant in California showed that some significant changes to the facility had to be made to accommodate SCR, including cutting the duct between economizers and moving the stack and one economizer onto new foundations to make way for the SCR reactor.[540] Thus, before NMED accepts a very brief claim of retrofit difficulty of SCR at any emissions unit being evaluated for reasonable progress controls, it is imperative that NMED ask Enterprise for a site plan and photos that shows whatever space constraints are being claimed. Moreover, NMED must ask Enterprise to consult with SCR vendors for options for SCR installation at the gas turbines of the Blanco C&D Compressor Station.

If any of the combustion turbines are in close proximity to another turbine, that provides opportunities for a shared SCR reactor which could help with retrofit space issues as well as with costs. NMED must require all possibilities for SCR installation be evaluated and documented by Enterprise. The state must not simply discount this highly effective NOx control based on a claim of some retrofit difficulty.

In terms of the costs of SCR control, NPCA's March 2020 Oil and Gas Four-Factor Report showed the cost effectiveness in 1999 dollars for SCR achieving about 90% NOx reductions would range from $2000/ton to $3400/ton for a 5 MW combustion turbine (~6800 hp engine) depending on the operating capacity factor, and costs decrease for larger turbines like Units 17 and 19 which are approximately 19500 hp engines.[541] For much larger combustion turbines of 75 MW generating capacity (~100,500 hp), cost effectiveness of SCR was significantly lower in the range of $560-$850/ton depending on operating capacity factor.[542]

To get an idea of the costs for SCR at Units T-C01, T-C02, and T-D01 in current dollars, one can use EPA's SCR cost spreadsheet made available as part of EPA's Control Cost Manual. It is difficult to estimate an actual cost effectiveness because it is not clear what the 2016 actual annual fuel throughput was at each unit, which is necessary for estimating annual operations and maintenance costs for SCR. However, a 2017 Title V Permit Application for Blanco C & D

[542] *Id.*

compressor stations does have information to enable an estimate of the capital cost of SCR. A review of the EPA SCR cost spreadsheet shows that the capital cost of SCR is based primarily on two factors: maximum hourly heat input to the unit in MMBtu/hr and the site elevation.[543] A 2017 Title V Permit Application for Blanco C&D compressor stations has the maximum hourly heat input to each unit as well as other data, although some of the other data is not legible in the copy of the document on NMED's Emissions Analysis Tool website.[544] Specifically, the hourly heat input to Units T-C01 and T-C02 is identified as 283 MMBtu/hr and the hourly heat input to Unit T-D01 appears to be 311.18 MMBtu/hr.[545]
The site elevation is listed as 5605 feet.[546]

Enterprise's claimed baseline NOx emission rates of 57.2 ppm, 87.3ppm, and 65.0 ppm for Units T-C01, T-C02, and T-C03 were utilized and assumed to be reflective of ppm by dry volume at 15% oxygen. As previously discussed, NMED should ensure that this 2016 test data reflects operations at maximum operating capacity and ensure that these emission rates are a reasonable projection of NOx emissions as of 2028. The company's actual NOx rates were converted to lb/MMBtu emission rates using a conversion formula from EPA's 1993 Alternative Control Techniques Document for Stationary Gas Turbines.[547] Enterprise's ppm NOx baseline rates thus were converted to 0.231 lb/MMBtu for Unit T-C01, 0.334 lb/MMBtu for Unit T-C02, and 0.341 lb/MMBtu for Unit T-D01. With this data, unit-specific information was input into EPA's SCR cost spreadsheet to estimate cost effectiveness of SCR at these units. For Units T-C01 and T-C01, the average exhaust gas temperature of the bypass stacks of 625 degrees Fahrenheit was used and for Unit T-D01 the exhaust gas temperature of 904 degrees Fahrenheit was used.[548] Two different SCR control levels were assumed: a 15 ppmvd NOx rate, which reflects 74% to 82% NOx removal at the Blanco C&D combustion turbines, and a 90% control efficiency from current uncontrolled actual NOx rates at each turbine. With Enterprise's 2016 actual annual NOx emissions and its reported ppm NOx emissions and the reported heat value of the fuel, actual annual gas consumption rates were estimated for each unit for input into the SCR cost spreadsheet. Capital costs were annualized applying a cost recovery factor using a 4.7% interest rate, and a 25-year life which EPA has identified as typical for SCR systems used at industrial boilers.[549] One reagent type was evaluated: 29% aqueous ammonia. The results of these analyses are provided in the table below.

[543] *See* equations in "Cost Estimate" tab, cell B19 (Total Capital Investment), which in turn points to cells G19 and H19, which in turn are based on "Data Inputs" tab cells C10 and C24.

Table 33. Cost Effectiveness of SCR at Blanco C&D Compressor Stations Units T-C01, T-C02, and T-D01 Combustion Turbines, Using EPA's SCR Cost Calculation Spreadsheet for Boilers (2018 $)

Unit	Assumed NOx Removal Efficiency with SCR	Capital Cost SCR	Annual Operational and Maintenance Cost	Total Annualized Costs	NOx Reduced, tpy	Cost Effectiveness
T-C01	74.0%	$7,536,749	$155,039	$676,647	119	$5,693
T-C01	90.0%	$7,536,749	$161,977	$683,585	144	$4,731
T-C02	82.0%	$7,536,749	$160,398	$682,006	180	$3,787
T-C02	90.0%	$7,536,749	$164,425	$686,034	198	$3,472
T-D01	77.0%	$8,016,420	$159,735	$714,374	153	$4,684
T-D01	90.0%	$8,016,420	$166,270	$720,909	178	$4,044

The cost estimates of SCR based on EPA's boiler SCR cost spreadsheet project costs for SCR that are significantly lower than the other NOx control evaluated by Enterprise – water or steam injection or dry low NOx combustion for Unit T-D01, for which capital costs were projected to range from $6.6 to $8.2 million.[550] Given that SCR can achieve much higher levels of control at much lower costs than water or steam injection, NMED must require Enterprise to more fully evaluate the ability to install SCR at Unit 17 and/or 18 . Ninety percent control should be readily achievable with SCR at these units to meet a NOx emission rate of 5 to 8 ppmv (0.0231 to 0.0334 lb/MMBtu). Before allowing Enterprise to dismiss SCR due to claims that it is not feasible to locate one or more SCR reactors at Units T-C01, T-C02, and T-D01, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at the units, including any options for shared SCR reactors between Units T-C01 and T-C02. SCR can be a very effective method for reducing NOx emissions from the Blanco C & D compressor station gas turbines and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for the Blanco C & D Compressor Station.

XV. Harvest Pipeline – San Juan Gas Plant

The Harvest Pipeline Company San Juan Basin Gas Plant is a facility that extracts and processes natural gas liquids and residue gas products from field gas via a cryogenic process. It is located about 2 miles northeast of Bloomfield, New Mexico. The facility consists of several combustion turbines, a diesel generator, heaters, a thermal oxidizer, and a flare.[551] It is located adjacent to the Blanco Compressor Stations of EPNG (Blanco C&D) and El Paso Field Services (Blanco A).[552]

[550] November 2019 Regional Haze Four-Factor Analysis for Enterprise Blanco C&D Compressor Station at 8-1 to 8-3.
[551] *Id.* at A6.
[552] Title V Permit No. P124-R3 for San Juan Basin Gas Plant, at A3.

In fact, the three Blanco Compressor Stations and the San Juan Gas Plant are all considered one source under the New Source Review program by NMED.[553]

In Harvest Pipeline's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Rolls Royce 155 Natural Gas Turbines (Units 1-4)
- Solar Centaur T4501 Natural Gas Turbines (Units 4-7).[554]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[555] The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

Harvest Pipeline used a 5.5% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[556] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. This is the same interest rate that EPA has used in its cost spreadsheet for SCR, but EPA also states that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[557] The current bank prime rate is 3.25%.[558] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[559] In a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[560] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. For these reasons, in the cost effectiveness calculations provided herein, a 4.7% interest rate is used rather than a 5.5% interest rate.

B. Rolls-Royce 155 Combustion Turbines: Units 1-4 at San Juan Gas Plant

Units 1-3 of the San Juan Gas Plant are Rolls-Royce Natural Gas Turbines that were manufactured in the mid-1980's.[561] The turbines have a permitted capacity of 15000 hp each, although they have a manufacture rated capacity of 23,800 hp.[562] Unit 4 is a rotating spare for Units 1 – 3, which operates only when Units 1, 2, or 3 are down for repair.[563] The turbines have catalytic oxidation for carbon monoxide and volatile organic compound (VOC) control.[564] The units are each subject to a NOx limit of 56.3 lb/hr and 246.4 tpy.[565] The units are also subject to a NOx limit of 150 ppmv at 15% O_2 pursuant to 40 C.F.R. Part 60, Subpart GG.[566]

For these units, Harvest Pipeline did not evaluate any additional NOx pollution controls. The company stated that it contacted Siemens, the company that currently owns the Rolls-Royce Avon gas turbine and compressor business, and that Siemens stated that neither dry low NOx combustion nor water or steam injection was an available control option for retrofit to the mid-1980's era Rolls-Royce turbines at the San Juan Gas Plant.[567] Siemens indicated that SCR is available for the turbine model, yet Harvest Pipeline did not evaluate SCR. The following provides comments on SCR applicability for the Rolls-Royce turbines.

1. Evaluation of SCR at the Rolls-Royce Turbines (Units 1-4)

Although, according to the four-factor analysis for the San Juan Gas Plant, Siemens claimed that SCR was an available technology for the Rolls-Royce turbines, Harvest Pipeline did not evaluate SCR technology for the turbines. The company claimed that the high exhaust temperature of the turbines (1250 degrees Fahrenheit according to the four-factor analysis) and concerns about space and power usage made SCR not feasible for the Rolls-Royce turbines.[568] SCR should not have been so readily discounted as a pollution control for the Rolls-Royce turbines. With respect to space limitations, as discussed in Section I.B.3. above, most SCR retrofits have space limitations, because the facility was not likely designed to have space to accommodate SCR. There have been numerous SCR retrofits installations at various industrial facilities that have had to overcome space constraints. For example, for many large coal-fired power plants, SCR reactors have been elevated above the air preheaters. Indeed, a report about SCR retrofits at GE LM2500 turbines at Chevron's Eastridge Cogeneration plant in California showed that some significant changes to the facility had to be made to accommodate SCR, including cutting the duct between economizers and moving the stack and one economizer onto new

foundations to make way for the SCR reactor.[569] Thus, before NMED accepts a very brief claim of retrofit difficulty of SCR at any emissions unit being evaluated for reasonable progress controls, it is imperative that NMED ask Harvest Pipeline for a site plan and photos that shows whatever space constraints are being claimed, and that NMED ask the company to consult with SCR vendors for options for SCR installation at the gas turbines.

Depending on the proximity of the gas turbines, it is possible that one SCR reactor could be used by more than one combustion turbine. This would reduce costs and potentially be easier to install at the site. NMED should require all possibilities for SCR installation be evaluated and documented by Enterprise. The state must not simply discount this highly effective NOx control based on a claim of some retrofit difficulty.

Regarding the company's stated exhaust temperature of 1,271 degrees Fahrenheit, NMED should determine if this is the sustained temperature of the gas turbines or the maximum temperature of the exhaust expected from the turbines. It must be noted that this exhaust temperature of 1,271 degrees Fahrenheit claimed in the four-factor analysis is much higher than the exhaust temperatures of the units cited in the February 2017 Title V permit application for the San Juan Gas Plant. Specifically, the 2017 permit application listed the exhaust temperature of Units 2 and 3 of 370 degrees Fahrenheit and the Unit 1, Unit 2 bypass, and Unit 3 bypass exhaust temperature as 750 degrees Fahrenheit.[570] Thus, NMED must ensure the accuracy of any stated claims about SCR being infeasible due to exhaust gas temperatures before allowing SCR to be eliminated as a control option. In addition, there are options for dealing with high exhaust temperature of simple cycle turbines to enable the use of SCR. The Buckingham Compressor Station which is proposed to be constructed in Virginia would be equipped with Solar turbines with SoLoNOx, SCR, and cooling air skids.[571] Essentially, the cooling air skids provide for the injection of tempering air at the turbine discharge (upstream of the SCR) to cool the exhaust temperature to the optimal temperature of the SCR catalyst.[572]

Further, if the Rolls-Royce turbines truly have exhaust temperatures of 1,271 degrees Fahrenheit, that is another reason why NMED should investigate routing more than one combustion turbine exhaust to a common SCR. The routing of turbine exhausts from multiple turbines to one SCR reactor will allow for some cooling of the exhaust before it enters the SCR. As previously discussed, SRP is planning to route the flue gas from one boiler at the Coronado

Generating Station in Arizona to an existing SCR reactor that had previously been constructed at the coal-fired power plant Coronado Unit 2. Such an approach seems like it could be a viable, more cost effective, control option for co-located combustion turbines at compressor stations.

To estimate the cost effectiveness of SCR for the Rolls-Royce combustion turbines, EPA's SCR cost spreadsheet was used along with the turbine operational data presented in the company's February 2017 Title V Permit Application.[573] Because Harvest Pipeline did not evaluate any emissions controls for the Rolls-Royce units, there was no information in the four-factor analysis on actual emissions and/or actual operating hours for the units. Thus, this SCR cost effectiveness analysis had to be based on an allowable emissions baseline. The uncontrolled NOx rate for input into the spreadsheet was estimated by dividing the allowable hourly emission rate of 56.30 by the hourly fuel consumption of the turbines of 123.2 MMBtu/hr,[574] for an uncontrolled NOx rate of 0.457 lb/MMBtu. Consistent with other SCR analyses presented herein and in NPCA's March 2020 Oil and Gas Four-Factor Report, it was assumed that SCR could achieve a NOx emission rate of 15 ppmv at 15% O_2,[575] which converts to 0.06 lb/MMBtu. That NOx rate reflects an 87% reduction across the SCR system from the lb/MMBtu allowable NOx emission rate. To reflect a lower capacity factor than potential to emit, an analysis was also done assuming the unit operated at 70% of maximum annual fuel throughput. Consistent with all other SCR cost analyses provided herein, a 25-year life of SCR and a 4.7% interest rate was used. The results of this cost effectiveness analysis are provided in the table below.

Table 34. Cost Effectiveness of SCR to Achieve ~87% NOx Reduction (15 ppmv at 15% O_2) at Unit 1, 2, and 3 of the San Juan Gas Plant, Assuming a 25-Year Life of SCR and a 4.7% Interest Rate

Annual Capacity Factor	Capital Cost of SCR	Annual Operational and Maintenance Costs of SCR	Annualized Cost of SCR	NOx Emission Reductions, tpy	Cost Effectiveness of SCR
100%	$4,388,725	$98,826	$403,662	214	$1,884/ton
70%	$4,388,725	$79,310	$387,146	150	$2,562/ton

Harvest Pipeline also indicated that the electricity currently available at the San Juan facility is sufficient to power SCR systems at the Rolls-Royce units, and stated that "[i]nstallation of [SCR] will require the facility to expand its current power generation."[576] Based on electricity calculations of EPA's SCR cost spreadsheet, if SCR systems were operated for each unit and each unit was operated at 100% of maximum capacity, the electricity needs would be 71.91 kW per hour per unit for an hourly demand need of 0.216 MW. NMED should ask Harvest Pipeline

[576] November 2019 Regional Haze Four-Factor Analysis for Harvest San Juan Gas Plant at 2-6.

for more information on its current levels of power generation and/or power supply and to estimate what would be necessary to increase the power generation at the site or to the site to accommodate SCR systems. If one SCR reactor could be shared between the three combustion turbines, that could not only reduce the cost of SCR and allow for a less complicated retrofit, but it could also reduce the energy needs of SCR.

Thus, NMED must not allow Harvest Pipeline to discount SCR for the Rolls-Royce units. It is a highly effective NOx control that the turbine manufacturer (Siemens) states is an available retrofit for the existing turbines. NMED must require a thorough evaluation of SCR to reduce NOx emissions from the Rolls-Royce turbines.

C. Solar Centaur T4501 Natural Gas Turbines (Units 4-7)

Units 4-7 of the San Juan Gas Plant are Solar Centaur turbines model T4501 with a permitted capacity of 3735 hp that were each manufactured in 1986.[577] The units each have NOx limits of 15.9 lb/hr and 69.8 tpy.[578] The units are also each subject to a NOx limit of 150 ppmv at 15% O_2 pursuant to 40 C.F.R. Part 60, Subpart GG.

Harvest Pipeline evaluated the following pollution controls for these units:

- SoLoNOx Combustion Technology
- SCR.

The following provides comments on Harvest Pipeline's analyses of these controls.

1. Evaluation of SoLoNOx for Units 4-7 at San Juan Gas Plant

Harvest Pipeline states that SoLoNOx is available for the existing Solar Centaur combustion turbines at Units 4-7, but it would require the units to be uprated to model Centaur T4701 to support the SoLoNOx technology.[579] Harvest Pipeline states that such controls could reduce NOx to 25 ppm, a reduction of 65-75% from 2016 hourly NOx rates.[580]
In terms of the life of SoLoNOx controls in the cost effectiveness analyses, Harvest Pipeline's analysis assumed a 20-year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[581] In the table below, Harvest Pipeline's cost effectiveness analyses of SoLoNOx were revised to take into account a longer lifetime of controls and a lower 4.7% interest rate.

[577] Title V Permit No. P124-R3 for San Juan Basin Gas Plant, at A6.
[578] *Id.* at A7.
[579] November 2019 Regional Haze Four-Factor Analysis for Harvest San Juan Gas Plant at 2-3.
[580] *Id.*
[581] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.

Table 35. Revised Cost Effectiveness of SoLoNOx at Units 4-7 of the Harvest Pipeline San Juan Gas Plant, to Reflect a 4.7% Interest Rate and a 25-Year Life

Unit	Harvest Pipeline's Total Annual Costs of SoLoNOx (at 5.5% Interest and 20-Year Life)	Harvest Pipeline's Cost Effectiveness at 5.5% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25 Year Life
4	$69,637	$1,952/ton	$61,274	$1,717/ton
5	$69,637	$2,412/ton	$61,274	$2,122/ton
6	$69,637	$1,894/ton	$61,274	$1,667/ton
7	$69,637	$1,500/ton	$61,274	$1,319/ton

Thus, the cost effectiveness of SoLoNOx at the Units 4-7 Solar Centaur Combustion Turbines should be in the range of $1,319/ton to $2,122/ton assuming a more appropriate 25-year life at lower interest rate. These controls should be considered quite cost effective by NMED.

2. Evaluation of SCR for Units 4-7 of the San Juan Gas Plant.

Harvest Pipeline evaluated SCR as a technically feasible control option for the Units 4-7 Solar Centaur gas combustion turbines, using EPA's SCR cost spreadsheet made available with EPA's Control Cost Manual.[582] However, Harvest Pipeline only assumed a 25 ppm NOx rate could be met with SCR, which only reflects 65% to 76% NOx reduction efficiency with SCRAs presented NPCA's Oil and Gas Four-Factor Report, NESCAUM assumed 90% control with SCR in its 2000 Status Report to control small gas turbines down to 15 ppmv.[583] SCR at the San Juan Gas Plant Units 4-7 should be able to at least achieve a 15 ppmv NOx limit, which reflects 79% to 85% control at each unit.

Harvest Pipeline presented cost effectiveness data for SCR at Units 4-7, but the costs appear to be significantly inflated. The company assumed a $4,000,000 capital cost of SCR that it purportedly obtained from the manufacturer, which is Solar Turbines.[584] It is not clear that Solar Turbines is a vendor for SCR systems. The company also apparently used the EPA cost spreadsheet for the direct annual costs including operating and maintenance costs.[585] Yet, when the inputs used by Harvest Pipeline for each unit are independently input in the EPA SCR cost spreadsheet, the annual operation and maintenance costs are shown to be much lower than assumed by Harvest Pipeline, and the capital cost of SCR is shown to be much lower than $4,000,000 per unit. For example, when one enters into the EPA spreadsheet the same

[582] November 2019 Regional Haze Four-Factor Analysis for San Juan Gas Plant, Appendix C.
[583] NPCA March 2020 Oil and Gas Four-Factor Report at 74-75. *See also* NESCAUM, December 2000, Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, Internal Combustion Engines, Technologies & Cost Effectiveness at III-21 through III-24 and at III-40 (see referenced 11, 16, 9, 14, and 15), available at http://www.nescaum.org/documents/nox-2000.pdf/view.
[584] November 2019 Regional Haze Four-Factor Analysis for San Juan Gas Plant at 3-2.
[585] *Id.*

information in the data input page for Unit 4 provided in the San Juan Gas Plant Four-Factor Report, the resulting calculation of operations and maintenance costs are $10,703 per year plus $2,718 in administrative charges for a total of $13,421 per year, whereas Harvest Pipeline assumed annual operating and mainatenance costs of $122,869 per year, costs that are nine times higher than calculated with EPA's cost spreadsheet. In addition, the EPA SCR cost spreadsheet calculates the capital cost of SCR at $1.5 million for the unit rather than Harvest Pipeline's claimed $4 million cost, a value that is 2.7 times what the EPA SCR cost spreadsheet calculated.

In the table below, we recalculated cost effectiveness of SCR at Units 4-7 of the San Juan Gas Plant. For this analysis, we used EPA's SCR cost spreadsheet with the same inputs as identified in Harvest Pipeline's Four Factor report.[586] However, for the controlled level of NOx, an emission rate of 15 ppmv was assumed to be met (reflective of 0.10 lb/MMBtu and NOx removal efficiencies in the range of 79% to 85%. For the reasons previously described in this report, an interest rate of 4.7% and a 25-year life of SCR were assumed. The table below presents the results of this analysis.

Table 36. Cost Effectiveness of SCR at San Juan Gas Plant Units 4, 5, 6 and 7 Combustion Turbines to Meet 15 ppmv NOx Rate, Using EPA's SCR Cost Calculation Spreadsheet for Boilers (2018 $)

Unit	Assumed NOx Removal Efficiency with SCR	Capital Cost SCR	Annual Operational and Maintenance Cost	Total Annualized Costs	NOx Reduced, tpy	Cost Effectiveness
4	82%	$1,501,589	$20,793	$126,820	41	$3,059/ton
5	79%	$1,495,807	$21,342	$126,972	44	$2,869/ton
6	82%	$1,465,046	$21,012	$124,523	44	$2,839/ton
7	85%	$1,475,477	$22,001	$126,230	52	$2,405/ton

The above table shows that SCR, based on EPA's cost algorithms, can be cost effective at Units 4, 5, 6 and of the San Juan Gas Plant.

Moreover, SCR combined with SoLoNOx, which is commonly required to meet BACT for gas turbines, could reduce NOx by 97% or more. As discussed in Section I.C.2 of this report, this combination of NOx controls has been permitted for the Buckingham Compressor Station to achieve a NOx emission rates of 3.75 ppmv @ 15% oxygen.[587] However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as BACT or LAER for

[586] *Id.* in Appendix B, pdf pages 27, 31, 35, and 39 of the report.

[587] See January 9, 2019 Registration No. 21599, available at: https://www.deq.virginia.gov/Portals/0/DEQ/Air/BuckinghamCompressorStation/21599_Signed_Permit.pdf. Note that this permit was recently vacated by the Courts, see https://www.cbs19news.com/story/41533113/permit-forbuckingham-county-compressor-station-vacated.

such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15% oxygen.[588] NMED should require Harvest Pipeline to evaluate the cost effectiveness of the combination of SoLoNOx and SCR to achieve the greatest level of NOx reduction.

XVI. Oxy USA WTP -Indian Basin Gas Plant

The Oxy USA WTP (Oxy) Indian Basin Gas Plant is a gas sweetening plan (removing hydrogen sulfide and CO_2 from raw natural gas to make commercial natural gas) and also extracts natural gas products (propane and butane) from natural gas.[589] The facility is located 15 miles west of Carlsbad, New Mexico in Eddy County.[590] The emission units at the plant include an amine unit, heaters, turbine generators and turbine compressors, boilers, and flares.[591]

In Oxy's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Natural Gas Simple Cycle Solar Centaur 40-4002 Turbines (Units ES-06/07 & ES-08/09)
- Natural Gas Simple Cycle Solar Centaur 40-4702 Turbine (Unit ES-10/11)
- Amine Gas Treating Units.[592]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[593] The following provides a review of the company's four-factor analyses. Comments on the four-factor analysis for the amine gas treating units are provided further below in Section XXIII.

A. Interest Rate Used in Cost Analyses.

Oxy used a 5.5% interest rate in the cost analyses for all of the controls evaluated in its 4-factor analyses.[594] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. This is the same interest rate that EPA has used in its cost spreadsheet for SCR, but EPA also states that the interest rate used in cost effectiveness analyses should be the bank prime interest

[588] *See*, e.g., Chupka, Mark, The Brattle Group, and Anthony Licata, Licata Energy & Environmental Consulting, Inc., Independent Evaluation of SCR Systems for Frame-Type Combustion Turbines, Report for ICAP Demand and Curve Reset, at 9.

[593] *Id.*
[594] *Id.* at Appendix B Cost Analysis Calculations.

rate.[595] The current bank prime rate is 3.25%.[596] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[597] In a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[598] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. For these reasons, in the cost effectiveness calculations provided herein, a 4.7% interest rate is used rather than a 5.5% interest rate.

B. Natural Gas Simple Cycle Solar Centaur 40-4002 Turbines (Units ES-06/07, ES-08/09, and ES-10/11)

The combustion turbines evaluated for controls at the Indian Basin Gas Plant are all Solar Centaur turbines that were manufactured in 1980.[599] The turbines have a permitted capacity of 4000 hp (Units ES-06/07 and ES-08/09) and 4700 hp (Unit ES-10/11).[600] The units each are either routed to a heat recovery generator or a bypass stack.[601] Units ES-06/07 and ES-08/09 are each subject to a NOx limit of 15.4 lb/hr and 67.4 tpy, and Unit ES-10/11 is subject to a 23.7 lb/hr NOx limit and 104.0 tpy.[602]

Oxy only evaluated one control technology for the combustion turbines: SoLoNOx combustion technology. Oxy did not evaluate SCR. Yet, SCR is a technically feasible control technology for combustion turbines.

1. Evaluation of SoLoNOx for Solar Centaur Turbines at Indian Basin Gas Plant

Oxy states that SoLoNOx is available for the existing Solar Centaur combustion turbines, but it would require the 4002 turbines at Units ES-06/07 and ES-08/09 to be uprated to model 4702 to support the SoLoNOx technology.[603] Oxy states that such controls could reduce NOx to 25

[601] *Id.*
[602] *Id.* at A10.
[603] November 2019 Regional Haze Four-Factor Analysis for Indian Basin Gas Plant at 2-3.

ppm.[604] Based on a comparison to Oxy's reported recent testing data for the units, SoLoNOx would reduce NOx by 75% at Units ES-06/07 and ES-08/09 and by 84% at Unit ES-10/11. It also must be noted that Oxy's capital cost estimates for installation of SoLoNOx at Units ES-06/07 and ES-08/09 (Solar Centaur T4002 turbines) are significantly higher than the costs to upgrade the same model turbines at Kutz Canyon Gas Plant. Specifically, Units 1-6 at Kutz Canyon Gas Plant are the same model turbines (Solar Centaur T4002) and would also need to be uprated to model T4702 with the installation of SoLoNOx.[605] Yet, Harvest Four Corners identified the capital cost for SoLoNOx at Units 1-6 of the Kutz Canyon facility as $467,400 with annual operations and maintenance costs of $22,500[606] whereas Oxy identified the capital cost for SoLoNOx at the same model turbines at Units ES-06/07 and ES-08/09 three times as much at $1,510,295 and with a higher operations and maintenance cost of $30,407 per year.[607]

While Oxy submitted supplemental information to NMED in a February 2020 submittal, the supplemental information appears to be for a different turbine model and also is from four years ago. Specifically, in response to NMED's request for the vendor specifications for the SoLoNOx costs and emission rate guarantee, Oxy submitted a sheet on "Predicted Emission Performance" for SoLoNOx at a Centaur 40-4700S turbine with a NOx emission rate of 42 ppmvd and submitted cost data as confidential business information for a "similar unit that was installed at the facility."[608] Yet, the turbines being reviewed in this four-factor analysis are of a different model and of a model for which a 25 ppm NOx emission rate was evaluated for SoLoNOx. NMED must collect more current cost information as to why SoLoNOx at the combustion turbines currently being evaluated for controls at Indian Basin Gas Plant would cost three times as much at the Indian Basin Solar Centaur T4002 gas turbines compared to the Kutz Canyon Solar Centaur T4002 gas turbine

In terms of the life of SoLoNOx controls in the cost effectiveness analyses, Oxy's analysis assumed a 20-year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[609] In the table below, we revised Oxy's cost effectiveness analyses of SoLoNOx were revised to take into account a longer lifetime of controls and a lower 4.7% interest rate.

[604] *Id.*
[605] November 2019 Regional Haze Four-Factor Analysis for Harvest Four Corners Kutz Canyon Gas Plant at 2-3.
[606] *Id.* at Appendix B (pdf 30 of document).
[607] November 2019 Regional Haze Four-Factor Analysis for Indian Basin Gas Plant at Appendix B (pdf pages 21-22 of document).
[608] February 2020 Four-Factor Addendum for Oxy Indian Basin Gas Plant at pdf page 3 and at Appendix A. Cost data in Appendix B is not publicly available.
[609] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.

Table 37. Revised Cost Effectiveness of SoLoNOx at Units ES-06/07, ES-08/09, and ES-10/11 of the Indian Basin Gas Plant, to Reflect a 4.7% Interest Rate and a 25-Year Life

Unit	Oxy's Total Annual Costs of SoLoNOx (at 5.5% Interest and 20-Year Life)	Oxy's Cost Effectiveness at 5.5% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25 Year Life
ES-06/07	$156,787	$3,809/ton	$134,367	$3,265/ton
ES-08/09	$156,787	$4,132/ton	$134,367	$3,542/ton
ES-10/11	$147,290	$1,834/ton	$127,096	$1,582/ton

Thus, the cost effectiveness of SoLoNOx at the Solar Centaur turbines based on Oxy's capital cost of SoLoNOx should be in the range of $1,582/ton to $3,542/ton assuming a more appropriate 25-year life at lower interest rate. However, assuming that the costs of SoLoNOx are instead the same as the capital and operating and maintenance costs for SoLoNOx (including uprating of the turbines) of the same model turbine (Solar T4002) at the Kutz Canyon plant, the cost effectiveness of SoLoNOx at Units ES-06/07 and 08/09 would be $1,328/ton at Unit ES-06/07 and $1,441/ton at Unit ES-08/09. It is thus imperative that NMED determine why Oxy's cost estimates for SoLoNOx at these units are so much more expensive as the costs for controls (and turbine uprates) at the same model turbines as Units 1-6 of the Kutz Canyon Gas Plant.

2. Evaluation of SCR for the Solar Centaur Combustion Turbines at the Indian Basin Gas Plant

Oxy did not evaluate SCR as a control option for any of the combustion turbines at Indian Basin Gas Plant. Oxy acknowledged that Solar Turbines indicated that SCR is an available technology for the Solar Centaur turbines at Indian Basin Gas Plant, but Oxy determined that the additional power demands of SCR make the controls infeasible because the power at the plant would "need to be upgraded significantly and re-designed in order to power the SCR controls."[610] If the power at the plant would need to be upgraded to accommodate SCR, that should be evaluated as part of the cost of SCR rather than deem the control as technically infeasible. Further, NMED should request information from Oxy to determine whether the power would need to be upgraded for SCR systems at just one combustion turbine, or if the company's claim of power supply upgrades apply to SCR systems installed at all three combustion turbines. SoLoNOx at Unit ES-10/11 is very cost effective and will reduce NOx by 84%. Thus, it is likely SCR is the better control choice just for units ES-06/07 and ES-08/09, for which SoLoNOx has higher cost effectiveness values and will only result in 75% control. NMED should request that Oxy look into the option of shared SCR reactor for these two units, which could reduce electricity needs as well as reduce costs of control.

SCR would be more effective at reducing NOx at the Solar Centaur combustion turbines than SoLoNOx. As presented NPCA's Oil and Gas Four-Factor Report, NESCAUM assumed 90%

[610] November 2019 Regional Haze Four-Factor Analysis for Indian Basin Gas Plant at 2-4.

control with SCR in its 2000 Status Report to control small gas turbines down to 15 ppmv.[611] SCR at Units ES-06/07 and ES-08/09 of the Indian Basin Gas Plant should be able to at least achieve a 15 ppmv NOx limit, which reflects 85% NOx control at each unit.

Based on the fact that the combustion turbines at its Eunice Gas Plant (Units 17A, 18B, 19A, 25A, and 26A) evaluated for SCR by DCP Midstream are of similar size as the Indian Basin Gas Plant turbines, one would expect SCR to have a similar cost effectiveness. As shown in Table 9 above, the cost effectiveness SCR at the DCP Eunice Gas Plant turbines ranged from $2,600/ton to $3,800/ton (assuming a 4.7% interest rate and 25-year life). Thus, one would expect the similar (or same) model turbine and similar size units at Indian Basin Gas Plant combustion turbines to have a similar cost effectiveness of SCR to achieve 15 ppmv at 15% O_2.

Moreover, SCR combined with SoLoNOx, which is commonly required to meet BACT for gas turbines, could reduce NOx by 97% or more. As discussed in Section I.C.2 of this report, this combination of NOx controls has been permitted for the Buckingham Compressor Station to achieve a NOx emission rates of 3.75 ppmv @ 15% oxygen.[612] However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as BACT or LAER for such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15% oxygen.[613] NMED should require Oxy to evaluate the cost effectiveness of the combination of SoLoNOx and SCR to achieve the greatest level of NOx reduction.

XVII. Enterprise South Carlsbad Compressor Station

The Enterprise South Carlsbad Compressor Station is a natural gas compressor station and dew point plant.[614] According to a January 2020 NMED Statement of Basis for a Title V Permit modification,[615] after compression, the gas is sent to an amine unit to remove CO2. Water is then removed from the treated gas from the amine unit by routing through a glycol dehydrator. Salable hydrocarbons are then removed. The compressed gas then has liquids removed in a three-phase separator. Dry gas is sent into a pipeline for transport. The gas stream from the three-phase separator is used as turbine fuel along with other fuel if needed from the discharge residue gas stream or the gas stream from the condensate stabilizer. The facility is located

[611] NPCA March 2020 Oil and Gas Four-Factor Report at 74-75. *See also* NESCAUM, December 2000, Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, Internal Combustion Engines, Technologies & Cost Effectiveness at III-21 through III-24 and at III-40 (see referenced 11, 16, 9, 14, and 15), available at http://www.nescaum.org/documents/nox-2000.pdf/view.
[612] See January 9, 2019 Registration No. 21599, available at: https://www.deq.virginia.gov/Portals/0/DEQ/Air/BuckinghamCompressorStation/21599_Signed_Permit.pdf. [615] *Id.*

about 2.8 miles northwest of Loving, New Mexico in Eddy County.[616] The plant consists of two compressors driven by natural gas-fired combustion turbines, a glycol reboiler, an amine heater, tanks, and a flare, among other air emissions sources.[617]

In Enterprise's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Solar Centaur T4702 Turbines (Units 1 and 2).[618]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[619] The following provides a review of the company's four-factor analyses.

A. Interest Rate Used in Cost Analyses.

Enterprise used an 8.38% interest rate in the cost analyses for the controls evaluated in its 4-factor analyses.[620] This is an unreasonably high interest rate for cost effectiveness analyses. EPA's Control Cost Manual indicates that the interest rate used in cost effectiveness analyses should be the bank prime interest rate.[621] The current bank prime rate is 3.25%.[622] The highest the bank prime rate has been in the past five years is 5.5%, and that was only for a period of 7-8 months in 2019 out of the past five years.[623] In NPCA's March 2020 Oil and Gas Four-Factor Report, an interest rate of 5.5% was used to reflect the highest the bank prime interest rate has been in the past five years. However, in a cost effectiveness analyses being done today, even a 5.5% interest rate is unreasonably high, given the current bank prime lending rate of 3.25%. In a recent four-factor cost effectiveness analysis for reasonable progress controls, the owner of Craig Power Plant in Colorado (Tri-State Generation & Transmission) used an interest rate of 4.7%.[624] That tracks closely with the 4.75% interest rate that was in place before the global COVID-19 pandemic. Thus, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls. Enterprise's use of an 8.38% interest rate is unreasonably high and overstates the cost effectiveness of pollution controls evaluated in the four-factor analyses.

B. Solar Centaur T4702 Turbines (Units 1 and 2)

The combustion turbines evaluated for controls at the South Carlsbad Compressor Station are both model T4702 Solar Centaur turbines that were manufactured in 2004.[625] The turbines have a permitted capacity of 4328 hp and a heat input of 42.8 MMBtu/hr.[626] The units each power a compressor engine.[627] The units are each subject to a NOx limit of 27.0 lb/hr and 90.8 tpy.[628]

Enterprise only evaluated one control technology for the combustion turbines: SoLoNOx combustion technology. Enterprise did not evaluate SCR. Yet, SCR is a technically feasible control technology for combustion turbines.

1. Evaluation of SoLoNOx for Solar Centaur Model T4702 Turbines

Enterprise states that SoLoNOx is available for the existing Solar Centaur model T4702 combustion turbines and that the controls could reduce NOx to 25 ppm.[629] Oxy states that such controls could reduce NOx to 25 ppm.[630] According to Enterprise's Four-Factor Analysis, SoLoNOx would reduce NOx by 64% at Unit 1 and by 66% at Unit 2.[631]
In terms of the life of SoLoNOx controls in the cost effectiveness analyses, Enterprise's analysis assumed a 20-year life. For the reasons described above on the evaluation of dry low NOx combustors at the gas turbines at the Chaco Gas Plant, a 25-year life is a more appropriate assumption for the cost effectiveness analysis.[632] In the table below, we revised Enterprise's cost effectiveness analyses of SoLoNOx were revised to take into account a longer lifetime of controls and a lower 4.7% interest rate.

Table 38. Revised Cost Effectiveness of SoLoNOx at Units 1 and 2 of the South Carlsbad Compressor Station, to Reflect a 4.7% Interest Rate and a 25 Year Life

Unit	Enterprise's Total Annual Costs of SoLoNOx (at 5.5% Interest and 20-Year Life)	Enterprise's Cost Effectiveness at 5.5% Interest and 20 Year Life	Revised Total Annual Costs of SoLoNOx	Revised Cost Effectiveness at 4.7% Interest and 25 Year Life
1	$178,387	$8,584/ton	$130,180	$6,265/ton
2	$178,387	$6,629/ton	$130,180	$4,838/ton

[632] *See also* NPCA March 2020 Oil and Gas Four-Factor Report at 69-70.

Thus, the cost effectiveness of SoLoNOx at the Solar Centaur T4702 turbines should be in the range of $4,800/ton to $6,200/ton assuming a more appropriate 25-year life at lower interest rate. The cost effectiveness of SoLoNOx at Units 1 and 2 of the South Carlsbad Compressor Station are much higher than the cost effectiveness of SoLoNOx at Unit ES-10/11 of the Indian Basin Gas Plant, despite the turbine models being the same Solar Centaur T4702 model. It appears this is due to the low 2016 emission rates of the Units 1 and 2 at the South Carlsbad Compressor Station. As discussed in Section I.B.1. of this report, it is imperative that NMED ensure that the emissions considered as baseline emission for cost effectiveness analyses be a reasonable estimate of current and future NOx emissions. The 2016 emissions reported by Enterprise for Units 1 and 2 are less than half of the NOx emission limits for the units, despite the units both operating 8,544 hours in 2016 (or 97.2% of the available hours in a year). These low 2016 NOx emissions either reflect the need to reduce the allowable emission limits for the units to more accurately reflect current emissions levels or the 2016 emissions data may not have been measured when the units were operating at maximum capacity. If the baseline NOx emissions are going to make the difference for NMED as to whether a pollution control is cost effective or not (especially if that pollution control is considered to be cost effective for other similar size or same model turbines, then NMED must ensure that the cost effectiveness analyses for pollution controls evaluated for the company's four-factor analyses are based on an accurate estimate of emissions expected in 2028.

2. Evaluation of SCR for the Solar Centaur T4702 Turbines at the South Carlsbad Compressor Station

Enterprise did not evaluate SCR as a control option for the Units 1 and 2 combustion turbines. Enterprise states the South Carlsbad facility was designed and constructed without plans for installation of SCR, and that based on size estimated provided by CECO-Peerless, Enterprise determined that it is "not possible" to install SCR at Units 1 and 2 of the South Carlsbad Compressor Station.[633]

While the facility and gas turbines may not have been originally designed to have space to accommodate SCR, that is typically the case with most SCR retrofits. As such, there have been numerous SCR retrofits installations at various industrial facilities that have had to overcome space constraints. For example, for many large coal-fired power plants, SCR reactors have been elevated above the air preheaters. Indeed, a report about SCR retrofits at GE LM2500 turbines at Chevron's Eastridge Cogeneration plant in California showed that some significant changes to the facility had to be made to accommodate SCR, including cutting the duct between economizers and moving the stack and one economizer onto new foundations to make way for the SCR reactor.[634] Thus, before NMED accepts a very brief claim of retrofit difficulty of SCR at any emissions unit being evaluated for reasonable progress controls, it is imperative that NMED ask Enterprise for a site plan and photos that shows whatever space constraints are being

[633] November 2019 Regional Haze Four-Factor Analysis for South Carlsbad Compressor Station at 2-3.
[634] *See* Seebold, James et al., Gas Turbine NOx Reduction Retrofit, , available at https://www.onepetro.org/conference-paper/SPE-66501-MS.

claimed, and that NMED ask Enterprise to consult with SCR vendors for options for SCR installation at the gas turbines of South Carlsbad Compressor Station. In addition, there may be other options for the location of the SCR system. Depending on the proximity of the gas turbines, it is possible that one SCR reactor could be used by both Units 1 and 2, which would reduce costs and potentially be easier to install at the site. NMED must require all possibilities for SCR installation be evaluated and documented by Enterprise. The state must not simply discount this highly effective NOx control based on a claim of some retrofit difficulty.

SCR would be more effective at reducing NOx at the South Carlsbad combustion turbines than SoLoNOx. As presented NPCA's Oil and Gas Four-Factor Report, NESCAUM assumed 90% control with SCR in its 2000 Status Report to control small gas turbines down to 15 ppmv.[635] That would reflect a 78% reduction in NOx emissions at Units 1 and 2. However, because SCR can achieve NOx reductions of 90%, SCR could be even more effective at reducing NOx from these units.

Based on the fact that the combustion turbines at its Eunice Gas Plant (Units 17A, 18B, 19A, 25A, and 26A) evaluated for SCR by DCP Midstream are of similar size as the South Carlsbad Compressor Station turbines, one would expect SCR to have a similar cost effectiveness. As shown in Table 9 above, the cost effectiveness SCR at the DCP Eunice Gas Plant turbines ranged from $2,600/ton to $3,800/ton (assuming a 4.7% interest rate and 25-year life). Thus, one would expect the similar (or same) model turbine and similar size units at Indian Basin Gas Plant combustion turbines to have a similar cost effectiveness of SCR to achieve 15 ppmv at 15% O_2.

Moreover, SCR combined with SoLoNOx, which is commonly required to meet BACT for gas turbines, could reduce NOx by 97% or more. As discussed in Section I.C.2 of this report, this combination of NOx controls has been permitted for the Buckingham Compressor Station to achieve a NOx emission rates of 3.75 ppmv @ 15% oxygen.[636] However, emission rates with SoLoNOx and SCR at gas-fired combustion turbines could be even lower, as BACT or LAER for such turbines operated for power generation are generally set at 2 to 2.5 ppmv at 15% oxygen.[637] NMED should require Enterprise to evaluate the cost effectiveness of the combination of SoLoNOx and SCR to achieve the greatest level of NOx reduction.

XVIII. El Paso Natural Gas Company – Blanco Compressor Station A

The El Paso Natural Gas Company, LLC. (EPNG) Blanco Compressor Station A is located in San Juan County. NMED has described the facility processes as follows:

The Blanco Compressor Station A is a natural gas compressor station that compresses natural gas for the purpose of transportation to another facility or a major transportation pipeline.[638]

According to the permit, the plant includes 14 2-stroke lean-burn reciprocating internal combustion engines (RICE).[639] In EPNG's four-factor submittal, the company evaluated air pollution controls for these units:

- Cooper-Bessemer 2SLB RICE GMV10-TF: Units A01 through A14.[640]

The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses.[641] The following provides a review of the company's four-factor analyses.

A. Units A01 through A14: Cooper-Bessemer GMV10-TF 2-Stroke Lean-Burn Compressor Engines

Units A01 through A14 are 2-stroke lean-burn RICE that were constructed in 1953, each with a capacity of 943 hp.[642] The units each have an hourly NOx limit of 21.9 lb/hr and an annual NOx limit of 95.97 tpy.[643]

1. Use of Low Emission Combustion Technology

EPNG presents three options for reducing NOx emissions from these compressor engines, with varying low emission combustion (LEC) control techniques to meet NOx emission levels of 3 g/hp-hr, 1 g/hp-hr, and 0.5 g/hp-hr. Uncontrolled NOx emissions (tpy) are based on 2016 emissions. The 2016 actual emissions for these units and the allowable NOx emission rates are shown in the table below.[644]

Table 39. EPNG Blanco Compressor Station A 2SLB RICE Unit NOx Emission Rates

Unit	Size [hp]	Allowable NOx Emissions [tpy]	2016 NOx Emissions [tpy]
A01	943	95.97	73.711
A02	943	95.97	0.025
A03	943	95.97	54.915
A04	943	95.97	1.093
A05	943	95.97	3.081
A06	943	95.97	0.613
A07	943	95.97	65.341
A08	943	95.97	0.019
A09	943	95.97	27.382
A10	943	95.97	0.019
A11	943	95.97	48.253
A12	943	95.97	0.016
A13	943	95.97	82.061
A14	943	95.97	0.019

It appears that many of these units operate infrequently, with several emitting less than 1 tpy in 2016. NMED should request more information on the typical operating schedules for these engines to ensure that EPNG's four-factor analysis is based on usage that is expected in 2028.

EPNG's four-factor analysis is based on detailed cost estimates for retrofitting these units with LEC technologies; control costs include capital costs and net annual costs (annual recurring costs).[645] EPNG does not provide any details on the source of the cost information included in the four-factor analysis; we assume they represent current costs (2019$). These cost estimates are high, at $138—$217/hp, compared to other capital cost estimates for LEC controls at other similar engines.[646] EPNG presents cost effectiveness, in dollars per ton of NOx reduced, ranging from $32K/ton to as high as $2.9M/ton.[647] However, these cost effectiveness figures do not take into account the annualized costs over the lifetime of the controls, they are simply the total per unit capital cost divided by the NOx emissions reductions from 2016 emissions. The following three tables present the cost effectiveness based on EPNG's capital cost estimates—for Options 1, 2, and 3—annualized over the life of the controls. Note, this updated analysis uses an interest rate of 4.7%, reflective of current and likely near future interest

[647] *Id.*

rates.[648] Further note, the LEC controls are assumed to last 25 years, consistent with other cost effectiveness analyses submitted to NMED for LEC controls.[649]

Table 40. Cost Effectiveness of LEC at Uncontrolled Blanco Compressor Station A Units A01 through A14 for Option 1 (3 g/hp-hr), Assuming a 4.7% Interest Rate and a 25-Year Life

Unit	Capital Cost of LEC to Reduce NOx Option 1 3 g/hp-hr [assuming 2019$]	Total Annualized Costs	NOx Removed, tpy Based on 2016 Source Data	Cost Effectiveness of LEC at 3 g/hp-hr [2019$], $/ton
A01	$1,884,728	$129,734	52.718	$2,461
A02	$1,884,728	$129,734	0.018	$7,207,430
A03	$1,884,728	$129,734	39.275	$3,303
A04	$1,884,728	$129,734	0.782	$165,900
A05	$1,884,728	$129,734	2.204	$58,863

A10	$2,804,837	$193,069	0.018	$10,726,039
A11	$2,804,837	$193,069	45.963	$4,201
A12	$2,804,837	$193,069	0.016	$12,066,794
A13	$2,804,837	$193,069	78.166	$2,470
A14	$2,804,837	$193,069	0.018	$10,726,039

For many of these units, LEC controls can be cost effective for reducing NOx emissions to emission rates as low as 0.5 g/hp-hr. NMED must request a revised four-factor analysis from EPNG for the Blanco Compressor Station A that includes the annualization of costs. Also, NMED should request additional information on the usage of these engines to determine if the units are consistently used as in 2016 or if usage varies from year to year. NMED must ensure that the cost effectiveness analyses for LEC evaluated for the company's four-factor analyses are based on a more comprehensive representation of emissions reduction and operating hours expected in 2028.

2. Use of SCR

EPNG did not evaluate SCR for Units A01 through A14 primarily because it claimed that it was not technically feasible for this engine type.[650] As discussed above regarding the combustion turbines at the Chaco Gas Plant, before NMED dismisses SCR as a possible regional haze control, it must request more information and documentation. Specifically, NMED must 1) ask for site photographs, plot plans, dimensions of buildings and open spaces, etc., and 2) ask for SCR vendor analyses for SCR installation options at these units, including any potential options for a shared SCR system between the units. SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. It should not be summarily dismissed as not feasible for these engines, particularly because EPNG has not found LEC to be a cost effective NOx reduction strategy for some of these units.

In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[651]

If LEC technology is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[652] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[653] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should not discount SCR as a potentially viable control option for lean burn engines in its analysis of available controls to achieve reasonable progress towards the national visibility goal.

XIX. Transwestern Pipeline Company Roswell Compressor No. 9

The Transwestern Pipeline Company (Transwestern) Roswell Compressor Station No. 9 is a natural gas compressor station located about 5 miles north of Roswell, New Mexico in Chaves

[650] October 2019 Regional Haze Four-Factor Analysis for El Paso Natural Gas Company, LLC Blanco Compressor Station A at 9.
[651] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[652] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.
[653] Available at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution.

County.[654] The plant consists of two natural gas-fired four-stroke lean-burn compressor engines compressors and a natural gas-fired rich burn engine used as a generator, as well as several tanks and other emissions sources.[655] The compressor station also has two electric-driven compressor engines with no associated air emissions.[656] In Transwestern's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Two Four-Stroke Lean-Burn RICE (Units 903 and 904).[657]

The rich burn generator engine is used as an emergency generator and operates less than 100 hours per year, and so was not evaluated for controls.[658] The selection of these engines for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses. The following provides a review of the company's four-factor analyses.

A. Lean Burn Natural Gas-Fired Compressor Engines (Units 903 and 904)

The primary sources of NOx emissions at the Roswell Compressor Station No. 9 are two four-stroke lean burn natural gas-fired RICE (Units 903 and 904). The engines are both 4,500 hp Cooper-Bessemer LSV-16G compressor engines used for transportation of natural gas.[659] The engines were constructed in 1959, and are subject to allowable emission limits of 125 lb/hr and 547.5 tpy each.[660]

According to documentation submitted with the four-factor analysis, the 2016 emissions and operating hours used as baseline were as follows:

Table 43. Units 903 and 904 of Roswell Compressor Station No. 9 2016 Emissions and Operating Hours[661]

Unit No.	NOx Emission Rate, lb/hr	2016 Operating Hours	NOx Emissions, tpy
903	37.19 (Tested)	3,607	67.07
904	125 (PTE)	971	60.69

The source's Title V renewal application indicates that the allowable annual number of operating hours for Units 903 and 904 was increased from 6,620 to 8,760, which was the

[654] Title V Permit No. P154-R4, Roswell Compressor Station No. 9, 9/28/2018, at A3.
[655] *Id.* at A6.
[656] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.

[658] *Id.*
[659] *Id.*
[660] Title V Permit No. P154-R4, Roswell Compressor Station No. 9, 9/28/2018, at A7.
[661] October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9, Appendix A at 1. Apparently, the company only had NOx emissions test data for Unit 903.

allowable number of hours in Permit No. P154-R2M1.[662] So presumably the 2016 operating hours are lower than what might be expected in current and future years for these units, especially for Unit 904. And, in fact, a review of the facility's NOx emissions from 2016 through 2019 show an increase in NOx emissions as shown in the table below.

Table 44. Roswell Compressor Station No. 9 NOx Emissions 2016-2019, as Presented in NMED's Emissions Analysis Tool

2016	2017	2018	2019
74.4 tons	185.5 tons	136.5 tons	436.8 tons

NOx emissions are over five times higher in 2019 than they were in 2016. And NOx emissions in all years since 2016 are significantly higher. And it is safe to assume that the bulk of those NOx increases are coming from the Units 903 and 904 lean burn compressor engines, because the only other sources of NOx emissions at the compressor station are Unit 921 (four-stroke rich burn emergency generator engine operating less than 100 hours per year) and two thermal oxidizers. These three NOx sources are limited to a combined total NOx emissions of 27.54 tons per year.[663] Even if we assume that these three units emitted NOx at their allowable emissions of 27.54 tons per year total, that means over 400 tons of NOx were emitted in 2019 by Units 903 and 904, rather than the 127.76 tons per year in total assumed in Transwestern's four-factor cost effectiveness analysis.[664] NMED must ensure that Transwestern's cost effectiveness analysis of controls is based on emissions expected in 2028. Given the significant increases in emissions since 2016 and the permitted increased levels of operation, 2016 emissions should not be used as baseline emissions in the company's cost effectiveness analysis for controls. Use of more recent data would result in more favorable cost effectiveness values because of the increased reduction in NOx that would occur from more recent emissions levels.

1. Evaluation of Low Emissions Combustion for Units 903 and 904

Transwestern assumes a controlled NOx emission rate from LEC retrofits on units 903 and 904 of 2.5 g/hp-hr.[665] For unit 903, Transwestern reports that this represents a 33% reduction from baseline NOx emission rates that are based on the 2016 emissions inventory.[666] For unit 904, Transwestern reports that this represents an 80% reduction from the unit's permitted NOx emission rate; according to Transwestern, "permitted hourly NO_X emission rates were used for Unit 904 in this analysis due to the 2016 emissions inventory showing lower NO_X emission rates

[662] February 1, 2017 Title V Operating Permit Renewal Application, Permit P154-R3M1 Transwestern Pipeline Company, LLC Roswell Compressor Station No. 9 Section 3 Page 2.
[663] *See* Title V Permit No. P154-R4, Roswell Compressor Station No. 9, 9/28/2018, at A8.
[664] Note, Transwestern's four-factor analysis is based on PTE emissions for unit 904. Even so, actual emissions in 2019 are much higher that what was used in the company's four-factor analysis.
[665] October 2019 Regional Haze Four-Factor Analysis for Transwestern Pipeline Company, LLC Roswell Compressor Station No. 9 at 3 and Appendix A.
[666] *Id.* Appendix A.

than what was feasible to obtain by the engine vendor."[667] The permitted maximum hourly NOx emission rate of 125.0 lb/hr for these units is significantly higher than the 2016 emissions inventory data used for baseline emissions, even for unit 903. The allowable hourly NOx emission rate is equivalent to 12.6 g/hp-hr for these 4,500 hp engines. The source's Title V renewal application notes that the NOx emission factors are based on the permitted hourly rate in Permit No. P154-R2M1; it's not clear if the rates are based on stack testing or AP-42 emission factors but since all other emission factors (besides NOx) are identified as EPA AP-42 emission factors it's assumed that the permitted hourly rates are either based on stack tests or are source requested limits.[668] So for both units, emissions reductions to meet a controlled NOx rate of 2.5 g/hp-hr, based on a baseline emission rate that is reflective of the units' allowable emission rate, represents an 80% reduction in NOx emissions.

In January 2020, Transwestern submitted additional information in response to a request from NMED, including the specific technologies included in the quote from Cooper Machinery for LEC upgrades that lower NOx emissions to 2.5 g/hp-hr (e.g., precombustion chambers, turbocharger upgrades, larger intercoolers, etc.).[669]

It's possible that the controlled emission rate with LEC for these specific engines could be even lower that 2.5 g/hp-hr. NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable with LEC technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).[670] EPA's Alternative Control Techniques document for RICE includes emissions test results for Clean Burn, low-emission retrofits (with a pre-combustion chamber) for LSV model dual-fuel engines demonstrating NOx emission rates of 2.0 g/hp-hr and as low as 1.27 g/hp-hr.[671] And, more generally, EPA's updated information on stationary RICE NOx emissions and control technologies concludes, for lean-burn engines, an emission rate of 2.0 g/bhp-hr is achievable for "new engines and most engines retrofitted with LEC technology."[672] Emissions reductions to meet a controlled NOx rate of 2 g/hp-hr, based on a baseline emission rate that is reflective of the units' allowable emission rate, represents an 84% reduction in NOx emissions.

Revising Transwestern's cost effectiveness analyses to reflect the quoted emissions reductions of 80% but based on potential operation at permitted levels for both units (not just for unit 904), results in more favorable cost effectiveness of these controls, as shown in the table below.

[667] *Id.* at 1 and Appendix A.

Table 45. Cost Effectiveness of LEC at Uncontrolled Roswell Compressor Station No. 9 Units 903 and 904 to Reduce NO_x Levels to 2.5 g/hp-hr, Assuming 80% Control

Unit	Size [hp]	Capital Cost of LEC [current vendor quote, assuming 2019$]	Annual O&M Costs (15% of Capital Costs) [2019$]	Total Annualized Costs of LEC to Reduce NOx to 2.5 g/hp-hr (80% NOx Reduction) [2019$]	Annual Operating Hours, hr/yr	NOx Removed, tpy	Cost Effectiveness of LEC [2019$], $/ton
903	4,500	$1,800,000	$270,000	$342,000	3,607	180	$1,896/ton
904	4,500	$1,800,000	$270,000	$342,000	971	49	$7,044/ton

Note, the cost effectiveness of LEC controls would be more favorable for unit 904 at higher operating hours and would be more feasible for both units if they were able to meet controlled emission rates below 2.5 g/hp-hr, which, as discussed earlier, has been demonstrated for other LEC retrofits for similar engines. NMED should request that Transwestern research other available retrofit options from additional vendors that may be able to guarantee NOx emission rates less than 2.5 g/hp-hr.

2. Evaluation of SCR for Units 903 and 904

Although Transwestern identified concerns with utilization of SCR for the lean burn engines (which included reagent injection control, exhaust temperature requirements, variations in exhaust NO/NO2 ratio, and engine oil carryover), Transwestern evaluated SCR as a NOx control option for the Units 903 and 904 engines.[673] In the May 21, 2020 Review of SCR Claims for Lean Burn Engines report, these issues and methods to resolve these concerns were addressed.[674] Transwestern said as a result of its stated concerns, LEC is the preferred control. Yet, the company's cost analysis showed that SCR was more cost effective, and it can achieve 90% NOx reduction.[675]

Transwestern appears to have used EPA's SCR Chapter of its Control Cost Manual to either estimate annual operations and maintenance costs of SCR and used a formula from the December 2000 NESCAUM Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, and Internal Combustion Engines to estimate capital costs for SCR.[676]

[673] *Id.* at 3-4.
[674] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.
[675] October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 4-5 and Appendix A.
[676] December 2000 NESCAUM Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, and Internal Combustion Engines at III-30.

Specifically, the NESCAUM formula which was based on only one case study for a RICE unit to "approximate" SCR capita costs for lean burn RICE is as follows:

$310,000 + ($72.7 x hp)[677]

This NESCAUM equation is twenty years old and is likely based on cost data from the 1990's. SCR has been implemented on numerous source types over the past twenty years, and the much wider-scale implementation and innovation in catalyst design has lowered the cost of SCR.[678] Yet, Transwestern's analysis escalated the capital costs developed with the above equation from the 2000 NESCAUM report by assuming the NESCAUM cost equation was based on 1994 costs and escalating to 2019, using the differences in the Consumer Price Index between 1994 and 2019.[679] EPA's Control Cost Manual cautions against escalating costs more than five years due to the potential for significant inaccuracies in price estimates.[680] EPA currently has a spreadsheet available to estimate the capital and operating costs for SCR. While the spreadsheet was developed for fossil fuel fired boilers, it can be used as an estimate for SCR at other natural gas-fired sources and, in fact, has been used oil and gas companies for several four-factor analyses submitted to NMED. Transwestern included the necessary information to be able to utilize the EPA SCR cost spreadsheet to estimate SCR costs for the Units 903 and 904 engines. Specifically, the company provided the hourly heat input in MMBtu/hr, the inlet NOx emission rate in lb/MMBtu, the engine fuel consumption in terms of Btu/hp-hr (with which the annual fuel consumption can be estimated based on the 2016 operating hours for each unit and each unit's rated horsepower of 4500), the flue gas flow rate in actual cubic feet per minute, and the SCR inlet temperature. The elevation for the location was estimated to be 3600 feet above sea level.

Using the unit-specific operating hours for 2016 and assuming 90% NOx reduction across the SCR, the cost effectiveness based on EPA's SCR spreadsheet is estimated as shown in the table below. Transwestern assumed a 25-year life of SCR, which was also assumed in the SCR cost effectiveness calculation presented below which is consistent with EPA's Control Cost Manual for the expected life of SCR at an industrial unit. For reasons discussed above in this report, a 4.7% interest rate was used rather than Transwestern's assumed 5.5% interest rate. (See, e.g., Section I.A. above).

[680] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017.

Table 46. Estimated Cost Effectiveness of SCR Using EPA's SCR Cost Spreadsheet and 2016 Operational Data for Units 903 and 904 Cooper-Bessemer LSV-16G Compressor Engines at Roswell Compressor Station No. 9 (25-Year Life, 4.7% Interest Rate), 2018 $

Unit Number	Capital Cost	Operations and Maintenance Costs	Total Annual Costs	NOx Reduced from 2016 Emissions, tpy	Cost Effectiveness
903	$1,778,670	$25,746	$150,853	60	$2,449/ton
904	$1,832,960	$26,173	$128,846	55	$2,835/ton

In comparison, Transwestern's SCR cost estimates are much higher. The table below provides the company's SCR cost estimates for comparison to Table 46 above.

Table 47. Transwestern's Cost Effectiveness of SCR for Units 903 and 904 Cooper-Bessemer LSV-16G Compressor Engines at Roswell Compressor Station No. 9 (25-Year Life, 5.5% Interest Rate), 2019 $[681]

Unit Number	Capital Cost	Operations and Maintenance Costs	Total Annual Costs	NOx Reduced from 2016 Emissions, tpy	Cost Effectiveness
903	$1,100,282	$218,527	$262,538	60	$4,376/ton
904	$1,100,282	$255,446	$299,457	55	$5,445/ton

Interestingly, EPA's SCR cost spreadsheet estimates a much higher capital cost than Transwestern's escalation of NESCAUM's capital cost equation for RICE units. But what makes most of the differences in the cost estimates is Transwestern's operations and maintenance costs. A review of the company's cost data sheet found two significant errors that lead to the overstatement of operations and maintenance costs. First, an error was made in the calculation of catalyst volume by Transwestern, due to an error in the formula used for the NOx efficiency adjustment factor η_{adj}. The formula for η_{adj} in EPA's Control Cost Manual chapter for SCR is:

$$\eta_{adj} = 0.2869 + (1.058 \underline{x} \eta_{NOx})$$ [682]

However, Transwestern used the formula

$$\eta_{adj} = 0.2869 + (1.058 \mathbf{+} \eta_{NOx})$$ [683]

Transwestern's error resulted in a significant overestimate of the volume of catalyst, in which η_{adj} is a multiplier, which then resulted in an overestimate of annual catalyst replacement costs.

[681] October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9, Appendix A (pdf pages 13-14 of report).
[682] EPA Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, at pdf page 61 (Equation 2.23).
[683] October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9, Appendix A (pdf pages 16 and 18 of report).

In addition, Transwestern assumed 8,760 hours per year of operation in determining annual operations and maintenance costs which significantly overstated the costs of reagent, catalyst replacement, and labor.[684]

In summary, SCR is a more cost effective NOx control for the Units 903 and 904 engines at Roswell Compressor No. 9 compared to LEC which Transwestern estimated would have a cost effectiveness of $7,000/ton to $15,000/ton.[685]

XX. Transwestern Pipeline Mountainair Compressor Station

The Transwestern Pipeline Company (Transwestern) Mountainair Compressor Station is a natural gas compressor station located in Torrance County, New Mexico. NMED has described the facility processes as follows:

> The facility is a natural gas compressor station. The station is equipped with three 4,500- horsepower (hp) Cooper-Bessemer LSV-16SG compressor engines (701-703) and two 335- hp Ingersoll-Rand PSVG-6 generator engines (721-722), a pipeline condensate storage tank (T-006), and a mist extractor (MIST).[686]

In Transwestern's Four-Factor submittal, the company evaluated air pollution controls for the following emission units:

- Cooper-Bessemer 4SLB RICE LSV-16G: Units 701, 702, and 703.[687]

The rich burn generator engines are equipped with NSCR and are achieving 85% reduction in NOx emissions based on recent engine performance testing.[688] The selection of the 4SLB RICE units for review was based on whether the engines had the potential to emit NOx in excess of 10 lb/hour or 5 tpy, which is the criteria established by NMED to identify sources subject to four-factor analyses. The following provides a review of the company's four-factor analyses.[689]

A. Lean Burn Natural Gas-Fired Compressor Engines (Units 701, 702, and 703)

The primary sources of NOx emissions at the Mountainair Compressor Station are three four-stroke lean-burn natural gas-fired RICE (Units 701, 702, and 703). The engines are each 4,500 hp Cooper-Bessemer LSV-16G compressor engines used for transportation of natural gas.[690]

[685] *Id.* at pdf page 13.
[686] Title V Permit No. P153-R3M1, Mountainair Compressor Station, 9/26/2016, at 3.
[687] October 2019 Regional Haze Four-Factor Analysis for Transwestern Pipeline Company, LLC Mountainair Compressor Station at 2.
[688] *Id.*
[689] *Id.* at 1.
[690] Title V Permit No. P153-R3M1, Mountainair Compressor Station, 9/26/2016, at 5-6.

The engines were constructed in 1960 (701 and 701) and 1967 (703), and are subject to allowable emission limits of 165.3 lb/hr and 724.2 tpy each.[691]

1. Baseline Emissions for Units 701, 702, and 703

According to documentation submitted with the four-factor analysis, the 2016 emissions and operating hours used as baseline were as follows:

Table 48. Units 701, 702, and 703 of Mountainair Compressor Station 2016 Emissions and Operating Hours[692]

Unit No.	2016 NOx Emission Rate, lb/hr	2016 Operating Hours	2016 NOx Emissions, tpy	NOx Allowable Emissions, tpy	NOx Allowable Emissions, lb/hr
701	59.07	1,535	45.34	724.2	165.3
702	98.03	3,116	152.73	724.2	165.3
703	100.86	4,586	231.27	724.2	165.3
TOTAL	258.0	9,237	429.34	2,172.6	495.9

The company's 2016 NOx emissions, used as baseline emissions, are significantly lower than the units' allowable emission limits of 165.3 lb/hr and 724.2 tpy each. And more recent actual emissions from the facility are also much higher.

In fact, the facility obtained a permit in 2016 that allowed for a three-fold increase in startup, shutdown, maintenance, and malfunction emissions because the facility was operating more due to increased volume of natural gas being processed at the facility.[693] Prior to 2016, NMED referred to the compressor station as a "peaking station."[694] A review of the facility's NOx emissions from 2016 through 2019 show a dramatic increase in NOx emissions as shown in the table below.

Table 49. Mountainair No. 7 Compressor Station NOx Emissions 2016-2019, as Presented in NMED's Emissions Analysis Tool

2016	**2017**	**2018**	**2019**
436.6 tons	449.2 tons	1,048.1 tons	932 tons

NOx emissions have more than doubled since 2016 at the Mountainair No. 7 Compressor Station. The most recent two year average NOx emissions are 990.05 tons compared to 436.6 tons of NOx emitted in the 2016 base year used in Transwestern's cost analysis. And it is safe

[691] *Id.*
[692] October 2019 Regional Haze Four-Factor Analysis for Transwestern Pipeline Company, LLC Mounatinair Compressor Station Appendix A at 1.
[693] *See* 9/26/2016 NMED Statement of Basis -Narrative for Title V Permit Significant Permit Modification for Mountainair No. 7 Compressor Station (Permit No. P153-R3M1) at 1.
[694] *Id.* at 3.

to assume that the bulk of those NOx increases are coming from the Units 701, 702, and 702 lean burn compressor engines, because the only other sources of NOx emissions at the compressor station are Units 721 and 722 (four-stroke rich burn generator engines) that are limited to a combined total NOx emissions of 90.9 tons per year.[695] If we assume that Units 721 and 722 emitted NOx at their allowable emissions of 90.9 tons per year total (which is not likely to occur),[696] that means at least 899.15 tons of NOx were emitted on average over 2018 to 2019 by Units 701, 702, and 703, rather than the 429.34 tons per year in total assumed in Transwestern's four-factor cost effectiveness analysis. NMED must ensure that Transwestern's cost effectiveness analysis of controls is based on emissions expected in 2028. Given the significant increases in emissions since 2016 and the permitted increased levels of operation, 2016 emissions should not be used as baseline emissions in the company's cost effectiveness analysis for controls. Use of more recent data would result in lower cost effectiveness values because of the increased reduction in NOx that would occur from more recent emissions levels.

2. Evaluation of Low Emissions Combustion for Units 701, 702, and 703

Transwestern assumes a controlled NOx emission rate from LEC retrofits on units 701, 702, and 703 of 2.5 g/hp-hr.[697] This represents a 58% (unit 701) and 75% (units 702 and 703) NOx emissions reduction from baseline NOx emission rates that are based on the 2016 emissions inventory.[698] The permitted maximum hourly NOx emission rate of 165.3 lb/hr for these units is significantly higher than the 2016 emissions inventory data used for baseline emissions. The allowable hourly NOx emission rate is equivalent to 16.7 g/hp-hr for each of these 4,500 hp engines. No test data are provided for these units and the source's recent Title V modification application does not specify the basis for the source's allowable NOx emission limits.[699] For both units, emissions reductions to meet a controlled NOx rate of 2.5 g/hp-hr, based on a baseline emission rate that is reflective of the units' allowable emission rate, represents an 85% reduction in NOx emissions.

It's possible that the controlled emission rate with LEC for these specific engines could be even lower that 2.5 g/hp-hr. NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable with LEC technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).[700] EPA's

[695] *See* 9/26/2016 Title V Operating Permit No. P153-R3M1 for Mountainair Compressor Station (Station No. 7) at 3 and at 5-7.
[696] For example, in 2016, Units 701, 702, and 703 emitted 429.34 tons (based on what was reported for these units' 2016 emissions in the Mountainair No 7 Compressor Station Four-Factor Analysis in Appendix A). The total reported NOx emissions as shown in Table 49 above were 436.6 tons, which would mean Units 721 and 722 only emitted 7.26 tons of NOx in 2016.
[697] October 2019 Regional Haze Four-Factor Analysis for Transwestern Pipeline Company, LLC Mounatinair Compressor Station at 3 and Appendix A.
[698] *Id.* Appendix A.
[699] *See* March 3, 2016 Title V Operating Permit Application for Significant Modification, Permit P153-R3 Transwestern Pipeline Company, LLC Mountainair Compressor Station Section 6, Page 4.
[700] March 6, 2020 NPCA Oil and Gas Four-Factor Report at 28.

Alternative Control Techniques document for RICE includes emissions test results for Clean Burn, low-emission retrofits (with a pre-combustion chamber) for LSV model dual-fuel engines demonstrating NOx emission rates of 2.0 g/hp-hr and as low as 1.27 g/hp-hr.[701] And, more generally, EPA's updated information on stationary RICE NOx emissions and control technologies concludes, for lean-burn engines, an emission rate of 2.0 g/bhp-hr is achievable for "new engines and most engines retrofitted with LEC technology."[702] Emissions reductions to meet a controlled NOx rate of 2 g/hp-hr, based on a baseline emission rate that is reflective of the units' allowable emission rate, represents an 88% reduction in NOx emissions. Revising Transwestern's cost effectiveness analyses to reflect higher baseline emission levels that are more in line with recent NMED actual emissions data, results in more favorable cost effectiveness of these controls, as shown in the table below. This revised analysis assumes baseline emissions that are reflective of more recent NMED emissions data (e.g., 899.15 tons per year for units 701, 702, and 703 based on 2018-2019 actual emissions and assuming units 721 and 722 concurrently operated at permitted allowable levels during that time). These annual emissions are distributed equally across units 701, 702, and 703 since 2018-2019 operating hours are not known. The table below presents cost effectiveness assuming an 85% reduction in NOx emissions, which reflect reducing hourly allowable NOx emission rates to a level of 2.5 g/hp-hr.

Table 50. Cost Effectiveness of LEC at Uncontrolled Mountainair Compressor Station Units 701, 702, and 703 to Reduce NO_x Levels to 2.5 g/hp-hr, Based on 2018-2019 Baseline Emission Levels Evenly Distributed Across Units 701, 702, and 703

Unit	Size [hp]	Total Annualized Costs of LEC to Reduce NOx to 2.5 g/hp-hr [2019$]	NOx Removed, tpy	Cost Effectiveness of LEC [2019$], $/ton
701	4,500	$342,000*	255	$1,341/ton
702	4,500	$342,000*	255	$1,341/ton
703	4,500	$342,000*	255	$1,341/ton

*Quote from Cooper Machinery Services 10/17/19

Note, if units 701, 702, and 703 operate with the same distribution as in 2016 (i.e., with unit 701 operating roughly 15% of the time, unit 702 operating 35% of the time, and unit 703 operating 50% of the time), the cost effectiveness would range from $900–$3,000/ton. And the cost effectiveness of LEC controls would be even more favorable, under any operating scenario, if LEC at these units were able to meet controlled emission rates below 2.5 g/hp-hr, which, as discussed earlier, has been demonstrated for other LEC retrofits for similar engines. NMED should request that Transwestern research other available retrofit options from additional

[701] *See* EPA 1993 Alternative Control Techniques Document for RICE at 5-82 and 5-83.
[702] *Id.* at 4-12.

vendors that may be able to guarantee NOx emission rates less than 2.5 g/hp-hr for these engines.

3. Use of SCR

Transwestern also evaluated SCR as a control for the four-stroke lean burn engines at Mountainair Compressor Station (Units 701, 702, and 703). The company did identify concerns with applicability of SCR to the two-stroke lean burn units including reagent injection control, exhaust temperature requirements, variations in the exhaust NO/NO_2 ratio, and engine oil carryover harming the SCR catalyst.[703] In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[704]

Irrespective of the company's concerns with applicability of SCR to the lean burn engines, Transwestern did conduct a cost effectiveness evaluation for SCR at Units 701, 702, and 703 assuming a target NOx emission rate of 0.060 to 1.02 g/hp-hr which purported reflects 90% reduction from current NOx emission levels.[705] Specifically, the company estimated the cost effectiveness of SCR at Unit 701 as $6,596/ton, at Unit 702 as $2,114/ton, and at Unit 703 as $1,372/ton.[706] The company's analyses show that SCR is more cost effective than LEC. Yet, these cost effectiveness values are in error and true cost effectiveness of SCR would be even lower, as discussed below.

One reason the cost effectiveness values are likely lower is because Transwestern relied on 2016 emissions as baseline emissions, but 2016 emissions were much lower than more recent years' emissions as discussed earlier.

Transwestern appears to have used a 2000 NESCAUM Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, and Internal Combustion Engines to estimate capital costs for SCR.[707] Specifically, the NESCAUM formula which was based on only one case study for a RICE unit to "approximate" SCR capita costs for lean burn RICE is as follows:

$$\$310{,}000 + (\$72.7 \times hp)$$[708]

[707] *Id.* at 8. *See also* December 2000 NESCAUM Status Report on NOx Controls for Gas Turbines, Cement Kilns, Industrial Boilers, and Internal Combustion Engines at III-30.
[708] *Id*.

This NESCAUM equation is twenty years old and is likely based on cost data from the 1990's. SCR has been implemented on numerous source types over the past twenty years, and the much wider-scale implementation and innovation in catalyst design has lowered the cost of SCR.[709] Yet, Transwestern's analysis escalated the capital costs developed with the above equation from the 2000 NESCAUM report by assuming the NESCAUM cost equation was based on 1994 costs and escalating to 2019, using the differences in the Consumer Price Index between 1994 and 2019.[710] EPA's Control Cost Manual cautions against escalating costs more than five years due to the potential for significant inaccuracies in price estimates.[711]

EPA currently has a spreadsheet available to estimate the capital and operating costs for SCR. While the spreadsheet was developed for fossil fueled fired boilers, it can be used as an estimate for SCR at other natural gas-fired sources and, in fact, has been used oil and gas companies for several four-factor analyses submitted to NMED. Transwestern included the necessary information to be able to utilize the EPA SCR cost spreadsheet to estimate SCR costs for the Units 701-703 engines. Specifically, the company provided the hourly heat input in MMBtu/hr, the inlet NOx emission rate in lb/MMBtu, the engine fuel consumption in terms of Btu/hp-hr (with which the annual fuel consumption can be estimated based on the 2016 operating hours for each unit and each unit's rated horsepower of 4500), the flue gas flow rate in actual cubic feet per minute, and the SCR inlet temperature. The elevation for the location was estimated to be 6,519 feet above sea level (the elevation of the city of Mountainair, New Mexico)

.

Using the unit-specific operating hours for 2016 and assuming 90% NOx reduction across the SCR, the cost effectiveness based on EPA's SCR spreadsheet is estimated as shown in the table below. Transwestern assumed a 25-year life of SCR, which was also assumed in the SCR cost effectiveness calculation presented below which is consistent with EPA's Control Cost Manual for the expected life of SCR at an industrial unit. For reasons discussed above in this report, a 4.7% interest rate was used rather than Transwestern's assumed 5.5% interest rate. (See, e.g., Section I.A. above).

[709] See EPA, Combined Heat and Power Partnership, Catalog of CHP Technologies, Section 3. Technology Characterization-Combustion Turbines, March 2015, at 3-18.

[710] October 2019 Regional Haze Four-Factor Analysis for Transwestern Pipeline Company, LLC Mountainair Compressor Station at Appendix B.

[711] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017.

Table 51. Estimated Cost Effectiveness of SCR Using EPA's SCR Cost Spreadsheet and 2016 Operational Data for Units 701, 702, and 703 at Mountainair Compressor Station No. 7 (25-Year Life, 4.7% Interest Rate), 2018 $

Unit Number	Capital Cost	Operations and Maintenance Costs	Total Annual Costs	NOx Reduced from 2016 Emissions, tpy	Cost Effectiveness
701	$1,996,770	$22,760	$162,886	41	$3,989/ton
702	$1,996,397	$36,662	$176,761	137	$1,286/ton
703	$1,886,138	$44,591	$177,098	208	$850/ton

In comparison, Transwestern's SCR cost estimates are much higher. The table below provides the company's SCR cost estimates for comparison to Table 51 above.

Table 52. Transwestern's Cost Effectiveness of SCR for Units 701, 702, and 703 at Mountainair Compressor Station No. 7 (25-Year Life, 5.5% Interest Rate), 2019 $[712]

Unit Number	Capital Cost	Operations and Maintenance Costs	Total Annual Costs	NOx Reduced from 2016 Emissions, tpy	Cost Effectiveness
701	$1,100,282	$225,152	$269,152	40.81	$6,596/ton
702	$1,100,282	$246,513	$290,525	137.46	$2,114/ton
703	$1,100,282	$241,474	$285,485	208.14	$1,372/ton

Interestingly, EPA's SCR cost spreadsheet estimates a much higher capital cost than Transwestern's escalation of NESCAUM's capital cost equation for RICE units. But what makes most of the differences in the cost estimates is Transwestern's operations and maintenance costs. A review of the company's cost data sheet found two significant errors that lead to the overstatement of operations and maintenance costs. First, an error was made in the calculation of catalyst volume by Transwestern, due to an error in the formula used for the NOx efficiency adjustment factor η_{adj}. The formula for η_{adj} in EPA's Control Cost Manual chapter for SCR is:

$$\eta_{adj} = 0.2869 + (1.058 \underline{\mathbf{x}} \eta_{NOx})$$ [713]

However, Transwestern used the formula

$$\eta_{adj} = 0.2869 + (1.058 \mathbf{+} \eta_{NOx})$$ [714]

[712] October 2019 Regional Haze Four-Factor Analysis for Mountainair Compressor Station No. 7, Appendix A (pdf page 12 of report).
[713] EPA Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, at pdf page 61 (Equation 2.23).
[714] October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9, Appendix A (pdf pages 14, 16, and 18 of report).

Transwestern's error resulted in a significant overestimate of the volume of catalyst, in which η_{adj} is a multiplier, which then resulted in an overestimate of annual catalyst replacement costs.

In addition, Transwestern assumed 8,760 hours per year of operation in determining annual operations and maintenance costs which significantly overstated the costs of reagent, catalyst replacement, and labor.[715]

With these deficiencies in Transwestern's cost analysis along with its use of 2016 emissions to define the NOx emissions reduced with SCR, Transwestern's cost effectiveness values for SCR are greatly overstated. While the increased hours of operation would mean increased operational costs, the capital cost of SCR would remain the same. And the annual reduction in NOx emissions would be much greater (i.e., 90% control from 2018-2018 average NOx emissions versus 90% control from the much lower 2016 NOx emissions). Thus, with more recent NOx emissions used as baseline, SCR will be even more cost effective than shown above.

In summary, SCR is a more cost effective NOx control for the Units 701, 702, and 703 compared to LEC, which Transwestern estimated would have a cost effectiveness of $1,961/ton to $13,002/ton.[716] However, if more recent emissions data are used, the cost effectiveness of LEC would also be much lower than estimated by Transwestern at $1,341/ton.

XXI. Transwestern Pipeline Company – Corona Compressor Station

The Transwestern Pipeline Company, LLC. (Transwestern) Corona Compressor Station was not a facility for which NMED requested a four-factor analysis, yet the facility has a Q/d value (based on 2014 emissions) of 5.9. The closest Class I area to the plant is the White Mountains Wilderness, which is 60 kilometers away, according to the NMED Emissions Analysis Tool. The Corona Compressor Station is located in Lincoln County. NMED has described the facility processes as follows:

> The function of the facility is to compress natural gas. This facility receives natural gas from an upstream compressor station which goes through an inlet separator. The gas is then compressed by two (2) natural gas fired RICE compressors (units 801 and 802) and is sent to the next downstream compressor station. Two Waukesha generator engines supply electrical power to the station.[717]

According to the permit, the plant includes two 2-stroke lean-burn compressor engines, two 4-stroke rich-burn RICE, and two tanks.[718]

[716] *Id.* at pdf page 12.
[717] Title V Operating Permit P151-R3 for Corona Compressor Station at A3.
[718] *Id.* at A5.

A. Units 801 and 802: Cooper-Bessemer V-250 2-Stroke Lean-Burn Compressor Engines

Units 801 and 802 are Cooper-Bessemer V-250 2-stroke lean-burn RICE constructed in 1967 (801) and 1968 (802), each with a capacity of 5,000 hp.[719] The units each have an hourly NOx limit of 205.5 lb/hr and an annual NOx limit of 900 tpy.[720]

1. Use of Low Emission Combustion Technology

The uncontrolled allowable NOx emission rates for units 801 and 802 of 205.5 lb/hr are equivalent to 18.6 g/hp-hr for these 5,000 hp engines. NPCA's March 2020 Oil and Gas Four-Factor Report stated that a wide range of emission rates are achievable with low emission combustion (LEC) technology, with NOx emissions generally no higher than 2 g/hp-hr and often significantly lower (e.g., as low as 0.5 g/hp-hr).[721] In 2002, EPA collected data on emission rates of lean burn engines that have been retrofitted with LEC, including data from several state agencies for specific engine models.[722] Test results for eight Cooper-Bessemer V-250 engines ranged from 1.6 to 3.4 g/hp-hr, with an average controlled NOx rate of 2.9 g/hp-hr.[723] And, overall, EPA calculated the weighted average for installation of LEC technology retrofit on all of the large IC engines in the dataset to be 2.9 g/bhp-hr.[724] At this controlled emission rate, NOx emissions reductions for units 801 and 802 would be 84%. These emissions reductions could prevent up to 1,500 tons per year of NOx emissions from these two units, combined, for operation at permitted annual levels. NMED should request a four-factor analysis for these units to evaluate the cost effectiveness of controlling NOx emissions from these units with LEC to 2.9 g/hp-hr.

2. Use of SCR

SCR can be a very effective method for reducing NOx emissions and the technology is often retrofit to constricted industrial sites. In a May 21, 2020 report, many of the claims made by New Mexico oil and gas companies regarding the retrofit issues with SCR on lean burn engines were addressed. That report is incorporated herein by reference and we refer the reader to that report for justification for considering SCR at lean burn engines to significantly reduce NOx emissions.[725]

[719] *Id.*
[720] *Id*. at A7.
[721] March 6, 2020 NPCA Oil and Gas Four-Factor Report at 28.

[723] *Id.* Table 4.
[724] *Id.* at 25.
[725] *See* Stamper, Victoria and Megan Williams, Review of Claims Made by New Mexico Oil and Gas Companies Regarding Applicability of Selective Catalytic Reduction (SCR) to Lean Burn Engines, May 21, 2020, provided to NMED via a May 22, 2020 letter from NPCA.

If LEC is not a viable or cost effective control for lean burn engines, SCR could possibly be a more cost effective control. That is what Transwestern Pipeline found in its four-factor analysis for its two Cooper-Bessemer LSV-16G four-stroke lean-burn engines at the Roswell Compressor No. 9.[726] In Section XIX.A.2. of this report, we provided a revised cost effectiveness analysis of SCR using the SCR cost spreadsheet EPA provides with its Control Cost Manual[727] that showed SCR would be even more cost effective than reflected in Transwestern Pipeline's four-factor submittal, in the range of $2,400/ton to $2,800/ton at engines that, based on 2016 data, operate at 11%-41% of available hours. In addition, the costs of SCR could be reduced if there were options for a shared SCR system between engines. For all of these reasons, NMED should consider SCR as a potentially viable control option for lean burn engines in a company's analysis of available controls to achieve reasonable progress towards the national visibility goal.

B. Units 821 and 822: Waukesha F3520GU 4-Stroke Rich-Burn RICE

Units 821 and 822 are Waukesha F3520GU 4-stroke rich-burn RICE constructed in 1967, each with a capacity of 418 hp.[728] The units each have an hourly NOx limit of 18.5 lb/hr and a combined annual NOx limit of 83.4 tpy.[729]

1. Use of Non-Selective Catalytic Reduction

The uncontrolled allowable NOx emission rates for units 821 and 822 of 18.5 lb/hr are equivalent to 20.1 g/hp-hr for these 418 hp engines. NPCA's March 2020 Oil and Gas Four-Factor Report provides an analysis of the cost effectiveness of NSCR to reduce NOx emissions from rich-burn RICE by 94%.[730] This cost analysis is laid out below, as applied to these two specific units at the Corona Compressor Station.

EPA describes NSCR and potential controlled emission rates in its Alternative Control Techniques document for RICE:

> Catalyst vendors quote NOx emission reduction efficiencies of 90 to 98 percent. Based on an average uncontrolled NOx emission level of 15.8 g/hp-hr (1,060 ppmv), the expected range of controlled NOx emissions is from 0.3 to 1.6 g/hp-hr….[731,732]

[726] *See* October 2019 Regional Haze Four-Factor Analysis for Roswell Compressor Station No. 9 at 2.
[727] Available at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution.
[728] *Id.* at A5.
[729] *Id*. at A7.
[730] March 6, 2020 NPCA Oil and Gas Four-Factor Report at 17-20 and Table 7 at 26.
[731] EPA 1993 Alternative Control Techniques Document for RICE at 2-10 to 2-11.
[732] Note, employing NSCR to reduce NOx emissions from EPA's uncontrolled emission rate of 15.8 g/bhp-hr to 1.0 g/bhp-hr corresponds to a NOx emission reduction efficiency of 94%. This control efficiency is used in the analysis presented here as a reasonable achievable emission rate but certainly not the lowest possibility.

A cost effectiveness analysis of NSCR was performed in 2010 for EPA, to help determine national impacts associated with EPA's final rule for Reciprocating Internal Combustion Engine National Emission Standards for Hazardous Air Pollutants (RICE NESHAP).[733] The analysis, performed by E^C/R Incorporated, was based on 2009 cost data for retrofitting NSCR on existing 4SRB engines from industry groups, vendors, and manufacturers of RICE control technology. E^C/R Incorporated performed a linear regression analysis[734] on the data set to determine the following linear equation for annual cost, which includes annual operating and maintenance costs plus annualized capital costs based on a 7% interest rate and 10-year life of controls:

NSCR Annual Cost = $4.77 x (hp) + $5,697 (2009$)

The capital cost equation for retrofitting an air-to-fuel ratio controller (AFRC) and NSCR on a 4SRB engine was determined by E^C/R Incorporated to be, as follows:

NSCR Capital Cost = $24.9 x (hp) + $13,118 (2009$)

These relationships are derived from a data set that includes engines ranging in size from 50–3,000 hp.

The E^C/R document does not explain why it assumed a 10-year life of controls for estimating the annualized capital costs. The life of a RICE unit is generally much longer than ten years, and is often at least thirty years.[735] The assumed 10-year life was not based on the catalyst replacement timeframe, because the E^C/R operating costs took into account the cost for replacing the catalyst every three years, as well as replacing the thermocouple every 7.5 years, the crankcase filters every three months, the oxygen sensor on a quarterly basis, and rotating the catalyst for cleaning annually.[736] Thus, the assumed 10-year life of an NSCR system seems arbitrary. In cost analyses done in 2000 for EPA, an equipment life of NSCR of fifteen years was assumed.[737] The state of Colorado also recently assumed a 15-year life of NSCR for RICE

[733] Memo from E^C/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010), *available at*: https://www.epa.gov/sites/production/files/2014-02/documents/5_2011_ctrlcostmemo_exist_si.pdf.

[734] *Id.* The report notes that the linear equation has a correlation coefficient (R) of 0.7987, concluding that it "shows an acceptable representation of cost data."

[735] *See, e.g.*, EPRI, 20 Power Companies Examine the Role of Reciprocating Internal Combustion Engines for the Grid, *available at*: https://eprijournal.com/start-your-engines/. The authors also note that, in reviewing permits for gas processing facilities and compressor stations in New Mexico, it is not uncommon to have engines that were constructed from the 1950's to 1970's still operating at such facilities.

[736] Memo from E^C/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010), at 4 and at 11, 13, and 15.

[737] *See* August 11, 2000, E.H. Pechan & Associates, Inc., NOx Emissions Control Costs for Stationary Reciprocating Internal Combustion Engines in the NOx SIP Call States, at 5 and at A-2, *available at*: https://www3.epa.gov/ttn/ecas/regdata/cost/pechan8-11.pdf. *See also* EPA, Regulatory Impact Analysis for the NOx SIP Call, IP, and Section 126 Petitions, September 1998, at 5-5 (Table 5-3).

units.[738] Given that EPA assumed a selective catalytic reduction (SCR) system at an industrial fossil fuel-fired boiler has a life of 20-25 years,[739] it seems very likely that NSCR would have a useful life of at least fifteen years if not longer. For the purpose of the NSCR cost analyses presented here, a 15-year life of the NSCR system was assumed.

In addition, a lower interest rate than 7% is assumed in determining annualized costs of controls for this report. As discussed earlier, a 4.7% interest rate seems like the highest bank prime interest rate (and it will likely be lower) that could be in place in the next year when NMED adopts reasonable progress controls.

The table below shows the cost effectiveness of NSCR and an AFRC achieving 94% NOx reduction efficiency and operating at 2,000 hours per year and 8,000 hours per year, based on these cost equations from EPA's 2010 RICE NESHAP, adjusted to reflect a 4.7% interest rate and 15-year life of controls.

Note that lower NOx emission limits may be possible that reflect a higher NOx removal efficiency than the 94% assumed in the table below and the costs of employing NSCR to meet these lower limits will be even more cost effective than what is shown here.

Table 53. Cost Effectiveness to Reduce NOx Emissions from 4SRB RICE with NSCR and an AFRC, Based on EPA RICE NESHAP Cost Equations for Existing Stationary RICE[740]

UNIT	SIZE, hp	ANNUALIZED COSTS OF NSCR AND AFRC, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 2,000 HR/YR, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 8,000 HR/YR, 2009$
801	418	$6,544	$499/ton	$125/ton
802	418	$6,544	$499/ton	$125/ton

We did not escalate these costs to 2019 dollars. The Chemical Engineering Plant Cost Index (CEPCI) has been used extensively by EPA for escalating costs, but EPA states that using the CEPCI indices to escalate costs over a period longer than five years can lead to inaccuracies in

[738] *See* Colorado Department of Public Health and Environment, Air Pollution Control Division, Reasonable Progress Evaluation for RICE Source Category, circa 2008 [hereinafter referred to as "CDPHE RP for RICE"], at 8, *available at*: https://www.colorado.gov/pacific/sites/default/files/AP_PO_Reciprocating-Internal-Combustion-Engine-RICE-engines_0.pdf.

[739] *See* EPA, Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, at pdf page 80, *available at*: https://www.epa.gov/sites/production/files/2017-12/documents/scrcostmanualchapter7thedition_2016revisions2017.pdf.

[740] *See* Memo from E^{C}/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010). Annualized costs of control were calculated using a capital recovery factor of 0.099626 (assuming a 15-year life of controls and a 4.7% interest rate). Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032) and a 94% NOx removal efficiency.

price estimation.[741] Further, the prices of an air pollution control do not always rise at the same level as price inflation rates. As an air pollution control is required to be implemented more frequently over time, the costs of the air pollution control often decrease due to improvements in the manufacturing of the parts used for the control or different, less expensive materials used, etc. However, even today's costs for NSCR are assumed to be very cost effective given that the cost effectiveness based on 2009$ is on the order of $100/ton.

XXII. Durango Midstream - Empire Abo Gas Plant

The Empire Abo Gas Plant is a natural gas processing and gas sweetening plan located in Eddy County, New Mexico, operated by Durango Midstream. NMED did not request a four-factor analysis for this facility, but the source does have a Q/d value of 24.2 based on 2014 emissions and it is 68.9 kilometers from Carlsbad Caverns National Park according to NMED's Emission Data Analysis Tool. The plant is permitted to operate under two operating scenarios: 1) a gas sweetening and processing plant, and 2) a compressor station that receives gas at low pressure and routes it to the Maljamar Gas Plant for processing.[742] A review of data on NMED's Emissions Analysis Tool shows that the plant has varying emissions, with the last three years (2017-2019) being much lower emissions than in the past. For the 2016 year that most facilities used as a baseline, the plant emitted 271.1 tons of SO2. However, currently, the plant emitted 72 tons in 2019 and only 19 tons of SO2. In the 2012 to 2015 timeframe, the plant had about 200 tpy of NOx emissions and approximately 450-850 tpy of SO2 emissions. The state should request information from Durango Midstream as to the planned operation of the plant (whether it will be primarily as a gas sweetening plant or a compressor station) in 2028 to determine which sources to focus on for control.

Of all of the emission limits identified in the Title V permit, the SRU/Incinerator is allowed the highest level of emissions of 565 tpy.[743] Based on the discussion in Section XXIII below, NMED should thus require the company to evaluate an AGI well and/or an acid gas scrubber to add after the tail gas incinerator to remove SO2 when the SRU is down for maintenance.

XXIII. Comments on Pollution Control Evaluations for Amine Units/Acid Gas Flares at Gas Sweetening Plants

NMED requested four-factor analyses of controls for several amine units at New Mexico gas processing plants. Amine treating units are used to remove hydrogen sulfide (H2S) and carbon dioxide (CO2) from natural gas. Plants that remove H2S are referred to as gas sweetening plants. Amines such as Monoethanolamine (MEA), Diglycolamine (DGA), Diethanolamine (DEA) and Methyldiethanolamine (MDEA) can form salts with H2S and CO2 in an aqueous solution.

Targa's four-factor submittal for the Saunders gas plant describes and amine unit as follows:

[741] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017.
[742] 6/30/2017 Title V Permit No. P146-R3 for Empire Abo Gas Plant.
[743] *Id.*at A11.

> An amine treating unit operates by feeding the inlet gas stream into the bottom of a contactor and simultaneously feeding a lean amine solution at the top of the contactor. The two streams interact in counter flow, resulting in CO2 and H2S being stripped from the natural gas stream. The lean amine solution must be kept at a higher temperature than the gas feeding into the contactor, or condensation of heavier hydrocarbons could occur. Trays or packing in the contactor provide a place for the lean amine solution to interact with the inlet gas stream. The natural gas leaving the contactor will be "sweet gas."
>
> The rich amine leaving the contactor is usually sent to a flash tank which reduces the pressure of the stream and causes dissolved hydrocarbons to flash off. The rich amine will then pass through a heat exchanger and enter a solvent regenerator. The heated vapor generated at the bottom of the regenerator flows upward through the trays or packing where it comes in contact with the rich amine and removes the acid gases from the amine. The lean amine is then cooled and reenters the first contactor to start the process over. The acid gas that is dissolved in the vapor is then sent to a control device such as a sulfur recover unit (SRU) with a tail gas incinerator, a flare, or an acid gas injection (AGI) well.

November 2019 Four-Factor Analysis for Saunders Gas Plant at 2-8 to 2-9.

The acid gas exiting the amine unit is essentially composed of H2S and CO2. While the percentage of H2S and CO2 can vary depending on the sulfur content of the natural gas, as one example, a gas amine unit in Texas in the Permian Basin is composed of approximately 45% H2H and 54% CO2.[744] According to EPA's AP-42 Emission Factor documentation, emissions from gas sweetening units only result when gas is flared or incinerated and the major pollutant of concern from such flaring or incineration is SO2.[745] When the acid gas stream is flared rather than injected into the geologic strata or controlled with an SRU, all or most of the H2S is converted to SO2. While flaring may be a control for H2S in the acid gas stream, it is a cause of SO2 emissions and does not control SO2.

The typical controls for amine units are acid gas injection (AGI) well or a sulfur recovery unit (SRU). An AGI well should result in no emissions because the acid gas stream is injected into the geologic strata. However, if there are any malfunctions in the equipment that pumps the acid gas stream into the AGI, then air emissions can result. An SRU converts hydrogen sulfide to element sulfur. The most commonly applied method is the Claus method, which can typically recover 95-97% of the hydrogen sulfide feed stream.[746] According to EPA, older SRUs or very

[744] *See* Oil and Gas Docket No. 08-0289658, Application of James Lake Midstream, LLC, available for download at https://www.rrc.state.tx.us/hearings/dockets/oil-gas-proposals-for-decision-and-orders/index-for-336/.
[745] EPA, AP-42, Section 5.3 Natural Gas Processing at 5.3-3.
[746] EPA, AP-42, Sulfur Recovery at 8.13-1.

small Claus plants producing less than 22 tons of sulfur per day have varying sulfur recovery efficiencies.[747] The following table lists those amine units for which NMED requested four-factor analyses for the control of SO2.

Table 54. List of Facility Amine Units (or Acid Gas Flares) For Which NMED Requested Four-Factor Analysis of Controls and Potential to Emit (PTE) SO2 as Reported in Company Analysis

Facility	Amine Unit	Existing Controls	PTE SO2 tpy	PTE SO2 lb/hr
Jal No. 3	Unit 9S (Thermal Oxidizer)	SRU and AGI well	1,205.9	275.3
DCP-Eunice Gas Plant	Unit 31	SRU	257.2	9,368.2
Targa-Eunice Gas Plant	Unit AM-01/F-01	AGI well	776.5	5,176.6
Targa-Monument Gas Plant	Unit AM-01/F-03	AGI well	872.6	5,817.5
Targa – Saunders Gas Plant	Unit A-01/I-01	SRU with tail gas incinerator	1,397.0	316.7
DCP-Artesia Gas Plant	Amine-C Unit 23 (Acid Gas Flare)	AGI well	328.2	4918.4
Davis Gas Processing - Denton Gas Plant	Unit 005 (amine regeneration still and reboiler) and Unit 007 (acid gas flare)	None	1,195.9	312.5
Oxy-Indian Basin Gas Plant	Unit AMINE -1 & SELEXOL	AGI	Not indicated	Not Indicated

It must be noted that there are facilities listed in the above table that did not specifically list amine units but that otherwise did list startup, shutdown, and maintenance (SSM) emissions as triggering the need for a four-factor analysis due to SO2 emissions. For those facilities listed in the above table (DCP Eunice Gas Plant and DCP Artesia Gas Plant), the units have gas sweetening plants and the SO2 emissions from SSM are from flaring of the acid gases. Yet, those companies' four-factor analyses claimed they did not need to evaluate controls for SSM emissions that occur during "non-steady state" operations.[748] Flaring of the acid gas stream at units with amine units appear to, unfortunately, be part of the normal operations of the unit even though due to SSM, and there are control options available to reduce SO2 emissions from flaring – by reducing flaring via redundant acid gas steam control options (second AGI well, or

redundant compressor at AGI well, or SRU plus AGI well) or by replacing a flare with an incinerator and acid gas scrubber to be used when the primary acid gas control for the amine unit is not functioning. Thus, NMED must not allow facilities with significant SO2 emissions due to SSM to be exempt from a four-factor analysis of controls.

The following provides a discussion of controls for SO2 emissions at gas sweetening plants in the context of reviewing and commenting on the four-factor submittals for the facilities listed in the above table.

A. Amine Units with No Acid Gas Controls – Denton Gas Plant

There is one amine unit listed in the above table which apparently has no H2S controls – the Davis Gas Processing Denton Gas Plant. Although the Denton Gas Plant used 2017-2018 SO2 emissions as baseline emissions for its cost effectiveness analysis, the plant's two-year average SO2 emissions have varied from 713.00 tpy (2017-2018 average) to 1,061.27 tpy over the past ten years.[749] Davis Gas Processing states that the sulfur recovery process (both the Claus process and another processed called LO-CAT) were eliminated from further consideration because of concerns of the level of control achievable with variable flowrates and H2S concentrations, which the company claims are common at Denton, and apparently because of the low throughput rate that would apply to an SRU at the Denton amine unit.[750] While a properly designed, operated, and maintained acid gas injection well would achieve a higher level of SO2 control (SO2 removal efficiency should be 100% with an AGI well), we note that NMED has requested some companies to analyze installing an AGI well in addition to having a sulfur recovery unit.[751] Such duplicative controls should be considered, even for units with AGI wells. Although an AGI well in theory should provide 100% control of SO2, problems with the equipment to compress and pump the acid gas steam into the AGI well can occur – or sometimes even with the AGI well. For example, Targa explained that its Monument AGI well "failed an OCD required pressure test on July 27, 2016" and the well had to be shut down August 8th and ultimately was abandoned, resulting in significant flaring of acid gas until the new well became operational in March 2017.[752] This flaring resulted in approximately 2,000 tons of SO2[753] from a pollution control that should have 100% SO2 reduction efficiency. While this AGI well malfunction may have been unique, there clearly are also problems with AGI compressors because other New Mexico companies have installed, or are in the process of installing, redundant compressors.[754] Yet, redundant compressors are not necessarily enough to prevent significant SO2 emissions from flaring that may occur during upsets or maintenance. NMED should ask each company with gas sweetening plants, including the Denton Gas Plant, to evaluate the cost of redundant SO2 pollution controls. One option is to install an SRU if the

facility already has an AGI well, to be used when the AGI well cannot be used for control. Another option is to have the gas routed to an incinerator with an add-on acid gas scrubber, when the AGI well is not functioning.[755] For those facilities that have SRUs to control SO2 from amine units or that have no SO2 controls such as the Denton Gas Plant, adding an AGI well as a duplicative control should be evaluated first.

The four-factor analysis for the Denton Gas Plant evaluated the costs of installing an AGI well. While the Denton analysis used a 5.25% interest rate and a 20-year life as well as the lowest 2-year baseline of all of the past 10 years of SO2 emissions, the company's cost effectiveness analysis shows that an AGI well would be quite cost effective at $1,014/ton of SO2 removed.[756] Davis Gas Processing likely overstated the capital costs of an AGI well, by adding 25% to the purchased equipment costs as well as using EPA's Control Cost Manual's percentage of purchased equipment costs for foundations and supports, handling and erection, etc.[757] As the company notes in its four-factor analysis, the use of AGI for the disposal of acid gas "is becoming increasingly common…"[758] Thus, rather than adding a 25% contingency factor to the purchased equipment cost and then adding EPA's Control Cost Manual estimates (which are a percentage of the purchased equipment costs) for installation of an AGI, the company could have obtained a reliable estimate of the cost of AGI well installation. With respect to operating expenses, David Gas Processing's analysis assumed a cost per kW hour of $0.11 which appears to be the cost for residential service in New Mexico.[759] The electricity cost for an industrial user is generally much lower than a residential user. EPA estimates the cost for electricity in its SCR cost spreadsheet of $0.0676/kWh. A web search for average electricity cost in New Mexico for industrial use shows a cost of $0.0583/kWh.[760] Thus, annual electricity costs for the electric compressors for an AGI well in New Mexico should be in the range of $41,893 to $48,575 rather than the $79,043 assumed for the Denton Gas Plant. Further, this cost reflects electricity use when the compressors are used at maximum capacity for all hours of the year, so this is a worst case annual operating cost. The company's assumed cost for electricity has a significant impact on the cost effectiveness of an AGI well. When just the cost for electricity is revised to be $0.0583/kWh, the cost effectiveness of an AGI well at the Denton Gas Plant reduced from $1,014/ton to $663/ton. If the interest rate is lowered to a more reasonable 4.7% for the reasons discussed in this report and the life of an AGI well is increased to 25 years which seems reasonable given the life of gas sweetening plants like Denton, the cost effectiveness of an AGI well further reduces to $574/ton. Moreover, if one removes the 25% contingency factor that Davis Gas Processing applied to its estimate of equipment costs, the cost effectiveness of AGI to reduce SO2 would be $481/ton. Clearly, installation of an AGI well is very cost effective for the Denton Gas Plant.

B. Amine Units with SRUs – DCP Eunice Gas Plant and Targa Saunders Gas Plant

With respect to the DCP Eunice Gas Plant which has an SRU, DCP's four-factor analysis claims that the area is not suitable for an AGI well[761] despite being near to the Targa Monument Gas Plant which also has an AGI well. It appears that the plants are roughly 10 miles apart. NMED should request more information from DCP as to why it claims an AGI well is not viable for its Eunice Gas Plant. Not only could this provide more information to enable NMED to thoroughly consider the Targa Monument Plant's SO2 controls for its amine plant, but it is needed to justify DCP's claims that an AGI well is not feasible for its location especially given how cost effective an AGI well can be based on the revised Denton Gas Plant analysis discussed above. DCP states that AGI wells typically include a second redundant AGI well.[762] The fact that such redundancy is required for SO2 controls when an AGI well is used for control argues for redundancy in controls when an SRU (which is not nearly as efficient in SO2 reduction as a properly operating AGI well) is used for SO2 control. Use of an incinerator with an add-on acid gas scrubber as a redundant control for those amine units with SRUs should thus be evaluated as an additional SO2 control. This could be used downstream of the SRU to improve SO2 removal efficiency when the SRU is operating and could also be used when the SRU is down for maintenance or upsets. These types of duplicative control have been used in oil refineries and thus are a viable control option for a natural gas processing plant as well.[763] NMED should thus require DCP to evaluate this control option. In addition, NMED should ask DCP to report on its SO2 removal efficiency of its current SRU and to quantify its actual SO2 emissions from flaring the acid gas stream when the SRU is down for maintenance or upsets. As part of its four-factor analysis, NMED must evaluate the level of SO2 control currently being achieved at the gas sweetening plant and ensure that all available options for improving that level of control are evaluated. The Targa Saunders Gas Plant utilizes a "Select-Tox Single State Claus bed with a tail gas incinerator" as a control for the amine unit, with an acid gas flare when the SRU is down for maintenance.[764] Targa considered an AGI well, but claimed it could not install an AGI well without plugging/cementing some of the numerous other wells in the area because acid gas could vent from any unplugged wells.[765] NMED should request more information on the documentation collected by Targa to support this claim. Targa did not evaluate any other controls to reduce SO2 emissions from its amine unit after finding an AGI well was not feasible for the Saunders plant.[766] NMED should require Targa to evaluate the option of adding an acid gas scrubber to its tail gas incinerator and to operate the incinerator and scrubber when the SRU is not available due to maintenance or upsets. This would enable the continued control of SO2 even during SRU downtime, rather than flaring which does not control SO2 emissions at all. In addition, NMED should ask DCP to report on its SO2 removal efficiency of its current SRU and

[765] *Id.* at 2-10.
[766] *Id.* at 3-3.

to quantify its actual SO2 emissions from flaring the acid gas stream when the SRU is down for maintenance or upsets. As part of its four-factor analysis, DCP must evaluate the level of SO2 control currently being achieved at the gas sweetening plant and ensure that all available options for improving that level of control are evaluated.

C. Amine Units with AGI Wells – Targa Eunice Gas Plant, Targa Monument Gas Plant, DCP Artesia Gas Plant, and Oxy Indian Basin Gas Plant

As indicated above, the Targa Monument Gas Plant flared its acid gas stream for several months in 2016 -2017 due to a failed AGI well after five years of service.[767] This facility provides a pertinent example of how - even an amine unit controlled by an AGI well, which should theoretically eliminate 100% of the potential SO2 emissions - acid gas injection wells need backup and/or redundancy to ensure control of SO2. Indeed, NMED must require all amine plants with AGI wells in the table above to consider duplicative controls for removal of sulfur from the acid gas stream or prevention of SO2 emissions from flaring. Options to consider are 1) a duplicative AGI well, 2) an incinerator and add-on acid gas scrubber or an SRU for when the acid gas stream cannot be routed to the AGI well, and 3) duplicative equipment for ensuring the acid gas is continually injected into the acid gas well, such as a redundant electric compressor. The four-factor analysis submitted by Targa for the Eunice Gas Plant claims the AGI well is in the process of having redundant electric compression added to the AGI well to further reduce SO2 emissions during SSM.[768] Targa did not evaluate any other controls. Similarly, Targa stated that it is adding redundant electric compression to the Monument AGI well, and the company did not evaluate any other controls for its amine plant.[769] While having redundant compression will help to ensure that the acid gas stream is not flared due to the AGI well compressor malfunctioning or being down for maintenance, NMED should ask Targa to evaluate the costs of adding an SRU or adding an incinerator and acid gas scrubber for further redundancy in its SO2 control systems. With respect to the Monument Gas Plant AGI well, given the statements made by DCP in its four-factor analysis for the Eunice Gas Plant that the area is not well-suited for acid gas injection and given the Monument plant's proximity to the DCP Eunice Gas Plant, NMED must determine if the failure of the Monument AGI well is due to any of the reasons that DCP indicated in its Eunice Gas Plant four-factor analysis for an AGI well not being viable in the region. Further, NMED should collect and present data on the last five years of how much SO2 was emitted due to flaring of the acid gas stream at Monument due to upsets at the AGI well's compressors or other causes of flaring of the acid gas stream. Given the failure of the Monument AGI well after five years and the resulting 2,000 tons of SO2 emitted, it seems that redundant controls such as an SRU or an incinerator with acid gas scrubber must be considered as a duplicative SO2 control for the amine unit at the Monument Gas Plant. NMED should also require an evaluation of such controls for the Targa Eunice Gas Plant.

[767] *See* Targa's February 2020 Four-Factor Addendum for the Eunice Gas Plant at pdf page 9.
[768] November 2019 Four-Factor Submittal for Targa Eunice Gas Plant at 2-6.
[769] November 2019 Four-Factor Submittal for Targa Monument Gas Plant at 2-1.

In the Oxy Indian Basin Gas Plant four-factor submittal, Oxy only evaluated one control – a redundant compressor for the AGI.[770] Oxy's submittal indicated a cost effectiveness of $27,600/ton of SO2 reduced due to an estimated cost for electric compression of $11 million.[771] The company assumed baseline emissions from 2016 of NMED of 41.92 tpy and assumed a redundant compressor would reduce those emissions by 90%. NMED should ensure that the company is using realistic baseline emissions due to flaring of the acid gas stream. If 2016 was an exceptionally good year (not much flaring), but prior years had much higher emissions, cost effectiveness should be based on a longer term average of emissions. If baseline emissions were 200 tpy of SO2 from flaring, and with a more appropriate interest rate and lifetime of electric compressor of 4.7% and 25 years (instead of 5.50% and 20 years), the cost effectiveness of a redundant compressor would reduce to $4,873/ton. If the plant emitted 500 tpy, the cost effectiveness would be about $2,000/ton. Thus, it is imperative that NMED ensure that the company uses a realistic SO2 baseline for evaluating redundant controls such as duplicative compressor for its acid gas injection well. NMED did ask Oxy to consider adding a second control to its AGI system to reduce flaring emissions, such as the LO-CAT sulfur recovery technology.[772] The company indicates that it had an SRU that has been shut down due to poor reliability.[773] Given that the SRU already exists on site, NMED should ask the company to evaluate the cost for bringing the SRU back online to use only as a backup to the AGI well. That could be a very cost effective way to ensure redundancy in the SO2 removal systems at the Indian Basin Gas Plant.

DCP did not evaluate any controls for its amine plant at the Artesia Gas Plant. The company's four-factor analysis only listed emissions from flaring and stated that, based on NMED's September 23, 2019 guidance, it did not need to evaluate controls from flaring.[774] Yet, it listed acid gas flaring (Unit 23) as a significant source of SO2 emissions.[775] A review of the Title V permit for the facility shows that the facility has an amine plant and an AGI well.[776] NMED must request that the company provide information on its actual SO2 emissions from flaring the acid gas stream from its amine unit. Further, NMED must request DCP to evaluate duplicative controls and/or redundant AGI well compression.

Moreover, as part of evaluating SO2 control options for any gas processing plant, NMED should collect information on the time periods, causes, and SO2 emissions of acid gas stream flaring at the plant to determine if additional maintenance requirements should be imposed with reporting and recordkeeping to NMED.

D. Units with SRU and AGI Well – Jal No. 3

The four-factor analysis for the Jal No. 3 amine plant states that the acid gas from its amine units is sent to a sulfur recovery unit which scrubs the H2S at 92% efficiency and that the leftover H2S from the SRU is sent to the thermal oxidizer to be combusted.[777] During downtime of the SRU and/or thermal oxidizer, the acid gas is sent to the AGI wells, and during AGI well downtime, the acid gas is sent to the SRU and thermal oxidizer.[778] The company's four-factor analysis states that "[t]hese existing controls are the best known technologies for controlling acid gas and, to our knowledge, there are no other technically feasible control options to further reduce SO2 emissions from the thermal oxidizer."[779] While this suite of controls does reflect the type of duplicity in controls that is necessary for addressing SO2 emissions as gas sweetening plants, it does seem that there are additional control options that the company should have considered. Despite these duplicative controls, the facility emits significant quantities of SO2. According to date on NMED's Emissions Analysis Tool, the Jal No. 3 plant emitted almost 2,000 tons of SO2 in 2016, the year NMED is apparently using as the baseline year for company four-factor analyses. While SO2 emissions have decreased since then, annual SO2 emissions have varied from 207 tons in 2017 to 1,444 tons in 2018 to 587 tons in 2019. Presumably these emissions are all from the Unit 9S thermal oxidizer, as that appears to be the primary source of SO2 emissions based on a review of the Title V permit.

Two additional control options should have been considered for the Jal No. 3 amine unit/thermal oxidizer: 1) Routing the cleaned acid gas stream from the SRU to the AGI well during normal operation of the SRU, which would improve SO2 removal efficiency from 92% to 100% (when the AGI well was operating and not down for maintenance or upset). Under this control option, the plant should continue to route the acid gas stream directly to the AGI wells during SRU downtime; or 2) Revise the configuration to inject the acid gas stream from the amine units to AGI wells, but route the acid gas stream to the SRU/thermal oxidizer during AGI well downtime to at least achieve 92% H2S removal before combusting the acid gas. It seems like either of these two options could provide for significant additional control of SO2 from the amine units at the Jal No. 3 gas plant. NMED must require ETC Texas Pipeline to evaluate these available control options at Jal No. 3 (given that the SRU and the AGI wells already exist at the facility) to control the SO2 emissions from the facility which can be quite significant despite the plant's duplicative controls.

E. Summary

In summary, because the flaring or incineration of acid gas streams from amine units at gas sweetening plants can be such a significant source of SO2, NMED must ensure a thorough evaluation of control options for such sources. NMED should not consider such sources of emissions to be non-steady state and exempt from the four-factor review of controls, because

[777] October 2019 Regional Haze Four-Factor Analysis for ETC Texas Pipeline, Ltd. Jal No. 3 Gas Plant at 7.
[778] *Id.*
[779] *Id.* at 8.

such emissions of SO2 can be very high and can be addressed through duplicative or redundant controls. NMED must also ensure that reasonable evaluations of baseline emissions are used in evaluating the cost effectiveness of controls, in that the baseline emissions must realistically depict emissions from acid gas incineration at a facility.

NMED Regional Haze Planning Website:

https://www.env.nm.gov/air-quality/reg-haze/

Background

- Haze is caused by tiny particles in the air that absorb and scatter light
- Haze-forming pollutants come from natural and manmade sources. Manmade sources can include motor vehicles, fuel combustion, and manufacturing operations.
- Haze reduces visibility, obscuring scenic vistas
- Haze-forming pollutants can also impact human health

Background

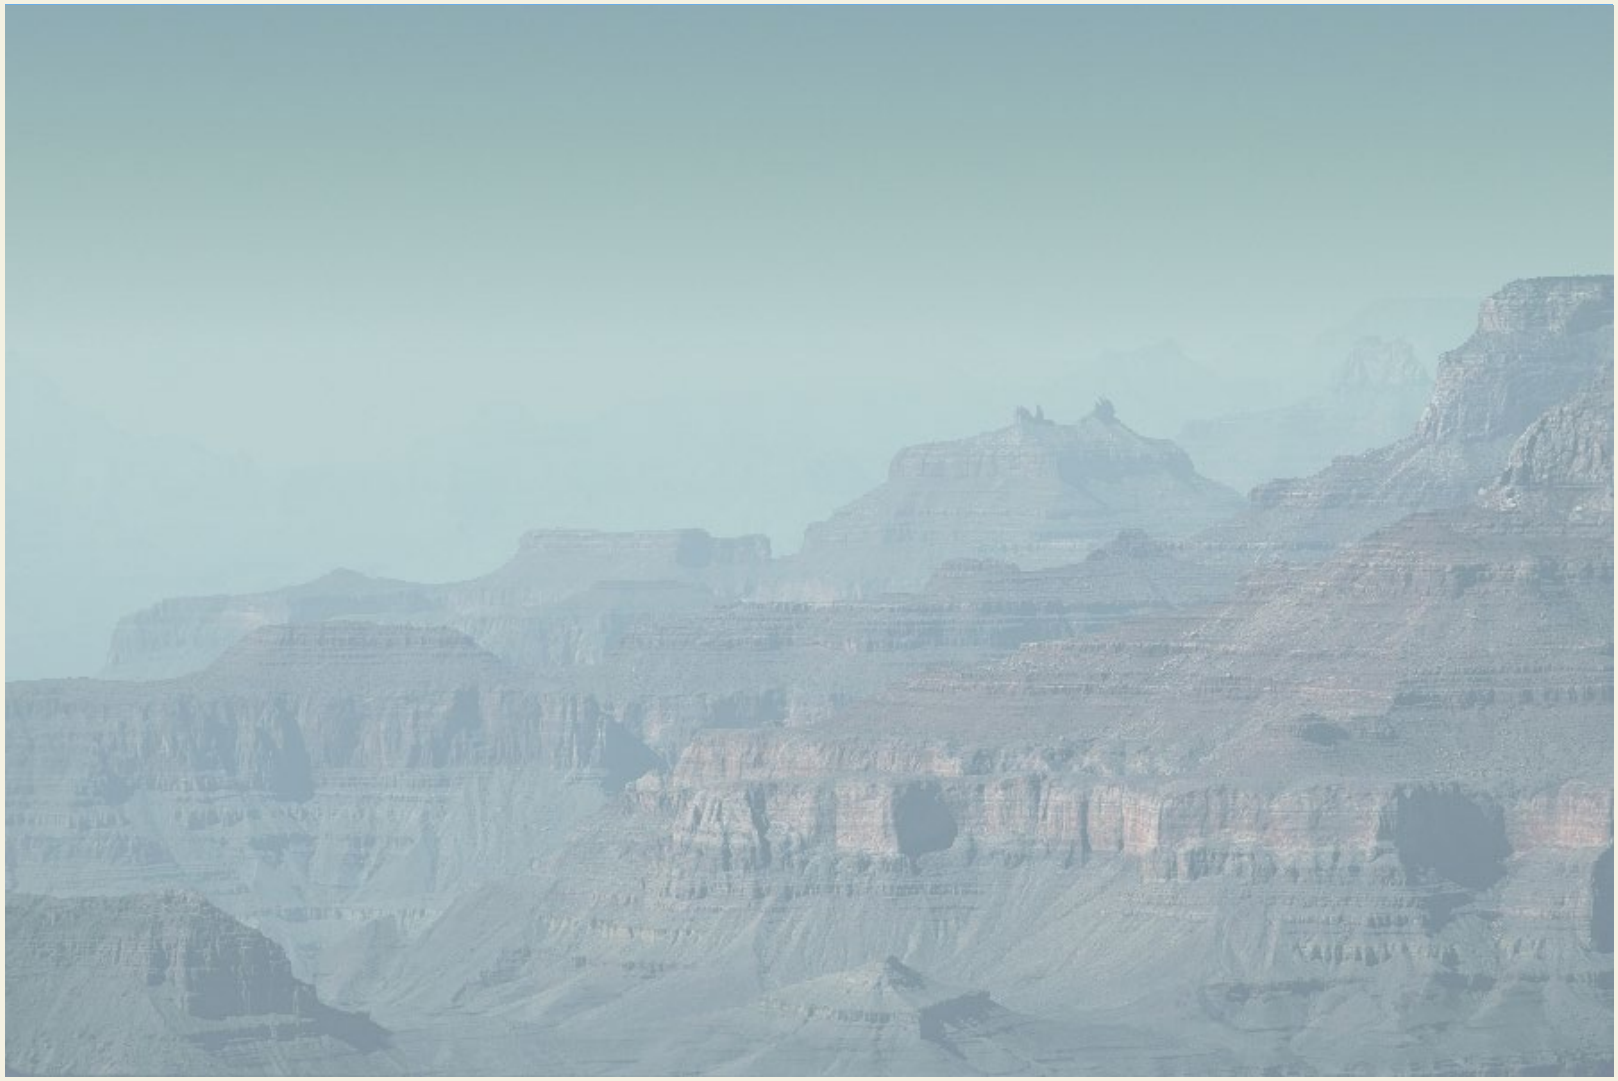

Photo Credit: WESTAR-WRAP

Background

- The Regional Haze Rule calls for state and federal agencies to work together to improve visibility in 156 national parks and wilderness areas across the United States.
- States are required to develop plans to reduce the pollution that causes visibility impairment in these protected areas; these plans must be revised every 10 years
- States coordinate and consult with EPA, other states, Tribal governments, the general public, and others when developing their Regional Haze plans

Background

Source: https://www.epa.gov/visibility/regional-haze-program

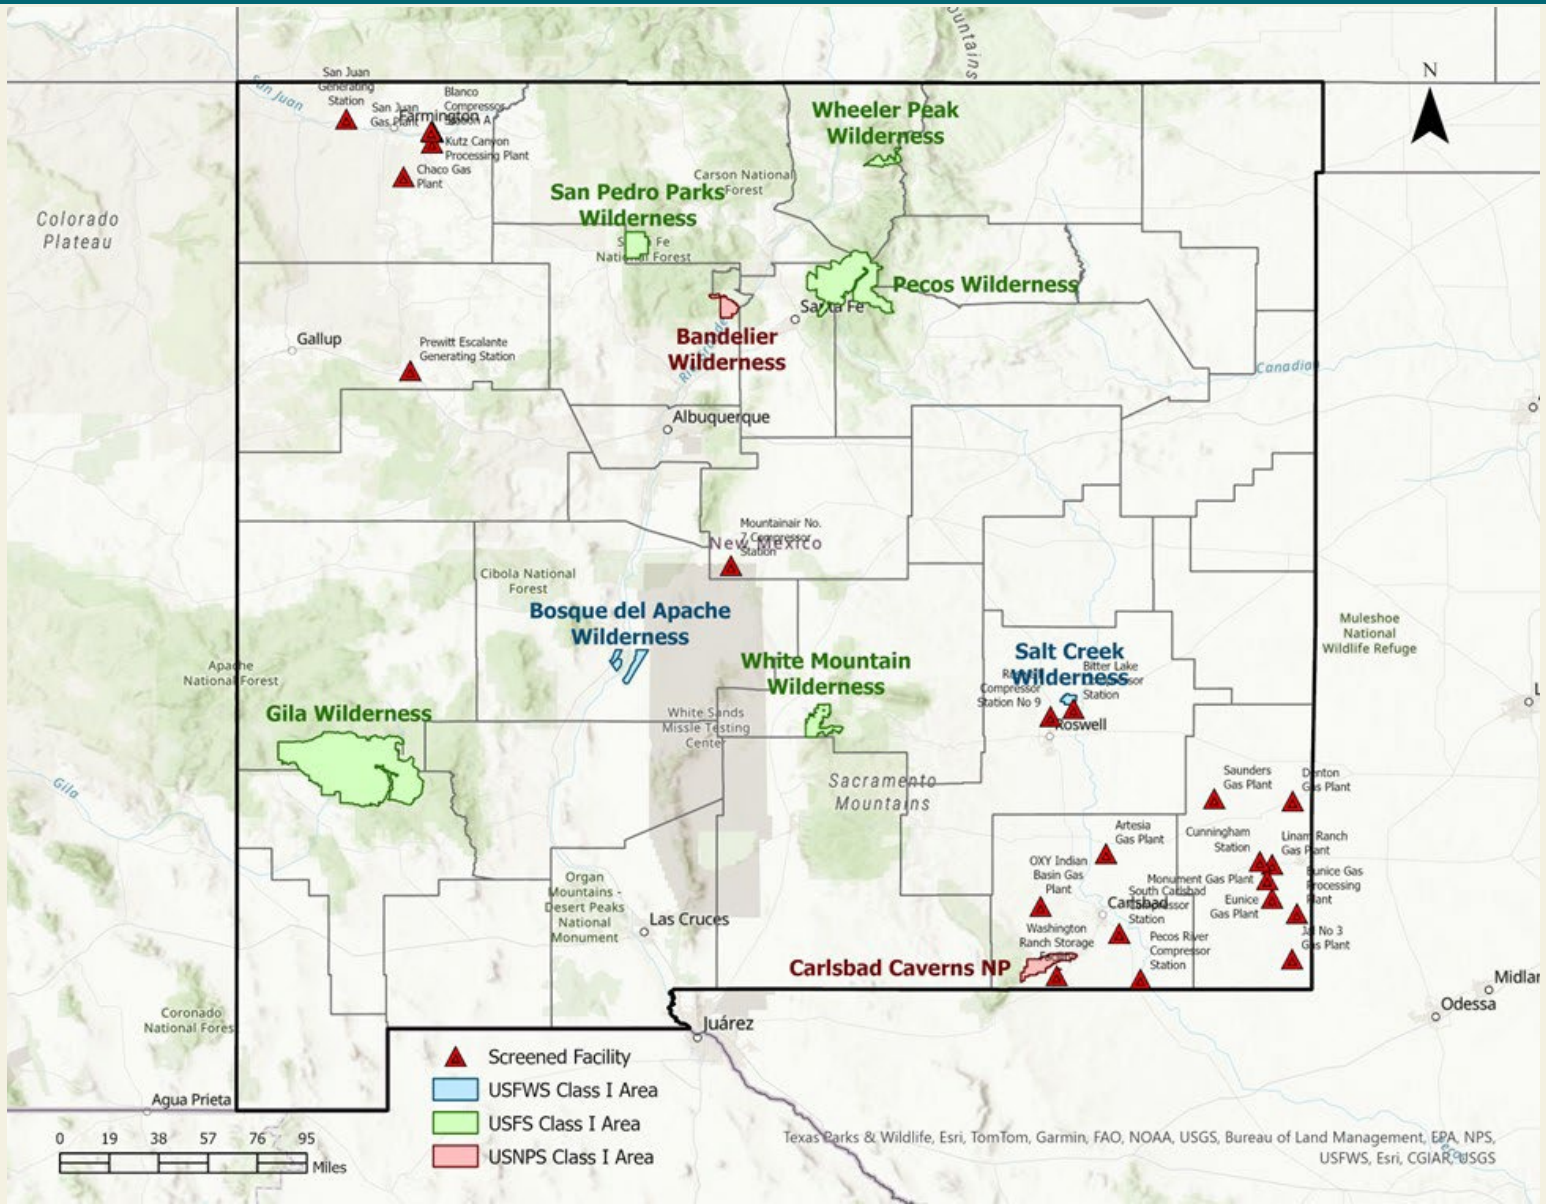
Overview of Draft Plan

SELECTED SOURCES

Selected Sources

- NMED used a screening process to select 23 facilities for an analysis of potential control measures
- NMED evaluated 133 individual emissions units at those facilities based on additional screening criteria
- The goal of NMED's screening process was to focus efforts on higher emitting units at the largest sources of air pollution that are most likely to affect visibility in protected areas based on their emissions and proximity to those areas

Selected Sources



Selected Sources

Selected Sources

Overview of Draft Plan

CONTROL EVALUATIONS

Control Evaluations

- Identify all feasible control options for each unit
- For each feasible option:
  - Determine cost to implement ($)
  - Estimate emissions reductions (tons/year)
  - Calculate cost effectiveness ($/ton)
- Determine appropriate cost threshold
- Select required controls

Overview of Draft Plan

RESULTS OF ANALYSIS

Results of Analysis

- New Controls on 54 Emissions Units
- Permanent Retirement of 34 Emissions Units
- Measures to Ensure Continued Use of In-Place Controls on 11 Emissions Units
- Significant Reductions in Emissions of Pollutants that Contribute to Visibility Impairment
  - Nitrogen Oxides > 18,000 tons/year
  - Sulfur Dioxide > 5,000 tons/year

New Rule 20.2.68 NMAC

- The emission limitations and other measures in the draft plan must be enforceable by EPA
- To ensure federal enforceability, NMED developed a new companion rule, 20.2.68 NMAC – Regional Haze Requirements
- The new rule's requirements are identical to those in the draft plan
- The new rule also includes monitoring, recordkeeping, and reporting requirements mirroring existing requirements

Navigating Draft Plan

Re: Request for Extension of Comment Period

Dear Mr. Jones:

On August 26, 2024, the New Mexico Environment Department ("NMED") published a draft state implementation plan and proposed companion rule ("Draft SIP") to address the Clean Air Act's requirements for the second planning period of the regional haze program. NMED established an abbreviated comment period of just 25 days, with a deadline of September 20, 2024. Enterprise Field Services, LLC ("Enterprise") requests that NMED extend this deadline by 30 days, until October 20, 2024.

Three Enterprise facilities—the Blanco C & D Compressor Station, the Chaco Gas Plant, and the South Carlsbad Compressor Station—would be subject to the Draft SIP's proposed requirements. As such, the Draft SIP's consistency with the law and whether it is supported by sound technical analysis are of great importance to Enterprise.

Additional time is needed to prepare comprehensive comments on such a significant and wide-ranging set of proposed new regulatory requirements. To that end, Enterprise is diligently working to develop new technical analyses to address the state's proposal. Despite our best efforts, completing that labor-intensive work by the existing September deadline will be incredibly challenging. Because this analysis is crucial to the record, Enterprise believes an extension is warranted.

Enterprise recognizes that NMED had not intended to extend the comment period of the Draft SIP and that the Department is seeking to finalize the Draft SIP consistent with deadlines for action by the U.S. Environmental Protection Agency on the New Mexico regional haze SIP. Nevertheless, Enterprise has identified serious flaws in the Draft SIP and believes NMED must take the necessary time to correct these deficiencies and to respond to substantive comments, including the information Enterprise is working to develop. To that end, if NMED is unable to formally extend the comment period, Enterprise asks that NMED commit to considering late-filed

information that Enterprise is working to develop if that information cannot be finalized by the current comment deadline.

Thank you for your consideration of this request. If you have any questions or wish to discuss how to ensure information Enterprise is developing is included in the record and considered in these proceedings, we welcome further discussion.

Sincerely,

Aaron Flynn
Counsel to Enterprise Field Services, LLC

RE: New Mexico Regional Haze SIP for the Second Planning Period

Public Service Company of New Mexico ("PNM") appreciates the opportunity to comment on the regional haze state implementation plan ("SIP") prepared by the New Mexico Environment Department ("NMED") for the second planning period. Overall, PNM supports the SIP because it satisfies all of the mandatory requirements of the Clean Air Act visibility provisions and regulations, generally follows EPA's preferred regional haze policies, and includes a reasonable selection of emission control measures from a wide range of sources. Accordingly, PNM supports submission of the SIP to EPA for approval and also offers the following comments for consideration.

First, PNM supports NMED's decision to determine and rely upon an adjusted uniform rate of progress—the "glidepath" toward the 2064 goal of eliminating anthropogenic visibility impairment—by taking into account international emissions and wildland prescribed fires. Because these sources of visibility impairment cannot be eliminated by any action taken by NMED, PNM agrees that the ultimate goal of the program should be adjusted to recognize the uncontrollable nature of those emission sources. With the adjusted glidepath, NMED will be able to focus its efforts more clearly on reducing the controllable sources' anthropogenic emissions subject to its jurisdiction. This approach is fully consistent with EPA's regulations and guidance, and PNM expects EPA will approve it as a reasonable component of the SIP.

Second, PNM supports NMED's recognition of the fact that, even with the adjusted glidepath, a more robust demonstration of reasonable progress was needed for Salt Creek Wilderness Area because the modeling performed by the Western Regional Air Partnership ("WRAP") projected the area may be above the adjusted glidepath in 2028. Although visibility is continuing to improve in the area, and the area is projected to be above the glidepath by only a slim margin, PNM agrees further analysis was required by EPA's regional haze rule. However, PNM also agrees with the conclusions drawn from that additional analysis, confirming that all reasonable measures have been taken to improve visibility in the area, and that the modeling projection likely does not consider other emission reductions that will help ensure visibility continues to improve at the Salt Creek Wilderness Area.

Third, PNM supports the methodology NMED applied in identifying the sources to review for additional control measures and the control measures selected for those sources to include in the long-term strategy for the second round SIP. NMED's conservative screening process appropriately selected 23 facilities for potential controls measures, comprised of the 133 individual emission units

most likely to impact visibility in Class 1 areas based on their emission levels and distance to those areas. Of those emission units, NMED's plan includes control measures for 54 units, a far greater number of control measures than included in most state regional haze plans. Among those control measures are the retirements of 34 emissions units. Although NMED could not directly require retirements under the regional haze authority, those retirements will nevertheless assist in the state's efforts to improve visibility, and therefore they constitute an appropriate component of the SIP. In addition, the plan requires continued use of existing control measures at 11 units that, together with the expected retirements, will result in dramatic emission reductions—18,000 tons of NO_x and 5,000 tons of SO_2—that will make reasonable progress toward eliminating anthropogenic visibility degradation. The results of NMED's analysis are reasonable and should be submitted to EPA for approval.

However, some aspects of NMED's analysis, while perhaps appropriate for this round of the regional haze program, may be overly conservative for subsequent plans. For instance, the cost-effectiveness threshold of $10,000 per ton of emissions reduction selected by New Mexico for this plan is highly likely to be approved by EPA, but it is at the highest end of the spectrum of thresholds used by other states under the regional haze program. In future planning periods, NMED should reconsider whether such a high threshold is appropriate, and also reconsider whether establishing a bright line threshold is even necessary at all. In addition, although NMED was able to identify sufficient control measures to make reasonable progress in this planning period based solely on a "dollars per ton" cost-effectiveness metric, the cost-effectiveness of control measures imposed under this visibility-focused program could be more appropriately evaluated using a metric that accounts for visibility improvements, not just emission reductions. In particular, EPA's 2019 guidance recommends "dollars-per-inverse megameter" as a reasonable metric for evaluating costs per unit of visibility benefit. As visibility levels approach natural conditions and anthropogenic impairment approaches *de minimis* levels, weighing the compliance costs against potential visibility benefits of possible control measures will become more important than cost-effectiveness metrics based solely on emission reductions.

Finally, PNM supports NMED's recognition in the SIP that the deadline for submission has passed and that EPA's deadline for a federal implementation plan (FIP) is fast approaching. In light of these circumstances, PNM recommends that NMED include in its SIP an express request for EPA to act on the SIP despite the late submission because the SIP reflects the best plan for the state after extensive analysis by the expert state regulators best positioned to determine appropriate policy approaches for the state.

Again, we appreciate the opportunity to submit these comments on NMED's regional haze SIP for the state of New Mexico, and we would be happy to discuss the content of this letter with you at your convenience, please contact me at 505-241-2019 or Claudette.Horn@PNMResources.com if you have any questions.

Sincerely,

Claudette Horn

Hello and thanks for the opportunity to comment on this initial phase of the Regional Haze State Implementation Plan. In a recent stakeholder meeting PNM implied that it would extend the life of what appears to be in the attached presentation, the Valencia Natural Gas Plant in Belen NM. The continued operation of this plant after 2028 for another 11.5 years before PNM has committed to be carbon free by 2040 could be a factor in haze generation. Thanks for your consideration, Camilla

Stakeholder Briefing: Solicit input on 2028 RFP Evaluation and Planned 2028 Resource Regulatory Filing

JUNE 25, 2024

2028 RFP RESOURCE EVALUATION

- Focusing on 2028 needs only (~400 MW)
  - Valencia PPA contract expiration 5/31/2028
  - Includes higher PNM load forecast (~200 MW incremental)
  - System needs additional capacity resources – currently energy heavy

- Resource Optimization & Resource Adequacy Portfolio Analysis
  - Least cost (20-year NPVRR)
  - Least cost with CCSD project

PNM'S INTENT FOR RESOURCES IN CCSD

- 2028 Resource filing
  - Include a CCSD located resource in the 2024 anticipated regulatory filing either in the PNM preferred portfolio or an alternative portfolio

- 2029 -2032 Resource Portfolio Request for Proposal
  - Include a CCSD locational preference in the RFP that is issued for the recently accepted IRP resources

OPTIMAL PORTFOLIOS

Portfolio 1 - Least Cost:

- Extension of CT PPA, 161 MW
- Two ESA bids totaling 300 MW of 4 hr BESS
- Provides firm capacity of about 400 MW

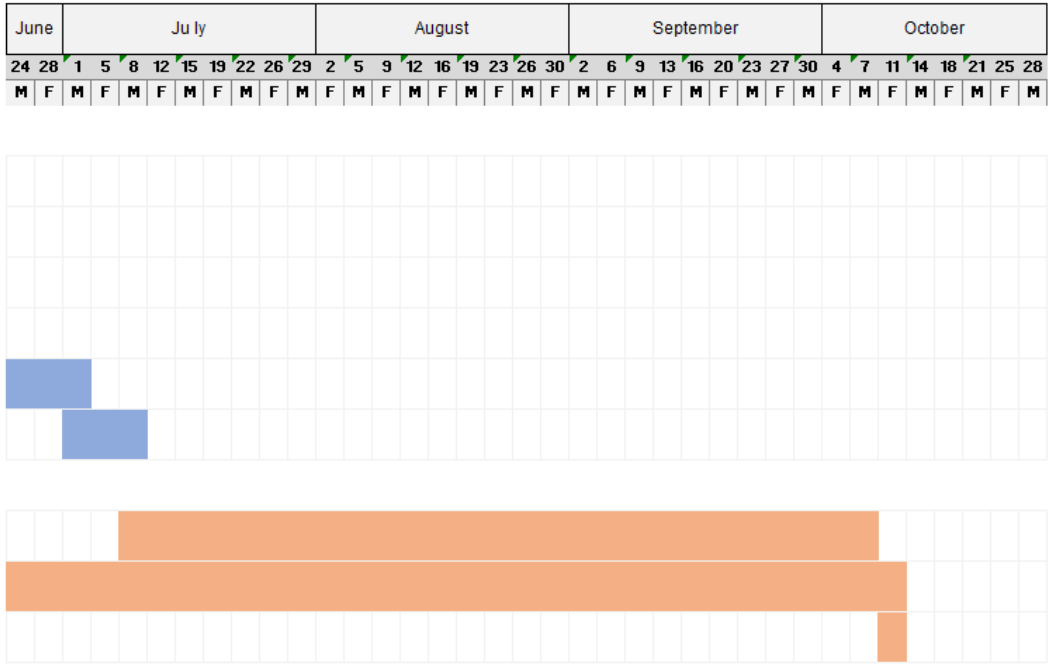
Portfolio 2 – Least Cost with CCSD project:

- Extension of CT PPA, 161 MW
- One ESA bid totaling 150 MW of 4 hr BESS
- Three hybrid bids totaling 240 MW of Solar and 125 MW 4 hr BESS
- Provides firm capacity of about 400 MW
- 20 Year NPV Increase of $<$ 1% over Portfolio 1

MAIN TAKEAWAYS

- Portfolios 1 and 2:
  - Address capacity needs of system
  - Meet projected ETA carbon intensity and RPS requirements
  - Extend CT PPA for 11.5 years
  - Include Albuquerque Area 150 MW BESS
  - Utilize existing plant which requires no additional transmission construction cost benefitting customer costs
  - Result in no ELCC degradation in the near-term

- Portfolio 1 is least cost and includes exclusively capacity resources
  - Includes a second Albuquerque Area 150 MW BESS



- Portfolio 2 provides additional resources in the CCSD
  - Lowest cost CCSD portfolio utilizes utility owned solar hybrid project
  - Customer Benefits: Provides benefits to San Juan area community and contributes to CCSD tax base
  - Satisfies IRP Action Plan commitment to utilize existing resource locations where possible
  - Alleviates transmission congestion flowing out of system load center to Four Corners
  - No imputed debt costs to customers over ESA options

NEXT STEPS

- Complete Phase III analysis
  - LOLE validation remaining
  - Revised analysis results with best and final offer prices
- Review analysis results with IE
- Commence Contract Negotiations with counterparties
- 2028 Resource Filing with NMPRC - Targeting October 2024

REMAINING SCHEDULE

TASK	PROGRESS	START	END
RFP Bid Evaluation			
Phase 1 Screening	100%	3/1/24	3/14/24
Phase 2 Shortlist	95%	3/15/24	5/31/24
Phase 3 Modeling	75%	5/1/24	6/18/24
Stakeholder Meeting	0%	6/18/24	6/18/24
Management Approval	0%	6/18/24	7/1/24
Independent Evaluator Review	0%	7/2/24	7/10/24
Approvals, Contracts & Filing			
Contract Negotiations	0%	7/11/24	10/8/24
Regulatory Case Prep	0%	6/18/24	10/11/24
Regulatory Filing	0%	10/11/24	10/11/24

Re: Comments on New Mexico's Draft Regional Haze SIP

Dear Mr. Jones:

Thank you for this opportunity to submit comments on New Mexico's draft Regional Haze State Implementation Plan Revision for the Second Planning Period (2019-2028). I am writing on behalf of WildEarth Guardians, which protects and restores the wildlife, wild places, wild rivers, and health of the American West. WildEarth Guardians has more than 206,000 members and supporters across the United States, including in New Mexico. Our members and supporters cherish, visit, recreate, live, and make their livelihoods in and near America's national parks and wilderness areas. Visibility in these parks and wilderness areas is important to them. The pollutants that cause regional haze in New Mexico's Class I areas are additionally significant because they can affect community health, especially in parts of the state that are hard hit by the impacts of oil and gas extraction, such as the Greater Chaco region and the SE corner/Carlsbad region. Emissions reductions are necessary to improve visibility in New Mexico's national parks and wilderness areas; they will also improve air quality in frontline and fenceline communities that bear the brunt of New Mexico oil and gas extraction.

We support the National Park Service's requests for additional emissions controls in its July 26, 2024 comments. We particularly support its recommendations on cost effectiveness (pages 5 and 6), recommendations on selective catalytic reduction (pages 5-8), and requests that NMED further reduce NOx emissions by (1) addressing smaller engine size classes and (2) requiring lower NOx limits for various engine size classes/configurations (page 26).

Given NMED's staff statement in the webinar for this SIP that virtually none of the equipment analyzed for this SIP currently has emissions controls, it is important that controls be implemented as quickly as possible, noting again that controls not only improve visibility, but also remove pollutants that can affect community health.

We note that the Appendix F of the draft Regional Haze SIP, which contained comments from the U.S. Forest Service and the National Park Service, did not include comments from the U.S. Fish and Wildlife Service, so the public was unable to review them during the informal comment period. Apparently USFWS did provide comments, because one comment was included on NMED's Regional Haze webpage. USFWS's comments should be posted online with the draft SIP before the hearing, so that the public can review.

Thank you again for this opportunity to provide comment and please notify us of the upcoming public hearing.

Sincerely yours,

Kelly Fuller

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hi Mark,

Would it be possible to get a copy of the U.S. Fish and Wildlife Service's comments on New Mexico's draft Regional Haze SIP? They were not included in Appendix F that is posted on NMED's regional haze website. But USFWS does appear to have commented because a quote from them is posted on the NMED Regional Haze website in the section titled "Copies of the draft plan and rule are available for download at the following links:"

Thanks,

Comments of Enterprise Field Services, LLC on NMED's Draft Regional Haze State Implementation Plan Revision and 20.2.68 NMAC - Regional Haze Requirements

Dear Mr. Jones:

Enterprise Field Services, LLC ("Enterprise") submits herein to the New Mexico Environment Department ("NMED") comments on NMED's draft State of New Mexico Regional Haze State Implementation Plan Revision Second Planning Period (2019-2028) ("Draft SIP") and 20.2.68 NMAC – Regional Haze Requirements ("Companion Rule").

I. Introduction

On August 26, 2024, the NMED announced the release of a Draft SIP to address the Clean Air Act's ("CAA") regional haze requirements for the second planning period of the program (2018-2028). NMED established a comment deadline of September 20, 2024 for these proceedings.[1]

Enterprise is the owner and operator of three facilities that would be subject to the Draft SIP:

- South Carlsbad Compressor Station located in Eddy County, New Mexico (South Carlsbad) – located approximately 26 miles from the nearest Class I Area

[1] *See* NMED, Regional Haze Planning, https://www.env.nm.gov/air-quality/reg-haze/.

- Blanco C & D Compressor Station located in San Juan County, New Mexico (Blanco) – located approximately 39 miles from the nearest Class I Area

- Chaco Gas Plant located in San Juan County, New Mexico (Chaco) – located approximately 49 miles from the nearest Class I Area[2]

Throughout the development of the Draft SIP, Enterprise has engaged with NMED, providing information to support the state's four-factor analyses, responding to information requests, and proposing reasonable regulatory approaches. The Draft SIP, however, takes a very different approach than NMED appeared to be considering during these discussions. Despite indications that NMED agreed with Enterprise that selective catalytic reduction ("SCR") for the control of oxides of nitrogen ("NOx") was not feasible at the Enterprise facilities, the Draft SIP would impose emission limits for eight (8) of the thirteen (13) Enterprise units evaluated that are based on installation and operation of SCR.

NMED has not appropriately evaluated "reasonable progress," as defined by the CAA, for the Enterprise facilities addressed in the Draft SIP. As described in these comments, the Draft SIP is based on an incorrect determination of SCR's technical feasibility and faulty and unrealistic cost assumptions. Further, the SIP would impose control requirements to satisfy the CAA's reasonable progress standard without considering visibility improvement in any meaningful way. Failure to consider visibility and to take all of the statutory factors into account when devising the control requirements for the Enterprise facilities is arbitrary and capricious and contrary to the requirements of the CAA. For all of these reasons, Enterprise requests that NMED withdraw the Draft SIP, reconsider its analysis consistent with these comments, and develop more reasonable and better-supported control requirements for the Enterprise facilities.[3]

II. Background on the Regional Haze Program

The CAA's visibility protection provisions establish as a national goal "the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas[4] which impairment results from manmade air pollution." CAA § 169A(a)(1). The Act directs the U.S. Environmental Protection Agency ("EPA") to issue regulations designed "to assure … reasonable progress toward meeting the national goal" and to require each state to submit a SIP containing "such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal." *Id*. § 169A(a)(4), (b)(2). Accordingly, pursuant to CAA section 169A, the ultimate requirement

[2] Collectively, the "Enterprise facilities."

[3] If NMED plans to proceed to seek approval of the Draft SIP, Enterprise requests, in the alternative, that NMED submit a partial SIP, excluding the Enterprise facilities, to allow Enterprise and NMED to work together to develop a separate SIP submittal that more appropriately addresses the Enterprise facilities.

[4] Class I federal areas are specified units of federal land receiving special protections, such as National Parks and Wilderness areas.

states must satisfy with their regional haze SIPs is to provide for "reasonable progress" towards the national visibility goal.

EPA implements the regional haze program in successive ten-year "planning periods." The first planning period ran from 2008 to 2018. The second planning period of the program covers the period from 2018 to 2028. SIPs to address second planning period control requirements were due to EPA by July 31, 2021. 40 C.F.R. § 51.308(f). As NMED notes in its announcement of the availability of the Draft SIP, EPA "is currently under a September 29, 2024 deadline to approve New Mexico's regional haze plan or promulgate a federal plan for New Mexico satisfying the visibility protection requirements of the Clean Air Act."[5] That deadline, negotiated with environmental groups, is already well past the July 31, 2021 regulatory deadline for second planning period regional haze SIPs. 40 C.F.R. § 51.308(f).

A regional haze SIP has a number of required elements. Most importantly for purposes of these comments, regional haze SIPs must include: (1) technical analyses to inform and support the SIP's control determinations, including calculation of visibility conditions, development of the "uniform rate of progress" ("URP") for each of the state's Class I areas, and interstate and Federal Land Manager ("FLM") consultation demonstrations; (2) a Long-Term Strategy ("LTS"), which includes measures necessary to make reasonable progress toward the national visibility goal; and (3) reasonable progress goals ("RPGs"), which are visibility goals for each mandatory Class I federal area located in the state and which are based on the control measures included in the LTS.

The CAA and EPA's regional haze rule ("RHR") require states to evaluate potential control requirements for sources within their jurisdiction using the four reasonable progress factors: "[1] the costs of compliance, [2] the time necessary for compliance, [3] the energy and non-air quality environmental impacts of compliance, and [4] the remaining useful life of any potentially affected sources." *Id*. § 51.308(f)(2)(i). If a four-factor analysis supports the establishment of new control requirements, those requirements may be appropriate for inclusion in the state's regional haze SIP. Under certain conditions, a state may be required to include existing control measures in their regional haze SIPs to ensure that the state continues to make reasonable progress.

EPA guidance establishes that states may consider visibility alongside the four statutory factors when evaluating controls, stating "EPA has interpreted the CAA and RHR as allowing states to consider visibility alongside the four statutory factors when determining the emission reduction measures that are necessary to make reasonable progress."[6] In fact, EPA "anticipate[s] that the outcome of the decision-making process by a state regarding a control measure may most often depend on how the state assesses the balance between the cost of compliance and the

[5] https://www.env.nm.gov/air-quality/reg-haze/.

[6] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period at 12 (July 8, 2021) ("Clarifications Memo").

visibility benefits."[7] Moreover, as discussed above, the CAA requires states to make reasonable progress determinations that are tied by law to consideration of the national visibility goal.

In addition, under the RHR, states must determine and take into account URP, *i.e.*, the rate of progress that would be needed to attain natural visibility conditions by the year 2064, assuming consistent progress is maintained from the baseline to the program's aspirational endpoint. *Id*. § 51.308(f)(3)(ii)(A). Under the RHR, a state may establish an RPG that differs from the URP if the state demonstrates that the URP for the Class I area in question would not be reasonable. A state makes such a showing by conducting a reasonable progress analysis that considers the four reasonable progress factors and makes a "robust" demonstration. *Id*.[8] The RHR also allows states to adjust the URP to account for the effects of international emissions and emission from prescribed fires on wildlands. 40 C.F.R. § 51.308(f)(1)(vi)(B).

States whose emissions may cause visibility impairment in another state's Class I area and states with Class I areas that may experience visibility impairment caused by emissions from other states may be subject to an interstate-consultation requirement. *Id*. § 51.308(f)(2)(ii). The purpose of that requirement is to provide a forum for states to decide collaboratively on reasonable emission reductions and appropriate apportionment of responsibility for reducing emissions during each planning period of the regional haze program. In addition, all states are subject to a requirement to consult with the FLMs in the development of their SIPs. *Id*. § 51.308(i).

III. The New Mexico Environment Department Has Not Adequately Engaged with the Regulated Community.

During the development of the Draft SIP, Enterprise undertook extensive work to assist in the preparation of four-factor analyses for the Enterprise facilities. Enterprise further submitted written materials explaining potential legal and policy justifications to support the state's reasonable progress determinations. To further those efforts, Enterprise met multiple times with NMED staff. Enterprise worked with the state to understand its process, the emission controls under consideration, and the information NMED needed to make informed reasonable progress determinations. As noted in Appendix C, this engagement included:

- The FFA completed by Trinity Consultants for Enterprise Field Services, LLC (Enterprise) and submitted to NMED on 10/30/19 and 11/14/19, respectively.
- Additional information provided by Enterprise on 2/14/20, 2/26/20, 5/19/20, 6/2/20, 9/8/20, 10/1/20, 3/4/21, and 8/30/23.
- Detailed discussions between Enterprise and NMED on 8/28/20 and 7/13/23.

[7] EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period at 37 (Aug. 20, 2019) ("2019 Guidance").

[8] The statutory basis for EPA's "robust" demonstration requirement is, at best, unclear.

• Written comments submitted to NMED regarding Draft Final Cost Evaluations on 1/15/24.[9]

In addition to the engagement described above, Enterprise, in a February 19, 2020 presentation given to NMED, explained using aerial photographs that there was insufficient space available for SCRs at each of the Enterprise facilities.[10] At no time during the many interactions since that presentation did NMED indicate that it was evaluating SCR for the Enterprise facilities or that it had reason to reject Enterprise's assertions as to the problems posed by space constraints. On the contrary, in an email dated December 20, 2023, NMED provided Enterprise with " draft final cost evaluations" for the Enterprise facilities to facilitate Enterprise providing comments on those cost evaluations.[11] Two spreadsheets containing the state's cost analysis were attached to this email and indicated that NMED had concluded that, due to space constraints, other site-specific factors, and costs for other similar facilities in New Mexico, "SCR is cost prohibitive" for the Enterprise facilities.[12]

Despite all of this early engagement, NMED has now released its Draft SIP with vastly different conclusions as to the feasibility of SCR and would impose especially stringent emission rate limits on the Enterprise facilities as a result. Had NMED shared with Enterprise that it was considering a significant change in course, Enterprise would have worked to provide the state with additional information to further assist in its assessment of SCR. Unfortunately, Enterprise did not have that opportunity. Similarly, NMED has now provided only a 25-day period for comment on the Draft SIP. Although Enterprise understands that the regulatory process in New Mexico will provide additional opportunities to participate, by failing to transparently engage with Enterprise during development of the Draft SIP, NMED has substantially limited Enterprise's ability to develop and provide much-needed information to correct the record in these proceedings.

In the limited time available, Enterprise has developed the analysis presented here, which further demonstrates the significant costs of SCR for the Enterprise facilities. Because NMED is using SCR as the basis of the NOx limits, as expressed in the Companion Rule, and due to the limited time available to evaluate SCR, Enterprise has not been able to quantify the full scope of facility modifications, with their attendant cost, complexity, and uncertainty, that would be needed to attempt to achieve the proposed NOx limits. This would have required a full constructability evaluation as well as an analysis of infrastructure reconfiguration and potential electrical upgrade requirements. Enterprise appreciates that NMED has committed to considering any additional information that may be developed subsequent to the close of the current

[9] Draft SIP, App. C at 65. For ease of reference, Citations to NMED Appendices refer to the PDF pagination rather than the pagination of the individual reports contained therein.

[12] *Id*. at attachments, SCR Tab.

comment period and to reasonably accommodate the need for additional time that may be needed to complete complex analyses and to obtain information from third parties.

The information that is available makes clear that SCR is not necessary to make reasonable progress when considered in light of the four factors and the limited visibility improvement that could be achieved through installing these controls. Accordingly, just as Enterprise has worked diligently in very short time to provide NMED with information that necessitates revising the Draft SIP's requirements for the Enterprise facilities, NMED must revise the Draft SIP before submitting it for review by the state's Environmental Improvement Board ("EIB"). Indeed, proceeding to seek approval of the Draft SIP after consideration of the information provided in these comments would be unreasonable and unsupported by the record. Accordingly, NMED should withdraw the Draft SIP or substantially revise it based on these comments before proceeding with EIB review.[13]

IV. New Mexico Has Unreasonably Refused to Consider Visibility in Violation of the CAA.

As explained above, section 169A of the CAA imposes one overarching requirement on states: they must include in their SIPs "such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal." 42 U.S.C. § 7491(b)(2). The national goal that states must ensure "reasonable progress" towards is a visibility goal: "the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution." *Id*. § 7491(a)(1). While states must consider the four reasonable progress factors when assessing the level of progress that is reasonable, plainly, states cannot make a determination as to the measures needed to ensure reasonable progress without considering the overall goal of the program.[14] Thus, as should be clear, a regional haze SIP must be based on consideration of visibility to satisfy the CAA.

In describing how it selected control requirements for sources subject to the SIP, NMED says:

> NMED did not directly consider the visibility benefits of potential control measures when making its control determinations. EPA has

[13] If, in spite of these comments, NMED intends to proceed with finalizing the Draft SIP without appropriate revisions, Enterprise requests that NMED provide Enterprise with the opportunity to respond to any of the Department's remaining questions and to provide any necessary additional information. As noted above in footnote 3, addressing the Enterprise facilities in a separate SIP submittal could provide NMED with additional time to respond to these comments (as well as any additional information that is developed) while still proceeding with approval of the remainder of the Draft SIP.

[14] In its Clarifications Memo, EPA appears to assert that states may only consider visibility in certain ways or for certain purposes. Clarifications memo at 13. For instance, EPA says visibility should not be used to "summarily dismiss" cost-effective controls, but that it could be used to select among different cost-effective controls. *Id*. EPA has presented no principled basis for limiting consideration of visibility. Moreover, as described above, the CAA must be interpreted to require consideration of visibility in support of measures needed to make reasonable progress under the regional haze provisions of the Act.

> consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making control determinations. NMED's approach is based on the assumption that substantial reductions in emissions of NOx and SO_2 will translate into visibility benefits.

Draft SIP at 104-05. According to NMED, therefore, the state did not consider visibility other than to assume that emission reductions would translate to visibility benefits, essentially failing to consider visibility at all. This is an unreasonable approach to developing a regional haze SIP, and it is inconsistent with the requirement that states develop SIPs that ensure reasonable progress toward the national visibility goal. In short, failure to consider visibility is a failure to consider a factor Congress intended states to take into account when developing regional haze SIPs. NMED has therefore failed to consider "an important aspect of the problem," which renders the Draft SIP arbitrary and capricious under the law. *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43, (1983) ("Normally, an agency rule would be arbitrary and capricious if the agency has relied on factors which Congress has not intended it to consider, entirely failed to consider an important aspect of the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise.")

In addition, New Mexico law requires that the EIB consider visibility when taking action. NM Stat § 74-2-5(f) (2023). The EIB is tasked with weighing visibility improvements against "the public interest, including the social and economic value of the sources and subjects of air contaminants;" as well as "technical practicability and economic reasonableness of reducing or eliminating air contaminants from the sources involved and previous experience with equipment and methods available to control the air contaminants involved." *Id*. The EIB cannot fulfill its statutory obligations without an assessment of visibility by NMED. On the contrary, in the absence of a visibility assessment in support of the Draft SIP, the EIB will have no choice but to disapprove it for failure to comport with the CAA minimal requirements.[15]

NMED must correct this shortcoming in the Draft SIP before proceeding to seek approval from the EIB. A proper consideration of visibility, moreover, as described in the next section, demonstrates that existing controls at the Enterprise facilities are sufficient to address the CAA's reasonable progress requirement for the second planning period and that SCR cannot be justified.

V. Any Reasonable Assessment of Visibility Demonstrates that Additional Controls, Including SCR, Cannot Be Justified for the Enterprise Facilities.

All evidence in the record supports a finding that visibility conditions in Class I areas potentially affected by the Enterprise facilities are already achieving reasonable progress. The evidence in the record further establishes that any new emission control requirements for the

[15] While the technical information included in the Draft SIP on visibility conditions is useful information, without analysis of visibility impacts and an assessment of how such impacts should figure into control determinations by NMED in the first instance, the EIB will not have an adequate basis on which to evaluate the Draft SIP.

Enterprise facilities will result in, at most, imperceptible visibility impacts. In short, considered by every metric, the visibility effects that would result from the requirements of the Draft SIP cannot support the imposition of costly new control requirements. As such, the Draft SIP should be revised to recognize that existing controls at the Enterprise facilities are sufficient to ensure reasonable progress.

The progress achieved to date and projected for the future without requiring additional controls, including SCR, at the Enterprise facilities should be deemed sufficient to address the reasonable progress requirement for the second planning period. The Draft SIP acknowledges, for instance, that all Class I areas affected by New Mexico sources "have shown visibility improvement over the monitoring period." Draft SIP at 42. This improvement, when compared to the URP, demonstrates that the areas affected by New Mexico sources are generally improving faster than the URP metric. The Draft SIP explains:

> NMED's glidepath checks show that eight of New Mexico's nine Class I Areas are projected to fall below the URP glidepath in 2028, which is indicative of a faster rate of improvement than the URP. Only Salt Creek Wilderness Area in Chaves County is projected to be above the glidepath, indicating a slower rate of improvement than the URP.

Draft SIP at xiii. Despite devoting a chapter of the Draft SIP to describing the results of its comparison of the URP to visibility conditions, NMED fails to draw any conclusions or present any analysis of how it took the performance of these Class I areas relative to the URP into account in evaluating requirements for the Draft SIP. Indeed, it does not appear that NMED actually took the URPO into account in any way. NMED must include such an analysis to satisfy the requirements of the RHR and to provide a well-supported SIP. Any reasonable assessment of the URP, moreover, supports the conclusion that additional controls for the Enterprise facilities, including SCR, are not needed for reasonable progress.[16]

In each of the four-factor assessments that Enterprise submitted to NMED to assist in the development of the Draft SIP, Enterprise's consultant included an assessment of likely visibility impacts that would result from controls at the Enterprise facilities. For Blanco, Enterprise reported:

> The Blanco C&D Compressor Station is located approximately 50 miles from the Mesa Verde Class I areas at a wind vector range of approximately 155 degrees to 165 degrees (SSE). According to 2015 meteorological data collected in Bloomfield, NM . . . wind blows from this direction range at a frequency of only 2.4%.

[16] As explained below, although Salt Creek Wilderness Area is not yet projected to be below the URP glidepath, a Q/d assessment for South Carlsbad using recent emissions data shows that its emissions would have minimal impacts on visibility that fall below NMED's screening threshold for bringing sources forward for four-factor analysis.

> Moreover, when the wind direction is within this range, the wind speed is typically relatively low; the frequency of wind speeds greater than 3.09 m/s (or ~7 mph) is only 0.3%, or about 25 hours per year. Higher wind speeds would be needed to effectively transport emissions from Blanco to the Mesa Verde Class I area. Moreover, over the 50 miles of transport, pollutants undergo significant dispersion. While full dispersion and photochemical modeling would be needed to more robustly evaluate Blanco's impact, based on this evidence, Blanco's impact on visibility is likely insignificant.

See Draft SIP, App. D. at 488.

Similarly, for Chaco, Enterprise reported:

> The Chaco Gas Plant is located approximately 50 miles from the Mesa Verde Class I area at a wind vector range of approximately 155 degrees to 165 degrees (SSE). According to 2015 meteorological data collected in Bloomfield, NM . . . wind blows from this direction range at a frequency of only 2.4%. Moreover, when the wind direction is within this range, the wind speed is typically relatively low; the frequency of wind speeds greater than 3.09 m/s (or ~7 mph) is only 0.3%, or about 25 hours per year. Higher wind speeds would be needed to effectively transport emissions from Chaco to the Mesa Verde Class I area. Moreover, over the 50 miles of transport, pollutants undergo significant dispersion. While full dispersion and photochemical modeling would be needed to more robustly evaluate Chaco's impact, based on this evidence, Blanco's impact on visibility is likely insignificant.

Id. at 581.

For South Carlsbad, Enterprise reported:

> The South Carlsbad Compressor Station is located approximately 16.2 miles [sic][17] from the Carlsbad Caverns Class I area at a wind vector range of approximately 60 degrees to 70 degrees (NE). According to 2017 meteorological data collected in Carlsbad. . . wind only blows from this direction at a frequency of 1.4% or approximately 120 hours per year. Moreover, over the 16 miles of transport, pollutants would undergo significant dispersion. While

[17] The distance is 25.88 km (16.1 miles) according to SIP table 6-1. Draft SIP at 96.

> full dispersion and photochemical modeling would need to be conducted to more accurately evaluate South Carlsbad's impact, based on this evidence, the facility's impact on visibility is likely insignificant.

Id. at 644.

As explained above, NMED has not conducted any additional visibility assessment or reached any conclusions about the impact of the Enterprise facilities on visibility in Class I areas. Accordingly, the only information in the record supports the conclusion that the impacts from the controls under evaluation are not likely to be meaningful. NMED cannot nevertheless impose emission control requirements without even considering this crucial information, much less carefully weighing it.

Since preparation of the NMED and Enterprise four-factor assessments, additional data has become available to demonstrate that visibility impacts from Chaco and South Carlsbad—and any benefit that would result from further controlling their emissions—have grown even smaller. As shown in the table below, since 2016, emissions from Chaco and South Carlsbad have generally fallen, with resulting Q/d values falling appreciably as well. Most significantly, the Q/d values for South Carlsbad for four of the last five years have been below the state's adopted Q/d threshold of 5.6. This is adequate grounds in itself to remove control requirements for South Carlsbad from further consideration.

	Blanco		Chaco		South Carlsbad	
Year	Q	Q/d	Q	Q/d	Q	Q/d
2014	513.2	8.1	2250.0	28.0	149.5	5.8
2015	528.3	8.3	2175.6	27.1	160.3	6.2
2016	494.8	7.8	2270.7	28.3	153.0	5.9
2017	515.0	8.1	1943.9	24.2	156.5	6.0
2018	512.6	8.1	1976.2	24.6	160.0	6.2
2019	573.7	9.1	1829.2	22.8	133.8	5.2
2020	883.1	13.9	1861.0	23.2	135.6	5.2
2021	591.5	9.3	1826.9	22.8	140.2	5.4
2022	456.9	7.2	777.1	9.7	121.6	4.7
2023	658.7	10.4	707.6	8.8	156.7	6.1

Q = Sum of reported annual NOx and SO2 emissions (tons)

d = distance from Class I area (km) per Table 6-1 of draft SIP

Blanco =	63.4	km
Chaco =	80.2	km
S. Carlsbad =	25.9	km

Finally, the lack of a visibility assessment obscures the truly de minimis nature of the visibility impacts from the Enterprise facilities further demonstrating why refusing to consider visibility is unreasonable and inconsistent with the CAA. When EPA promulgated a Federal Implementation Plan ("FIP") to address regional haze for New Mexico during implementation of the first planning period of the program, EPA conducted a full visibility assessment to evaluate whether SCR could be justified. *See* 76 Fed. Reg. 491 (Jan. 5, 2011) (Proposed FIP for New Mexico). In determining that SCR could be justified for the San Juan Generating Station, EPA determined that the installation and operation of SCR would result in a visibility improvement of 21.69 deciviews across 16 different Class I areas. *Id*. at 503. Improvements within individual Class I areas ranged from 0.31 deciviews to 3.11 deciviews. *Id*. To put this context, EPA says that a 0.5 deciview impact "contributes" to visibility impairment, a 1.0 deciview impact "causes" visibility impairment, and a 1.0 deciview impact is generally the threshold for human perception of a change in visibility conditions. To further put this into perspective, to achieve this level of visibility improvement, EPA projected that the FIP would eliminate 17,518 tons per year of NOx. *Id*. at 502, Table 7.

By contrast, the Draft SIP's tons per year NOx reductions estimated for Blanco are 974.4 tons. Draft SIP at 115. For Chaco, they are 363.6 tons. *Id*. at 116. For South Carlsbad, they are 138.7. *Id*. at 118. The visibility benefits that might result from these reductions would be a mere fraction of those previously deemed sufficient to justify requiring SCR. Accordingly, the minimal visibility impacts that may result from emissions from the Enterprise facilities cannot reasonably serve as the basis for imposing the enormously costly, if not infeasible, emission controls contemplated in the Draft SIP.

A full and reasonable evaluation of visibility, as required by the CAA and New Mexico law, demonstrates that the Draft SIP's control determinations for the Enterprise facilities are unsound and must be revised. The only information in the record supports the conclusion that the visibility impacts of the Enterprise facilities, and the visibility improvements that could be achieved with additional controls, do not support requiring additional costly requirements to address reasonable progress at this time. NMED is obligated to consider this information and to revise the requirements of the Draft SIP to better align the Draft SIP's requirements with the requirements of the CAA.

VI. New Mexico Has Failed to Justify Its Decision to Pursue Reductions in Nitrogen Oxides.

The Draft SIP explains that visibility impairment is overwhelmingly dominated by "ammonium sulfate, organic mass, and coarse mass on both the Most Impaired Days and the Clearest Days." Draft SIP at 53.[18] EPA guidance makes clear that it is appropriate for states to evaluate controls for the most significant visibility-impairing pollutants:

[18] The only exceptions are Salt Creek Wilderness and San Pedro Parks Wilderness, "when ammonium nitrate was one of the top three contributors instead of either organic mass or coarse mass." Draft SIP at 53. None of the Enterprise facilities is located near these areas or could reasonably be expected to influence their visibility conditions. Blanco is 471.14 kilometers ("km") from Salt Creek and 89.47 km from San Pedro. Chaco is 461.68 km

> When selecting sources for analysis of control measures, a state may focus on the PM species that dominate visibility impairment at the Class I areas affected by emissions from the state and then select only sources with emissions of those dominant pollutants and their precursors. Also, it may be reasonable for a state to not consider measures for control of the remaining pollutants from sources that have been selected on the basis of their emissions of the dominant pollutants.

2019 Guidance at 11. Had NMED followed this guidance and focused on the greatest pollutants of concern, the Enterprise facilities would not have even been considered for additional controls. This is itself an adequate basis for removing the Enterprise facilities from further consideration for reasonable progress controls.

EPA's guidance goes on to provide one pertinent example:

> For example, organic mass by carbon (OMC) light extinction might be dominant in the IMPROVE data for a western Class I area on the average of the 20 percent most anthropogenically impaired days, even though days heavily affected by fires will tend not to be included in the 20 percent most anthropogenically impaired days. This may cause sulfate to account for only a small percentage of total light extinction. However, it could be clear that most of the OMC is natural and that sulfate dominates anthropogenic light extinction. In this situation, we recommend that a state consider SO_2 sources and SO_2 control measures.

This is the situation facing New Mexico. Yet instead of focusing on SO_2 controls, as the data suggests would be appropriate and a*s EPA guidance calls for*, the state has unreasonably focused on the negligible impacts that might result from NOx emissions, including the relatively small NOx emissions from the Enterprise facilities.

New Mexico rationale for pursuing NOx reductions is that "[t]he largest haze reductions over time (i.e., the largest reduction in individual species' contributions to light extinction) are generally associated with ammonium sulfate and ammonium nitrate, which have likely occurred due to reduced SO_2 and NOx emissions since EPA first promulgated the Regional Haze Rule in 1999." Draft SIP at 53. Although significant reductions in NOx in the past may have been associated with commensurate reductions in haze, there is no basis for concluding that eliminating minor amounts of NOx will have a significant effect on visibility at this time.

---

from Salt Creek and 99.97 km from San Pedro. South Carlsbad is 141 km from Salt Creek and 477.04 km from San Pedro.

Indeed, as described above, EPA's FIP for New Mexico for the first regional haze planning period would have eliminated 17,518 tons per year of NOx. *Id*. at 502, Table 7 and improved visibility by an appreciable 21.69 deciviews across 16 different Class I areas. 76 Fed. Reg. at 502-03. EPA withdrew that FIP and approved a subsequently submitted regional haze SIP for New Mexico that achieved *even greater* emission reductions and visibility improvements than the FIP. See Approval and Promulgation of Implementation Plans; New Mexico; Regional Haze and Interstate Transport Affecting Visibility State Implementation Plan Revisions, 79 Fed. Red. 60,985 (Oct. 9, 2014). The Draft SIP achieves nothing approaching this level of visibility improvement from its proposed NOx controls.

For all of these reasons, NMED has "offered an explanation for its decision [to focus on NOx] that runs counter to the evidence before the agency." *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43, (1983). New Mexico, consistent with EPA guidance, should elect to focus the current regional haze SIP on the visibility impairing pollutants of most significance. It should not continue to pursue NOx controls for this planning period. For that reason, NMED should revise the Draft SIP to acknowledge that existing controls at the Enterprise facilities are adequate to ensure reasonable progress.

VII. NMED Has Adopted an Unreasonable Q/d Screening Threshold.

The Draft SIP explains that NMED performed Q/d assessment to identify sources with emissions significant enough to warrant further evaluation pursuant to the four factors. Draft SIP at 93. NMED adopted a Q/d screening threshold of 5.6. *Id*.

This screening threshold is significantly out of step with the thresholds used by other states, including those that have previously been approved as reasonable for use in the regional haze program by EPA. Indeed, every state to adopt such a screening threshold appears to have adopted one substantially higher than New Mexico:

- Air Plan Partial Approval and Partial Disapproval; Wyoming; Regional Haze Plan for the Second Implementation Period, 89 Fed. Reg. 63,030, 63,042 (August 1, 2024) (screening threshold of Q/d > 10).

- Air Plan Partial Approval and Partial Disapproval; Utah; Regional Haze State Implementation Plan for the Second Implementation Period; Air Plan Disapproval; Utah; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 89 Fed. Reg. 67,208, 67,220 (August 19, 2024) (screening threshold of Q/d ≥ 6).

- Air Plan Approval; Wisconsin; Second Period Regional Haze Plan, 89 Fed. Reg. 65,492, 65,503 (August 9, 2024) (screening threshold of 10).

- Approval and Promulgation of Air Quality Implementation Plans; State of Florida; Regional Haze State Implementation Plan, 77 Fed. Reg. 31,240, 31,253

(May 25, 2012) (screening threshold of 50).

- Partial Approval and Disapproval of Air Quality Implementation Plans; Arizona; Regional Haze State Implementation Plan for the Second Implementation Period and Prong 4 (Visibility) for the 2015 Ozone and 2012 Particulate Matter Standards, 89 Fed. Reg. 47,398, 47,412 (May 31, 2024) (screening threshold of 10).

- Promulgation of Air Quality Implementation Plans; State of Texas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan: Proposal of Best Available Retrofit Technology (BART) and Interstate Transport Provisions, 83 Fed. Reg. 43,586, 43,596 (Aug. 27, 2018) (screening threshold of 10).

- Approval and Promulgation of Air Quality Implementation Plans; Montana; Regional Haze Federal Implementation Plan, 82 Fed. Reg. 17,948, 17,955 (Apr. 14, 2017) (screening threshold of 10).

- Approval and Promulgation of Implementation Plans; South Dakota; Regional Haze State Implementation Plan, 76 Fed. Reg. 76,646, 76,661 (Dec. 8, 2011) (screening threshold of 10).

- Approval and Promulgation of Implementation Plans; State of Colorado; Regional Haze State Implementation Plan, 77 Fed. Reg. 18,052, 18,078 (Mar. 26, 2012) (screening threshold of 20).

The vast majority of similarly situated states have adopted screening threshold of 10 or higher. Such a threshold is consistent with EPA's BART Guidelines,[19] which provide:

> Based on our analyses, we believe that a state that has established 0.5 dv as a contribution threshold could reasonably exempt from the BART review process sources that emit less than 500 tons per year of NO—T2X or SO—T22 (or combined NO—T2X and SO—T22), as long as these sources are located more than 50 kilometers from any Class I area; and sources that emit less than 1000 tons per year of NO—T2X or SO—T22 (or combined NO—T2X and SO—T22) that are located more than 100 kilometers from any Class I area."

40 C.F.R. 51, appendix Y, section III, How to Identify Sources "Subject to BART." According to the BART Guidelines, therefore, a facility with minimal impacts such as these can reasonably be excluded from the regional haze program. As EPA explained in another final regional haze rule,

[19] Although the BART Guidelines are not binding in setting reasonable progress requirements, the BART Guidelines nonetheless provide useful precedent.

"[t]he values described [in the BART Guidelines] equate to a Q/D of 10." 82 Fed. Reg. at 17,955 n.53.

Had New Mexico adopted such a threshold, based on review of the most recent Q/d calculations, presented above, at least two of the three the Enterprise facilities (Chaco and South Carlsbad) should have screened out of further evaluation. For this reason alone, NMED should revise the Draft SIP to impose no additional control requirements for Chaco and South Carlsbad on this basis.

NMED has not offered a valid rationale for adopting such a low screening threshold. The explanation contained in the Draft SIP is that the threshold was intended:

> to capture 80% of the total NOx and SO_2 emissions from all New Mexico Title V facilities combined. NMED and EHD chose this 80% threshold based on guidance in the WRAP Source Selection Protocol. The Protocol noted draft guidance from EPA recommending an 80% threshold applied to emissions from all stationary sources.

Draft SIP at 92 (citation omitted). The draft guidance recommending an 80% threshold was never adopted by EPA. EPA instead issued the 2019 Guidance, which did not adopt the 80% threshold. Accordingly, NMED has adopted an extreme outlier screening threshold on the basis of guidance that was never adopted as formal EPA policy.

NMED should withdraw the Draft SIP and apply a more reasonable screening threshold, consistent with the actions of its sister states. It should further revise the Draft SIP to recognize that the visibility impacts of the Enterprise facilities are too small to justify imposing additional controls and are indeed, small enough to reasonably be screened out from a four-factor assessment.

VIII. NMED Has Failed to Adequately Consider Each of the Four Factors.

Under the CAA, states must consider four factors to determine reasonable progress: "the costs of compliance, the time necessary for compliance, and the energy and nonair quality environmental impacts of compliance, and the remaining useful life of any existing source subject to such requirements." 42 U.S.C. § 7491(g)(1). Rather than fully consider each of the four factors, NMED has focused almost exclusively on cost, contrary to the CAA. The Draft SIP explains, "[c]ost effectiveness was the predominant factor in NMED's decision-making regarding necessary control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations." Draft SIP at 104.

Although states have considerable discretion as to how they weigh the four statutory reasonable progress factors, states must, at a minimum, give reasonable consideration to each one. *See Nat'l Parks Conservation Ass'n v. McCarthy*, 816 F.3d 989, 992 (8th Cir. 2016) (states "must consider four factors").

NMED has not considered the disbenefits of SCR. Specifically, in evaluating SCR or any other control, the state must take into account "the energy and nonair quality environmental impacts of compliance" to satisfy the CAA's requirements. Operation of SCR will have at least four such impacts.

First, a disbenefit of SCR is ammonia ("NH_3") emissions. Based on approximate exhaust rates for the 8 Enterprise turbines for which NMED has proposed to require SCR, and an estimated 10 ppmv NH_3 slip, aggregate annual NH_3 emissions would be approximately 196 tons assuming no restriction in operating hours.

NH_3 Emissions (Annual)

Facility	Estimated NH_3 Emissions
Blanco	86.6 tons
Chaco	87.6 tons
S. Carlsbad	21.8 tons

Emissions of ammonia have a range of environmental impacts. *See generally* U.S. EPA. Integrated Science Assessment (ISA) for Oxides of Nitrogen, Oxides of Sulfur and Particulate Matter Ecological Criteria (Final Report, 2020). NMED has not considered this disbenefit.

Second, the SCR system will involve the use of hazardous materials. SCR can use either aqueous or anhydrous ammonia for the reduction reaction. Anhydrous ammonia is classified as a hazardous material and often requires special permits as well as additional procedures for transportation, handling and storage. Aqueous ammonia, on the other hand, requires more storage capacity than anhydrous ammonia. Both pose environmental and safety risks. Again, NMED has not considered this.

Third, operation of SCR requires power. Due to the limited amount of time to evaluate SCR as a control option for the Enterprise facilities, a feasibility and constructability evaluation has not been completed at the time of submittal. It is therefore unknown if existing electrical power is sufficient or if upgrading or adding electrical infrastructure would be required. NMED has not considered these energy impacts either.

Fourth, operation of SCR could impact engine performance by creating additional working load on the engine. A detailed engineering study could not be performed in the limited time available for public comment. It is therefore not known issue will impact the ability of the Enterprise facilities to meet commercial throughput requirements. This is also an energy impact that NMED is obligated to consider.

Before NMED can lawfully propose its reasonable progress and related emission control determinations, it must present an assessment of each of the four factors evaluating the use of the controls under consideration. NMED has not done that in support of its proposed SCR requirements for the Enterprise facilities. A proper and complete evaluation of "the energy and nonair quality environmental impacts of compliance" would, moreover, provide further support

for the conclusion that SCR is not needed to achieve reasonable progress and that the existing controls at the Enterprise facilities ensure that reasonable progress will be achieved during the second planning period of the regional haze program.

IX. NMED Has Unreasonably Concluded SCR Is Technically Feasible.

According to EPA's 2019 Guidance, "[t]he first step in characterizing control measures for a source is the identification of technically feasible control measures for those pollutants that contribute to visibility impairment." 2019 Guidance at 28. EPA's regulatory BART Guidelines for the regional haze program provides further information on the methodology for assessing control to address visibility. In the BART Guidelines, EPA explained:

> You should clearly document a demonstration of technical infeasibility and should show, based on physical, chemical, and engineering principles, that technical difficulties would preclude the successful use of the control option on the emissions unit under review. You may then eliminate such technically infeasible control options from further consideration….
>
> Alternatively, a demonstration of technical infeasibility may involve a showing that there are unresolvable technical difficulties with applying the control to the source (e.g., size of the unit, location of the proposed site, or operating problems related to specific circumstances of the source).

Proposed Guidelines for Best Available Retrofit Technology (BART) Determinations Under the Regional Haze Regulations, 66 FR 38108, 38,123-24 (July 20, 2001).

During development of the Draft SIP, Enterprise demonstrated to NMED that SCR was not a technically feasible control for the Enterprise facilities. Enterprise communicated to NMED that it had eliminated consideration of SCR as a feasible technology due to the current configuration and available space.[20] Enterprise provided vendor-supplied SCR dimensions as CBI to NMED in support of that assessment.[21] Maps were also provided in this response that overlayed the area required for SCR showing existing facility infrastructure.

NMED has not explained its reason for changing course with respect to the technical feasibility of SCR for the Enterprise facilities. All that NMED says in this regard is the following:

[20] *See* Draft SIP, App. D at 481-82, 494-502, 574, 589-598, 639, 651-661 (Various Enterprise four-factor analysis submittals).

[21] *Id*. (providing CBI materials to NMED).

> Enterprise asserted that limited physical space precludes the option of installing SCR and provided an aerial image with measurement overlays to support this assertion. However, the image provided suggests there is physical space for SCR if building modifications are made.

Draft SIP, App. C at 80. This minimal level of assessment is not sufficient to serve as a basis for finding that SCR is technically feasible. NMED must revise the Draft SIP to reflect this reality.

X. New Mexico's Cost Evaluation for the Enterprise Facilities Is Substantially Flawed.

To support its proposed control requirements for the Enterprise facilities, NMED focused predominately on costs. Draft SIP at 102 ("To characterize the cost of compliance, which was the predominant factor in NMED's decision-making regarding control measures…."). NMED considered a single cost metric: "cost effectiveness of each control, expressed in terms of cost per ton of emissions reduced." *Id*.

The regional haze program is intended to evaluate real-world, site-specific costs. NMED says that it made use of such information in a limited fashion:

> NMED utilized source-specific cost estimates provided by the facilities in its calculations whenever possible. In cases where facilities failed to provide source-specific cost estimates or NMED found estimates provided by facilities to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including -four-factor analyses developed for similar facilities in New Mexico and other states, to estimate costs.

Id. There are substantial flaws in NMED's consideration of costs that necessitate reevaluation of and modifications to the Draft SIP's proposed control requirements for the Enterprise facilities.

A. NMED Has Not Considered Relevant Cost Metrics.

NMED has only considered cost-effectiveness on a simple dollar-per-ton basis. Such limited consideration does not fully evaluate costs and has resulted in Draft SIP requirements that go beyond what is needed to make reasonable progress. In the body of the Draft SIP, for instance, NMED presents only $/ton cost-effectiveness values for SCR. Draft SIP at 114-118. Appendix C, which contains additional narrative explaining NMED's four-factor analysis confirms that the $/ton metric was the only manner in which NMED considered costs. Draft SIP, App. C, at 68-91.

According to EPA's 2019 Guidance, a cost assessment in furtherance of a reasonable progress assessment "will typically produce estimated values of capital costs, annual operating and maintenance costs, annualized costs, and cost per ton of emission reductions, as well as

multiple values for daily visibility benefits." 2019 Guidance at 38. NMED has calculated annualized costs, but does not appear to have considered them. NMED has not considered a $-per-deciview or dollar-per-inverse megameter metric at all. These factors have been determinative in the regional haze proceedings of other states.

- Approval, Disapproval and Promulgation of Implementation Plans; State of Nebraska; Regional Haze State Implementation Plan; Federal Implementation Plan for Best Available Retrofit Technology Determination, 77 Fed. Reg. 40,150, 40,151, 40,156 (July 6, 2012) (EPA partially disapproving Nebraska's SIP after recalculating Nebraska's cost effectiveness analysis for BART using $/dv. Additionally, EPA defended its use of $/dv in response to a comment: "We believe that dollars per deciview is one of several metrics that can be used to analyze cost of visibility improvement, and reaffirm our position that the calculation is more meaningful if cumulative visibility benefits are accounted for.")

- Environmental Protection Agency: Rules and Regulations: Approval and Promulgation of Implementation Plans; State of Oregon; Regional Haze State Implementation Plan and Interstate Transport Plan, 76 Fed. Reg. 38997, 38999 (July 5, 2011) (EPA approving and promulgating Ohio's Regional Haze SIP for the first implementation period based on a dollars/dv threshold of $10 million per deciview; the EPA responded to a comment challenging the threshold by stating that the threshold was "consistent with EPA's review of dollars/dv cost effectiveness data…").

NMED's failure to consider cost metrics in addition to its dollar-per-ton calculations has left NMED with an incomplete picture of the costs of the controls it has proposed. New Mexico must further evaluate all potentially informative cost metrics to ensure that the state has met its obligation to weigh the four factors in determining reasonable progress. Failure to consider this information—which Congress intended the states to take into account—is arbitrary and capricious. *See Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43, (1983).

B. NMED's Cost-Estimates Are Unrealistic and Result in Unreasonable Control Determinations for the Enterprise Facilities.

NMED's assessment of the costs of SCR is incomplete, lacks site-specific information, and understates the costs associated with this control option. For each of the Enterprise facilities, the NMED spreadsheet presenting its SCR cost assessment indicates that NMED relied on default values from EPA's Control Cost Manual and its SCR cost calculation tool. Draft SIP, App. D at 455, 460 (Blanco), 536, 540 (Chaco), 622 (South Carlsbad).

Because Enterprise and NMED had previously concluded that SCR was not technically feasible at the Enterprise facilities due to space constraints, Enterprise did not seek vendor quotes or other information prior to release of the Draft SIP. Enterprise maintains that the site-specific

impediments to construction of SCR should be considered sufficiently onerous to render SCR technically infeasible at the Enterprise facility sites.

In the short time provided for public comment on the Draft SIP, Enterprise has not been able to develop the sort of detailed engineering studies that would be needed to fully assess the true costs of installing and operating SCR at the Enterprise facilities. Such information is needed for a true and accurate cost assessment. Accordingly, NMED should pause its efforts to seek approval of the Draft SIP and ensure that an adequate cost assessment, including site-specific information and vendor quotes, if available, is included in the record and comprises the basis for the SIP's requirements. Proceeding on the basis of NMED's more generic cost assessment when better data could have been obtained is arbitrary and capricious. *Conservation Cong. v. Finley*, 774 F.3d 611, 620 (9th Cir. 2014) ("Agencies 'must support their conclusions with accurate and reliable data'"). If Enterprise is able to obtain additional information further characterizing SCR costs, we will provide it to NMED as expeditiously as possible.

In the time provided, Enterprise has obtained two preliminary vendor quotes that demonstrate the values NMED has relied on are unrealistic. It is first important to emphasize that the quotes Enterprise has received significantly understate likely actual costs. Because of limited time, these quotes were developed without taking into account factors that will significantly impact costs:

1) No SCR feasibility or constructability walk-downs were performed to prepare these estimates.
2) Costs assume no relocations of existing infrastructure would be required; however, as explained further below, substantial relocation and additional construction will be required.
3) Costs are not based on detailed engineering studies.
4) The quotes assume sufficient electricity is available and do not include costs associated with upgrading or adding electrical infrastructure.

Even with these limitations, the vendor quotes indicate that NMED's cost estimates are too low.

Facility	Unit No.	Unit Type	NMED's Proposed NOx Control Measure	NMED's Total Capital Investment Estimate	NMED Cost Effectiveness	Enterprise Capital Investment Estimate	Enterprise Cost Effectiveness (Using NMED Methodology)
	35	Solar Mars T-15000	SCR (90% Reduction)	$5.3 MM	$9,000/ton	$6.8 MM	$10,107/ton
	36	Solar Mars T-15000	SCR (90% Reduction)	$5.3 MM	$9,000/ton	$6.8 MM	$10,713/ton
	37	Solar Mars T-15000	SCR (90% Reduction)	$5.3 MM	$10,000/ton	$6.8 MM	$12,062/ton

South Carlsbad Compressor Station	1	Solar Centaur T-4700	SCR (90% Reduction)	$2.5 MM	$5,000/ton	$7.2 MM	$13,617/ton
	2	Solar Centaur T-4700	SCR (90% Reduction)	$2.5 MM	$5,000/ton	$7.2 MM	$13,670/ton

Thus, even using marginally more accurate cost information substantially affects the outcome of a cost-effectiveness analysis. Without accounting for the complications and additional costs needed to address relocation of existing infrastructure and adequate power supplies, preliminary vendor information provided to Enterprise indicates that NMED has generally underestimated costs, in some cases substantially. Indeed, Enterprise's more accurate cost information establishes clearly that three of the units at Chaco and both units at South Carlsbad would exceed NMED's threshold for cost-effectiveness, even based on incomplete cost data. Enterprise is working to develop additional, more complete cost data for al of the Enterprise facilities and will seek to supplement the record as appropriate.

At least two additional factors excluded from NMED's and Enterprise's cost information will further increase costs significantly: (1) the costs associated with site-specific retrofit complications; (2) the use of an unsupported 90% NOx removal efficiency assumption.

First, costs associated with retrofitting the Enterprise facilities, including moving existing structures and equipment, will considerably affect cost-effectiveness. NMED explains that it attempted to account for the additional costs associated with retrofit complexity at the Enterprise facility sites by using a retrofit factor in EPA's cost calculation tool:

> A retrofit factor of 1.1 was used in the EPA SCR Tool to account for the additional capital costs anticipated to create physical space for the SCR system. This factor was selected based on Enterprise's recurring assertion that the current layout of the existing building cannot accommodate the physical space needed for SCR. Aerial photos provided by Enterprise suggest there is space for SCR if building modifications are made[.]

Draft SIP, App. D at 455. There is no explanation in the Draft SIP, however, as to how this factor affected costs or why it was the appropriate value to select. According to NMED documentation, EPA's SCR cost tool suggests a range of retrofit factors of "between 0.8 and 1.5 based on the level of difficulty" with a value of 1 being "for projects of average retrofit difficulty." *See id*. at 463. At the very least, to provide adequate support for its Draft SIP, NMED must explain why it has selected its chosen retrofit factor and why its choice is reasonable. A full analysis is likely to find that this figure does not fully capture the costs likely to be incurred to install and operate SCR.

Second, both the NMED and Enterprise cost effectiveness values are also overinflated due to the assumption by NMED, which Enterprise replicated in its assessment of the vendor information, that SCR can achieve a 90 percent removal efficiency at the Enterprise facilities.

The basis for that assumption appears to be that 90 percent is a default value in EPA's SCR cost tool. Draft SIP, App. D at 460. The Draft SIP provides no other explanation than the value is an assumption: "Emissions limitations for selective catalytic reduction are based on current actual emissions and an assumed 90% control efficiency." Draft SIP at 140.

This assumption may be appropriate for some industries under certain conditions, but it is not likely applicable to the Enterprise facilities. As explained in the attached letter from Solar Turbines to Enterprise, a much lower removal efficiency is more likely to apply to at least some the Enterprise units. A 60% to 80% NOx reduction may be a more realistic range of NOx reduction achievable with SCRs placed on certain Enterprise units.[22]

The reduction efficiencies Solar Turbines supports are consistent with EPA's analysis. In its AP-42: Compilation of Air Emissions Factors from Stationary Sources, EPA explains that "[t]he removal efficiency of an SCR system in good working order is typically from 65 to 90 percent." AP-42 at § 3.1.4.3. NMED should, at the least, assume a more realistic removal efficiency. NMED should further conduct a full assessment of removal-efficiency achievability for the Enterprise facilities. Such a change will further increase the cost-effectiveness values.

Enterprise believes that the best available information indicates that SCR is not cost-effective. Just as importantly, however, NMED has not made an adequate demonstration that SCR is cost-effective. Because that burden falls upon the state, NMED should withdraw its Draft SIP, conduct a more fulsome cost analysis, consistent with these comments, and propose a substantially revised Draft SIP.

C. NMED's Cost-Estimates Threshold is Too High.

NMED has adopted a "cost effectiveness threshold value (CETV) to remove control measures deemed not cost-effective from further consideration." Draft SIP at 102. NMED set its CETV at $10,000/ton NOx removed. *Id*. This threshold is too high and an outlier among states.

- Partial Approval and Disapproval of Air Quality Implementation Plans; Arizona; Regional Haze State Implementation Plan for the Second Implementation Period and Prong 4 (Visibility) for the 2015 Ozone and 2012 Particulate Matter Standards, 89 Fed. Reg. 47,398, 47,429 (May 31, 2024) (Cost-effectiveness threshold of $6,500/ton for point sources).
- Disapproval and Promulgation of Air Quality Implementation Plans; Texas and Oklahoma; Regional Haze State Implementation Plans; Federal Implementation Plan for Regional Haze; Completion of Remand, 88 Fed. Reg. 48,152, 48,167 (July 26, 2023) (cost-effectiveness threshold of $2,700/ton).

[22] Letter from Solar Turbines, Re: Solar Compressor Sets - NOx Reductions per NM Regional Haze Rule Requirements (Sept. 9, 2024) (Attachment C).

- Approval, Disapproval and Promulgation of Implementation Plans; State of Nebraska; Regional Haze State Implementation Plan; Federal Implementation Plan for Best Available Retrofit Technology Determination, 77 Fed. Reg. 40,150, 40,159 (July 6, 2012) (cost effectiveness threshold of $5,000 incremental cost per ton).

In addition to relying on much lower cost-effectiveness thresholds, several of these states failed, in EPA's view, to adequately support their chosen cost-effectiveness thresholds. *See, e.g.*, *id*. NMED has likewise failed to explain why its threshold is reasonable.

In one recent rulemaking action addressing the regional haze SIP for Missouri, EPA reviewed cost-effectiveness thresholds used in the regional haze context. In that action, EPA notes that Missouri selected cost-effectiveness thresholds of $3,658 per ton for SO_2 controls and $5,370 per ton for NOx controls. Air Plan Partial Approval and Partial Disapproval; Missouri; Regional Haze, 89 FR 55140, 55154 (July 3, 2024). Although EPA proposed to find those values were too low, EPA instead found costs in the range of $5,000/ton to $6,000/ton for SO_2 control would be more appropriate. *Id*.

EPA further explained that the regional planning organization for Missouri had recommended cost-effectiveness thresholds in a range from $4,000 to $5,000/ton (in 2005 dollars) which becomes $6,060 to $7,600/ton in 2021 dollars. *Id*. EPA provided another example with its own cost-effectiveness threshold of $4,200 to $5,100/ton range (escalated to 2020 dollars) for a Texas regional haze federal implementation plan. EPA further noted that, in 2021 dollars, this range is $5,300/ton to $6,500/ton. *Id*.

The one thing all of these values have in common is that they are much lower than NMED's cost-effectiveness threshold. If NMED were to adopt a threshold more in line with the practice of other states and EPA itself, it is likely that none of the Enterprise facilities would be deemed to have additional cost-effective control options, and SCR would certainly not be deemed cost-effective.

D. NMED Should Provide Enterprise an Opportunity to Address Specific Cost Items.

In the Draft SIP, NMED says that it excluded certain cost items provided by Enterprise or relied on default values where information was not available:

> In cases where Enterprise failed to provide source-specific cost estimates or NMED found estimates provided by Enterprise to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs.

Draft SIP, App. C at 69. Enterprise believes the information it has provided is reliable, and requests that NMED identify gaps in information that it deems crucial or that might otherwise address any shortcomings NMED perceives with the information Enterprise has provided. Enterprise will work with the Department to provide the more reliable possible information.

XI. In the Alternative, NMED Should Provide Enterprise With Additional Compliance Flexibility.

As drafted, NMED's proposed regulation would impose unit-by-unit emission rate limits for each of the Enterprise facilities. NMED can achieve the same emission reductions and the same improvements in visibility (minimal as they may be) while providing for greater operational flexibility for the Enterprise facilities.

Specifically, if NMED proceeds to seek final approval of its Draft SIP without changing course on requiring emission limits based on SCR for the Enterprise facilities—which it should not—Enterprise requests that NMED allow for facility-wide averaging. Allowing this additional compliance flexibility will ensure that each facility meets an overall emission rate limit while allowing Enterprise to operate the respective emissions units at each facility in the most efficient manner possible.

Allowing for averaging in this manner is fully consistent with the state's legal authority under the regional haze program and similar approaches have been adopted to address reasonable progress requirements in the past.

- Approval and Promulgation of Air Quality Implementation Plans; New Hampshire; Regional Haze, 77 Fed. Reg. 11,809 11,818 (Feb. 28, 2012) (placing two unit within a regulatory "bubble" for compliance purposes).

- Approval, Disapproval and Promulgation of Air Quality Implementation Plans; Arizona; Regional Haze State and Federal Implementation Plans, 77 Fed. Reg. 72,512, 72,527 (Dec. 5, 2012) (applying a compliance "bubble" across multiple units)

Enterprise further requests that NMED reevaluate the emission rate limits contained in the Companion Rule. Those limits are likely too stringent even with installation of SCR, although Enterprise will continue to evaluate this issue. Emission rate limits in the SIP should instead be based on the existing controls at the Enterprise facilities.

CONCLUSION

For all of the foregoing reasons, NMED's Draft SIP would impose unwarranted emission control requirements on Enterprise's facilities. The Draft SIP's requirements are based on a flawed cost assessment and a failure of the Department to fully consider the four reasonable progress factors and the visibility implications of its proposed emission control requirements. NMED should withdraw the Draft SIP and propose regional haze requirements for the Enterprise facilities consistent with the site-specific analysis Enterprise has provided and the CAA's goal that states make reasonable progress toward the national visibility goal.

Should you have any questions regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828 (bjcooley@eprod.com).

Sincerely,

Aaron M. Flynn

Subject:	[EXTERNAL] Revised Regional haze cost evaluations for Blanco C&D and Chaco Gas Plant
Date:	Wednesday, December 20, 2023 10:54:16 AM
Attachments:	2023-12-19_Corrected Draft Final NMED Cost Evaluation_Enterprise - Blanco C and D Compressor Station.xlsx 2023-12-19_Corrected Draft Final NMED Cost Evaluation_Enterprise - Chaco Gas Plant.xlsx

[Use caution with links/attachments]

Dear Mr. Jacobson,

After sending you NMED's draft final cost evaluations for Enterprise Field Services, LLC's Blanco C&D Compressor Station, Chaco Gas Plant and South Carlsbad Compressor Station last Thursday (12/14), our Regional Haze planning team discovered a formula error in the following sheets:

- Sheet "Eval – EMD" of the Blanco C&D Compressor Station workbook, resulting in an incorrect 2023$ cost effectiveness value for Unit T-C02
- Sheet "EMD1" of the Chaco Gas Plant workbook, resulting in an incorrect 2023$ cost effectiveness value for Unit 18
- Sheet "EMD2" of the Chaco Gas Plant workbook, resulting in incorrect 2023$ cost effectiveness values for Units 36 and 37
- Sheet "EMD3" of the Chaco Gas Plant workbook, resulting in incorrect 2023$ cost effectiveness values for Units 13 and 14

The errors have been corrected in the attached workbooks. Please disregard the Blanco C&D Compressor Station and Chaco Gas Plant workbooks we provided last week and review the sheets in the attached, corrected versions instead. As a reminder, the deadline to submit review comments is Jan. 15, 2024.

Regards,
Kirby Olson

This email is intended to serve as general guidance and is in no way a formal statement of Department policy. Unique operating conditions may result in different determinations and may require a site specific analysis to accurately determine requirements and applicability.

Methodology/Note
Enterprise provided a cost estimate for electrification using EPA Cost Control Manual Section 5.2, which pertains to acid gas scrubbers. As this is not applicable to replacement with EMD, a Total Capital Cost metric of $2,084 (2023$/hp) was calculated using detailed cost information provided by other facilities. The TCI figure assumes no costs associated with substation or distribution line upgrades. This assumption underestimates costs given that Enterprise indicated in its August 2023 update that utility infrastructure upgrades would be needed to support electrification at all three of its facilities.

osts associated with replacement with an equivalent/like-kind unit

Enterprise indicated in its initial 2019 FFA submittal, 2020 follow-up and 2023 update that there is insuff
accommodate SCR. In support of its assertion, it indicated (2020 follow up) that CECO-Peerless stated th
approximately 40' x 20' is required for an SCR unit" and a copy of the correspondance was provided. An
facility was provided in the 2020 follow up which suggests that new buildings (or substantial extensions
building) would be required to house an SCR. The associated costs of building construction coupled with
exhaust system modifications would be costly. Considering the calculated cost effectiveness of SCR for
Mexico, it is reasonable to conclude that SCR is cost prohibitive for the Blanco C/D units.

Submitted Electronically

September 9, 2024

Subject: **Solar Compressor Sets - NOx Reductions per NM Regional Haze Rule Requirements**

There are very few gas turbine compressor sets in the world equipped with SCR systems. While a 90% NOx reduction rate is generally applicable to base-loaded generator sets producing electrical energy usually in combined cycle or cogeneration configurations, the same NOx reduction cannot be assumed for compressor sets which operate in simple cycle mode and experience variable loads swings as part of normal operations.

For reference, there are two compressor stations in Virginia with Solar Turbines equipped with SCR systems. NOx limits for these stations are based on approximately a 60% reduction from the SCR systems. 60-80% NOx reduction is a more realistic range of NOx reduction achievable with SCRs placed on gas turbine compressor sets.

The Solar Centaur 40 and Mars 100 gas turbines at South Carlsbad Station and the Chaco Gas Plant, respectively are of the vintage diffusion flame version of gas turbines which have higher NOx emissions than modern dry-low emissions (DLE) gas turbines sold today. Solar offers upgrades for these turbines to DLE versions (termed 'SoLoNOx' – Solar's DLE system) which will reduce NOx emissions greater than SCR systems with the added benefit of avoiding NH3 emissions which are produced by the SCR process. The SoLoNOx upgrades will also be less costly and require much less unit downtime than SCR installation.

Specifically, Solar offers SoLoNOx upgrades on these units to levels of 15 ppm NOx for the Centaur 40 and to 9 ppm NOx for the Mars 100. The SoLoNOx levels represent NOx reductions of greater than 90% from the existing diffusion flame configurations.

In summary, upgrading the existing Solar turbines at South Carlsbad Station and the Chaco Gas Plant to modern SoLoNOx combustion systems is a more cost-effective and environmentally beneficial solution than retrofitting to SCR.

Please call me at 858.505.8554 if you have any questions.

To whom it may concern:

El Paso Natural Gas Company, L.L.C. ("EPNG") provides comment on the August 26, 2024 Draft of the Regional Haze State Implementation Plan ("SIP") Revision for the Second Planning Period (2019-2028) ("Draft SIP Revision") prepared by the New Mexico Environment Department ("NMED"), Air Quality Bureau ("AQB"), in partnership with the City of Albuquerque Environmental Health Department ("EHD").[1] The Draft SIP Revision identifies three EPNG facilities for consideration in imposing emissions rate limits or in certain cases, even full replacement of equipment, under the Regional Haze Program pursuant to the federal Clean Air Act ("CAA" or "the Act"): the Blanco Compressor Station A ("Blanco A"), Pecos River Compressor Station ("Pecos River"), and Washington Ranch Storage Facility ("Washington Ranch"). NMED states that it plans to request a hearing with the New Mexico Environmental Improvement Board ("EIB") based on the Draft SIP Revision in September 2024,[2] after incorporating public feedback received through this comment solicitation period.

NMED's proposed timeline for requesting a rulemaking with EIB, however, reveals that NMED will not have nearly enough time to digest and incorporate comments on a highly technical area of law, policy, and engineering. NMED took seven months from receiving the January 2024 comments on its proposed four-factor analyses, and then only left the public 25 days to comment on the Draft SIP Revision. Further, the New Mexico process for the second regional haze planning period has been ongoing since 2019. In this context, the mere 25-day timeline for EPNG and other subject parties to respond is unjust and deprives potentially regulated parties of their

[1] EHD is responsible for CAA compliance within its jurisdiction in Albuquerque. For the sake of simplicity, this comment letter refers to NMED as the author of the Draft SIP Revision.

[2] *See* NMED, Regional Haze Planning (last visited Sept. 10, 2024), https://www.env.nm.gov/air-quality/reg-haze ("NMED anticipates petitioning the Environmental Improvement Board to adopt the proposed plan and rule on or about September 11, 2024. NMED further anticipates requesting that the Board hold a mid-December hearing on the proposed plan and rule at the Board's September 27, 2024 regular monthly meeting.").

due process and CAA rights to be heard on the matter. NMED's significant delay in this process past the July 31, 2021, SIP submittal deadline should not be a justification for imposing unduly constrained timelines on public commenters including impacted sources, and which will also not allow the agency to meaningfully absorb, let alone respond and react to, comments on the Draft SIP. Stated otherwise, NMED and EPA cannot adopt deadlines that deprive stakeholders including EPNG of their due process including rights under the Administrative Procedure Act, the CAA, the New Mexico Administrative Procedures Act, and New Mexico Air Quality Control Act.[3]

EPNG understands that the New Mexico Oil and Gas Association ("NMOGA") has or will file a request for a reasonable extension of time to respond to NMED's Draft SIP. EPNG supports the NMOGA extension request.

I. Executive Summary

In this letter, we provide general background on the Regional Haze Program, comments on the Draft SIP Revision's methods and assumptions, along with source-specific comments related to EPNG's facilities identified for new emissions-rate limits by the Draft SIP Revision. In summary, we make the following conclusions and requests to NMED:

1. The Regional Haze Rule does not require a state to evaluate all emissions sources within each implementation period. NMED unreasonably ignored this important point, and instead of surgically identifying the most impactful sources, NMED's screening methodology uses an overinclusive and very rough metric for determining which sources to evaluate for further analysis. This was particularly unnecessary given the strong progress already made on reducing visibility impairment in Class I areas within New Mexico and out of state, especially through the retirement of large electric generating stations like the San Juan Generating Station. The bottom line is that NMED's approach for EPNG's facilities will result in costly retrofits that will have only a minimal (at most) impact on visibility conditions in Class I areas.

2. EPNG addresses three threshold legal issues. The first two caused NMED to erroneously propose controls for EPNG's units. EPNG discusses the last issue to support the Draft SIP Revision's current approach, and because NMED had earlier suggested it might have authority to impose operating restrictions on sources.

    a. The CAA, which NMED is acting under, does not authorize *replacement* of emissions *sources*, whether that includes replacement of a natural-gas fired unit with an electric unit or with another natural-gas fired unit.

    b. U.S. Environmental Protection Agency ("EPA") guidance provides that *actual* emissions should be used for cost-effectiveness analysis, not potential to emit.

[3] 42 U.S.C. § 7410(a)(2); 40 C.F.R. § 51.102; 5 U.S.C. § 553; NMSA 1978, §§ 12-8-3, 74-1-9.

c. NMED may not impose operating hour restrictions on engines and turbines regulated by the U.S. Federal Energy Regulatory Commission ("FERC") that are used to pump natural gas in interstate transport. While NMED is not proposing to do so, EPNG makes this point clear, should NMED consider changing approach.

3. On top of the legal errors identified in Item No. 2.a & 2.b., above, NMED's four-factor analyses for Blanco A and Pecos River make multiple technical errors that lead to significant understatement of the cost-per-ton of reductions from emissions units at these facilities. Without these understatements, none of the units at Blanco A or Pecos River would be subject to Regional Haze Program emissions-rate limits.

4. Regarding Washington Ranch, EPNG does not agree with the assessment of replacement or electrification, per Item No. 2.a., above. Setting that issue aside, EPNG does agree with the overall conclusion that there are no cost-effective incremental reduction options from Washington Ranch, even if replacement or electrification were allowed. EPNG does not oppose an emission limit of 3.0 g/hp-hr based on the existing LEC on the two units at Washington Ranch.

5. Finally, the overall consideration of air-quality improvements shows why imposing limits on the units selected for additional emissions limits at Blanco A and at Pecos River is unnecessary and unreasonable, consistent with EPA guidance.

II. Legal and Factual Background

A. Brief Regional Haze Program Background

EPNG does not provide an exhaustive background on the Regional Haze Program but instead provides a brief overview as a framing for this comment letter.

Through the CAA, Congress declared "as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution."[4] Class I areas are national parks and certain protected wilderness areas. To attain that goal, Congress directed that EPA promulgate regulations that require, for states with Class I areas (or with emissions that may reasonably be anticipated to cause or contribute to any impairment of visibility in any out-of-state Class I area) "to contain such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward the national goal [of no human-caused visibility impairment]."[5]

[4] 42 U.S.C. § 7491(a)(1).

[5] *Id.* § 7491(b)(2).

Relevant here, for determining reasonable progress, states must consider "**[1]** the cost of compliance, **[2]** the time necessary for compliance, and **[3]** the energy and nonair quality environmental impacts of compliance, and **[4]** the remaining useful life of any existing source subject to such requirements."[6] The four enumerated items here are those factors that states and EPA consider as part of a "four-factor analysis." The Act also specifies that each SIP should contain a long-term strategy for making reasonable progress toward meeting the national goal.[7]

EPA has promulgated several iterations of regulations, known as the "Regional Haze Rule" or "RHR," under this statutory authority, which includes the most recent update in 2017.[8] Through the RHR, EPA set the goal date for achieving natural visibility conditions of 2064.[9] The RHR, consistent with the Act, uses distinct planning periods in which states aim to reduce their emissions at a rate of progress that will achieve the national goal by 2064. Currently, states are in the second implementation period of this process, and the key provision from the RHR applicable here is therefore 40 C.F.R. § 51.308(f), which provides the requirements for periodic SIP review.

After the amended RHR was promulgated in 2017, EPA then issued guidance to states in 2019 that walks through a step-by-step process for states to follow in developing their SIPs for the second regional haze planning period. The guidance is entitled, "Guidance on Regional Haze State Implementation Plans for the Second Implementation Period," dated August 20, 2019 ("2019 EPA Guidance").[10] Nearly two years later, on July 8, 2021, EPA issued additional guidance, entitled "Clarifications Regarding Regional Haze State Implementation Plans for the Second Planning Period" ("2021 Clarification").[11]

B. Relevant Background on Draft SIP Revision.

NMED's Draft SIP Revision is proposed for promulgation to satisfy the RHR's requirements for the second planning period. The second planning period covers the years 2019 to 2028, and SIP revisions for this period were due on July 31, 2021,[12] but the New Mexico process has been delayed and has not met the deadline. The Draft SIP Revision takes a multi-step approach that, in broad strokes: (1) identifies Class I areas in New Mexico and nearby out-of-state Class I areas; (2) explains and applies a screening methodology for determining which sources of emissions would be subjected to a four-factor analysis; (3) summarizes the four-factor analyses performed

[6] *Id.* § 7491(g)(1).

[12] Draft SIP Revision at 7.

for certain emissions units at each selected source; (4) summarizes the emissions-rate limits resulting from the four-factor analysis; and (5) reviews the assessed emissions reductions against the uniform rate of progress that is needed to attain natural visibility conditions at each Class I area.[13]

Specific to EPNG, the Draft SIP Revision proposes imposing emissions limits on six units owned by EPNG, as set forth in Table 1, below. The limits are based on selective catalytic reduction ("SCR") as a control, continued use of existing low-emission combustion ("LEC") as a control, and replacement of gas-fired units with new gas-fired units (which is beyond NMED's authority, as described in Section III.A).

Table 1. – Draft SIP Revision Proposed Emissions-Rate Limits on EPNG Units

Facility	Unit	Proposed NOx Emissions-Rate Limit	Basis for Limit	EPNG Position
Blanco A	A11	0.5 g/hp-hr	Replacement	Oppose
Blanco A	A13	0.5 g/hp-hr	Replacement	Oppose
Pecos River	A-02	3.64 lb/hr	SCR	Oppose
Pecos River	A-03	4.05 lb/hr	SCR	Oppose
Washington Ranch	1	3.0 g/hp-hr	Existing LEC	Does not oppose
Washington Ranch	2	3.0 g/hp-hr	Existing LEC	Does not oppose

For the Blanco A and Pecos River units, NMED established the emissions-rate limits based on capital-intensive projects at each. For Blanco A, NMED would have EPNG replace the existing units with new natural gas-fired engines. The emissions-rate limit for Pecos River is based on installation of SCR. NMED should not move forward with these proposed emissions-rate limits because (1) these sources should not have been screened in for four-factor analysis, (2) NMED does not have the legal authority to require replacement of the Blanco A units, (3) NMED's four-factor analysis used technically flawed assumptions, and (4) an overall evaluation of visibility impacts demonstrates that New Mexico can make reasonable progress to achieving the 2064 visibility goal without requiring reductions from Blanco A or Pecos River.

III. Threshold Legal Issues.

Before turning to the more technical issues in the Draft SIP Revision, EPNG highlights three significant threshold legal issues. The first is that NMED does not have authority to require replacement or electrification of a source.[14] In the context of natural-gas fired engines and

[13] *See* Draft SIP Revision, at 10.

[14] NMED's Draft SIP Revision categorically excludes electrification as a potential requirement on the basis that "there are simply too many unknowns to reliably estimate the costs involved" and feasibility. Draft SIP

turbines, this means NMED is incorrect in its assertion that it can require replacing an engine or turbine with a new natural-gas fired unit or that NMED can require either type to be converted to an entirely different technology—i.e., an electric motor, powered by the grid.

Second, NMED erroneously concluded that the proper emissions baseline to use in the four-factor analysis is the *potential* to emit rather than *actual* emissions. This position is a blatant attempt to reduce the cost/ton of the chosen technology and is directly contrary to authoritative EPA guidance on the matter, and would (if adopted) result in erroneously subjecting EPNG's engines to the Regional Haze SIP.

Third, EPNG notes that NMED may not impose operating hour restrictions on FERC regulated natural gas pipelines shipping natural gas in interstate commerce outside of the authority under the CAA.

A. The CAA and RHR Do Not Authorize Replacement or Electrification.

EPNG respectfully disagrees with NMED's consideration of replacement or electrification as an option for NOx emissions reductions.[15] Neither replacement nor electrification is authorized by the Regional Haze provision in the CAA or the implementing regulations, and units cannot be forced to undertake such a fundamental change to their facilities. The Regional Haze Rule is the authority under which NMED proposes that any final rules will be imposed by the EIB, and so any state law authority is not relevant.

A fundamental principle of the Clean Air Act is that Congress did not intend to eliminate emissions sources; rather, Congress simply intended for *control* of emissions sources—*e.g.*, through scrubbers, capture devices, or other methods that reduce emissions of a pollutant without affecting the fundamental engineering design of the source.[16] Congress took this approach in part to ensure that achieving clean air goals did not unnecessarily disrupt economic activity.[17]

The Clean Air Act's regional haze provision is no different. For example, in the preamble to the 2017 Regional Haze Rule Amendment, EPA explained that "states must evaluate the *control* measures that are necessary to make reasonable progress using the four factors and develop

---

Revision, at 105. However, in the Draft SIP, NMED does not disclaim authority to require electrification. As discussed herein, NMED does not have the authority to require electrification of any existing unit.

[15] As noted above, NMED categorically excluded electrification from consideration because of costs and feasibility, not because of its lack of legal authority.

[16] *See, e.g.*, *West Virginia v. EPA*, 597 U.S. 697, 728 n.3 (2022) (EPA may not "direct existing sources to effectively cease to exist" under 42 U.S.C. § 7411(d)); *Helping Hand Tools v. EPA*, 848 F.3d 1185, 1194 (9th Cir. 2016) (in determining "best available control technology" EPA may not "redefine the source" in a way that would disrupt the basic business purpose of the facility, which business purpose includes availability and use of on-site fuel).

[17] *See Sierra Club v. Costle*, 657 F.2d 298, 331 (D.C. Cir. 1981) (noting legislative history of Clean Air Act showed Congress did not want to impede long term growth or inhibit technological innovation).

their long-term strategies before they can predict future emissions reductions and conduct the regional-scale modeling used to establish [reasonable progress goals]."[18] Thus, EPA only contemplates that "controls" should be used to meet reasonable progress goals. Controls are defined in other areas of the Clean Air Act as "application of production processes and available methods, systems, and techniques, including fuel cleaning, clean fuels, or treatment or innovative fuel combustion techniques for control of each such pollutant."[19] This is further confirmed by the text of the relevant regulatory provision in the Regional Haze Rule, which refers to "installation" of a "control":

> In considering [one of the four statutory reasonable progress factors], if the State concludes that a *control measure cannot reasonably be installed* and become operational until after the end of the implementation period, the State may not consider this fact in determining whether the measure is necessary to make reasonable progress.[20]

The discussion of *installing* a *control* suggests reference to an *existing* emissions unit that will remain in place and be modified, not the wholesale replacement of the emissions unit. The basic logic is simple: a control has to be installed on *something*. If an emissions unit is removed, then there is nothing on which to install the control.

The 2019 EPA Guidance interpreting the 2017 Regional Haze Rule confirms and drives home EPA's intention that "control" will be used to achieve reasonable progress, and that replacement of existing sources with other technology is not included. EPA provided the following list of "control measures that states may consider":

1. Emission reductions through improved work practices.

2. Retrofits for sources with no existing controls.

3. Upgrades or replacements for existing, less effective controls.

4. Year-round operation of existing controls.

5. Fuel mix with inherently lower SO2, NOx, and/or PM emissions. States may also determine that it is unreasonable to consider some fuel-use changes because they would be too fundamental to the operation and design of a source.

[18] 82 Fed. Reg. 3,078, 3,090-91 (Jan. 10, 2017) (emphasis added).

[19] 42 U.S.C. § 7479(3).

[20] 40 C.F.R. § 51.308(f)(2)(i) (emphasis added). Moreover, the statutory term for the requirements on certain sources to require "retrofit technology" as part of best available technology also suggests a similar approach for other sources regulated under the RHR.

6. Operating restrictions on hours, fuel input, or product output to reduce emissions.

7. Energy efficiency and renewable energy measures that could be applied elsewhere in a state to reduce emissions from EGUs.

8. Basic smoke management practices and smoke management programs for agricultural or wildland prescribed fires.[21]

Self-evidently, none of these includes replacement or electrification. The only time "replacement" appears in this list is in reference to replacement of *controls*. Further, the use of "retrofit" for sources should not be interpreted as replacement or electrification. The best available *retrofit* technology in the Regional Haze Program has never been interpreted that way; rather, the plain text of "retrofit" means the *addition to* an existing emissions unit.[22] While this list is not exhaustive, it is certainly indicative of the types of controls EPA contemplated requiring, none of which compare to electrification or replacement.

The 2021 Clarification also confirms this understanding. In that guidance, EPA clarifies that greater *efficiency of controls* could also be considered, and that guidance notably does not suggest replacement or electrification is appropriate.[23] The 2021 Clarification's discussion of the remaining useful life of a source in the four-factor analysis also discusses how the control technology—not the actual emissions source (e.g., engine)—should be the piece of equipment considered in this evaluation.[24] This discussion again contemplates that there is a *control* technology, confirming the CAA's approach of only requiring control technology and not outright replacement.

Additionally, neither EPA nor NMED may now claim that the Act's principal provision on regional haze, 42 U.S.C. § 7491, is ambiguous and then leverage that ambiguity to broaden their regulatory authority beyond the words of the statute to impose replacement or electrification requirements. That approach is now forbidden under *Loper Bright Enterprises v. Raimondo*, under which courts (and only courts) are to determine whether a statute grants an agency

[21] 2019 EPA Guidance, at 29-30.

[22] *See* "retrofit" *Merriam Webster*.

[23] 2021 Clarification, at 7 (discussing efficiency improvements of an "existing control" as a control measure to consider but not suggesting that replacement of the entire emissions unit is appropriate).

[24] 2019 EPA Guidance, at 33 ("[A]nnualized compliance costs are typically based on the useful life of the control equipment rather than the life of the source, unless the source is under an enforceable requirement to cease operation.").

authority.[25] For the reasons discussed above, the plain meaning of the statute only leaves agencies authority to require *control*s.[26]

The Draft SIP Revision only offers a terse response in support of NMED's claimed authority to require replacement or electrification, citing a supposed "prodigious flexibility afforded to states by the Regional Haze Rule."[27] But that is not even the right question; states have flexibility *within* their authority but may not act *beyond* that authority. As the authorities above demonstrate, 42 U.S.C. § 7491 does not authorize replacement or change of sources, and so New Mexico may not require that drastic step for sources.

B. Emissions Levels Used in the Four-Factor Cost-Effectiveness Analysis Should Use Actual Emissions, not Potential Emissions.

NMED is directed to use actual emissions when calculating cost-effectiveness of controls, consistent with the 2019 EPA Guidance. In that guidance, EPA provided as follows concerning visibility modeling:

> Generally, we recommend that a reasonably projected actual level of source operation in 2028 be used to estimate 2028 *actual* emissions for purposes of selecting sources for control measure analysis. Source operation during a historical period can inform this projection, but temporary factors that suppressed or bolstered the level of operation in the historical period should be considered, along with factors that indicate a likely increase or decrease in operation.[28]

Then, in discussing "emissions information to estimate the emission reductions from the potential control measures," EPA cross-referenced the above language, stating: "EPA's recommendations in this area are similar to the recommendations in Section II.B.3.b of this document regarding how emissions information is selected . . . ."[29]

This is also consistent with the approach for Best Available Retrofit Technology ("BART"). BART is relevant because it provides the other statutory guidance found in the Act's section on regional haze for evaluating the types of controls to install on sources, and statutes must be read as a

[25] 144 S. Ct. 2244, 2273 (2024) ("Courts must exercise their independent judgment in deciding whether an agency has acted within its statutory authority.").

[26] And even if the plain language could be interpreted to allow replacement, that interpretation would run afoul of the Major Questions Doctrine. As the Supreme Court has noted, Congress does not hide elephants in mouseholes by "alter[ing] the fundamental details of a regulatory scheme in vague terms and ancillary provisions." *Whitman v. Am. Trucking Ass'ns*, 531 U.S. 457, 468 (2001). Thus, the authority to require replacement of existing sources requires "clear congressional authorization." *Utility Air Regulatory Group v. EPA*, 573 U.S. 302, 324 (2014). *See also West Virginia*, 597 U.S. at 728 n.3 (EPA may not direct "existing sources to effectively cease to exist").

[27] Draft SIP Revision, at 102.

[28] 2019 EPA Guidance, at 17 (emphasis added).

[29] *Id.* at 30.

whole.[30] EPA provided in its BART guidelines as follows: "The baseline emissions rate should represent a realistic depiction of anticipated annual emissions for the source. In general, for the existing sources subject to BART, you will estimate the anticipated annual emissions based upon *actual emissions* from a baseline period."[31] Given the close relationship between the BART analysis and reasonable progress analysis, the direction for BART analysis should be highly persuasive here.

Last, practical reasons support using actual emissions. It is not potential emissions from a source that may affect visibility conditions; rather, it is the actual emissions.[32] Likewise, the true and more accurate measure of a cost-effectiveness analysis depends on a unit's actual emissions. Without considering actual emissions, the cost-effectiveness prong of the four-factor analysis loses all of its meaning. The point of including cost-effectiveness in the evaluation is to ensure that resources are spent wisely, where they can have the most positive impact, in recognition of the limited societal resources available to tackle environmental problems.[33]

An example illustrates the point. Consider engine *A* that runs only 10 hours a year and emits 1 ton of NOx during that operation and an otherwise identical engine, engine *B*, that runs 8760 hours while emitting 100 tons of NOx. Using potential emissions would mean that engine *A* would be assessed to have emissions of 876 tons per year, and would therefore appear far more cost-effective than engine *B*. In reality, however, engine *A* would actually be far more expensive to control based on its actual expected emissions. NMED's four factor analysis should avoid such perverse outcomes.

C. State Authority Over Interstate Natural Gas Pipelines

FERC approves or "certificates" pipelines to deliver natural gas. EPNG's pipeline system, as certificated by FERC, allows EPNG to move gas 24 hours a day, 365 days a year at its designed capacity. Given the extensive federal regulation of natural gas pipelines under FERC, states are

[30] *FDA v. Brown & Williamson Tobacco Corp.*, 529 U.S. 120, 133 (2000) ("It is a fundamental canon of statutory construction that the words of a statute must be read in their context and with a view to their place in the overall statutory scheme." (quotation and citation omitted)).

[31] 40 C.F.R. Part 50, Appendix Y (Step 4.d.1.) (emphasis added).

[32] NMED recognized this fact when, in a separate context, NMED denied EPNG's request for an alternative compliance plan for the New Mexico ozone precursor rule that would have retired several engines at Blanco A. EPNG had also requested that such retirements would count toward regional haze reductions, but NMED rejected EPNG's calculation of emissions reductions for being based on emissions potentials. NMED's flip-flop on this issue demonstrates it aims to inflate baseline emissions to in turn drive down estimated costs-per-ton of reductions and inappropriately expand its regulatory reach.

[33] *See White Stallion Energy Ctr., LLC v. EPA*, 748 F.3d 1222, 1261 (D.C. Cir. 2014) (Kavanaugh, J., dissenting) (noting importance cost-effectiveness analysis "in an age of limited resources available to deal with grave environmental problems, where too much wasteful expenditure devoted to one problem may well mean considerably fewer resources available to deal effectively with other (perhaps more serious) problems" (quoting *Entergy Corp. v. Riverkeeper, Inc.*, 556 U.S. 208, 233 (2009)), rev'd *Michigan v. EPA*, 576 U.S. 743 (2015).

largely preempted from imposing additional regulations on such pipelines, except for specific and narrow exceptions, including the CAA.[34]

NMED should bear this in mind as it moves forward with the SIP revision. In particular, this means that New Mexico may not exercise its own state law authority to impose requirements on interstate natural gas pipelines that go beyond what the CAA authorizes.

IV. NMED's Source Selection Process Takes an Overly Aggressive Approach not Required by the Act or RHR and that Relies on Faulty Technical Assumptions.

As discussed herein, NMED's screening methodology for determining which sources to evaluate through the four-factor analysis is over-inclusive and not required by the Act or RHR. NMED's approach is also not technically supported and should be rejected as arbitrary and not based in substantial evidence on the record.[35]

A "key flexibility of the regional haze program is that a state is not required to evaluate all sources of emissions in each implementation period. Instead, a state may reasonably select a set of sources for an analysis of control measures."[36] Accordingly, NMED does not need to subject all sources of potential visibility-impairing emissions in New Mexico to a four-factor analysis for determining reasonable progress goals.

This is because, as the 2019 EPA Guidance observes, the CAA does not require a specific list of source types for which an analysis must be performed, in marked contrast to the statutory provisions directing that certain types of sources be subject to a BART analysis.[37] This is also consistent with the RHR, which takes a phased approach and does not require that states achieve natural visibility conditions in one fell swoop.[38] Thus, "it is reasonable and permissible for a state

---

[34] *See Dominion Transmission, Inc. v. Summers*, 723 F.3d 238, 240 (D.C. Cir. 2013) (Natural Gas Act establishes a comprehensive scheme of federal regulation but does not preempt state authority under the CAA).

[35] *See* NMSA 1978, § 74-2-9 (court of appeals shall set aside agency action if it is arbitrary, capricious, or an abuse of discretion or not supported by substantial evidence in the record); *Pub. Serv. Co. of N.M. v. New Mexico Envtl. Dept.*, 1976-NMCA-039, ¶ 18 ("There is no substantial evidence in the record to support the Board's final reason 'G'. . . . Whether sulfur dioxide emissions can or do combine with other elements in the atmosphere to produce a visible gas, or whatever, the record does not indicate.").

[36] 2019 EPA Guidance, at 9.

[37] *Id.*; *see also* 42 U.S.C. § 7491(b)(2)(A) ("[E]ach major stationary source which is in existence on August 7, 1977, but which has not been in operation for more than fifteen years as of such date, and which, as determined by the State (or the Administrator in the case of a plan promulgated under section 7410(c) of this title) emits any air pollutant which may reasonably be anticipated to cause or contribute to any impairment of visibility in any such area, shall procure, install, and operate, as expeditiously as practicable (and maintain thereafter) [BART] . . . .").

[38] 2019 EPA Guidance, at 9 ("Selecting a set of sources for analysis of control measures in each implementation period is also consistent with the Regional Haze Rule, which sets up an iterative planning

to distribute its own analytical work, and the compliance expenditures of source owners, over time by addressing some sources in the second implementation period and other sources in later periods."[39] Finally, "one function of the source selection step is to reduce the number of sources for which the full set of relevant factors will be characterized."[40]

The 2021 Clarification is also consistent with this view on source selection, stating: "In general, states with larger sources that contribute more to visibility impairment should select more sources, and states with relatively small sources compared to their neighbors should nonetheless select their largest in-state sources."[41] The 2021 Clarification's principal recommendation is that states should select sources that are "among the largest sources of visibility impairment in the state."[42] As discussed below, NMED's source-selection approach exceeded this direction, and NMED's over-inclusive approach appears to stem from a misinterpretation of guidance.

A. NMED's Use of the Q/d Metric Should be Reevaluated or at Least Better Supported.

In determining the sources for which a four-factor analysis would proceed, NMED used the "Q/d" metric. Q/d is a measure of the quantity (the "Q") of emissions from a source divided by the distance (the "d") of the emissions from a particular Class I area. To select the Q, NMED aggregated emissions of NOx and SO2 from each source, weighting both emission types equally.[43] To select the d, NMED used the distance to the closest (in-state or out-of-state) Class I area from the particular source.[44] This process yields source specific Q/d scores, provided in the Draft SIP Revision's Table 6-1 (beginning on page 94).

The highest Q/d score was 461, for San Juan Generating Station, and NMED set a cut-off threshold where every facility with a Q/d score of 5.6 or greater would be selected for the four-factor analysis.[45] NMED adopted 5.6 as the cut-off "necessary to capture 80% of the total NOx and SO2 emissions from all New Mexico Title V facilities combined."[46] Notably, EPNG's Blanco

---

process and anticipates that a state may not need to analyze control measures for all its sources in a given SIP revision. . . .").

[43] *See* Draft SIP Revision, at 92 ("NMED and EHD chose NOx and SO2 as the targeted pollutants because monitoring data indicates that aerosol species related to emissions of these two precursor pollutants (i.e., ammonium nitrate and ammonium sulfate) are the key drivers of anthropogenic visibility impairment at Class I Areas . . . ."), at 94 tbl. 6-1 (showing final Q/d scores).

[44] *See id.* at 92.

[45] *Id.* at 93.

[46] *Id.* at 92.

A is the very last facility that was screened in by NMED's misinterpretation of the proper threshold to apply; it has a Q/d score of just 5.63 compared with NMED's selected threshold of 5.6.[47]

NMED states that it selected 80% of NOx and SO2 emissions threshold based on the Western Regional Air Partnership ("WRAP") Protocol, which in turn references EPA draft guidance.[48] However the process in both the WRAP Protocol and EPA draft guidance differs significantly from NMED's.

First, the WRAP Protocol suggests using a Q/d score cut-off nearly two times higher than what NMED selected – at a score of 10: "[T]he Subcommittee suggests that states should first screen sources at a Q/d > 10 level to determine if a reasonable number of sources are identified for further review."[49] Then, only if no sources are selected does the WRAP Protocol suggest stepping down to a lower Q/d level: "**If no sources are identified**, the Subcommittee recommends stepping down the Q/d screening level in increments of one until a reasonable number of sources are identified for further review." [50] In stark contrast, NMED stepped down to scores well below 10 even though "a Q/d threshold of 10 or more would capture 13 Title V facilities responsible for" approximately 70% of the total NOx and SO2 emissions from all New Mexico Title V facilities.[51] In other words, even though the WRAP Protocol provides that a Q/d score lower than 10 is recommended only if *no sources* are identified at that level, NMED nevertheless stepped down when 13 sources have a score of 10 or above, accounting for approximately 70% of combined statewide NOx and SO2 emissions.

And NMED's explanation that it needed to include 80% of statewide NOx and SO2 emissions is based on a facially erroneous interpretation of both the WRAP Protocol and 2016 EPA Draft Guidance. Both those sources specify that the 80% measurement is related to 80% of the *visibility impacts*, not total emissions.[52] NMED's comparison of total emissions (rather than visibility impacts) is an apples-to-oranges comparison given that actual impacts of visibility depend on many other factors beyond total emissions volumes, including "transport direction/pathway,

dispersion and photochemical processes, or the particular days that have the most anthropogenic impairment due to all sources . . . ."[53]

Further, if NMED felt that an 80% coverage analysis was required (contrary to the WRAP Protocol), then a more accurate and consistent approach would have been for NMED to assess how many sources must be included to cover 80% of combined Q/d scores. The 2016 EPA Draft Guidance contemplates such an approach, stating: "Mechanically, it is possible to compare the sum of the individual Q/d values for the 'above threshold sources' to the sum of the Q/d values for all in-state sources."[54] However, that document nevertheless cautions that an even more precise approach for determining visibility impacts might be appropriate.[55] NMED's 80% comparison with total NOx and SO2 emissions is therefore an even rougher method than the method EPA expressed cautioned against using.

Lastly, even if the 80% threshold were correct—contrary to the foregoing arguments—NMED did not even apply that threshold properly as a matter of arithmetic, causing NMED to erroneously pull in Blanco A. As shown in Table 6-2 of the Draft SIP Revision, excluding Blanco A would have still captured sources that emit 79.98% of statewide NOx and SO2 emissions.[56] Under any rational method for rounding, 79.98% rounds up to 80%, and NMED's failure to round here elevates form of substance, pulling in a source based on a 0.02% difference. Indeed, under New Mexico's air-quality regulations, 79.98% (in fact, 79.51% and up) rounds up to 80% in other contexts,[57] and it is arbitrary and capricious to select a different rounding mechanism in this context.

In sum, EPNG recommends that NMED follow the WRAP Protocol more closely by simply using the Q/d score of 10 as a threshold. Alternatively, using 7 as a threshold appears to be a breakpoint, as the drop from 8 to 7 pulls in several more percent of statewide NOx + SO2 emissions, going from 71.5% to 78%.[58] As relevant for EPNG, this would eliminate Blanco A from further consideration. At the very least, NMED should at least round 79.98% up to 80% so that only 23 sources are selected for further consideration and thereby eliminating Blanco A.[59]

[55] *See id.* ("[T]his [approach] may not give a good indicator of what fraction of in-state light extinction impacts are attributable to the first set of sources.").

[56] *See* Draft SIP Revision, at 98.

[57] *See* 20.2.1.116(C)(2), 20.2.71.111(A)(3), 20.2.81.104(C) NMAC.

[58] *See* Draft SIP Revision, at 98 tbl. 6-2.

[59] In addition to these flaws, the Draft SIP Revision also erroneously weights NOx emissions and SO2 emissions equally. *See id.* at 94-96 tbl.6-1 (using combined, equally weighted emissions of NOx and SO2 to calculate Q/d scores). This is despite the fact that SO2 has a much greater impact on visibility impairment in the relevant areas and in fact is "*the primary driver of light extinction* at all New Mexico Class I Areas." *Id.* at 53 (emphasis added). Blanco A, Pecos River, and Washington Ranch all emit de minimis levels of SO2. But NMED arbitrarily and capriciously failed to consider this important aspect of the problem in deciding to subject those facilities to a four-factor analysis.

B. NMED Should Actually Evaluate Whether Emissions Reductions in New Mexico Will Improve Visibility at Mesa Verde.

Blanco A was selected for four-factor analysis based on its proximity to Mesa Verde National Park ("Mesa Verde"). Because it is in Colorado, Mesa Verde is an out-of-state Class I area. The Draft SIP Revision has not even determined whether sources in New Mexico should have been subject to a four-factor analysis based on proximity to Mesa Verde. Any explanation, let alone a reasoned explanation, is lacking. The RHR mandates that NMED must perform such an evaluation.

Under the RHR, states must only address regional haze "in each mandatory Class I Federal area located outside the State *that may be affected by emissions from within the State*."[60] The 2019 EPA Guidance drives this home by providing that states have "the flexibility to use any reasonable method for *quantifying* the impacts of [their] own emissions on out-of-state Class I areas."[61]

But the Draft SIP Revision arbitrarily and capriciously makes only a barebones effort at determining whether New Mexico emissions may affect out-of-state Mesa Verde, and if so, in what quantity.[62] The Draft SIP Revision states that "it is a challenging exercise to estimate with *any* degree of certainty what the quantitative impacts of individual point sources are at Class I Areas, especially when projecting visibility into the future."[63] Despite this challenge and with little technical analysis, the Draft SIP Revision states that "reductions of visibility-impairing pollutant emissions from sources in [New Mexico] can reasonably be expected to improve visibility at Mesa Verde."[64] No rigorous analysis or modeling was undertaken to support these generic statements. Thus, NMED makes contradictory statements that (1) it cannot estimate visibility impacts "with any degree of certainty" and that (2) emissions reductions in New Mexico can be expected to improve visibility in Mesa Verde. This contradiction results in arbitrary and capricious action if there is not rational connection between the facts found and the choice made, and these statements also demonstrate a lack of adequate record support.[65]

Thus, contrary to the EPA 2019 Guidance, NMED did not quantify impacts to Mesa Verde. Without more evidence and analysis in the record, NMED cannot defensibly use proximity to Mesa Verde as a basis for subjecting Blanco A to four-factor analysis. Otherwise, NMED potentially

subjects sources in New Mexico that are not required under the RHR and reaches a decision not based on substantial evidence.

V. Critique of NMED Four-Factor Analysis for Blanco A and Pecos River

In this section, EPNG discusses technical flaws in the four-factor analysis conducted by NMED for Blanco A and Pecos River. NMED selected a cost-effectiveness threshold of $10,000/ton of NOx reduced.[66] EPNG reserves the right to assert that $10,000/ton is arbitrarily and capriciously high as a cost threshold in the forthcoming EIB rulemaking, especially when $7,500 was used as part of the recent Ozone Precursor Rule and where New Mexico is already making considerable progress on visibility impacts in Class I areas, as described in more detail in Section VII.

Under EPNG's more accurate approach for assessing cost-effectiveness of actual emissions reductions, the costs of emissions reduction projects at the Blanco A and Pecos River units selected for emissions limits would have been well over the $10,000/ton threshold selected by NMED. Accordingly, these are material assumptions that NMED should support with a strong technical basis.

EPNG raised these issues in its January 19, 2024 letter to Ms. Kirby Olson of NMED regarding NMED's draft final evaluations for Blanco A, Pecos River, and Washington Ranch.[67] EPNG provides that letter, along with its enclosures, as Attachment 1 to this letter. While the January 19, 2024 letter includes many of the same technical arguments made below, EPNG nevertheless spells the arguments out in further detail again here because NMED's Draft SIP Revision does not address the substantive technical arguments raised nine months ago. If NMED were to review these technical arguments a second time, NMED should find them persuasive and adjust course prior to requesting a hearing with EIB.

A. Overarching Critique: Baseline Actual Emissions

NMED used a potential-to-emit approach for determining baseline emissions as part of the cost-effectiveness analysis for Blanco A and Pecos River because NMED scaled up each unit as if they always operate at 100% load. Consistent section III.C, this approach is not appropriate for Regional Haze Program purposes.

Additionally, from a technical standpoint, EPA already has adequate guidance for how an appropriate measure of emissions baseline can be determined, through the proper application of the Baseline Actual Emissions ("BAE") concept.

In the EPA's Prevention of Significant Deterioration ("PSD") program, "EPA determined that it is fair and reasonable for a source to use a 10-year look back period for calculating '[BAE]' because it allows the source to consider a full business cycle in setting a baseline emissions rate *that*

[66] *Id.* at 102.

[67] *See* Attachment 1 (January 2024 Letter), at 1-8.

represents normal operation of the source for that time period."[68] As indicated in the PSD rules, the data (needed to calculate the actual emission factors, utilization rate, etc.) must adequately describe the operation and associated pollution levels for each emission unit.[69] EPA has taken the same approach to BAE for establishing a source baseline for the purpose of imposing emissions fees under 42 U.S.C. § 7511d(b). Scaling the emission factor to 100% load, as NMED did, is not in conformity with EPA's guidance on establishing BAE because that does not represent "normal operation," especially for natural gas pipeline engines, which can have variable load because of energy demand fluctuations both seasonally and year to year.

B. Blanco A Critique

As explained in this subsection, Units A-11 and A-13 at Blanco A should not be required to undertake significant capital projects as part of any final SIP developed by NMED for the regional haze program because of the costs significantly exceeding $10,000/ton. Even if NMED had authority to require replacement with new natural-gas fired engines (which it does not), NMED's four-factor analysis is deeply flawed because of multiple erroneous assumptions that collectively result in costs below the $10,000/ton threshold that NMED has selected for this process.

Before turning to the specific critiques of the Blanco A analysis, EPNG also briefly notes that NMED denied EPNG's request for an alternative compliance plan ("ACP") under 20.2.50.113 NMAC, which would have included the voluntary retirement of several engines at Blanco A. NMED rejected that request. NMED's denial in part critiqued EPNG's proposed approach for being based on potential to emit. However, NMED's four-factor analysis for both Blanco A and Pecos River is driven by inflated baseline emissions calculations that effectively result in a potential-to-emit approach, demonstrating NMED's arbitrary picking and choosing of baseline calculations. While EPNG proposed voluntarily retiring several units at Blanco A, that overall proposal was in the context of an entire ACP, where EPNG weighed the benefits of displacing costly projects at other facilities against the cost of retirements (which a company may voluntarily consider as part of an ACP under the Ozone Precurser Rule). By no means does it represent a basis, in this different context, for concluding that mandated retirement is legally permissibly or cost-effective. For the reasons explained in Section III.A, NMED may not mandate retirement under the Regional Haze program, which is likely an even more extreme remedy than replacement/electrification.

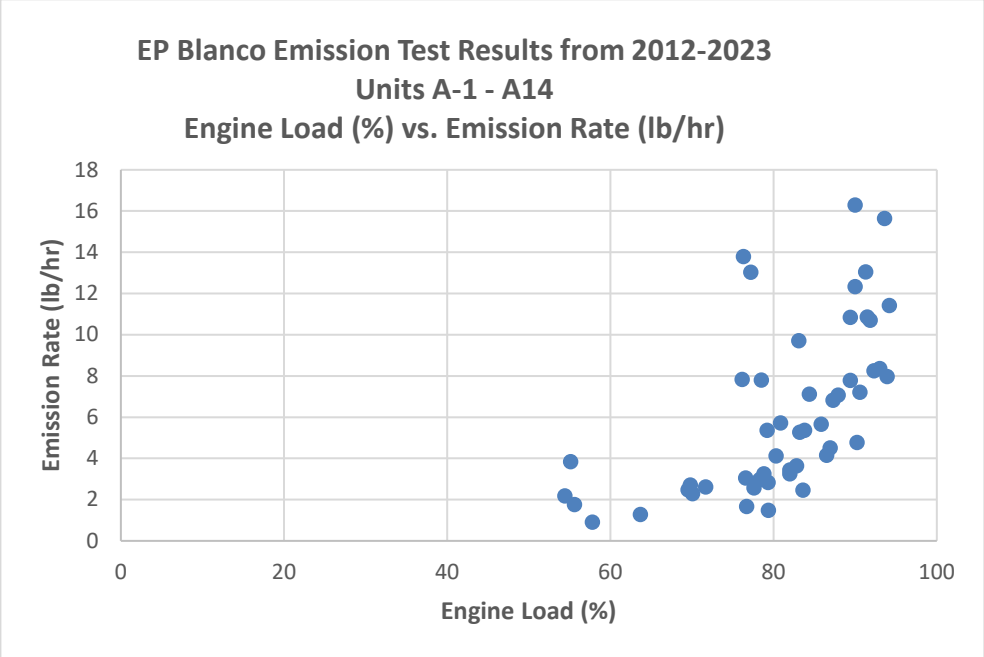
[68] EPA, Guidance on Establishing Emissions Baselines Under Section 185 of the Clean Air Act for Severe and Extreme Ozone Nonattainment Areas that Fail to Attain the 1-Hour Ozone NAAQS by Their Attainment, at 3 (Mar. 21, 2008) (emphasis added), https://www3.epa.gov/ttn/naaqs/aqmguide/collection/cp2/20080321_harnett_emissions_basline_185.pdf; *see also* 40 C.F.R. § 52.21(b)(48).

[69] *See* 40 C.F.R. § 52.21(b)(48)(ii)(e) (Average rate may not "be based on any consecutive 24-month period for which there is inadequate information for determining annual emissions.").

1. Baseline Emissions Calculations



Contrary to EPNG's method, NMED relied on one emission test data (in lb/hr) from the period of 2022-2023 for each of the six units (units A-2, A-3, A-4, A-9, A-11 AND A-13) and then extrapolated it to 100% load to calculate the Baseline Actual Emissions BAE rate (in lb/hr). For the remaining eight units, NMED used the average of the six units' BAE rates to be the BAE rate for these remaining eight units (in lb/hr). This method of calculating BAE is flawed for the following reasons:

- The engines at Blanco A Compressor Station operate at variable loads. It is incorrect to calculate the BAE rate assuming the engines operate at 100% load all the time. In fact, these engines rarely operate at 100% load, if at all, as demonstrated in Table 2, below, which shows average annual operating hours far below 8760 for all units, and as low as 1 and 2 for two others. Additionally, some engines are restricted by the attached compressors, and they cannot physically operate at 100% load.

- NMED averaged six (6) emission test data points (one each from units A-2, A-3, A-4, A-9, A-11 and A-13) from the period of 2022-2023 to establish the BAE rates for all 14 units. As stated by EPA in its BAE guidance, a longer look back period is needed to allow the source to consider a full business cycle in setting a BAE rate that represents normal operation for that time period. One emission test data is not representative of normal operation of the source, and certainly not as averaged across 14 units.

- NMED relied on a linear function of the engine load percent and test data to establish the BAE rate. As demonstrated in Figure 3, the relationship between the test data and engine load percent is not a linear function. The emission rate depends on many variables; engine load percent is one of the many variables.

Figure 3. – Blanco A Emission Test Results

2. O&M Costs

In NMED's draft final control cost evaluations spreadsheet, NMED assumed that the incremental O&M cost of a LEC retrofit is expected to be negligible. EPNG submitted these costs several years ago as part of its initial submissions. Considering the passage of time and the rate of inflation during that time, EPNG obtained up-to-date estimated costs for primary parts associated with the emission controls from the vendor. EPNG updated additional O&M costs to provide in its January Letter, in Enclosure 1 therein. NMED did not update its costs to reflect the recommendations that EPNG provided in the January Letter, but EPNG urges NMED to do so now because failing to use the most updated data that is already available would result in arbitrary and capricious agency action.

3. Allowance for Funds Used During Construction ("AFUDC")

AFUDC is a generally accepted regulatory accounting method under which the cost of financing the capital construction projects incurred during construction phase is added to the cost of the asset. AFUDC offers a way for the entity to recover its pre-operational financing costs. Including AFUDC in construction projects follows the guidelines for accounting in FERC's Uniform System of Accounts. Because a FERC-regulated entity, such as EPNG, does not earn a return on assets under construction to cover financing costs incurred during the construction period, regulators typically allow entities to capitalize an allowance for funds used during construction for future recovery. EPNG requests that NMED incorporate the use of AFUDC in its cost analysis as shown in EPNG's January Letter, in Enclosure 1 therein.

4. Replacement Capital Costs

The Draft SIP Revision's conclusion on the cost-per-ton for replacement of engines at Blanco A is based on a replacement capital cost of $3,043,061 for a replacement engine.[70] This value is too low. If EPNG were to replace the two units with a single engine based on the site rating, this would cost nearly $15 million, which greatly exceeds the Draft SIP Revision's input cost for the replacement ($6,086,122 for two engines).[71] This change would make replacement far less cost-effective and would exceed the $10,000/ton threshold set by NMED.

Additionally, even using many of NMED's same assumptions, replacement still costs more than $10,000/ton because NMED made critical errors for two assumptions. First, NMED used the wrong measure of inflation to scale up costs from an estimate EPNG provided on September 8, 2020. EPNG's estimate calculated the capital cost based on $/hp and the permitted hp of each engine ($3,227/hp x 943 hp), and this cost estimate was in 2020 dollars. Since that time, costs have gone up dramatically. To calculate the replacement cost in 2023 dollars, NMED used the U.S. Bureau of Labor Statistics' CPI inflation calculator. However, per the U.S. Bureau of Labor Statistics website, the calculated data for that inflation measure represents changes in the prices of all goods and services purchased for consumption by urban ***households***. This method is not suitable for estimating changes in capital cost of industrial machinery like natural gas-fired engines. Rather, the appropriate method to calculate the change in replacement capital cost is by using the Chemical Plant Cost Indexes. The published Chemical Plant Cost Indexes for calendar year 2020 and calendar year 2023 are 596.2 and 797.9, respectively, which amounts to an approximate 33.8% increase in capital cost from the 2020 estimate that EPNG provided. This cost increase is consistent with the $/hp increase that EPNG has experienced for natural-gas fired engines over that timeframe.

Second, NMED assumed the other indirect annual cost of the replacement engine is $0.[72] This is contrary to EPA's Control Cost Manual, which suggests that other indirect annual costs should be set at 4% of the total capital investment cost.[73]

By using the Chemical Plant Cost Indexes and with the addition of the other indirect annual cost of the replacement engine, the cost effectiveness in 2023 dollars for the two units at Blanco A

---

[70] Draft SIP Revision, Attachment D, at 211.

[71] *See* Attachment 2 (Blanco A cost data).

[72] Draft SIP Revision, Attachment D, at 211.

[73] EPA, Cost Estimation: Concepts and Methodology, Chapter 2, at 35 (Nov. 2017), https://www.epa.gov/sites/default/files/2017-12/documents/epaccmcostestimationmethodchapter_7thedition_2017.pdf (noting that other indirect costs, such as taxes, insurance, and administrative charges and permitting costs are "usually combined into a single, 4% factor" "from the system total capital investment"); *see also id.* at 13 (noting that administrative charges are an element of fixed annual costs).

(units A-11 and A-13) are $10,501 and $12,895, respectively.[74] Both cost values exceed NMED's cost threshold of $10,000, and these units should therefore not be subject to emissions-rate limits for that reason alone.

Finally, the $/ton values provided above are derived by only changing two of NMED's input assumptions (capital cost inflation and indirect annual costs). Going even further and correcting for NMED's flawed use of inflated baseline emissions and assumed emissions reduction quantities, the $/ton using the proper BAE amounts for A-11 and A-13 (of 21.28 tpy and 14.76 tpy, respectively, as shown in Table 2) results in costs dramatically exceeding $10,000/ton. A-11 and A-13 would have costs of $29,780/ton and $44,210/ton, respectively.[75]

5. Blanco Conclusion

In this last subsection, EPNG sets forth the four-factor analysis that should apply to Blanco A if the errors in NMED's methods and assumptions are corrected.

Because NMED used emission test data from 2022 to 2023 in establishing the BAE rate (in lb/hr), EPNG has expanded the lookback period from 2015-2019 to 2015-2023 when reviewing emission test data for Blanco A Compressor Station. Additionally, consistent with NMED's methodology, EPNG is using the average test results of that period. EPNG recalculated the cost effectiveness using the average emission test data from 2012-2023 by engine and the average actual hours from 2016 to 2021 by engine, as provided in Table 2. Incorporating the above points on emission calculations, the appropriate BAE for Blanco A Compressor Station is as follows:

Table 2. – Blanco A Baseline Actual Emissions

Unit ID	NOx EF (lb/hr) Based on the Average Test Data (2012-2023)	Operating Hours (hr/yr) Based on the Average Annual Hours (2016-2021)	Baseline Actual Emissions (tpy)
A-1	4.47	3120	6.97
A-2	7.52	1312	4.93
A-3	7.09	3277	11.62
A-4	1.58	2275	1.80
A-5	5.66	50	0.14
A-6	6.43	1297	4.17
A-7	6.57	3698	12.15
A-8	7.24	1	0.00
A-9	8.49	2307	9.79
A-10	6.04	2	0.01
A-11	7.02	6065	21.28

[74] *See* Attachment 8, Blanco A Replacement Cost Scenarios (showing calculation methodology).

[75] *See id.* (showing calculation methodology).

A-12	7.83	631	2.47
A-13	5.99	4931	14.76
A-14	1.57	1762	1.38

Furthermore, considering the revised BAE numbers and the O&M, AFUDC, and capital costs, EPNG computes the final cost per ton for Blanco A Compressor Station as follows in Table 3:

Table. 3 – Cost Analyses for Low Emission Combustion at Blanco A

Unit ID	Total Annualized Cost ($) – LEC1	Total Annualized Cost ($) – LEC2	Total Annualized Cost ($) – LEC3	Cost Effectiveness ($/ton) – LEC1	Cost Effectiveness ($/ton) – LEC2	Cost Effectiveness ($/ton) – LEC3
A-1	$367,750	$542,730	$500,805	NA	$145,642	$93,647
A-2	$348,694	$523,674	$481,749	$414,120	$146,677	$113,291
A-3	$369,506	$544,486	$502,561	$264,298	$66,312	$50,691
A-4	$358,753	$533,733	$491,808	NA	NA	$799,896
A-5	$335,504	$510,484	$468,559	NA	$5,730,671	$4,076,698
A-6	$348,531	$522,977	$481,052	$2,782,020	$185,385	$137,641
A-7	$373,680	$548,660	$506,735	$603,980	$66,060	$49,548
A-8	$334,992	$509,972	$468,047	$696,865,144	$347,116,726	$189,556,768
A-9	$359,114	$534,094	$492,169	$138,301	$72,250	$57,287
A-10	$334,999	$509,979	$468,053	NA	$134,345,216	$97,670,156
A-11	$398,509	$573,489	$531,564	$168,247	$38,288	$29,318
A-12	$341,576	$516,556	$474,631	$679,891	$284,838	$221,657
A-13	$386,637	$561,617	$519,692	NA	$58,288	$42,604
A-14	$353,397	$528,377	$486,452	NA	NA	$1,040,483

Note – “NA” no additional emissions reduction beyond baseline will occur so cost effectiveness cannot be calculated.

Detailed calculations are presented in Enclosure 1 to EPNG’s letter of January 19, 2024, which is provided as Attachment 1 here.

EPNG requests that NMED reflect these calculations in its petition for a public hearing with EIB, which would mean removing all Blanco A units from the proposed SIP for exceeding the cost threshold of $10,000/ton.

C. Pecos River Critique

As explained in this subsection, the cost-effectiveness calculations for the installation of SCR at the Pecos River turbines suffers from multiple erroneous assumptions. Once these erroneous assumptions are corrected, the cost-effectiveness calculations for SCR go up from NMED’s assessed $6,000/ton for unit A-02 and $7,000/ton[76] for A-03 to $26,790/ton and $28,369/ton,

[76] Draft SIP Revision, at 112.

respectively. Those corrected values are far in excess of NMED's selected $10,000 cost-effectiveness threshold, and these units should therefore be excluded from any emissions limits under the SIP revision process.

1. Capital Costs

NMED used the EPA SCR workbook to calculate the capital cost to be $2,875,450 for the SCR and $2,975,000 for turbine housing reconfiguration, adjusted to 2023 dollars.[77] In EPNG's comment response to NMED dated January 19, 2024, EPNG relied on the vendor quote of the SCR cost plus costs associated with removing the existing regenerator including all exhaust duct work and installation of a new regenerator equipment.[78] EPNG's estimated capital cost for the SCR is $11,371,394.[79] EPNG's capital estimate is therefore approximately double NMED's, which affects the overall cost-per-ton value. For the reasons discussed below, EPNG's more accurate estimated capital cost of $11,371,394 must be used by NMED.

NMED relied heavily on default values reported in the EPA SCR workbook in its cost estimate calculations. That approach is unreliable and problematic because the SCR workbook is not suited to predict SCR costs for the turbines at Pecos River. The EPA Cost Control Manual section states that the "procedures for estimating costs presented in this report are based on cost data for SCR retrofits *on existing . . . boilers for electric generating units larger than 25 Mwe (approximately 250 MMBtu/hr)*."[80] Thus, the estimate is for boilers—not turbines. That is an entirely different piece of equipment than a turbine. The procedures to estimate capital costs are not directly applicable to sources other than utility and industrial boilers. For example, EPA states that "[c]apital cost equations are provided for both coal-fired and oil- or gas-fired units. The capital cost equations are applicable to coal-fired utility boilers and to oil- or gas-fired utility boilers at facilities with generating capacity greater than or equal to 25 MW. Equations are also provided for coal-fired and oil- or gas-fired industrial boilers with a heat input capacity greater than approximately 250 MMBtu/hr."[81]

---

[77] Draft SIP Revision, Appendix D, at 285.

[78] Attachment 1 (January 19 Letter), at pdf page 36.

[79] *See* Attachment 7, SCR Cost Analysis and Vendor Capital Quote. While the analysis and vendor quote are for turbines at Caprock Compressor Station, the cost of SCR for the turbines at Pecos River is reflected by this estimate as well, given the similar unit and facility design. It should also be noted that the SCR capital cost would only have increased since this time, given the increase in the Chemical Plant Cost Indexes discussed above. This capital cost was used to support the analysis in the January 19, 2024 letter to NMED, but EPNG plans to present an updated vendor estimate for the hearing, should NMED continue proposing SCR at Pecos River.

[80] Control Cost Manual, Chapter 2, Selective Catalytic Reduction, at 6 (June 2019), https://www.epa.gov/sites/default/files/2017-12/documents/scrcostmanualchapter7thedition_2016revisions2017.pdf (emphasis added).

[81] *Id.* at 66.

The capital cost equations listed in the Control Cost Manual include the following applications: (1) coal-fired utility boilers greater than or equal to 25 MW; (2) oil- or gas-fired utility boilers range from 25 MW to 500 MW; (3) coal-fired industrial boilers greater than or equal to 250 MMBtu/hr; (4) oil-fired industrial boilers range from 275 MMBtu/hr and 5,500 MMBtu/hr; (5) gas-fired industrial boilers range from 205 MMBtu/hr and 4,100 MMBtu/hr; and (6) gas-fired industrial boilers greater than 4,100 MMBtu/hr.[82] Note that these are all for ***boiler*** units with capacity of at least 205 MMBtu/hr.

By comparison, the gas-fired turbines at Pecos River each have a maximum heat input of 56.45 MMBtu/hr at site elevation, far below the 205 MMBtu/hr minimum evaluated in the EPA SCR workbook and the EPA Control Cost Manual. And, capital costs do not necessarily scale with unit size because of certain size-invariant capital costs. Furthermore, the EPA Control Cost Manual SCR methodologies are developed for utility and industrial boilers, not turbines. Similarly, none of the cost equations in EPA Control Cost Manual are applicable to the turbines at Pecos River. Last, even if using boiler SCR costs to calculate costs for turbines was an accurate approach (which it is not), the cost formulas in the Cost Control Manual rely on outdated studies from the late 1990s and early 2000s. For all these reasons, NMED must rely on a recent vendor quote to estimate the SCR cost as opposed to relying on EPA SCR workbook to meet minimum standards of rational agency decision-making.

In the EIB's recent 2021 ozone rulemaking (part 20.2.50 NMAC), EPNG provided vendor quotes for SCR modifications at a similar facility in New Mexico, which information was accepted and relied on by NMED and EIB. These same numbers are appropriate for use in the four-factor analysis for Pecos River. Indeed, the 2019 EPA Guidance notes that vendor estimates are preferrable, stating: "We recommend that *states exercise caution before accepting or rejecting controls based on generic cost estimates if adequately documented source-specific estimates are available or can be prepared.*"[83] There is no reason NMED should reject this reliable cost data in the context of Regional Haze.

The 2019 EPA Guidance reflects the fact that source-specific vendor estimates are the best source of information available on a specific cost of control. That is why the 2019 EPA Guidance explains that "states may quantify control costs for particular types of control equipment by using generic cost estimates or estimation algorithms" "when site-specific cost estimates are not available," clearly demonstrating that site-specific estimates are preferrable.[84] Given that the Control Cost Manual's estimates are for large boilers (not turbines), the source-specific estimates are even more preferrable.

NMED's estimate of the cost of SCR installation using the EPA SCR Tool is unreliable for natural gas turbines for the reasons described herein, and NMED should instead use the capital cost $11,371,394.

2. Baseline Emissions Calculations and Cost-Effectiveness Result

While EPNG agrees that the BAE in tons per year ("tpy") calculation should be based on the representative annual operating hours from 2016-2021, EPNG disagrees with NMED on how the baseline NOx hourly emission rate (lb/hr) was established.

In the cost estimate, NMED adjusted turbines' tested NOx emission rates to 100% load assuming a linear relationship between NOx emission rate and percent load.[85] Figure 4, below, shows NMED scaled up Pecos River Unit A-01 June 2023 tested NOx emission rate from 22.4 lb/hr to 39.5 lb/hr assuming a linear relationship between percent load and NOx emission rate.[86] To establish the BAE in the cost estimate, NMED assumed the turbines will operate at 100% load at all time. In doing so, NMED artificially inflated the NOx BAE for these units.

As demonstrated in EPNG's comment response to NMED dated January 19, 2024, the NOx emission rate for turbines does not increase linearly with percent load as shown in Figure 5, below.

Next, while NMED used only the single most recent test data from 2023 to establish the baseline emission rate, EPNG reviewed and used the available test data over the period of 2016-2022. The average test results over this 2016-2021 period, as shown in Table 4, are more appropriate for establishing the BAE, to be consistent with the representative annual operating hours from 2016-2021.

Last, NMED used the ISO rating (expressed at sea level elevation and 59 degrees F) of the turbines to scale up the emission factors. However, that approach does not reflect actual operating conditions, making it less representative and less accurate. Pecos River is located at an elevation of 2,900 feet and has much higher average daytime temperatures. Because of the lower air density and resulting lower mass of air flow, power generated by turbines decreases in warmer temperatures and higher elevations. Based on GE power curves depicting this relationship, when fully loaded, the units will operate at a lower horsepower ("HP") at Pecos River than compared to the sea level ISO rating of 7,150 HP. If emission factors are to be scaled, the appropriate basis for scaling is the unit site rating of 5,650 HP, which is approximately 80% of 7,150 HP. For all the reasons above, EPNG recommends that the use of the inflated NOx emission rate be discarded, as it is not representative of BAE. In fact, NMED's estimated NOx emissions reductions (in tpy) *with* SCR control are higher than the Pecos River reported *annual* NOx emissions from 2016-2021,[87] further demonstrating that NMED's estimated NOx BAE are indeed the equivalent potential emissions.

The alternative BAE and cost effectiveness calculations recommended by EPNG are summarized in Table 4 below. EPNG provided similar substantive comment in its January 2024 letter.

3. SCR Efficiency

NMED cited an SCR efficiency rating of 90% its four-factor analysis calculations.[88] This efficiency rating is not representative and is an overestimate for turbine-driven natural gas transmission compression, including the turbines at Pecos River.

As shown in the EPA Control Cost Manual, Chapter 2, Selective Catalytic Reduction, the optimum temperature for SCR efficiency depends on both the type of catalysts used in the process and the flue gas composition.[89] For the majority of commercial catalysts, the operating temperatures for the SCR process range from 480 to 800 degrees F. Figure 2.2 from the EPA Control Cost Manual's Chapter 2, provided as Figure 6 below, is a graph of the NOx removal efficiency as a function of temperature for a typical metal oxide catalyst. The figure shows that the rate of NOx removal increases with temperature up to a maximum between 700 and 750F. As the temperature increases above 750F, the reaction rate and resulting NOx removal efficiency begin to decrease. The compressors at Pecos River CS typically have an exhaust temperature between 500 and 580F. Per Figure 6, below, from the EPA Control Cost Manual, SCR efficiency in the temperature range for the Pecos River turbines is closer to between 63% and 73%.

In EPNG's initial Four-Factor Analysis Report submitted on November 1, 2019 and the January 19, 2024 comment response to NMED, EPNG cited a 70% reduction efficiency for SCR as a

[88] *See* Draft SIP Revision, at 139 nn.22-23.

[89] Control Cost Manual, Chapter 2, Selective Catalytic Reduction, at 20 (June 2019).

conservative estimate.[90] NMED has not provided a reasoned response or other basis for selecting a 90% reduction efficiency, which is only achieved in a narrow temperature band.

Figure 6. – SCR Control Efficiency Vs. Temperature, EPA Control Cost Manual

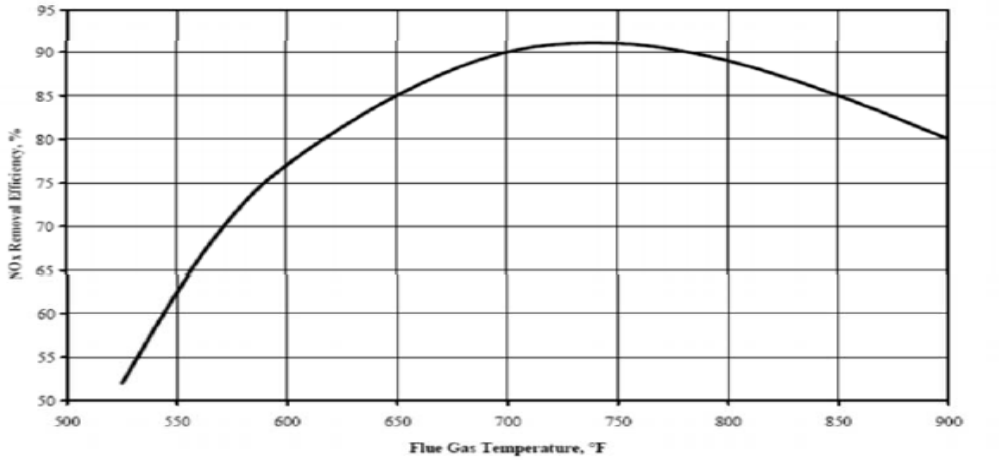

Figure 2.2: NO_x Removal versus Temperature [50]

4. Additional O&M Cost

While NMED relied heavily on outdated default values reported in EPA SCR workbook to estimate the additional O&M Costs,[91] EPNG relied on the more accurate vendor quotes for primary parts associated with the SCR controls. In its January 19, 2024 letter, EPNG updated the additional O&M costs based on vendor quotes received in Q3 2021 for reagent consumption and cost, as well as maintenance, labor, electricity, and catalyst replacement costs.[92] For example, to calculate the annual reagent cost, NMED used the EPA SCR workbook's default value of $0.293/gallon for 29% ammonia solution.[93] The $0.29/gallon ammonia solution cost is based on an outdated average for 2016 per USGS Mineral Commodity Summaries, January 2017.

Contrary to NMED's approach, the EPA SCR workbook notes that the user should use the actual value, if known.[94] The August 2021 quote received by EPNG from an aqueous ammonia vendor

[90] *See* Attachment 1 (January 2024 Letter), at 7-8; Draft SIP Revision, Attachment D, at 2-4 through 2-5.

[91] Draft SIP Revision, Appendix D, at 285.

[92] *See* Attachment 1 (January 2024 Letter), at 7.

[93] EPA Control Cost Manual, Chapter 2, Selective Catalytic Reduction, at 90 n.34.

[94] *See id.* at 90 n.33 ("When estimating direct annual operating costs, the current price of these commodities reflecting the year in which the cost estimate is made should be used. Catalyst and reagent prices can be obtained from vendors.").

was $1.80/gallon.[95] Although EPNG provided this actual value of ammonia solution in the January 19, 2024 response to NMED, NMED failed to update the annual O&M cost.

Further, NMED's approach failed to account for the catalyst cost required for SCR.[96] The catalyst would cost approximately $200,000 and would last for four years, representing an approximate $50,000 annual cost that must be reflected in the cost analysis.[97]

5. Other Indirect Annual Cost – Administrative, Insurance, and Taxes

In NMED's draft final control cost evaluations spreadsheet, Other Indirect Annual Costs ("OAC") are listed at $2,799 per unit. Costs should be slightly higher based on the vendor quote for the capital investment cost. The appropriate costs are shown in Table 5.

Table 5. – Pecos River Units A-01, A-02, A-03 Annual Administrative Costs

Cost type	Unit A-01	Unit A-02	Unit A-03
Administrative Costs	$3,059	$3,310	$3,310

These costs were incorporated into the detailed calculations in the January 2024 letter, in Enclosure 2A.[98] NMED did not incorporate these costs in its four-factor analysis for the Pecos River units.[99] These costs must be included.

6. Pecos River Emission-Rate Limits

In the proposed addition to 20.2.68 NMAC, NMED proposes NOx emission-rates limits of 3.64 lb/hr for Pecos River Unit A-02 and 4.05 lb/hr for Unit A-03. These limits are based on the assumption that SCR will achieve a 90% reduction efficiency. However, consistent with the discussion in Section V.B.3., above, that emission-rate limit is based on the optimal temperature range for SCR efficiency and not the actual exhaust gas temperature for the two Pecos River units. It is therefore not realistic, and the final rate should not be set at a value Pecos River cannot achieve. The CAA contemplates that requirements imposed on sources will be feasible to achieve. Indeed, throughout the Draft SIP Revision, NMED analyzed feasibility of controls, demonstrating feasibility is a critical consideration. As discussed above, a 90% reduction efficiency is infeasible at the Pecos River units and must be eliminated from consideration.

---

[95] *See* Attachment 3 (SCR Reagent Vendor Quote) (while the per-gallon cost is $1.35, shipping costs are $2,700 per 6,000-gallon load, equating to $0.45/gallon, for a total cost of $1.80/gallon).

[96] *See* Draft SIP Revision, Appendix D, at 285.

[97] *See* Attachment 1, at pdf page 30 (showing annual catalyst replacement costs of $42,912, $51,371, and $45,601 for Units A-01, A-02, and A-03, respectively).

[98] *See id.*

[99] *See* Draft SIP Revision, Attachment C, at 57 (showing cost inputs from EPNG that NMED adopted); *id.* Attachment D, at 285 (showing lower administrative costs than those shown here).

7. Pecos River Alternative Emissions Standard Under 20.2.50.113 NMAC

Pecos River Units A-01, A-02, and A-03 are all part of an approved Alternative Emissions Standard ("AES") under the New Mexico Ozone Precursor Rule, 20.2.50.113 NMAC, which was conditionally approved on June 26, 2023 by the AQB.[100] These units qualified for an AES based on economic infeasibility because of their high cost-per-ton of emissions reductions. The cost-per-ton assessed for units A-02 and A-03 in the request for the AES was $22,517 and $26,527, respectively, based on actual emissions, and $11,097 for both based on potential to emit.[101] All these values exceed the $10,000/ton threshold selected by NMED.

NMED's approval, through AQB, of the AES cost assessment just last year represents, per the Ozone Precursor Rule, a finding that "it is not . . . economically feasible for the individual engine or turbine to achieve the emissions standards."[102] NMED should not deviate from this finding now, as doing so would be "arbitrary, capricious or an abuse of discretion" or "not supported by substantial evidence in the record."[103]

8. Ammonia Use Required for SCR Presents Its Own Environmental Drawbacks.

As noted above, one of the four factors in the four-factor analysis requires consideration of other "environmental impacts of compliance."[104] This is notable because SCR presents its own *additional* environmental issues.

First, and as discussed above, an SCR system must maintain precise operational parameters to generate as complete of a reaction as possible. And even when these parameters are closely controlled, some level of ammonia does not react and joins the exhaust stream.[105] This is referred to as "ammonia slip."[106] Ammonia is itself an unhealthy gas to inhale for humans and animals, and ammonia can react with other atmospheric constituents that turn into other harmful

---

[100] *See* Attachment 4, AQB Letter Conditionally Approving AES (June 26, 2023). The approval was conditional "to the extent that, when any turbine is permanently replaced, the replacement turbine shall be considered 'new' pursuant to the rule." *Id.* at 1.

[101] *See* Attachment 5, Barr, New Mexico Alternative Emission Standards Proposal (Rev. April 2023), at 16 tbl. 4-1. The analysis for the AES used some different assumptions than EPNG's four-factor analysis, which are detailed in Attachment 6, Summary of Assumptions. For example, the AES used a 3.25% interest rate and a 25-year useful life, as opposed to an 8.53% interest rate and 20-year useful life. These differences contribute to EPNG's cost-per-ton estimate for the AES being lower than its estimate for the four-factor analysis.

[106] Control Cost Manual, Chapter 2, Selective Catalytic Reduction, at 23.

substances, like ammonium sulfates.[107] Further, ammonia plays a role in $PM_{2.5}$ formation, which itself has the potential to impact visibility.[108] Thus, ammonia slip itself is an environmental impact that should be considered under the four-factor analysis.

Second, SCR requires the continuous use of an ammonia solution to reduce NOx in the exhaust gas stream.[109] The amount of solution required varies by a unit's annual usage hours. Potentially thousands of gallons per year would be shipped to the facility via tanker trucks over local roads, and storage onsite in a large tanks. The ammonia solution requires safe storage, handling and disposal in compliance with state and federal regulation to avoid harm to the environment. These requirements include those under the Community Planning and Right-to-Know Act (including reporting obligations) and the Comprehensive Environmental Response, Compensation, and Liability Act, along with additional state-level requirements.[110] In addition to environmental requirements, the facility would be required to comply with applicable process safety management requirements applicable to chemicals such as ammonia.[111] While EPNG would, of course, aim to responsibly handle such materials consistent with applicable laws, it is not within the Company's practice or protocol to unnecessarily increase the frequency of handling chemicals like ammonia. Additionally, EPNG has no control over the safety of ammonia solution and byproducts thereof when in shipment.

Despite these environmental impacts, NMED's evaluation of SCR states that there are no significant energy and environmental impacts from requiring SCR installation at Pecos River.[112] NMED has therefore failed to consider an important aspect of the problem at this stage, which would result in arbitrary and capricious action if left uncorrected and if the final SIP revision requires SCR at Pecos River.[113] And even if a consideration of ammonia slip is still offered, an

[107] *Id.* at 23-24 (noting ammonia in the flue gas "causes a number of problems . . ., including health effects, visibility of the stack effluent").

[108] *See* Wu et al., *$PM_{2.5}$ Pollution is Substantially Affected by Ammonia Emissions in China*, Environmental Pollution (Aug. 20, 2016), https://pubmed.ncbi.nlm.nih.gov/27552041/.

[109] *See* Attachment 7, SCR Cost Analysis and Vendor Capital Quote.

[110] *See, e.g.*, 40 C.F.R. Part 355 Appendix A (listing ammonia as "extremely hazardous substance" under Emergency Planning and Community Right-to-Know Act); 40 C.F.R. § 302.4 (listing ammonia as hazardous substance under reporting requirements in Comprehensive Environmental Response, Compensation, and Liability Act). Under the thresholds listed in these regulations, the amount of ammonia stored onsite would likely require emergency planning, but EPNG has not fully reviewed the extent of the regulatory requirements and their potential application.

[111] *See* 29 C.F.R. § 1910.119 (Occupational Safety and Health Administration (OSHA) process safety management regulations applying provisions to ammonia solution); 40 C.F.R. Part 68 (EPA risk management program modeled after OSHA's program).

[112] *See* Draft SIP Revision, at 112-13 (table showing "none" on the column for "Energy & Non-Air Quality Impacts" for SCR).

[113] *See Bernalillo Cnty. Health Care Grp.*, 2014-NMSC-008, ¶ 9 (Agency action is arbitrary and capricious if the agency failed to consider an important aspect of the problem or offered an explanation that runs counter to the evidence.).

agency must still reasonably explain why environmental concerns about ammonia usage do not outweigh the other factors.

9. Pecos River Conclusion

In this last subsection, EPNG sets forth the cost-effectiveness values that should apply to Pecos River if the errors in NMED's methods and assumptions are corrected.

Considering the above points, the cost-per-ton values for NOx emissions reduced for Pecos River units A-01, A-02, and A-03 should be: $37,750, $26,790, and $28,369, respectively. Based on these values, none of the Pecos River units should be subject to any emissions limits under the SIP Revision. EPNG requests that NMED reflect this fact in its petition for a public hearing with EIB to avoid promulgating an arbitrary and capricious rule based on demonstrably false assumptions.

VI. Washington Ranch Four Factor Analysis

While EPNG does not agree with all the methodological choices (or consideration of replacement) used for the Washington Ranch four factor analysis, EPNG does agree with the bottom-line conclusion that the cost of emissions reductions would exceed $10,000/ton. Accordingly, EPNG agrees that no emissions limits should be imposed on units at Washington Ranch. Notably, if NMED had used proper assumptions for Washington Ranch, then the cost of emissions reductions therefrom would be even higher than NMED assessed.

However, EPNG does not oppose an emissions rate limit of 3.0 g/hp-hr based on *existing* controls at Washington Ranch. And no additional controls should be required for Washington Ranch, consistent with the results of NMED's cost-effectiveness analysis for those units.[114]

VII. NMED Should Consider Visibility Improvements In Deciding Whether to Impose Emissions Limits.

Last, even if it was reasonable and consistent with EPA guidance to subject Blanco A and Pecos River to a four-factor analysis (which it was not), final emissions limits do not need to be selected for these sources, considering visibility conditions and projected improvements compared with the costs of the controls (even using the faulty $/ton values that NMED assessed).

As the 2019 EPA Guidance explains, there are additional factors that states may consider in determining whether to ultimately impose emissions controls under the RHR to make reasonable progress toward reaching natural visibility conditions. Quite naturally, visibility conditions is one such factor: "[B]ecause the goal of the regional haze program is to improve visibility, it is

[114] Indeed, the cost-effectiveness evaluation for the units at Washington Ranch suffers from some of the same errors as those described above for Blanco A and Washington Ranch. Even with those errors, NMED's analysis still shows that the units at Washington Ranch have no cost-effective incremental control options, further confirming that additional controls are not reasonable at that facility.

reasonable for a state to consider whether and by how much an emission control measure would help achieve that goal."[115] In the 2019 EPA Guidance, EPA therefore "interpret[ed] the CAA and the Regional Haze Rule to allow a state reasonable discretion to consider the anticipated visibility benefits of an emission control measure along with the other [four] factors when determining whether a measure is necessary to make reasonable progress."[116] The 2021 Clarification confirms this interpretation, noting: "Another potentially reasonable approach might be for a state that identifies cost-effective new controls at a multitude of sources to choose to require controls at only a subset of those sources that constitute the vast majority of the visibility benefit."[117]

In considering actual visibility benefits against costs of controls, controls should not be required at Blanco A or Pecos River. As the Draft SIP Revision notes, all but one Class I area in New Mexico is projected to be below the uniform rate of progress glidepath toward natural visibility conditions by 2064.[118] The one exception is the Salt Creek Wilderness Area, but that is not the closest Class I area for either Blanco A or Pecos River. Thus, consistent with the 2021 Clarification, NMED can simply require controls "at only a subset of those sources that constitute the vast majority of the visibility benefit."[119]

Further supporting this position, as explained *supra* note 59, Blanco A and Pecos River are relatively small emissions sources of NOx and SO2 combined, and their emissions of SO2 are *de minimis*. Given the predominance of ammonium sulfate as the aerosol species with the greatest visibility impacts at all New Mexico Class I areas and at Mesa Verde, reductions of NOx emissions from Blanco A and Pecos River are not required to make reasonable progress. And even accepting NMED's (erroneous) cost-per-ton estimates for these sources, they are still in the upper range of the threshold that NMED identified for determining cost-effectiveness. That $10,000/ton threshold can be balanced against the actual expected visibility benefits that would occur.

Accordingly, after considering projected visibility conditions in New Mexico, emissions limits on Units A11 and A13 at Blanco A and Units A-02 and A-03 at Pecos River Blanco A are not required to make reasonable progress under the RHR.

[117] 2021 Clarification, at 13. *See also id.* ("While the CAA lists the four reasonable progress factors, it is silent as to whether states or the EPA may consider other, additional factors. This final rule neither requires nor prohibits states from considering visibility when making reasonable progress determinations. . . . However, a state that elects to consider an additional factor such as visibility benefit must consider it in a reasonable way that does not undermine or nullify the role of the four statutory factors in determining what controls are necessary to make reasonable progress." (citing Response to Comments on Protection of Visibility, at 186)).

[118] Draft SIP Revision, at 169 ("The future year visibility on the MID at each Class I Area in New Mexico is projected to be below the URP glidepath adjusted for international emissions and wildland prescribed fire, except for Salt Creek Wilderness area.")

[119] 2021 Clarification, at 13.

VIII. Conclusion

Based on the arguments presented herein, NMED should not impose any emissions rate limits on EPNG's units at Blanco A or Pecos River. For Washington Ranch, EPNG does not oppose the 3.0 g/hp-hr emission rate limit proposed for Units 1 and 2 based on existing controls, but no additional controls should be required for those units, consistent with NMED's cost-effectiveness evaluation. EPNG therefore requests that NMED not propose any emission limits for the units at Blanco A and Pecos River in its petition for a public hearing with EIB.

RE: Draft Final Evaluations, EPA's Regional Haze Rule, El Paso Natural Gas Company, LLC's Blanco Compressor Station A, Pecos River Compressor Station, and Washington Ranch Storage Facility

Dear Ms. Olson:

El Paso Natural Gas Company, L.L.C. (EPNG) appreciates this opportunity to review and comment on the draft final control cost evaluations for the Regional Haze Second Planning Period provided by the New Mexico Environment Department (NMED) for the Blanco Compressor Station A, Pecos River Compressor Station, and Washington Ranch Storage Facility. Below, we provide comments unique to each facility followed by some general comments.

I. Washington Ranch Storage

Other than the common comments provided above, no additional comments are submitted as NMED has agreed that LEC is already installed, and the evaluation demonstrated that electrification and replacement are not cost effective by any metric.

II. Blanco A Compressor Station

A. Emissions Calculations

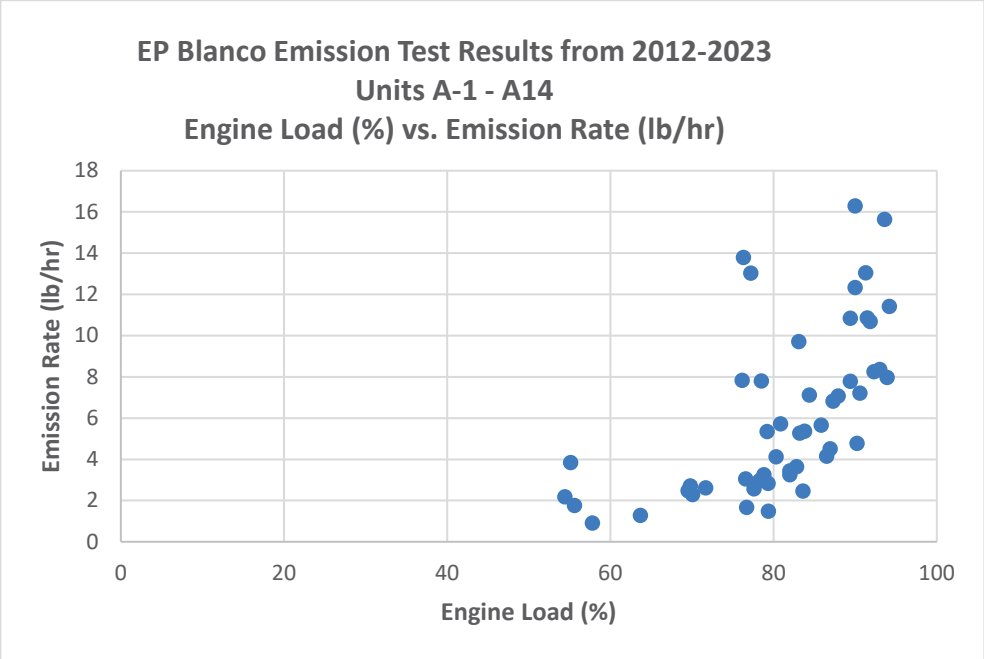
As a threshold matter, EPNG wishes to clarify that regarding the use of potential emissions versus actual emissions, NMED is directed to use actual emissions when calculating cost-effectiveness of controls, consistent with EPA's Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (at 17) where EPA provided as follows:

> Generally, we recommend that a reasonably projected actual level of source operation in 2028 be used to estimate 2028 actual emissions for purposes of selecting sources for control measure analysis. Source operation during a historical period can inform this projection, but temporary factors that suppressed or bolstered the level of operation in the historical period should be considered, along with factors that indicate a likely increase or decrease in operation.

This is also consistent with the approach for Best Available Retrofit Technology (BART). EPA provided in its BART guidelines as follows: "The baseline emissions rate should represent a realistic depiction of anticipated annual emissions for the source. In general, for the existing

sources subject to BART, you will estimate the anticipated annual emissions based upon actual emissions from a baseline period." 40 C.F.R. Part 50, Appendix Y (Step 4.d.1.).

With regard to how the baseline emissions are calculated, the Clean Air Act (CAA) provides EPA may issue guidance on the calculation of the "baseline amount" as the lower of the average actuals or average allowable over a period of more than one year. Under the presumptive calculation method provided in the CAA, the baseline amount would be considered representative of the source's normal operating conditions. In the PSD rule, "Baseline Actual Emissions" is defined as the average rate of emissions, in tons per year, from a source that actually occurred and is representative of sources in existence on the applicable baseline date. EPA's definition of "baseline actual emissions" enables a source to calculate its baseline rate using the actual operational data from a period other than the period immediately preceding a proposed change in order to select a period of time that is more representative of the source's normal operation. The longer look back period allows the source to consider a full business cycle in setting a baseline actual emission rate that represents normal operation of the source for that time period.



Contrary to EPNG's method, NMED relied on one emission test data (in lb/hr) from the period of 2022-2023 for each of the six units (units A-2, A-3, A-4, A-9, A-11 AND A-13) and then extrapolated it to 100% load to calculate the BAE rate (in lb/hr). For the remaining eight units, NMED used the average of the six units' BAE rates to be the BAE rate for these remaining eight units (in lb/hr). This method of calculating BAE is flawed for the following reasons:

1. The engines at Blanco A Compressor Station operate at variable loads. It is incorrect to calculate the BAE rate assuming the engines operate at 100% load all the time. In fact, these engines rarely operate at 100% load, if at all. Additionally, some engines are restricted by the attached compressors, and they cannot physically operate at 100% load.

2. NMED used six (6) emission test data (one each from units A-2, A-3, A-4, A-9, A-11 and A-13) from the period of 2022-2023 to establish the BAE rates for all 14 units. As stated by EPA, to establish the BAE, a longer look back period is needed to allow the source to consider a full business cycle in setting a BAE rate that represents normal operation for that time period. One emission test data is not representative of normal operation of the source.

3. All units except for units A-8 and A-10 have been tested from the period of 2015-2023. Units A-8 and A-10 were tested in 2012. The BAE rate (in lb/hr) should be based on the actual tested data for each individual unit, not the average test data of some other six units.

4. NMED relied on a linear function of the engine load percent and test data to establish the BAE rate. As demonstrated in the following chart, the relationship between the test data and engine load percent is not a linear function. Emission rate depends on many variables; engine load percent is one of the many variables.

B. Additional O&M Cost

In NMED's draft final control cost evaluations spreadsheet, NMED assumed that the incremental O&M cost of an LEC retrofit is expected to be negligible. EPNG submitted these costs several years ago as part of its initial submissions. Considering the passage of time and the rate of inflation during that time, EPNG obtained up-to-date estimated costs for primary parts associated with the emission controls from the vendor. The additional O&M costs have been updated using the up-to-date vendor estimate and are presented in Enclosure 1.

C. Allowance for Funds Used During Construction (AFUDC)

AFUDC is a generally accepted regulatory accounting method under which the cost of financing the capital construction projects incurred during construction phase is added to the cost of the asset. AFUDC offers a way for the entity to recover its pre-operational financing costs. Including AFUDC in construction projects follows the guidelines for accounting in the Federal Energy Regulatory Commission's Uniform System of Accounts (FERC USOA). Because a FERC regulated entity, such as EPNG, does not earn a return on assets under construction to cover financing costs incurred during the construction period, regulators typically allow entities to capitalize an allowance for funds used during construction for future recovery. EPNG requests that NMED allow the use of AFUDC in its analysis as shown in Enclosure 1.

D. Blanco Conclusion

Because NMED used emission test data from 2022 to 2023 in establishing the BAE rate (in lb/hr), EPNG has expanded the look back period from 2015-2019 to 2015-2023 when reviewing emission test data for Blanco A Compressor Station. Additionally, consistent with NMED's methodology, EPNG is using the average test results of that period. EPNG recalculated the cost effectiveness using the average emission test data from 2012-2023 by engine and the average

actual hours from 2016 to 2021 by engine. Incorporating the above points on emission calculations, EPNG believes that the appropriate BAE for Blanco A Compressor Station is as follows:

Baseline Actual Emissions

Unit ID	NOx EF (lb/hr) Based on the Average Test Data (2012-2023)	Operating Hours (hr/yr) Based on the Average Annual Hours (2016-2021)	Baseline Actual Emissions (tpy)
A-1	4.47	3120	6.97
A-2	7.52	1312	4.93
A-3	7.09	3277	11.62
A-4	1.58	2275	1.80
A-5	5.66	50	0.14
A-6	6.43	1297	4.17
A-7	6.57	3698	12.15
A-8	7.24	1	0.00
A-9	8.49	2307	9.79
A-10	6.04	2	0.01
A-11	7.02	6065	21.28
A-12	7.83	631	2.47
A-13	5.99	4931	14.76
A-14	1.57	1762	1.38

Furthermore, considering the revised BAE numbers and the cost issues of sections 2 and 3 above, EPNG believes the final cost per ton for Blanco A Compressor Station is as follows:

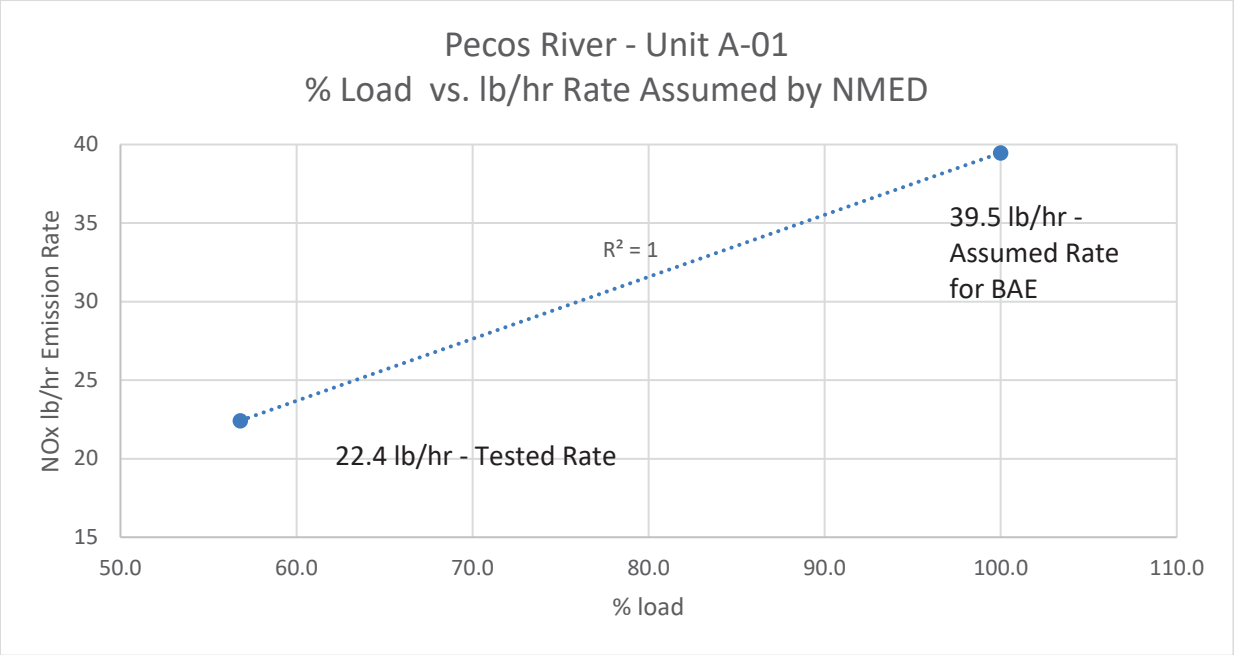
Cost Analyses for Low Emission Combustion

Unit ID	Total Annualized Cost ($) – LEC1	Total Annualized Cost ($) – LEC2	Total Annualized Cost ($) – LEC3	Cost Effectiveness ($/ton) – LEC1	Cost Effectiveness ($/ton) – LEC2	Cost Effectiveness ($/ton) – LEC3
A-1	$367,750	$542,730	$500,805	NA	$145,642	$93,647
A-2	$348,694	$523,674	$481,749	$414,120	$146,677	$113,291
A-3	$369,506	$544,486	$502,561	$264,298	$66,312	$50,691
A-4	$358,753	$533,733	$491,808	NA	NA	$799,896
A-5	$335,504	$510,484	$468,559	NA	$5,730,671	$4,076,698
A-6	$348,531	$522,977	$481,052	$2,782,020	$185,385	$137,641
A-7	$373,680	$548,660	$506,735	$603,980	$66,060	$49,548
A-8	$334,992	$509,972	$468,047	$696,865,144	$347,116,726	$189,556,768
A-9	$359,114	$534,094	$492,169	$138,301	$72,250	$57,287
A-10	$334,999	$509,979	$468,053	NA	$134,345,216	$97,670,156
A-11	$398,509	$573,489	$531,564	$168,247	$38,288	$29,318
A-12	$341,576	$516,556	$474,631	$679,891	$284,838	$221,657
A-13	$386,637	$561,617	$519,692	NA	$58,288	$42,604
A-14	$353,397	$528,377	$486,452	NA	NA	$1,040,483

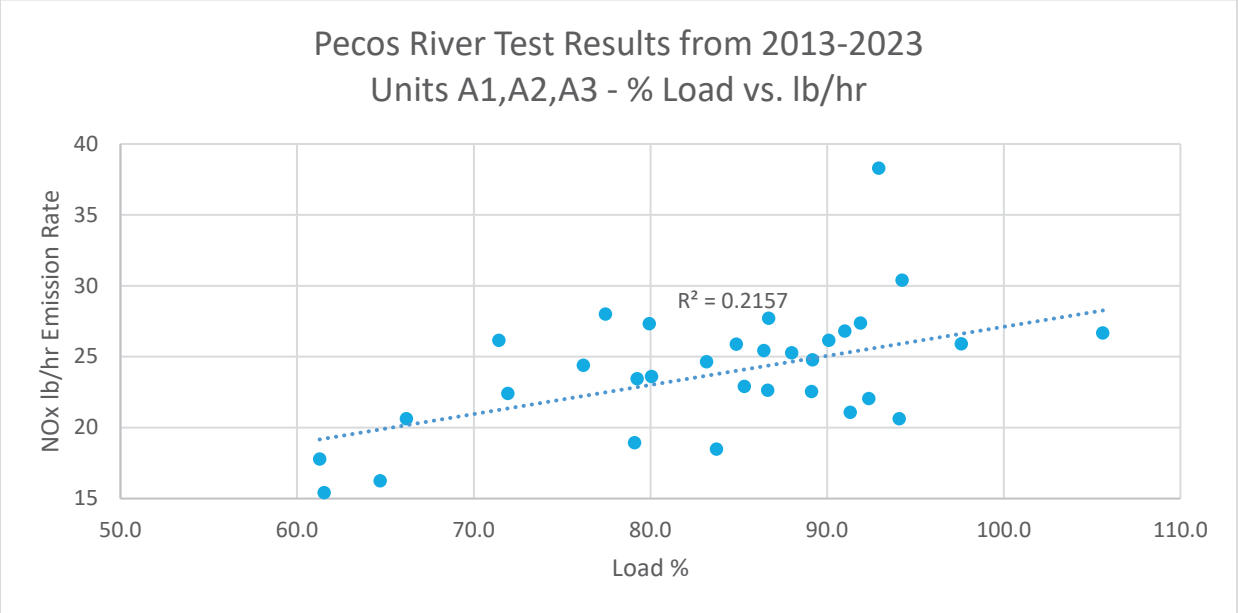
Note – "NA" no additional emissions reduction beyond baseline will occur so cost effectiveness cannot be calculated.

Detailed calculations are presented in Enclosure 1.

III. Pecos River Compressor Station



A. Emission Calculations



NMED followed substantially similar methodology for calculating emission factors at Pecos River Compressor Station as was done for Blanco A Compressor Station. Similarly, for the reasons stated in the Blanco A Compressor station response, EPNG disagrees with NMED's methodology. Additionally, for Pecos River Compression Station, EPNG notes:

1. The NOx emission rate for turbines does not increase linearly with load condition. As can be seen on the charts below, based on 10 years of emission test results, the observed R^2 is in the range of 0.22. A linear relationship would result in an R^2 value of 1. Thus, the existing correlation is considered insufficient to scale emission factors linearly with load; EPNG therefore recommends that the use of the inflated emission rate be discarded, as it is not representative of actual emissions.

2. While NMED used only the single most recent test data and EPNG believes that it is more appropriate to use the average test result over the 10-year period of 2013-2023, those two values are essentially the same and make no difference to the final results.

3. NMED used the ISO rating of the turbines to scale up the emission factors. For reasons stated above, EPNG believes that scaling emission factors is inappropriate. Additionally, NMED used the turbine's ISO rating expressed at sea level elevation, and 59 °F. Pecos River Compressor Station is located at an elevation of 2,900 feet and has much higher average daytime temperatures. Power generated by turbines decreases in warmer temperatures and higher elevations, due to less density and lower resulting mass of air flowing through the turbine. Based on GE power curves depicting this relationship, when fully loaded, the units will operate at a lower HP at the location than compared to the sea level ISO rating of 7,150. If emission factors are to be scaled, EPNG believes that the appropriate basis is the unit site rating of 5,650 HP.

B. SCR Efficiency

NMED cited an SCR efficiency rating of 90% in the calculations as "[C]onsistent with EPA and industry documentation". EPNG believes that not to be the case specifically for turbine driven natural gas transmission compression. The compressors at Pecos River Compressor station typically have an exhaust temperature of around 550F – 580F. Per the chart below from the June 2019 versions of the EPA Control Cost Manual, Section 4, Chapter 2 – Selective Catalytic

Reduction, Page 20[1], SCR efficiency in this temperature range is closer to 63%-73%. In EPNG's submittal we cited a 70% reduction efficiency as a conservative estimate.

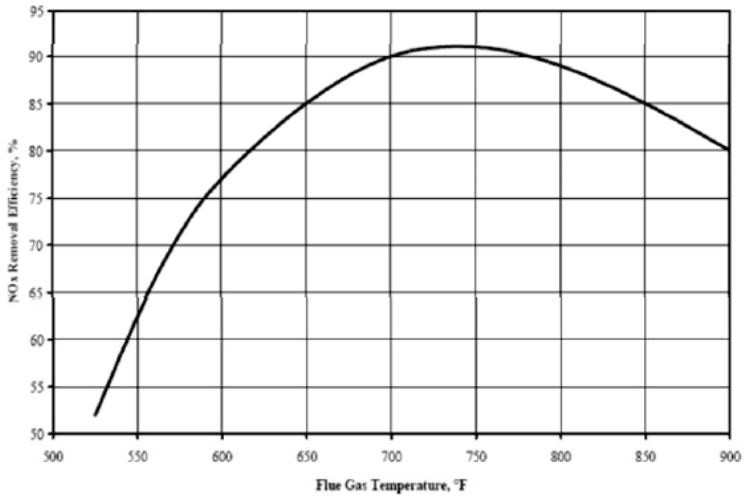


Figure 2.2: NO_x Removal versus Temperature [50]

C. Additional O&M Cost

EPNG submitted the O&M costs several years ago as part of its initial submissions. Considering the passage of time and the rate of inflation during that time, EPNG obtained up-to-date estimated costs for primary parts associated with the emission controls from the vendor. These updated O&M costs are also consistent with what EPNG submitted, and NMED relied on, for similar stations as part of the NM Ozone Rulemaking (20.2.50 NMAC). Accordingly, below, O&M costs are based on vendor quotes received in July of 2021 for reagent consumption, as well as maintenance, labor, electricity, and catalyst replacement costs.

Cost type	Unit A-01	Unit A-02	Unit A-03
Annual Maintenance	$35,905	$56,857	$56,857
Annual Operating Labor	$87,599	$87,600	$87,600
Annual Reagent	$90,114	$107,879	$95,762
Annual Electricity	$17,405	$20,836	$18,496
Annual Catalyst Replacement	$42,912	$51,371	$45,601
Direct Annual Cost	**$273,935**	**$324,543**	**$304,316**

These costs have been incorporated into the detailed calculations in Enclosure 2A.

D. Other Indirect Annual Cost - Administrative, Insurance, and Taxes

In NMED's draft final control cost evaluations spreadsheet, Other Indirect Annual Costs (OAC) are listed at $2,799 per unit. EPNG believes that costs should be slightly higher based on EPA

[1] https://www.epa.gov/sites/default/files/2017-12/documents/scrcostmanualchapter7thedition_2016revisions2017.pdf

recommended percentages of annual maintenance and operating costs. The appropriate costs are as follows:

Cost type	Unit A-01	Unit A-02	Unit A-03
Administrative Costs	$3,059	$3,310	$3,310

These costs have been incorporated into the detailed calculations in Enclosure 2A.

E. Capital Recovery Costs

In the part 20.2.50 NMAC 2021 rulemaking, EPNG provided vendor quotes for SCR modifications at a similar facility in New Mexico, which information was accepted and relied on by NMED. These same numbers are appropriate for use in the FFA for Pecos River Compressor Station. Based on these more up-to-date vendor quotes, and utilizing EPNG's documented, actual8.53% interest rate provided to NMED, total annual costs (including annualized capital recovery costs, direct annual costs, and administrative costs) are updated as follows:

Cost type	Unit A-01	Unit A-02	Unit A-03
Capital Recovery Costs	$760,473	$1,204,253	$1,204,253
Direct Annual Cost	$273,935	$324,543	$304,316
Administrative Costs	$3,059	$3,310	$3,310
Total Annual Cost (TAC)	**$1,037,467**	**$1,532,106**	**$1,511,879**

These costs have been incorporated into the detailed calculations in Enclosure 2A.

F. Pecos River Conclusion

Considering the above points 1 - 2, EPNG believes that the appropriate BAE for Pecos River Compressor Station should be based on NMED lb/hr rates cited in recent test results, which align with test averages for unit performance, as follows:

Unit	A-01	A-02	A-03
Average Hours (2016-2021)	3553	6378	5537
NOx (lb/hr)	22.4	25.3	24.4
BAE (ton/year)	39.8	80.7	67.5

Furthermore, considering the revised BAE numbers and all the information above, EPNG believes the final cost per ton for Pecos River Compressor Station is as follows:

Unit	A-01	A-02	A-03
NOx Control Efficiency (%)	70%	70%	70%
Estimated Reductions (ton/yr)	27.9	56.5	47.3
TAC ($/yr)	$1,037,467	$1,532,106	$1,511,879
2023$ Cost Effectiveness ($/ton)	**$37,248**	**$27,126**	**$31,976**

Detailed calculations are presented in Enclosure 2B.

IV. General Comments

EPNG wishes to clarify the appropriateness of various statements and considerations mentioned by NMED.

A. Electrification/Replacement

First, EPNG respectfully disagrees with NMED's consideration of replacement or electrification as an option for NOx emissions reductions. The Regional Haze Rule only requires analysis and application of *retrofit* technology (i.e., emissions control equipment) for existing engines. Neither replacement nor electrification is authorized by the Regional Haze provision or the implementing regulations, and units cannot be forced to undertake such a fundamental change to their facilities.

A fundamental principle of the Clean Air Act is that Congress did not intend to eliminate emissions sources; rather, Congress simply intended for *control* of emissions sources—*e.g.*, through scrubbers, capture devices, or other methods that reduce emissions of a pollutant without affecting the fundamental engineering design of the source. *See, e.g.*, *West Virginia v. EPA*, 142 S. Ct. 2587, 2612 n.3 (2022) (EPA may not "direct existing sources to effectively cease to exist" under 42 U.S.C. § 7411(d)); *Helping Hand Tools v. EPA*, 848 F.3d 1185, 1194 (9th Cir. 2016) (in determining "best available control technology" EPA may not "redefine the source" in a way that would disrupt the basic business purpose of the facility, which business purpose includes availability and use of on-site fuel). Congress took this approach in part to ensure that achieving clean air goals did not unnecessarily disrupt economic activity. *See Sierra Club v. Costle*, 657 F.2d 298, 331 (D.C. Cir. 1981) (noting legislative history of Clean Air Act showed Congress did not want to impede long term growth or inhibit technological innovation).

The Clean Air Act's regional haze provision is no different. For example, in the preamble to the 2017 Regional Haze Rule Amendment, EPA explained that "states must evaluate the control measures that are necessary to make reasonable progress using the four factors and develop their long-term strategies before they can predict future emissions reductions and conduct the regional-scale modeling used to establish [reasonable progress goals]." 82 Fed. Reg. 3,078, 3,090-91 (Jan. 10, 2017) (emphasis added). Thus, EPA only contemplates that "controls" should be used to meet reasonable progress goals. Controls are defined in other areas of the Clean Air Act as "application of production processes and available methods, systems, and techniques, including fuel cleaning, clean fuels, or treatment or innovative fuel combustion techniques for control of each such pollutant." 42 U.S.C. § 7479(3). This is further confirmed by the text of the relevant regulatory provision in the Regional Haze Rule, which refers to "installation" of a "control":

> In considering [one of the four statutory reasonable progress factors], if the State concludes that a *control measure cannot reasonably be installed* and become operational until after the end of the implementation period, the State may not consider this fact in determining whether the measure is necessary to make reasonable progress.

40 C.F.R. § 51.308(f)(2)(i) (emphasis added). The discussion of *installing* a *control* suggests reference to an *existing* emissions unit that will remain in place and be modified, not the wholesale replacement of the emissions unit. This is basic logic: a control has to be installed on *something*. If an emissions unit is removed, then there is nothing on which to install the control.

EPA's 2019 guidance interpreting the 2017 Regional Haze Rule confirms and drives home EPA's intention that "control" will be used to achieve reasonable progress, and that replacement of existing sources with other technology is not included. EPA provided the following list of "control measures that states may consider":

1. Emission reductions through improved work practices.

2. Retrofits for sources with no existing controls.

3. Upgrades or replacements for existing, less effective controls.

4. Year-round operation of existing controls.

5. Fuel mix with inherently lower SO2, NOx, and/or PM emissions. States may also determine that it is unreasonable to consider some fuel-use changes because they would be too fundamental to the operation and design of a source.

6. Operating restrictions on hours, fuel input, or product output to reduce emissions.

7. Energy efficiency and renewable energy measures that could be applied elsewhere in a state to reduce emissions from EGUs.

8. Basic smoke management practices and smoke management programs for agricultural or wildland prescribed fires.

EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period 29-30 (Aug. 20, 2019) (footnote omitted). Self-evidently, none of these includes replacement or electrification. The only time "replacement" appears in this list is in reference to replacement of *controls*. Further, the use of "retrofit" for sources should not be interpreted as replacement or electrification. The best available *retrofit* technology in the Regional Haze Program has never been interpreted that way; rather, then plain text of "retrofit" means the *addition to* an existing emissions unit. *See* "retrofit" *Merriam Webster*. While this list is not exhaustive, it is certainly indicative of the types of controls EPA contemplated requiring – none of which compare to electrification or replacement.

More recent EPA guidance issued in 2021 also confirms this understanding. In that guidance, EPA clarifies that greater *efficiency of controls* could also be considered, and that guidance notably does not suggest replacement or electrification is appropriate. *See* EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period 7 (July 8, 2021) (discussing efficiency improvements of an "existing control" as a control measure to consider but not suggesting that replacement of the entire emissions unit is appropriate).

Finally, NMED's website pertaining to the Second Implementation Period never mentions replacement or electrification, but NMED does mention *control* multiple times: "*control*

technologies to reduce haze" and "the cost of *control*, time necessary to install *controls*…" NMED, Regional Haze Planning (emphases added). In sum, an evaluation of replacement and/or electrification of engines is outside the bounds of the Regional Haze Rule.

B. Operating Restrictions

These engines, and in fact, the entire fleet of ENPG's engines and turbines, are part of interstate natural gas pipelines that are subject to regulation by the Federal Energy Regulatory Commission (FERC) under the federal Natural Gas Act. See, e.g., 18 C.F.R. §284.7(a) (setting forth requirements for interstate natural gas firm transportation service). FERC approves or "certificates" the pipeline to deliver natural gas. EPNG's pipeline system, as certificated by FERC, so that EPNG can move gas 24 hours a day, 365 days a year at its designed capacity. Reducing capacity of one or more of EPNG's engines or turbines through operating restrictions would require that EPNG seek and obtain approval from FERC. In certain circumstances, this might be viewed by FERC as abandonment of capacity and abandonment proceedings can take up to 11-13 months.

Additionally, as noted above, replacement of units, and by extension, retirement of existing units, is beyond the scope of the Regional Haze Rule. Accordingly, operating restrictions are not appropriate on EPNG's FERC-regulated engines and turbines.

Again, EPNG appreciates this opportunity to review and comment on the draft final control cost evaluations for the Regional Haze Second Planning Period in New Mexico. If you have any questions about our response, please contact Weiwen Daly by email at Weiwen_Daly@kindermorgan.com or by phone at 303-914-7616 or me by email at Tom_Mitchell@kindermorgan or by phone at 713-420-3463.

Sincerely,

R. Thomas Mitchell

Off-Engine Fuel System		$500,000	$500,000	$500,000	
Automation Panels		$3,500,000	$3,500,000	$2,250,000	
New Ignition Sysytem		$910,000	$910,000	$585,000	
Pulsation Bottles		$0	$0	$900,000	
Construction, Inspection, Commissioning, Company Labor		$10,500,000	$14,000,000	$9,000,000	
Total Cost per Engine (TC)		$1,884,728	$2,975,000	$2,804,838	
Contingency Cost per Unit		$188,473	$297,500	$180,311	10% of TC
AFUDC (from GN cost analysis for GMVA-10)		$103,121	$103,121	$103,121	from Good Neighbor cost estimate of similar unit
Total Capital Cost per Unit (TCC)		**$2,176,322**	**$3,375,621**	**$3,088,270**	
ANNUAL COST					
Direct Operating Cost					
Operating Labor Required		$6,480	$6,480	$6,480	.5 hr/shift, similar to EPA example
Supervisor labor		972	972	972	15% of operator
Parts & Repair Cost		$17,094	$17,094	$17,094	Vendor Estimate based on annual operating hours
Testing (Annual Reference Method Test)		$10,000	$10,000	$10,000	
Added Electricity Cost	5 kW/hr	$1,322	$1,322	$1,322	City of Farmington rate = $ 0.15/kWh
Total O&M Costs		**$35,868**	**$35,868**	**$35,868**	
Admin, insurance, taxes		$87,053	$135,025	$123,531	4% of TCI
Equipment Life	yr	20	20	20	
Interest Rate		8.53%	8.53%	8.53%	EPNG cost of borrowing
Capital Recovery Factor [1]		0.1059	0.1059	0.1059	
Annualized Capital Recovery		$230,477	$357,485	$327,054	
Total Indirect Cost		**$317,530**	**$492,510**	**$450,585**	
Total Annualized Costs		**$353,397**	**$528,377**	**$486,452**	
Baseline Actual NOx Emissions	tpy	1.38	1.38	1.38	Based on average test data (2012-2023) and average actual hours from 2016-2021
Post Control NOx Emissions	tpy	5.50	1.83	0.92	
Post Control NOx Concentration	g/hp-hr	3.0	1.0	0.5	
Estimated NOx Emissions Reduction	tpy	-4.11	-0.45	0.47	
Cost Effectiveness	$/ton	**($85,933)**	**($1,178,155)**	**$1,040,483**	

[1] Capital Recovery Factor for the new Solar Mars turbine:

Interest Rate	8.53%
Remaining useful life of source	20
Capital Recovery Factor	0.1059

Enclosure 2A
Pecos River Cost Summary

Enclosure 2A - Cost Calculations
Pecos River Compressor Station

Alternative O&M Costs Recommended by EPNG:

Cost type	A-01	A-02	A-03	Notes
Annual Maintenance	$35,905	$56,857	$56,857	See Enclosure 2B
Annual Operating Labor	$87,599	$87,600	$87,600	See Enclosure 2B
Annual Regeant Cost	$90,114	$107,879	$95,762	See Enclosure 2B
Annual Electricity Cost	$17,405	$20,836	$18,496	See Enclosure 2B
Annual Catalyst Replacement Cost	$42,912	$51,371	$45,601	See Enclosure 2B
Direct Annual Cost	**$273,935**	**$324,543**	**$304,316**	

Other Indirect Administratvie Costs Recommended by EPNG:

Cost type	A-01	A-02	A-03	Notes
Administrative Cost	$3,059	$3,310	$3,310	0.03 * (Operator Cost + 0.4*Annual Maintenance Cost)

Capital Recovery Costs and TAC Recommended by EPNG:

Cost type	A-01	A-02	A-03	
Capital Recovery Costs	$760,473	$1,204,253	$1,204,253	Based on 8.53% inflation and SCR capital investment (see Enc. 2B)
Direct Annual Costs	$273,935	$324,543	$304,316	
Administrative Costs	$3,059	$3,310	$3,310	
Total Annual Cost (TAC)	**$1,037,467**	**$1,532,106**	**$1,511,879**	

Alternative BAE Calculation Recommended by EPNG:

Unit	A-01	A-02	A-03	
Average Hours (2016-2021)	3553	6378	5537	Same as NMED
NOx (lb/hr)	22.4	25.3	24.4	Same as NMED, based on recent tests and not extrapolated to 100% ISO load
BAE (ton/year)	39.8	80.7	67.5	

Alternative Cost Effectiveness Calculation Recommended by EPNG

Unit	A-01	A-02	A-03	
NOx Control Efficiency (%)	70%	70%	70%	Justified based on exhaust temperatures
Estimated Reductions (ton/yr)	27.9	56.5	47.3	
TAC ($/yr)	$1,037,467	$1,532,106	$1,511,879	
2023$ Cost Effectiveness ($/ton)	**$ 37,248**	**$ 27,126**	**$ 31,976**	

Enclosure 2B
Pecos River Cost Estimate

El Paso Natural Gas Company, LLC

GE Model M3712R Turbine	Interest Rate:	8.53%	<-- EPNG Interest Rate
A-01	Period (yrs):	20	<-- EPA Air Pollution Control Cost Manual

Turbine Housing Reconfiguration	$	-	<-- Presumed to be included in CE2107005 shown below (Emission Controls CWIP)
SCR Capital Investment	$	7,180,921	<-- CE2107005 Caprock internal est 07/16/2021
Total Capital Investment	$	7,180,921	
Annualized TCI:	$	760,473	<-- Based on interest rate, year and TCI
Annual O&M Costs:	$	276,994	<-- EPA Cost Control Spreadsheet
Total Annual Costs:	$	1,037,468	

Unit A-01: Cost Estimate

Total Capital Investment (TCI) =	$ 7,180,921

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$273,935
Indirect Annual Costs (IDAC) =	$763,532
Total annual costs (TAC) = DAC + IDAC	$1,037,468

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI	$35,905	
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600	Per EPA Cost Manual Ch 2, 2.4.2 "operating and supervisory labor"
Annual Reagent Cost =	Reagent Consumption Rate/Hour x Cost of R_{eagent} x Operating Hours/Year =	$90,114	Vendor quote - $1.75/gal of aqueous ammonia delivered to site; Per ArieNox 7/08/21 quote, at 100% full load, ammonia consumption rate is approximately 10 gph, 2011-2020 average hours
Annual Electricity Cost =	Electricity Consumption Rate x Cost of $E_{lectricity}$ x Operating Hours/Year =	$17,405	Default rate of $0.0676/kWh used in the calculation
Annual Catalyst Replacement Cost =		$42,912	
Direct Annual Cost =		$273,935	

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,059
Capital Recovery Costs (CR)=	CRF x TCI =	$760,473
Indirect Annual Cost (IDAC) =	AC + CR =	$763,532

Total Annual Cost (TAC) =	$1,037,468 Per Year

Unit A-01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

What type of fuel does the unit burn?

Is the SCR for a new turbine or retrofit of an existing turbine?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty: 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]: 61.8 MMBtu/hour

What is the higher heating value (HHV) of the fuel?[1,2]: 1,031 Btu/scf

What is the estimated actual annual fuel consumption?: 220,915,390 scf/Year (based on unit heat rating and 2016-2018 average horus)

Enter the net plant heat input rate (NPHR): 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,941
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,690

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 4982.50/8760 hours/year = 298.55 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR}): 365 days

Number of days the turbine operates (tplant): 365 days

Inlet NO_x Emissions (NOx_{in}) to SCR[2]: 0.2751 lb/MMBtu (2016-2018 avg. test results)

Outlet NO_x Emissions (NOx_{out}) from SCR[2]: 0.0825 lb/MMBtu

Stoichiometric Ratio Factor (SRF): 1.050

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Estimated operating life of the catalyst ($H_{catalyst}$): 24,000 hours

Estimated SCR equipment life: 20 Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored}): 29 percent*

Density of reagent as stored (ρ_{stored}): 56 lb/cubic feet*

Number of days reagent is stored ($t_{storage}$): 14 days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Select the reagent used

Number of SCR reactor chambers (n_{scr}): 1

Number of catalyst layers (R_{layer}): 3

Number of empty catalyst layers (R_{empty}): 1

Ammonia Slip (Slip) provided by vendor: 2 ppm

Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known): UNK Cubic feet

Flue gas flow rate ($Q_{bulkgas}$) (Enter "UNK" if value is not known): UNK acfm

Gas temperature at the SCR inlet (T): 650 °F

Base case fuel gas volumetric flow rate factor (Q_{act})[4]: 25975.21 ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Permitted NO_x emission rate / permitted heat input (53.1 lb/hr / 61.8 Mmbtu/hr)

[3] Air Pollution Control Technology Fact Sheet, SCR, EPA-452/F-03-032; 70% efficiency

[4] Calculated based on the estimated actual annual fuel consumption and maximum heat input rate.

Enter the cost data for the proposed SCR:

Desired dollar-year: 2018

CEPCI for 2018: 603.1 Enter the CEPCI value for 2018 (541.7 2016 CEPCI)

CEPCI = Chemical Engineering Plant Cost Index

Annual Interest Rate (i): 5.5 Percent*

* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)

Reagent ($Cost_{reag}$): 0.293 $/gallon for 29% ammonia*

* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.

Electricity ($Cost_{elect}$): 0.0676 $/kWh

* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.

Catalyst cost ($CC_{replace}$): 227.00 $/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst

* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.

Operator Labor Rate: 60.00 $/hour (including benefits)*

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

Operator Hours/Day: 4.00 hours/day*

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) = 0.005

Administrative Charges Factor (ACF) = 0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution [a]ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf

Interest Rate (Percent)	5.5	Default bank prime rate	

Unit A-01: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	61.8	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year (based on unit heat rating and 2016-2018 average horus)	
Actual Annual fuel consumption (Mactual) =		220,915,390	scf/Year (based on unit heat rating and 2016-2018 average horus)	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.421	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	3685	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.90	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	21.93	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	1,536,075	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	7,082.81	/hour	
Residence Time	1/V_{space}	0.00	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	216.87	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	1,600	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	1,840	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	42.9	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	16	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	800	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage: Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Annual Costs

Total Annual Cost (TAC)
TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$324,543
Indirect Annual Costs (IDAC) =	$1,207,563
Total annual costs (TAC) = DAC + IDAC	$1,532,106

Direct Annual Costs (DAC)
DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI	$56,857	
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600	Per EPA Cost Manual Ch 2, 2.4.2 "operating and supervisory labor"
Annual Reagent Cost =	Reagent Consumption Rate/Hour x Cost of R_{eagent} x Operating Hours/Year =	$107,879	Vendor quote - $1.75/gal of aqueous ammonia delivered to site; Per ArieNox 7/08/21 quote, at 100% full load, ammonia consumption rate is approximately 10 gph, 2011-2020 average hours
Annual Electricity Cost =	Electricity Consumption Rate x Cost of $E_{lectricity}$ x Operating Hours/Year =	$20,836	Default rate of $0.0676/kWh used in the calculation
Annual Catalyst Replacement Cost =		$51,371	
Direct Annual Cost =		$324,543	

Indirect Annual Cost (IDAC)
IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,310
Capital Recovery Costs (CR)=	CRF x TCI =	$1,204,253
Indirect Annual Cost (IDAC) =	AC + CR =	$1,207,563

Total Annual Cost (TAC) =	$1,532,106 Per Year

Unit A-02: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

What type of fuel does the unit burn?

Is the SCR for a new turbine or retrofit of an existing turbine?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1] 61.8 MMBtu/hour

What is the higher heating value (HHV) of the fuel?[1,2] 1,031 Btu/scf

What is the estimated actual annual fuel consumption? 377,406,695 scf/Year (based on unit heat rating and 2016-2018 average horus)

Enter the net plant heat input rate (NPHR) 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,341
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,690

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

Method 1
Method 2
Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.
[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 7165.5/8760 hours/year = 429.3 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR}) 365 days

Number of days the turbine operates (tplant) 365 days

Inlet NO_x Emissions (NOx_{in}) to SCR[2] 0.4249 lb/MMBtu

Outlet NO_x Emissions (NOx_{out}) from SCR[2] 0.1275 lb/MMBtu

Stoichiometric Ratio Factor (SRF) 1.050

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr}) 1

Number of catalyst layers (R_{layer}) 3

Number of empty catalyst layers (R_{empty}) 1

Ammonia Slip (Slip) provided by vendor 2 ppm

Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known) UNK Cubic feet

Flue gas flow rate ($Q_{bluegas}$) (Enter "UNK" if value is not known) UNK acfm

Estimated operating life of the catalyst ($H_{catalyst}$) 24,000 hours

Estimated SCR equipment life 20 Years*
* For industrial turbines, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T) 650 °F *The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Base case fuel gas volumetric flow rate factor (Q_{act})[4] 44375.44 ft^3/min-MMBtu/hour

Concentration of reagent as stored (C_{stored}) 29 percent*

Density of reagent as stored (ρ_{stored}) 56 lb/cubic feet*

Number of days reagent is stored ($t_{storage}$) 14 days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:	
50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

Unit A-02: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year (based on unit heat rating and 2016-2018 average horus)	
Actual Annual fuel consumption (Mactual) =		377,406,695	scf/Year (based on unit heat rating and 2016-2018 average horus)	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.719	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6296	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	18.38	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	57.87	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2,624,195	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	11,511.83	/hour	
Residence Time	1/V_{space}	0.00	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	227.96	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	2,734	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	3,144	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	56.1	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	41	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	25	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,200	gallons (storage needed to store a 14 day reagent supply rounded to

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage: Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	31.78	kW

Total Annual Costs:	$	1,511,879	

Unit A-03: Cost Estimate

Total Capital Investment (TCI) =	$ 11,371,394

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$304,316
Indirect Annual Costs (IDAC) =	$1,207,563
Total annual costs (TAC) = DAC + IDAC	$1,511,879

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI	$56,857	
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$87,600	Per EPA Cost Manual Ch 2, 2.4.2 "operating and supervisory labor"
Annual Reagent Cost =	Reagent Consumption Rate/Hour x Cost of R_{eagent} x Operating Hours/Year =	$95,762	Vendor quote - $1.75/gal of aqueous ammonia delivered to site; Per ArieNox 7/08/21 quote, at 100% full load, ammonia consumption rate is approximately 10 gph, 2011-2020 average hours
Annual Electricity Cost =	Electricity Consumption Rate x Cost of $E_{lectricity}$ x Operating Hours/Year =	$18,496	Default rate of $0.0676/kWh used in the calculation
Annual Catalyst Replacement Cost =		$45,601	
Direct Annual Cost =		$304,316	

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,310
Capital Recovery Costs (CR)=	CRF x TCI =	$1,204,253
Indirect Annual Cost (IDAC) =	AC + CR =	$1,207,563

Total Annual Cost (TAC) =	$1,511,879	Per Year

Unit A-03: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

What type of fuel does the unit burn?

Is the SCR for a new turbine or retrofit of an existing turbine?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty: 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?[1]: 61.8 MMBtu/hour

What is the higher heating value (HHV) of the fuel?[1,2]: 1,031 Btu/scf

What is the estimated actual annual fuel consumption?: 384,017,879 scf/Year (based on unit heat rating and 2016-2018 average horus)

Enter the net plant heat input rate (NPHR): 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 2900 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,941
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,690

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the Cost Estimate tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Fuel consumption adjusted for actual 2016 operating hours, per the 2016 Emission Inventory submittal (524.9 MMscf/yr * 6501.75/8760 hours/year = 389.6 MMscf/yr)

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR}): 365 days

Number of days the turbine operates (tplant): 365 days

Inlet NO_x Emissions (NOx_{in}) to SCR[2]: 0.3973 lb/MMBtu

Outlet NO_x Emissions (NOx_{out}) from SCR[2]: 0.1192 lb/MMBtu

Stoichiometric Ratio Factor (SRF): 1.050

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr}): 1

Number of catalyst layers (R_{layer}): 3

Number of empty catalyst layers (R_{empty}): 1

Ammonia Slip (Slip) provided by vendor: 2 ppm

Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known): UNK Cubic feet

Flue gas flow rate ($Q_{bulkgas}$) (Enter "UNK" if value is not known): UNK acfm

Estimated operating life of the catalyst ($H_{catalyst}$): 24,000 hours

Estimated SCR equipment life: 20 Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T): 650 °F

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Base case fuel gas volumetric flow rate factor (Q_{bef})[4]: 45152.79 ft^3/min-MMBtu/hour

Concentration of reagent as stored (C_{stored}): 29 percent*

Density of reagent as stored (ρ_{stored}): 56 lb/cubic feet*

Number of days reagent is stored ($t_{storage}$): 14 days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

NOTES: [1] Data referenced from the most recent Title V application for P129-R3M1.

[2] Permitted NO_x emission rate / permitted heat input (53.1 lb/hr / 61.8 Mmbtu/hr)

[3] Air Pollution Control Technology Fact Sheet, SCR, EPA-452/F-03-032; 70% efficiency

[4] Calculated based on the estimated actual annual fuel consumption and maximum heat input rate.

Enter the cost data for the proposed SCR:

Desired dollar-year: 2018

CEPCI for 2018: 603.1 Enter the CEPCI value for 2018 (541.7 2016 CEPCI)

CEPCI = Chemical Engineering Plant Cost Index

Annual Interest Rate (i): 5.5 Percent*

* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)

Reagent ($Cost_{reag}$): 0.293 $/gallon for 29% ammonia*

* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.

Electricity ($Cost_{elect}$): 0.0676 $/kWh

* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.

Catalyst cost ($CC_{replace}$): 227.00 $/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst

* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.

Operator Labor Rate: 60.00 $/hour (including benefits)*

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

Operator Hours/Day: 4.00 hours/day*

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) = 0.005

Administrative Charges Factor (ACF) = 0.03

Unit A-03: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	525,090,204	scf/Year (based on unit heat rating and 2016-2018 average horus)	
Actual Annual fuel consumption (Mactual) =		384,017,879	scf/Year (based on unit heat rating and 2016-2018 average horus)	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.731	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6407	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	17.19	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	55.06	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	2,670,165	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	11,819.40	/hour	
Residence Time	1/V_{space}	0.00	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.11		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1), where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	225.91	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	2,781	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1	feet

SCR Reactor Data:

No, it would be roughly 6,000/gal per truckload.

Hey James,

So for budgetary purposes the price on this material is going to run $1.35/gal plus freight, which at this time is running about $2,700 per load.

If at all possible I need some type of estimate by the end of the week because the state Arizona wants our feedback by Monday the 23rd. If it is something you don't think you can have by then let me know and I will see if I can find someone else that might have the information. I apologize for the rush but the state just told us they wanted our feedback by that date.

Thank you,

Hello James,

It was good to speak with you today, I really appreciate you taking the time! As soon as I have pricing on the aqueous ammonia, Ill send it over to you. Would you happen to know if the Kinder Morgan locations here in the Bloomfield, NM area are looking at doing the same thing?

Re: Alternative Emission Standards Proposal for El Paso Natural Gas – Conditional Approval

Dear Weiwen Daly,

Pursuant to 20.2.50.113.B(11) NMAC, Kinder Morgan submitted on December 2, 2022 to New Mexico Environment Department (Department), Air Quality Bureau (AQB or Bureau) a request to approve an Alternative Emission Standard (AES) for ten GE Gas Turbines for El Paso Natural Gas Company, L.L.C. (EPNG). The request included alternative reductions for nitrogen oxides (NOx) due to economic infeasibility for retrofit emissions control technologies deemed technically feasible. The submitted proposal included an independent third party certification of the evaluation.

On December 20, 2022, the Bureau requested further information, including a demonstration that the standards could not be met through an Alternative Compliance Plan and conversion of units to those found in 20.2.50.113 NMAC. This information was supplied to the Bureau on April 24, 2023.

On May 3, 2023, the Bureau notified Kinder Morgan that the complete proposal had been posted to the Department web site and would be available on the public comment portal for 30 days. This notice also included instructions for publishing “in a newspaper of general circulation.” Proof of publication in 4 county newspapers was submitted to the Bureau on May 15, 2023.

No public comments were received. However, the Bureau requested further clarification regarding ongoing costs on June 20, 2023. Kinder Morgan responded on June 21, 2023.

With the completion of all required documentation, notification and clarification, the Department hereby conditionally approves the AES proposal for the ten GE turbines referenced in the proposal. The approval is conditional only to the extent that, when any turbine is permanently replaced, the replacement turbine shall be considered “new” pursuant to the rule and must comply with the emissions standards in Table 3. However, short-term replacements and reinstallation of the existing turbines do not affect the status and will still be considered existing; they will remain covered under this Alternative Emission Standard.

Please note that the emissions reductions and alternative standards for the affected turbines are considered enforceable under this rule (20.2.50 NMAC). Please work with Permitting to determine what actions, if any, are necessary to memorialize the emission limits in permits.

1 Executive Summary

The New Mexico Environmental Department (NMED) proposed and the New Mexico Environmental Improvement Board (EIB) finalized the Ozone Precursor rule under 20.2.50 NMAC to reduce ozone emissions at sources causing or contributing to ambient ozone concentrations that exceed ninety-five percent of the national ambient air quality standard for ozone. In lieu of meeting the emission standards established under 20.2.50.113 for portable and stationary natural gas-fired combustion engines or turbines, owners and operators may submit a request for alternative emission standards for a specific engine or turbine based on technical impracticability or economic infeasibility. El Paso Natural Gas Company, L.L.C. (EPNG)., a subsidiary of Kinder Morgan, Inc. (Kinder Morgan), requests alternative emission standards for ten (10) GE stationary natural gas-fired combustion turbines on the basis of economic infeasibility.

EPNG conducted a technical and economic analysis of emission controls for the 10 GE stationary natural gas-fired combustion turbines to reduce NO_X emissions. The only technically practicable technology for each turbine is Selective Catalytic Reduction (SCR). In general, NMED considers costs in excess of $7,500/ton of pollutant reduced to be economically infeasible. As noted in Kinder Morgan's Technical Testimony filed on July 28, 2021, and further documented in this submission, the cost per ton of installing SCR on these 10 GE turbines ranges up to $458,302 based on actual historical operating hours. Even in the most conservative case, based on Potential to Emit (PTE), installing SCR on these 10 GE turbines is not economically feasible. A review of potential control technologies and cost analyses are presented in Sections 3 and 4. The economic infeasibility of SCR installation is summarized below in Table 1-1. EPNG has concluded that alternative emission standards (AES) for NOx for the 10 GE gas turbines are warranted because the cost of compliance for technically practicable retrofit emission control technologies is not economically feasible, and the units' NOx emissions cannot be addressed through an Alternate Compliance Plan (ACP).

Table 1-1 Summary of Cost Effectiveness Evaluation

Turbine Location	Unit No.	Permitted Turbine Rating (hp)	Cost Effectiveness ($/ton NOx Removed) Based on Actual Emissions*	Cost Effectiveness ($/ton NO_X Removed) Based on PTE
Afton	A-01	6,150	$123,236	$11,697
Afton	A-02	6,150	$458,302	$11,097
Afton	A-03	6,150	$48,516	$11,097
Belen	A-01	4,737	$88,704	$30,794
Belen	A-02	4,737	$60,982	$29,214
Caprock	A-01	6,026	$80,398	$9,933
Caprock	A-02	4,879	$54,935	$29,283
Pecos River	A-01	7,150	$27,877	$8,261
Pecos River	A-02	7,150	$22,517	$11,097
Pecos River	A-03	7,150	$26,527	$11,097

*The data in the second-to-last column are from Kinder Morgan's Technical Testimony filed on July 28, 2021 before the EIB in which KM used the average actual emissions from 2018 to 2020. This data was ultimately relied upon by the EIB in support of adoption of Paragraphs (10) and (11) of Subsection B of 20.2.50.113 NMAC, which are the options to comply with the emissions limits through an AES or ACP. See State of New Mexico, Environmental Improvement Board, Statement of Reasons and Final Order, In the Matter of Proposed New Regulation 20.2.50 NMAC – Oil and Gas Sector – Ozone Precursor Pollutants, No. EIB 21-27, at pp. 100-101 (June 27, 2022) (hereinafter, Statement of Reasons). The last column shows cost-ineffectiveness calculations based on the more conservative PTE scenario. Even if the Department considers the overly conservative approach of using PTE to estimate the cost-per-ton, installation of SCR remains economically infeasible. See Section 4, Cost Analysis, for additional discussion regarding the economic infeasibility evaluation.

2 Introduction

The regulatory background and turbine information are summarized below.

2.1 Regulatory Background

The New Mexico EIB finalized the Ozone Precursor rule under 20.2.50 NMAC to reduce ozone emissions at existing and new sources causing or contributing to ambient ozone concentrations that exceed ninety-five percent of the national ambient air quality standard for ozone. Sources located in Chaves, Dona Ana, Eddy, Lea, Rio Arriba, Sandoval, San Juan, and Valencia counties are subject to the rule.

EPNG owns and operates 10 existing GE stationary natural gas-fired combustion turbines with a maximum design rating equal to or greater than 1,000 hp, as summarized in Table 2-1. These 10 GE turbines are included in this AES proposal.

Table 2-1 EPNG Sources Included in The AES

Engine Location	Unit No.	Turbine Manufacturer	Turbine Model	Hourly NOx Permit Limit	Annual NOx Permit Limit
Afton	A-01	GE	MS3712R-A	51.3 pph	224.5 tpy
Afton	A-02	GE	MS3712R-A	51.3 pph	224.5 tpy

Total					2,082.4 tpy

The Ozone Precursor Rule, at 20.2.50.113.B(11) NMAC states that "the owner or operator may submit a request for alternative emission standards for a specific engine or turbine based on technical impracticability or economic infeasibility." The rule further states that "[t]he owner or operator is not required to submit an ACP proposal under Paragraph (10) of Subsection B of 20.2.50.113 NMAC prior to submission of a request for alternative emission standards under this Paragraph (11), provided that the owner or operator satisfies Subparagraph (b) of Paragraph (11) of Subsection B of 20.2.50.113 NMAC, below." See 20.2.50.113.B.(11) NMAC (emphasis added). Subparagraph (b) of Paragraph (11) of Subsection B of 20.2.50.113 NMAC requires the owner or operator "[p]repare a demonstration detailing why

emissions from the individual engine or turbine cannot be addressed through an ACP in a technically practicable or economically feasible manner." Thus, this demonstration does not require the submission of a comprehensive ACP, but does require a *reasonable* (but not exhaustive) showing that the target emission standards for these individual turbines are not technically practicable or economically feasible, even through an ACP.

Regarding technical practicability and economic feasibility, in particular, the EIB adopted Paragraphs (10) and (11) of Subsection B of 20.2.50.113 NMAC "for the reasons stated in the NMED Rebuttal . . . and the supporting argument by Kinder Morgan." State of New Mexico, Environmental Improvement Board, Statement of Reasons and Final Order, In the Matter of Proposed New Regulation 20.2.50 NMAC – Oil and Gas Sector – Ozone Precursor Pollutants, No. EIB 21-27, at pp. 111 (June 27, 2022) (hereinafter, Statement of Reasons). In particular, and citing to Kinder Morgan's supporting argument in the EIB rulemaking, the EIB stated that "[w]hile the emissions thresholds provided in Tables 1 and 3 for existing engines and turbines are appropriate in most cases, circumstances may exist where it is technically impracticable or economically infeasible to achieve compliance." Id. at 111. Recognizing these practical limitations, the EIB's final rule "offers significant flexibility for sources that are unable to meet the emissions standards of Part 50: they may reduce the annual hours of operation, they may seek an Alternative Compliance Plan ACP to meet an equivalent amount of emission reductions, and/or they may seek alternative emissions standards if they can demonstrate that they cannot meet the existing standards through an ACP." Id. at 111 (emphasis added). Thus, an operator may have in place both an AES (or multiple AESs for individual units), and an ACP. Further to costs, the EIB made clear that "[c]ost-effectiveness thresholds above which a certain control technology will be considered infeasible can vary, but, in general, the Department considers costs in excess of $7,500 per ton of pollutant reduced to be infeasible." Id.

EPNG is requesting an AES for NOx for these 10 existing GE gas turbines on the basis that achieving the Table 3 emission standards found in 20.2.50.113 NMAC is economically infeasible. The 10 GE gas turbines subject to the AES proposal are subject to the NOx emission standard of 50 ppmvd @15% O_2. EPNG converted the emission standard to pounds per hour (pph) for each GE gas turbine subject to the AES proposal. The allowable annual emission rates under the Ozone Precursor rule are calculated by converting the pph emission rates to an annual basis assuming continuous operation (8,760 hr/yr). The required emission reductions are calculated as the difference between the current permit limits (tpy) and the allowable annual emission rates (tpy) under the Ozone Precursor rule. The combined total permitted NOx emissions for the 10 GE turbines is 2,082.4 tpy. The total allowable NOx emissions under the Ozone Precursor rule, 20.2.50.113.B NMAC (Table 3), for the 10 GE turbines is 452.0 tpy by January 1, 2028. Therefore, the total required NOx emission reductions for the 10 GE turbines is 1,630.4 tpy, to be incrementally achieved, by January 1, 2028. See 20.2.50.113.B.(7) NMAC. A summary of allowable emissions under the rule and the reductions proposed by the AES for the 10 GE turbines is listed below in Table 2-2.

Table 2-2 Allowable Emissions and Proposed Reductions for 10 GE Turbines

Units	Permitted NOx Emissions (tpy)	Allowable Hourly NOx Emissions (pph) (equivalent of 50 ppmvd @15% O_2)	Allowable Annual NOx Emissions Complying the Rule (tpy)	NOx Reduction Required by the Rule (tpy)	NOx Reduction Proposed by AES (tpy)
Afton A-1	224.5	11.3	49.5	175.0	23.0
Afton A-2	224.5	11.3	49.5	175.0	23.0

Total	**2,082.4**		**452.0**	**1,630.4**	**418.3**

Kinder Morgan is in the process of developing an Alternate Compliance Plan (ACP) for the engines and turbines subject to the rule operated by Kinder Morgan or its affiliates and subsidiaries, including EPNG, TransColorado Gas Transmission Co., LLC, and Natural Gas Pipeline Company of America, LLC. The ACP will be submitted in accordance with 20.2.50.113(B)(10). The 10 GE turbines are excluded from the ACP for NOx emissions because they cannot meet the emission standards through an ACP for the following reasons:

- Technology limits the available control options for the 10 GE turbines to Selective Catalytic Reduction (SCR). See Section 3 (Potential Control Technology Review).
- Installing SCR on the 10 GE turbines is not economically feasible. See Section 4 (Cost Analysis and Proposed Alternative Emissions Standards); see also Appendix A-1 (Control Cost Estimate Based on Potential to Emit for El Paso Natural Gas Company GE Turbines); Appendix [A-2] (Control Cost Estimate Based on Actual Emissions for El Paso Natural Gas Company GE Turbines).
- Including the 10 GE turbines in an ACP with the remainder of Kinder Morgan's fleet is not possible. See Section 5 (Exclusion from ACP).

Notwithstanding the lack of cost effective control strategies, the inability to address via an ACP, and the limitations on reducing hours of operations or capacity, Kinder Morgan has proposed reductions in permit allowable emission rates

for NOx. Under the proposed AES, Kinder Morgan proposes to reduce 418.3 tons of NOx emission annually combined from the 10 GE gas turbines. See Section 6 (Proposed Alternative Emission Standards).

3 Potential Control Technologies Review

Potential control technologies and their feasibility are discussed in Section 3.1. The technical feasibility of the available control technologies is summarized in Section 3.2.

3.1 Potentially Available Control Technologies and Technical Feasibility Evaluation

Potentially available control technologies to reduce NO_X from the stationary natural gas-fired combustion turbines are summarized below. The technical feasibility of installation of each control technology is also evaluated for the ten turbines.

3.1.1 Water or Steam Injection

Water or steam injection operates by introducing water or steam into the flame area of the gas turbine combustor. The injected fluid provides a heat sink that absorbs some of the heat of combustion, thereby reducing the peak flame temperature and the formation of thermal NO_X. The water injected into the turbine must be of high purity such that no dissolved solids are injected into the turbine. Dissolved solids in the water may damage the turbine due to corrosion and/or the formation of deposits in the hot section of the turbine. The requirement of high-purity water can be expensive to retrofit because EPNG does not have water treatment systems on-site. Moreover, the consumption of water can be very high for a large turbine. Such high water usage may pose problems for the local water supply and is an added expense. This is important, especially in dry regions such as New Mexico. Although water/steam injection acts to reduce NO_X emissions, the lower average temperature within the combustor may produce higher levels of CO and hydrocarbons because of incomplete combustion. Additionally, water/stream injection results in a decrease in combustion efficiency and an increase in maintenance requirements due to wear on the turbine and combustor.

Water or steam injection is not, however, available for all types of unit. The ten turbines included in this request are GE Frame 3 turbines. Based on feedback from GE representatives, water or steam injection technology is not available to the GE Frame 3 gas turbines. Accordingly, this NOx control method is not technically feasible. See Appendix A-3 (Letter from Baker Hughes dated October 16, 2019 and provided in the Ozone Precursor rulemaking as attachment T to Kinder Morgan's rebuttal technical testimony).

3.1.2 Lean Head End Combustion Liner Upgrade and Dry Low-NOX (DLN) Combustors

The liner of a turbine surrounds the combustion process and allows for various airflows to pass through into the combustion zone. The liner is subject to high temperatures due to the combustion process which it contains. Because of this, the life of the liner is limited. Replacing the old combustion liner with a new, upgraded liner is a common retrofit. Combustion liners have a limited lifespan and are designed to be replaced.

Lean pre-mix technology, also referred to as dry low-NOX (DLN) combustion technology, is a pollution prevention technology that controls NO_X emissions. DLN inhibits the conversion of atmospheric nitrogen

to NO_X in the turbine combustor. This is accomplished by reducing the combustor temperature using lean mixtures of air and/or fuel staging or by decreasing the residence time of the combustor through combustion chamber design. For existing turbines, the combustion chamber would need to be redesigned and reconfigured to allow for lean pre-mixing or fuel staging.

In lean combustion systems, excess air is introduced into the combustion zone to produce a significantly leaner fuel/air mixture than is required for complete combustion. This excess air reduces the overall flame temperature because a portion of the energy released from the fuel must be used to heat the excess air to the reaction temperature. Pre-mixing the fuel and air prior to introduction into the combustion zone provides a uniform fuel/air mixture and prevents localized high-temperature regions within the combustor area. The fuel-to-air ratio must be maintained within a relatively narrow range to obtain low NO_X without blowout and without increasing carbon monoxide (CO) emissions, which are generated during incomplete combustion.[1] Since NO_X formation rates are an exponential function of temperature, turbines having frequent and rapid load changes may experience a brief spike in NO_X emissions with DLN technology.

Based upon feedback from GE, DLN control technology combined with a liner upgrade is not available to GE Frame 3 Models A and C turbines; therefore, this is not a technically feasible technology.

3.1.3 EM_X/$SCONO_X$

EM_X™ (the second generation of the $SCONO_X$ NO_X Absorber Technology) utilizes a coated oxidation catalyst to remove both NO_X and CO without a reagent, such as NH_3. Hydrogen (H_2) is used as the basis for the proprietary catalyst regeneration process. The $SCONO_X$ system consists of a platinum-based catalyst coated with potassium carbonate to oxidize NO and CO. The NO_2 molecules are subsequently absorbed on the treated surface of the $SCONO_X$ catalyst. The catalyst is installed in the flue gas with a temperature range between 300°F to 700°F.[2]

The EM_X™/$SCONO_X$™ catalyst system is designed to operate effectively at temperatures ranging from 300 to 700 °F. The 10 GE turbines requiring AES have an exhaust temperature of approximately 850-950°F.[3]

EM_X™/$SCONO_X$™ applications on turbines with outlet temperatures this high have not been identified. Consequently, EM_X™/$SCONO_X$™ is not technically feasible for the control of NO_X emissions from the 10 GE turbines.

3.1.4 Selective Catalytic Reduction (SCR)

Selective catalytic reduction (SCR) is a post-combustion gas treatment process in which urea or ammonia (NH_3) is injected into the exhaust gas upstream of a catalyst bed. On the catalyst surface, ammonia and nitric oxide (NO) react to form diatomic nitrogen and water vapor. The chemical reactions can be expressed as:

---

[1] "Retrofitability of DLN/DLE system," GE Technology Insights 2013.
[2] BACT Analysis for JEA-Greenland Energy Center Units 1 and 2, Combined Cycle Combustion Turbines. Prepared by Black & Veatch (September 2008).
[3] Per average of 2016, 2017, and 2018 emissions test summaries.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 \rightarrow 3\ N_2 + 6\ H_2O$$

When operated within the optimum temperature range, the reaction can result in removal efficiencies of 90 percent.[4] In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. SCR units have the ability to function effectively under fluctuating temperature conditions, although fluctuation in exhaust gas temperature reduces removal efficiency slightly by disturbing the NH_3/NO_X molar ratio. SCR installations typically have an operating range of 450 to 850ºF. The exhaust temperatures of the turbines included in this evaluation are approximately 850-950ºF, which is higher than the typical SCR operating range. SCRs may operate at higher temperatures but this generally results in lower efficiencies (between 70-85%).[5] SCR is therefore considered technically feasible.

It should be noted that there are several operational issues that may inhibit the effectiveness of SCR as a control option for turbines at natural gas compressor stations. The NH_3/NO_X molar ratio of 1:1 must be carefully controlled to allow for optimum NO_X reduction while limiting the amount of unreacted NH_3 emitted to the atmosphere (known as "ammonia slip"). This ratio is difficult to control in units that have the variable loads experienced at compressor stations. The unit loading and speed of the turbines fluctuate continually according to the time of day, changes in the weather, and customer demands. Throughout the day, units are started and stopped, and loads are changed to keep pipeline operating pressures within safe operating parameters and keep volumes sufficient to meet customer obligations. Although the variable nature of compressor station turbine loads does not make SCR operation technically infeasible, the inherent lag between CEM sampling and ammonia injection for the turbines may cause hourly NO_X emission limits to be exceeded during periods of increased load and unreacted NH_3 emissions ("ammonia slip") to increase during periods of load loss.

3.1.5 Selective Non-Catalytic Reduction (SNCR)

SNCR is a post-combustion NO_X control technology based on the reaction of urea or ammonia with NO_X. In the SNCR chemical reaction, urea [$CO(NH_2)_2$] or ammonia is injected into the combustion gas path to reduce the NO_x to nitrogen and water. The overall reaction schemes for both urea and ammonia systems can be expressed as follows:

$$CO(NH_2)_2 + 2\ NO + ½\ O_2 \rightarrow 2\ N_2 + CO_2 + 2\ H_2O$$
$$4\ NH_3 + 6NO \rightarrow 5\ N_2 + 6\ H_2O$$

[4] U.S. EPA, Office of Air Quality Planning and Standards. OAQPS Control Cost Manual Section 4-2 Chapter 2, updated on June 12, 2019.

[5] U.S. EPA, Office of Air Quality Planning and Standards. OAQPS Control Cost Manual Section 4-2 Figure 2.2, updated on June 12, 2019.

Typical removal efficiencies for SNCR range from 40 to 60 percent.[6] An important consideration for implementing SNCR is the operating temperature range. The optimum temperature range is approximately 1,600 to 2,000°F.[7] Operation at temperatures below this range results in ammonia slip (when non-reacted NH_3 is emitted to the atmosphere). The temperature range required for the effective operation of this technology is above the peak exhaust temperature for the GE gas turbines assessed here. For this reason, it has been determined that this control technology is not feasible for the GE gas turbines at EPNG facilities.

3.1.6 Replacement with Electric Drive

In anticipation of potential comments, EPNG documents in this submission that replacement of these 10 turbines with electric motors is neither required by the applicable rule.

In particular, in the context of existing sources in particular, the Department's purpose is to identify "control" opportunities. See NMSA 1978, Section 74-2-5(C) (providing the EIB authority to adopt a plan "to control emissions of oxides of nitrogen . . . .") (emphasis added). The use of "control" here contemplates that emissions sources will install controls to reduce emissions—not eliminate or replace those emissions sources altogether. See West Virginia v. EPA, 142 S. Ct. 2587, 2612 n.3 (2022) ("Section 111(d) empowers EPA to guide States in establishing standards of performance for existing sources, not to direct existing sources to effectively cease to exist.") (internal quotations and citations omitted). Cf. Sierra Club v. EPA,499 F.3d 653, 657 (7th Cir. 2007) (not requiring a control technology that would "redefine the source" in the context of new source permitting).

3.1.7 Good Combustion Practices (base case)

NO_X emissions are caused by the oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the combustion chamber, where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for the operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for the equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection were identified in this review for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the GE gas turbines at EPNG facilities. EPNG has developed Turbine Inspection and Maintenance Schedules Best Practices procedures, which are based on manufacturer recommendations, and EPNG has systems in place to ensure that its turbines are operated and maintained in accordance with these procedures. These practices are currently in use at all facilities, and the PTE is reflective of operations following good combustion practices. No further assessment of these control practices is included in this report.

3.2 Technical Feasibility Summary

The technical feasibility of potential control technologies is summarized in Table 3-1.

Table 3-1 Technical Feasibility of NO_X Emission Control Technologies for 10 GE Turbines

Section	Technology	Technically Feasible?
3.1.1	Water or Steam Injection	No
3.1.2	Lean Head End Combustion Liner Upgrade and Dry Low-NOX (DLN) Combustors	No
3.1.3	EM_X/$SCONO_X$	No
3.1.4	SCR	Yes
3.1.5	SNCR	No
3.1.7	Good Combustion Practices	Yes

4 Cost Analysis

4.1 Cost of Compliance

Economic impacts were analyzed using vendor cost estimates along with the procedures found in the EPA Air Pollution Control Cost Manual (CCM) as applicable. The sources of the control equipment cost data are noted in each of the control cost analysis worksheets in Appendix A-1 and Appendix A-2.

Overall, economic feasibility is evaluated on a dollar-per-ton ($/ton) basis using the annual operating cost ($/year) divided by the annual emission reduction achieved by the control device (ton/yr). The initial capital cost was annualized over a 25-year period and added to the annual operating costs, and the interest rate reflects EPNG's actual cost of borrowing. To be conservative in the cost analysis, the highest actual performance test data plus 20% safety factor is used to calculate the annual emission reduction rates. EPNG compared the cost-effectiveness to a $7,500/ton threshold to evaluate if the control is economically feasible.[8] This cost threshold is cited in the preamble to rulemaking for 20.2.50 NMAC and has been utilized by other states to define an acceptable level for determination of cost effectiveness for control technologies. EPNG calculated cost-per-ton estimates based on actual historic emissions as well as potential emissions. As shown above and below, the economic feasibility values (under both scenarios displayed) are above $7,500 for all 10 GE turbine units.

4.1.1 Control Cost Effectiveness Evaluation

The details of the turbine control cost effectiveness evaluation based on potential emissions are included in Appendix A-1 and Appendix A-2. The findings of the economic analysis based on the average actual annual emissions from 2018 to 2020 and PTE are summarized in Table 4-1.

[8] Statement of Reasons, at 111 ("[I]n general, the Department considers costs in excess of $7,500 per ton of pollutant reduced to be in feasible.").

Table 4-1 Cost Effectiveness of SCR for the Turbines

Turbine Location	Unit No.	Cost Effectiveness ($/ton NO_x Removed) Based on Actual Emissions	Cost Effectiveness Based on PTE ($/ton NO_X Removed)	Cost Effective?
Afton	A-01	$123,236	$11,697	No
Afton	A-02	$458,302	$11,097	No
Afton	A-03	$48,516	$11,097	No
Belen	A-01	$88,704	$30,794	No
Belen	A-02	$60,982	$29,214	No
Caprock	A-01	$80,398	$9,933	No
Caprock	A-02	$54,935	$29,283	No
Pecos River	A-01	$27,877	$8,261	No
Pecos River	A-02	$22,517	$11,097	No
Pecos River	A-03	$26,527	$11,097	No

Regarding Table 4-1, the data in the third column are from Kinder Morgan's Technical Testimony filed on July 28, 2021 before the EIB in which KM used the average actual emissions from 2018 to 2020. This data was ultimately relied upon by the EIB in support of adoption of Paragraphs (10) and (11) of Subsection B of 20.2.50.113 NMAC, which are the options to comply with the emissions limits through an AES or ACP. See State of New Mexico, Environmental Improvement Board, Statement of Reasons and Final Order, In the Matter of Proposed New Regulation 20.2.50 NMAC – Oil and Gas Sector – Ozone Precursor Pollutants, No. EIB 21-27, at pp. 100-101 (June 27, 2022) (hereinafter, Statement of Reasons). Notably, in NMED's rebuttal testimony (Ex. 1) during the Ozone Precursor rulemaking, the agency had raised questions with respect to how Kinder Morgan arrived at its cost-per-ton estimates, inquiring into the use of actual operating hours and actual emissions data. See NMED Ex. 1, at 46–48 (performing an estimation of cost effectiveness based on "full permitted capacity," i.e., PTE). In response, Kinder Morgan presented sur-rebuttal testimony on September 20, 2021 responsive to the Department's questions. In that sur-rebuttal testimony, Kinder Morgan presented additional cost-per-ton analyses using averaged operating costs over a 10-year period. The analysis demonstrated that the actual hours of operation/actual emissions were reasonably applied in the original analysis, and the cost-per-ton remained well above the reasonableness threshold of $7,500 per ton of NOx reduced. Based on this discussion and these findings, the Department presented and the EIB approved Paragraphs (10) and (11) of Subsection B of 20.2.50.113 NMAC to account for technical practicality and economic reasonableness, as required by statute. NMSA § 74-2-105(F) (requiring that the EIB "shall give weight it deems appropriate to . . . technical practicability and economic reasonableness of reducing or eliminating air contaminants . . ."). This approach, to consider historical actual emissions is further consistent with the recommendation made by the Western

Regional Air Partnership (WRAP) when conducting the four-factor analysis for Regional Haze.[9] These data show that this path forward is, without a doubt, not cost-effective.

Finally, the last column shows cost-ineffectiveness calculations based on the more conservative PTE scenario.

As demonstrated by the data in Table 1-1 and the enclosed Appendices, even if the Department considers the overly conservative approach of using PTE to estimate the cost-per-ton, installation of SCR remains cost ineffective.

Based on the information provided in Table 4-1, the only available control technology for the 10 GE turbines, SCR, was considered to be economically infeasible.

[9] Supplementary Information for Four Factor Analyses by WRAP States, Revised Draft Report (April 20, 2010); see also ADEQ Regional Haze State Implementation Plan 2028, Emissions Projection Methodology; 40 C.F.R. Part 51, Appendix Y (discussing in relevant part how to calculate baseline emissions for the purpose of cost-effectiveness analysis for Best Available Retrofit Technology, which should "represent a realistic depiction of the anticipated annual emissions for the source. . . . you will estimate the anticipated annual emissions based upon actual emissions from a baseline period.").

5 Exclusion from ACP is Appropriate

5.1 The 10 GE Turbines cannot be Incorporated into an ACP

As noted above, Subparagraph (b) of Paragraph (11) of Subsection B of 20.2.50.113 NMAC requires the owner or operator "[p]repare a demonstration detailing why emissions from the individual engine or turbine cannot be addressed through an ACP in a technically practicable or economically feasible manner." This demonstration does not require the submission of a comprehensive ACP, but does require a reasonable analysis showing that the target emissions standards for these individual turbines are not technically practicable or economically feasible, even through an ACP. This Section 5 is responsive to this requirement.

An ACP must include the list of engines or turbines subject to the ACP, and a demonstration that the total allowable emissions for the engines or turbines subject to the ACP will not exceed the total allowable emissions under the emission standards of this Part. See 20.2.50.113. B.(7) NMAC. Kinder Morgan cannot satisfy this requirement if it includes the 10 GE turbines in the ACP. Total allowable NOx emissions under the rule for the rest of Kinder Morgan's entire fleet consisting of 17 engines and nine (9) non-GE turbines (26 units in total), excluding the 10 GE turbines, is 1,064.6 tpy. If the GE turbines in question were included in the ACP, the required reduction from the 10 GE turbines alone would be 1,630.4 tpy, an amount that exceeds the total allowable emissions from the 26 units that comprise the remainder of Kinder Morgan's fleet subject to the rule. Even if the 26 non-GE units were entirely shut down, Kinder Morgan could not achieve the required reductions while still operating the 10 GE turbines.

Furthermore, shutting down or reducing the capacity of the fleet of GE turbines, is not a feasible option at this time. The GE turbines, and in fact, the entire fleet of Kinder Morgan engines and turbines, are part of interstate natural gas pipelines that are subject to regulation by the Federal Energy Regulatory Commission (FERC) under the federal Natural Gas Act. See, e.g., 18 C.F.R. § 284.7(a) (setting forth requirements for interstate natural gas firm transportation service). FERC approves or "certificates" the pipeline to deliver natural gas. Kinder Morgan's entire pipeline system, as certificated by FERC, is based on the fact that Kinder Morgan can move gas 24 hours a day, 365 days a year at its designed capacity. Shutting down one or more of the company's turbines or engines would require that Kinder Morgan seek and obtain approval from FERC to abandon these units. In addition to being a lengthy administrative process, it is unlikely that FERC would approve shutting down the 10 GE turbines because it would diminish Kinder Morgan's ability to meet its obligations under the Natural Gas Act, drive up the cost of natural gas in the southwest United States, and deprive downstream consumers in New Mexico and other states of clean-burning natural gas to heat their homes and cook their food. Notably, multiple recent news articles and industry studies have discussed the relationship between market prices and pipeline

capacity or deliverability. For example, an NGI article from January 20, 2023 discussed the high prices in New England caused by lack of adequate pipeline delivery capacity to into the region.[10]

Additionally, market conditions project stable, if not increased, demand for natural gas. The Energy Information Administration's 2023 Annual Energy Outlook (AEO) analyzes long-term energy trends in the United States. In the context of the energy transition, while the AEO anticipates growth in renewable generating capacity, relative to 2022, the AEO projects that "natural gas generating capacity ranges from an increase of between 20% to 87% through 2050."[11] The AEO also concludes that "[d]espite the shift toward renewable sources and batteries in electricity generation, domestic natural gas consumption remains relatively stable," however, "Natural gas production . . . in some cases continues to grow in response to international demand for liquefied natural gas, supported by associated natural gas produced along with crude oil."[12]

In summary, at this time, shutting down or reducing capacity of the GE turbines as part of an ACP is not a viable solution.

[12] See AEO, at Figures 14 and 17.

6 EPNG's Proposed Alternative Emissions Standards

Notwithstanding the limitations EPNG faces with respect to the 10 GE turbines, and to demonstrate its commitment to reasonable emissions reductions, EPNG will reduce its permitted limits as part of the AES. In particular, after a detailed review of testing conducted on the 10 GE Frame 3 turbines and similar turbines in Kinder Morgan's nationwide fleet, Kinder Morgan has identified achievable reductions in permitted NOx emissions for these GE turbines. Thus, EPNG has proposed 418.3 tpy of NOx emissions reductions (see Table 2-2) from the current permitted allowable NOx emissions for these GE Frame 3 turbines.

6.1 Proposed Alternative Emission Standards

Under 20.2.50.113.B(11), the Ozone Precursor rule states an owner or operator may submit a request for AES for a specific engine or turbine based on technical impracticability or economic infeasibility.

EPNG expects the turbine operation in the future to be similar to current operations. However, turbine operation is highly dependent on product demand, weather patterns, pipeline maintenance, and upstream/downstream pipeline impacts. These factors create a considerable amount of uncertainty as to the expected annual operating hours of each turbine for a specific year, and make hours limitations impracticable.

Thus, to be conservative in establishing the AES, the operating hours were assumed to be 8,760 hours per year. In order to maintain an acceptable margin to compliance, EPNG calculated the AES using the highest hourly performance test data for each model with a 20% safety factor and 8,760 operating hours per year. The resulting emissions are lower than permitted emissions for each turbine but are more representative of the physical and operational design at the locations these turbines are installed. Specifically, the combined proposed annual NOx emissions from the 10 GE turbines show a reduction of 418.3 tons compared to the current permitted values. Kinder Morgan believes these reductions demonstrate a good faith effort to meet the requirements of the rule to the best of our ability given cost, technology, and national regulatory obligations.

EPNG is proposing to accept these AES as enforceable emission limitations. Because the emission standards found in 20.2.50.113 NMAC are in units of parts per million by volume (ppmvd), expressed on a dry basis at 15 percent oxygen (15% O_2), EPNG converted the AES in pph to ppmvd @15% O_2. The proposed AES for each turbine are presented in Table 6-1, and the reduction in emissions, as compared with annual permitted emissions, are shown in Table 6-2.

Table 6-1 Proposed Alternative Emissions Standards for NOx in pph and ppmvd@15% O_2

Turbine Location	Unit No.	Proposed Hourly NOx Emissions	Proposed Annual NO_X Emissions	Proposed NOx Limit (ppmvd@15% O2)
Afton	A-01	46.0 pph	201.5 tpy	202
Afton	A-02	46.0 pph	201.5 tpy	202
Afton	A-03	46.0 pph	201.5 tpy	202
Belen	A-01	20.9 pph	91.5 tpy	131
Belen	A-02	20.9 pph	91.5 tpy	131
Caprock	A-01	41.2 pph	180.5 tpy	169
Caprock	A-02	20.9 pph	91.6 tpy	131
Pecos River	A-01	46.0 pph	201.5 tpy	202
Pecos River	A-02	46.0 pph	201.5 tpy	202
Pecos River	A-03	46.0 pph	201.5 tpy	202
Total			1,664.1	

Table 6-2 Annual NOx Emissions Comparisons between Current Permit and Proposed AES

Turbine Location	Unit No.	Annual NOx Permit Limit (tpy)	Proposed Annual NOx Emissions (tpy)	NOx Reduction Proposed by AES (tpy)
Afton	A-01	224.5	201.5	23.0
Afton	A-02	224.5	201.5	23.0
Afton	A-03	224.5	201.5	23.0
Belen	A-01	169.0	91.5	77.5
Belen	A-02	169.0	91.5	77.5
Caprock	A-01	201.0	180.5	20.5
Caprock	A-02	172.1	91.6	80.5
Pecos River	A-01	232.6	201.5	31.1
Pecos River	A-02	232.6	201.5	31.1
Pecos River	A-03	232.6	201.5	31.1
Total		2,082.4	1,664.1	418.3

In order to convert from pph to ppmvd@15% O_2, the following inputs are needed: $\%O_2$ measured in the test, high heating value (HHV) of natural gas, fuel specific EPA F-Factor (dscf/mmBtu), conversion factor for NOx from ppm to lb/dscf, and fuel flow of natural gas measured in the test (scfh). Because Pecos River A-03 had the highest hourly tested emission rate for GE model MS3712R-A, it is used in the sample calculation below to convert the hourly NOx emission rate to ppmvd@15% O_2.

Inputs: $\%O_2$ measured during test = 18.92%
HHV of pipeline quality natural gas = 1,032 Btu/scf
Fuel specific EPA F-Factor determine during test = 8,694 dscf/mmBtu
Conversion factor for NOx = (ppm x 1.194E-07)
Fuel flow measured in test = 59,867 scfh
Proposed AES NOx hourly emission rate = 46.0 lb/hr

lb/mmscf = 46.0 (lb/hr) x 1,000,000 (scf/1 mmscf) / 59,867 (scf/hr) = 768.04
lb/mmBtu = 768.04 (lb/mmscf) / 1,032 (Btu/scf) = 0.744
Concentration (lb/dscf) = 0.744 (lb/mmBtu) x ((20.9-%O2)/20.9) / 8,694 (dscf/mmBtu) = 8.11E-06
Bias corrected concentration (ppm) = 8.11E-06 / (1,194E-07) = 67.9
Bias corrected concentration (ppmvd@15% O2) = 67.9 x 5.9 / (20.9-$\%O_2$) = 202

October 16, 2019

SUBJECT: FRAME 3 EMISSIONS TECHNOLOGY FOR AGED MODELS (FR3 A to G)

The first General Electric 2 shaft, Frame size 3 gas turbines were introduced in 1951. The first-generation models were Frame 3 A to G which were manufactured from 1951 to 1966. Emissions abatement technology was not developed for the Frame 3 gas turbines until the 1970's.

Baker Hughes currently does not have an any NOx abatement systems applicable to the Frame 3 A - F machines. Only a preliminary study was performed several years ago on the Frame 3F for LHE liner, no material was manufactured or supplied. We do not have water injection or DLN for the 32F.

There are currently no plans to develop NOx abatement technology for this model machine. It would take significant resources for such a study to take place.

PECOS RIVER 1	Gas turbine unit serial number 95025
PECOS RIVER 2	Gas turbine unit serial number 95053
PECOS RIVER 3	Gas turbine unit serial number 95055

ATTACHMENT 6

Document Summarizing Differences in Cost-Effectiveness Analysis Parameters Between Alternative Emissions Standard Demonstration and Four-Factor Analysis for Pecos River

Assumptions Used in Regional Haze (Four-Factor Analysis) and Ozone Precursor Rules (AES):		
	AES	**4FA**
Interest Rate	Used 8.53% for cost estimates based on PTE and 3.25% for cost estimates based on actual annual emissions	8.53%
Baseline Annual Emissions Lookback Period	For the cost estimate based on actual annual emissions, used the period from 2018-2020	Used the period of 2016-2021 which is consistent with NMED's lookback period
Annual Emission Reduction Rate	Cost estimate based on PTE, Annual Reduction (tpy) = SCR control efficiency % x (highest test results +20% safety factor) lb/hr x 8760 hr/yr	Annual Reduction (tpy) = SCR control efficiency% x avg annual hours (hr/yr) x avg test results (lb/hr)
	Cost estimate based on actual emissions, Annual Reduction (tpy) = SCR control efficiency % x 2020 test results (lb/hr) x average hours (hr/yr)	
SCR Control Efficiency	If based on PTE, SCR control efficiency = [Highest Test Result (ppm) -Rule NOx Limit (50 ppm]/Highest Test Result (ppm)	70%
	If based on actual emissions, SCR control efficiency = [Most Recent Test Result (ppm) -Rule NOx Limit (50 ppm]/Most Recent Test Result (ppm)	
SCR Capital Investment Cost	If based on PTE, SCR capital Investment Cost = CE2107005 Caprock Internal Est 07/16/2021 + $1MM cost increase per vendor 2022 email	CE2107005 Caprock Internal Est 07/16/2021
	If based on actual emissions, SCR capital Investment Cost = CE2107005 Caprock Internal Est 07/16/2021	
Remaining (useful) Life	25	20
Notes	Cost analysis based on the actual emissions are filed from KM's Technical testimony filed on July 28, 2021 before the NM EIB in which the average actual emissions from 2018-2020 were used. In 2022, SCR vendor informed KM that the cost has gone up; therefore, additional $1MM was added to the cost.	
	EPA Cost Control Manual states the useful life is 20-30 year, therefore, used 25 year as useful life in the cost estimate	NMED used 20 years as useful life

Reservation Credits SCOPE:	Potential 2022 reservation credits on the XOver with one Caprock unit unavailable. Assumes three (3) months outage for SCR and Regen modifications per unit (6 months total).
CWIP- Unit 1 Emissions Controls SCOPE:	Install SCR Emissions control system provided by [redacted] New expansion joints (3 per unit) will be installed on ducting between new regen and new SCR. Install a new Aux building for a new air system and other SCR controls.
CWIP-Unit 1 Regen SCOPE:	Install a new Regeneration equipment on Unit 1. Estimate includes a PAL-CON purchase credit for a multiple unit purchase.
RWIP-Unit 1 Regen SCOPE:	Remove the existing regenerator on Unit 1 including all exhaust duct work from the first Turbine Exhaust Expansion Joint to the entire exhaust stack. Prep site for installation of new regen unit.
CWIP- Unit 2 Emissions Controls SCOPE:	Install SCR Emissions control system provided by [redacted] New expansion joints (3 per unit) will be installed but the existing exhaust stack will be reused. Install a new Aux building for a new air system and SCR controls.
CWIP-Unit 2 Regen SCOPE:	Install a new Regeneration equipment on Unit 2.
RWIP-Unit 2 Regen SCOPE:	Remove the existing regenerator on Unit 2 including all exhaust duct work from the first Turbine Exhaust Expansion Joint to the entire exhaust stack. Prep site for installation of new regen unit.

[redacted]	[redacted]
Project Name:	**Caprock**

James,

We are pleased to submit this REVISED BUDGETARY proposal for [redacted] **Control System** designed to reduce emissions for (2) Frame 3 Turbines.

Rev 1 – Added oxidation catalyst increased sized for lower NOx in the future, option for jib crane and unloading pump station. Housing designed to support future NOx guarantee to 10ppm @15%O2. Elements designed in this quote for 50ppm @15%O2.

The [redacted] **Emissions Control System** offered for this project is based on engine and emissions data provided by Kinder Morgan. The enclosed proposal details the price, scope of supply, warranty, commissioning and terms and conditions necessary to achieve the required emissions limits and long-term compliance.

Should you have any questions or comments, please do not hesitate to contact me.

[redacted]

[redacted] COMPLIANCE AT A COMPETITIVE COST

[redacted] is an environmental engineering company supplying reliable exhaust after-treatment based emissions control systems to the North American market. Our strength is helping customers comply with federal and local emission regulations targeting process machines, marine vessels, offshore rigs, stationary diesel and natural gas engines and turbines. We specialize in reducing NOx using a comprehensive systems approach based on Selective Catalytic Reduction (SCR). Our SCR systems are then combined with oxidation catalysts or particulate filter technologies to reduce other regulated pollutant emissions, such as carbon monoxide (CO), hydrocarbons (HC), volatile organic compounds (VOC) and particulate matter (PM). We also offer an array of supporting component options, from urea storage tanks to air compressors to silencers, with the goal of providing everything necessary for a successful and near-turnkey installation.

[redacted] leverages more than five decades of experience in environmental compliance, and draws upon the knowledge of over 1000 successful SCR systems in a wide variety of markets such as marine, power generation, oil and gas development, industrial and chemical processes.

Our structured engineering approach begins by comparing your project's emissions profile to the regulations, or to the project's unique requirements. We then design an emission control system tailored to your application. Our product manufacturing process is governed by exacting quality standards, and our systems are commissioned with the [redacted] Emissions Guarantee. To ensure compliance over the long-term, we provide support after the sale through extensive operator training, spare parts, and on-site maintenance.

[redacted] is simply defined as being your trusted partner, helping you comply with federal and local regulations with emission control systems that are:

- ***Proven***
- ***Reliable***
- ***Cost-Competitive***

In the proposal you will find the [redacted] Emissions Control System and Commissioning details in the Scope of Supply. We can also provide several optional components necessary for a comprehensive installation, such as a urea storage tank, silencer or air compressor. Our goal is to also provide the convenience of having all components necessary for a successful installation available from a single source.

Thank you for the opportunity to provide this proposal. Should you place an order with us, we can assure you seamless integration with your project management team, and exceptional quality of the delivered emissions control system, accompanying documentation, and post-installation parts and service support.

I. QUOTATION

PROPOSAL #: [redacted]

PROJECT: Caprock

DESCRIPTION: [redacted] Emission Control Systems to reduce emissions from GE Frame 3 Natural-Gas Fired Turbines

1. SCOPE OF SUPPLY

ITEM	DESCRIPTION	EXT. PRICE ($)

001	**EMISSIONS CONTROL SYSTEM (2 x Frame3)**
	• 2 x Ducting / SCR Housing / Silencer
	  ○ Oxidation Catalyst
	  ○ Ammonia Injection Grid
	  ○ SCR Catalyst
	  ○ Ducting from Regen Outlet to SCR
	  ○ Expansion joint at Regen Outlet
	  ○ Ducting from SCR to Tailpipe
	  ○ Silencer / Tailpipe with CEMS Ports
	• 2 x Recycle Gas Skid, each including:
	  ○ 1 x Two-Phase Injection Lance for ammonia/air
	  ○ 1 x Static mixer
	  ○ 1 x Ventilator fan
	• 1 x SCR Control System with Touch-screen and PLC
	  ○ With NO/O2 analyzer (dual channel, single O2 measurement)
	  ○ 2 x Sample Probes and Heated Sample Lines (Per Unit)
	• 2 x Ammonia/Air Dosing Panel
	• 1 x Reagent Pump Station
	• 1 x Reagent Storage Tank
	• Engineering, Operation & Maintenance Documentation (Thumb Drive Only)
		$6,200,000

002	**COMMISSIONING and TRAINING (2 x Units)** Estimated 12 man-days, per engine for the commissioning of the emission control system to meet the required emissions levels, plus 1 day of on-site training; includes costs of travel and accommodations. We can provide qualified personnel to supervise installation at the rate of $1,350 per man-day, plus travel expenses. Additional time will be billed per the time and material rates.	**$50,000**
003	**INSTALLATION ASSISTANCE (2 x Units)** Estimated 90 man-days for both units to assist with construction supervisions of the hardware included herein. All labor/expenses will be billed per a time and material rate of $1,350 per man-day, plus all travel expenses.	**$175,000**

Not included in the scope of supply:

- Load signal from the engine (4-20 mA)
- Fuel flow signal from the engine (4-20mA)
- Fuel composition (TCP/IP)
- Engine running signal (digital dry contact, closed when engine is running)
- Internet connection for remote PLC access and service support
- Structural and civil work necessary to complete the installation
- Catalyst element lift / crane (available as an option)
- Aqueous Ammonia Solution
- Unloading valve/pump skid and controller (available as an option)
- Platforms and other support structures not listed herein
- Compressed Air, per ISO 1.3.4 requirements
- Heat tracing of Ammonia tank or Ammonia lines (available as an option)
- Provision for electricity and connection of the power supply to the enclosure
- System integration (design and engineering) with the building structure
- Unloading of material at customer location
- Any 3rd party emission certification of stack test

OPTIONAL HARDWARE and SERVICES

ITEM	DESCRIPTION	EXT. PRICE ($)
4.1	**JIB REMOVAL CRANE (OPTIONAL, 2 UNITS)**	**$68,650**
4.2	**UNLOADING PUMP STATION (OPTIONAL, PER SITE)**	**$53,800**
4.3	**SCR ELEMENTS (OPTIONAL, PER UNIT)**	**$200,000**
4.4	**OXIDATION ELEMENTS (OPTIONAL, PER UNIT)**	**$145,000**

2. PRICE

The given prices for the SCR Emissions Control System are net prices, DDP to customer location in NM, according to Incoterms 2010. All prices are in US dollars. Not included are taxes. Shipping based on standard ground, sea vessel and non-expedited shipping.

3. PAYMENT

30% of the order value upon initial order;
15% of the order value with submittal of engineering documents
50% of the order value with ready for shipment of the hardware
5% of the order value after successful commissioning, not to exceed six (6) months after delivery
All payments are to be paid within 30 days after each date of invoice, net.

4. SCHEDULING & DELIVERY

Delivery of the drawings and technical documents is approximately 16 weeks after receipt of a purchase order. Delivery of the hardware is approximately 32 weeks after approval of all technical details. Total estimated schedule (with a 4-week customer review period) is 36 weeks for receipt of material at each station.

- Preliminary Engineering Drawings – Approximately 16 weeks after receipt of a purchase order
- Customer Review/Approval – 4 Weeks from Receipt of Preliminary
- Release IFC's – 4 Weeks From Receipt of Customer Comments
- Manufacturing – 26-30 Weeks From Customer Approval
- Shipping – 3-4 Weeks
- Total Estimated Time For 2 Units: ~56 Weeks (Accelerated Schedule Available At Additional Cost). Follow on unit likely at 2-3 month intervals

5. QUALITY STANDARD

All drawings will be in both metric and English units. We reserve the right to adapt the technical design of the emission control system based on the results of the final engineering work, provided this does not impact the affect the guaranteed performance characteristics and is approved by the customer before production begins.

6. OFFER VALIDITY

This offer is valid 90 days from date on proposal.

II. TECHNICAL DESCRIPTION

1. EXHAUST GAS DATA & EMISSION REQUIREMENTS

Unit Data:

Parameter = 100% Load	Unit	GE Frame 3*
Fuel	-	CQNG
Power	bhp	7,040
Exhaust Gas Flow Rate (wet)	lb/hr	~335,000
Exhaust Gas Moisture Content (actual, wet)	Vol. %	3.5
Oxygen Content (actual, wet)	Vol. %	18.1
Exhaust Temperature	°F	450**

** From KM provided data*
***Regen Outlet*

Emission Control System Design Parameters:

Parameter	Unit	Frame 3
Aqueous Ammonia Solution	%	19
Aqueous Urea Solution Consumption Rate (at 100% engine load) approximately, per engine	gph	~10.0
Total Estimated Backpressure Contribution	inH_2O	9.0
Air Consumption, per engine (Based on 87 psi nominal, max 160 psi	scfm	25**

**Based on worst case: Max exhaust flow, 150ppmvd@15%O2 NOx inlet and ~30ppmvd @15% O2 NOx outlet. Reduced loads and lower NOx inlet will yield lower aqueous reagent consumption rates*

***Type Z purge for control panel and dosing panel are not included in this air consumption*

Electrical Load:

Load	VAC	Watts
SCR Panel (Per Unit) Distributes: 480VAC to pump and blower 110VAC to tank distribution panel 24VDC to dosing panel and pump panel	480VAC, 3Ph	~50Watts

2. EMISSIONS GUARANTEE & WARRANTY

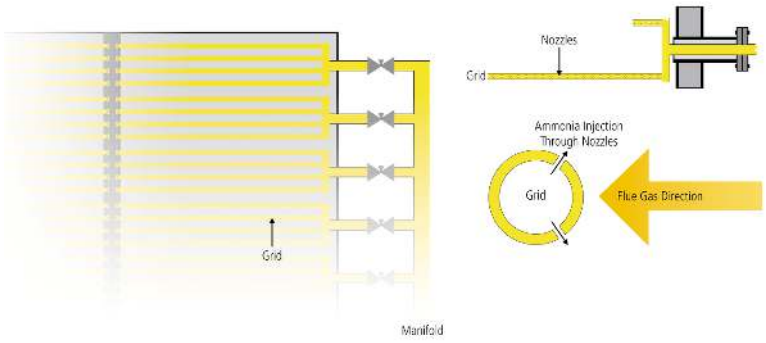
Constituent	Current Engine Out	Required Stack Out**
NOx as NO_2*	150 ppmvd @15% O_2	50 ppmvd @15% O_2
CO*	35 ppmvd @15% O_2	15 ppmvd @15% O_2
VOC*	20 ppmvd @15% O_2	9 ppmvd @15% O_2

** Based on 1 hour averaging with the engine operating at 100% load. Minimum temperature for SCR performance is 570F.*

***Based on a minimum 440F SCR outlet temperature with 19% NH3 and Maximum SCR inlet temperature of 750F*

Provided the engine is operating under stable operating conditions, [redacted] guarantees the stack emissions (Based on % reduction) for a period of 24,000 hours of operation or 36 months after the initial SCR commissioning, or 42 months after delivery, whichever comes first. All values are per EPA-approved measurement methods, with one-hour averaging while the engine is operating at 100% load. The mechanical warranty is 12 months after commissioning or 18 months after delivery, whichever comes first.

This guarantee is subject certain maintenance practices and engine operating conditions, [redacted] The guarantee is also based on the emissions data provided to [redacted] at the time of this quotation and defined in Section 1 of the Technical Description. [redacted] reserves the right to modify Items 001 in the Scope of Supply and associated price once more accurate and complete emissions data are obtained in order to ensure the emission limits can be maintained as required.



3. SCOPE OF SUPPLY

A. Engineering (Per Site)

- Project Management
  - Includes monthly conference calls and documented updates with action items
  - Manage change order process and site activity
  - Accounting and Invoicing
- 2 Engineering Meetings at Customer site, maximum 1 day on-site per trip
- Drawings
  - Ducting drawings including structure supports necessary for construction
  - Silencer and Tailpipe construction drawings
  - Recycle gas skid mechanical
  - SCR / OXI catalyst arrangement
- System flow diagram
  - P&I diagram for the process and the auxiliaries
  - Flow Diagram
- Control of the SCR system
  - Software and operational description for control of the SCR-system
  - Cable diagram
  - Instrument list
- Documentation
  - Installation instructions including check lists for mounting and structural work (at 'Ready to Ship' for structure/ducting)
  - SCR and OXI Element operation and maintenance manual (post commissioning)
- Supporting Analyses
  - Ducting/Silencer structural design and calculations related to geographic requirements (i.e. wind, seismic)
  - CFD modeling as required to support AIG design

B. Ammonia Injection Grid (Per Unit)

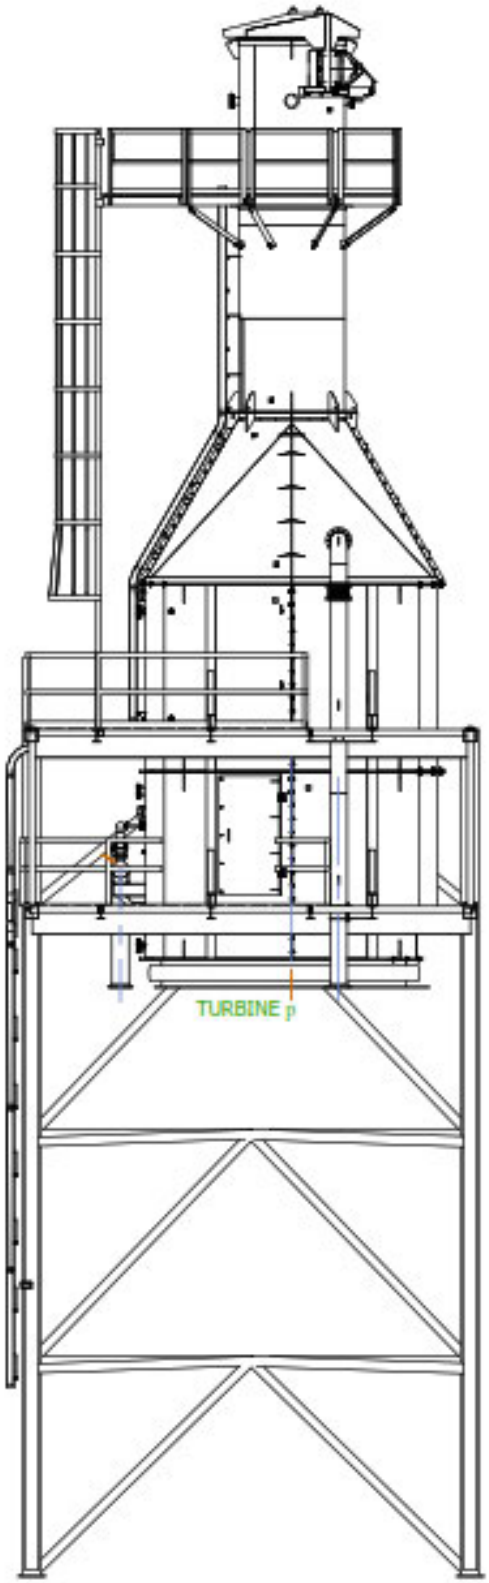
Includes one ammonia injection grid (AIG). The ammonia gas will be re-injected in the main exhaust gas duct with an ammonia injection grid. Each turbine will include (1) NH3 monitor with visual and audible indication.

Ammonia Injection Grid

- Piping with injection Nozzles
- Header
- Isolation and dosing valve

AIG Design figures:

- Material: Stainless Steel
- Flanges: ANSI



C. OXI / SCR Reactor Housing / Ducting / Silencer (Per Unit)

The reactor housing duct and stack is designed as a cool wall lined system. This design incorporates a high strength carbon steel casing complete with external structural stiffening and support steel with an internal floating liner decoupled from the casing using a proprietary liner isolation support system. Compressed thermal / acoustical insulation between the 409SS liner and casing reduce thermal and acoustic coupling between the two surfaces minimizing the transfer of heat and noise to outer surfaces of the duct system. Ducting/structure consists of the following major components:

- Inlet expansion joint, multi-layered composite belt style. Rated at 1100F +/- 2psig
- Acoustically and thermally lined inlet transition duct
- SCR reactor housing designed for AIG, SCR and Oxicat elements. Includes (2) personnel access doors for catalyst maintenance and replacement (Oxicat and SCR)
- Exhaust stack to include silencer section and (4) EPA approved flanged test ports. Acoustic design is based on 85 dBA @ 3ft perpendicular to stack exit, 100 mph wind load.
- Stack height from grade is 85ft with ~6ft inside diameter
- Includes all flanged joint hardware (bolts, nuts, washers and gasket material)
- Liner kits to include liner material, bolting for internal flanges will be supplied as needed
- Includes static rain cap to protect SCR elements from water damage
- Maintenance platform for installation and removal of the oxidation and SCR modules. Ladders will be compliant to the latest OSHA standards (Fall restraints per OSHA 1910.28)

CONSTRUCTION:
Baffles: 14 GA 409 SS Insulation: High temp mineral wool with SS erosion protection
TRANSITION / SILENCER / DUCT:
Casing: Continuously welded A-36 carbon steel Flanges/Stiffs: A-36 carbon steel Insulation: High temp mineral wool with SS erosion protection Liner: 12 GA 409 SS solid and 14 GA 409 SS Perf Exterior Only: SSPC-SP6 commercial blast Coating: (1) Coat zinc primer (2-3 mils DFT) (1) Coat Amercoat 741 (2-3 mils DFT)
LADDERS/PLATFORM:
Structure: Continuously welded A-36 carbon steel Coating: Hot dipped galvanized

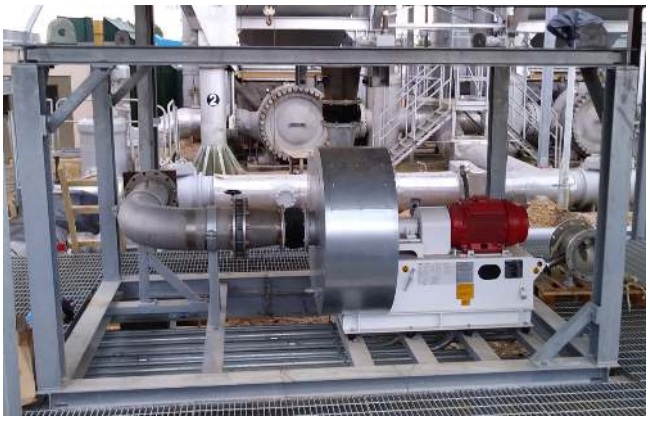
Representative Layout

D. SCR Catalyst (Per Unit)

The SCR catalyst is a corrugated monolith catalyst. The elements will be designed for installation within the framework of the ducting. Individually loaded in the SCR housing.

Type of Catalyst:	Honeycomb
Approximate Element Weight:	~12,000 lbs (~78 lbs each)
Catalyst Layers Per Housing:	2
Approximate Internal Reactor Cross-Section Dimensions: (W x H)	12.5 ft x 13.5 ft

Note the SCR catalyst impurity tolerance specification in Section IV and SCR manufacturer data sheet.



E. Recycle Gas Skid (Per Unit)

A small part of the exhaust gas will be taken out from the main exhaust gas duct downstream of the SCR reactor housing and sent to the recycle gas skid, where aqueous ammonia solution will be injected, evaporated and re-injected in the main exhaust gas duct via the ammonia injection grid. For a defined exhaust gas flow.

Blower Skid

Skid including:

- 1 x Blower, rated at ~11 kW, 480VAC, 3 Ph
- 1 x Steel Duct,
  - Diameter 10 in
  - Exhaust piping: SS304

Mixing Duct With Gas Mixer (2 Phase)

- 1 x Static mixer, Design features:
  - Flanges: ANSI 10 in
  - Mixer Type: Cross-impulse-mixer
  - Material disc: Stainless steel
  - One piece of air atomization nozzle integrated in the mixer

F. SCR Control (Per 2 Units)

The SCR unit is controlled by a single control system housed in a control cabinet. Includes an Allen-Bradley ControlLogix Programmable Logic Controller and an A-B 15in touch screen with menu-guided parameter inputs (without any program change); password protection; error message and clear readable display. Includes an Ethernet communication between the PLC and the customer's control system. SCR Control Panel will include a (2) day FAT to test and review PLC, IO, communications, power and HMI screens. Customer witness / approval is required before shipping.

- Operating hour indication
- (3) temperature measurements with thermocouples
- Pressure measurement (delta P over the SCR catalyst)
- Flow measurement for reducing agent with limit switch
- NO/O2 Analyzer (Per Turbine) for pre and post SCR measurement
  - Includes necessary gas conditioning
  - Includes <120ft sample line and probe
- Power: 480V, 60Hz, 3 Ph

NOTE: Designed for indoor installation. 5F to 95F Temperature range
NOTE: Approximate Cabinet Dimensions: 83 in x 71 in x 24 in (H x W x D)
NOTE: Panel will require Type Z Purge to meet Class, Div 2 Requirements. Option available for Class 1, Division 2 Building to house SCR control panel with gas analytics
NOTE: Based on Rosemount T/C based temp transmitters and DP pressure transmitters. DP transmitter to include 5-valve manifold for calibration
NOTE: [redacted] can support different PLC/HMI manufacturer(s) at the request of the customer. This will likely result in additional cost and time.
NOTE: NEMA 4 enclosure, painted standard manufacturer grey, ambient temperature 40-110F

G. Reagent Dosing Panel (Per Unit)

All components for aqueous ammonia dosing are mounted on a steel back panel; includes steel dosing valve, magnetic valves and shut-off valves. (Pressure indicators related to reagent solution supply to the dosing panel are the customer's scope.) Designed for indoor installation, NEMA 4x panel with Type Z purge. Ambient temperature range: 40-110F

Protection:	Suitable for Class 1, Division 2
Dimensions	24 in H x 24 in W
Connections: Reagent Solution: Atomizing Air:	 Panel connection with 3/8in Swagelok fitting Panel connection with 3/4in Swagelok fitting

NOTE: Panel to be <35 ft from injector
NOTE: Based on E&H or IFM Flow Meter, Burkert Control Valves, IFM pressure Sensor. No calibration manifolds included with the dosing valve components.

H. Ammonia Pump Station (Per Site)

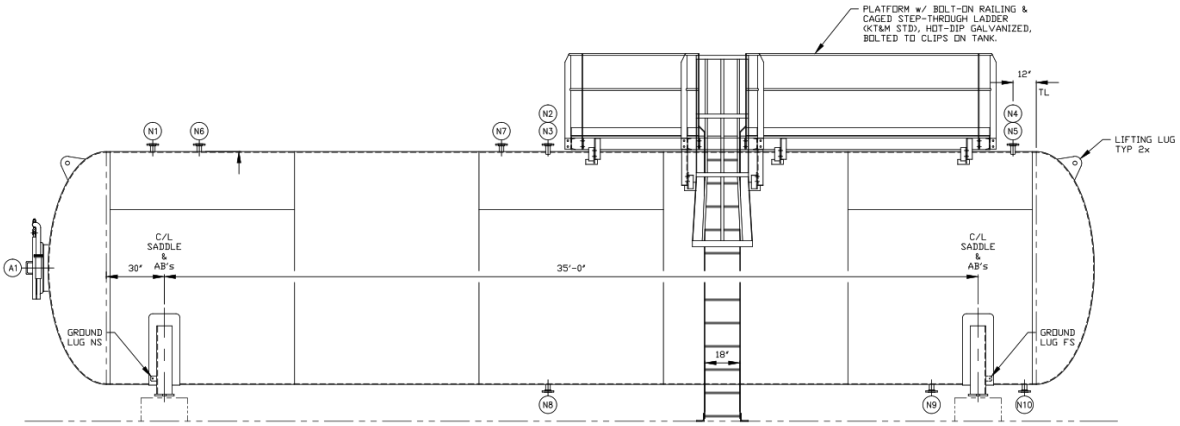
Pump station complete with auxiliary valves, filters; ships fully assembled and pretested from our factory. The pump station has been designed for 19% aqueous NH3 for simultaneous operation of all units at the facility. The pump station also comes with one 100% backup pump. NEMA standard protection with VFD's installed on skid. Designed for indoor installation. Power to pump station direct from customer MCC. 480VAC/3Ph/1.5kW per pump. NEMA4x electrical enclosure. Panel designed for ambient range: 40-100F

NOTE: Based on IFM pressure Sensor. No calibration manifold provided.

NOTE: Suitable for outdoor in non-hazardous location. Located next to reagent storage tank

I. Ammonia Tank and End Devices (Per Site)

Includes (1) horizontal, 25,000 USG, single-wall stainless-steel tank. 120in D x 42ft tangent to tangent length, made of 304 stainless steel, built to ASME Section VIII Division 1 Code, Design Parameters: 30 psig, 125˚F with 1/16 in corrosion allowance. Tank includes:



- 24 in ASME Manway
- (8) 2in FNPT fittings
- (2) 4in FNPT fittings
- (2) Lift lugs
- (1) Ground lug

With the following end devices: (Shipped Loose)

- (1) Ultrasonic level transmitter
- (1) Temperature transmitter
- (1) Pressure transmitter
- (1) Relief and Vacuum Valve
- (1) NH_3 leak detection sensor
- (1) Control panel for indication of level, pressure and temperature

NOTE: Suitable for outdoor installation in non-hazardous location. Distribution panel Located next to ammonia storage tank. Option available to add an unloading pump station to the control panel and ammonia storage tank at the request of the customer

Representative Tank Arrangement

III. OPERATING PRINCIPLE

Selective Catalytic Reduction Principle

NOx is a general term referring to Nitrogen Oxide (NO) and Nitrogen Dioxide (NO_2) gases. NOx forms at the high temperatures of a combustion process, typical of internal combustion engines. NOx is a precursor to smog and adversely effects health and the environment. As such, NOx is increasingly regulated by both the US Environmental Protection Agency and by local authorities.

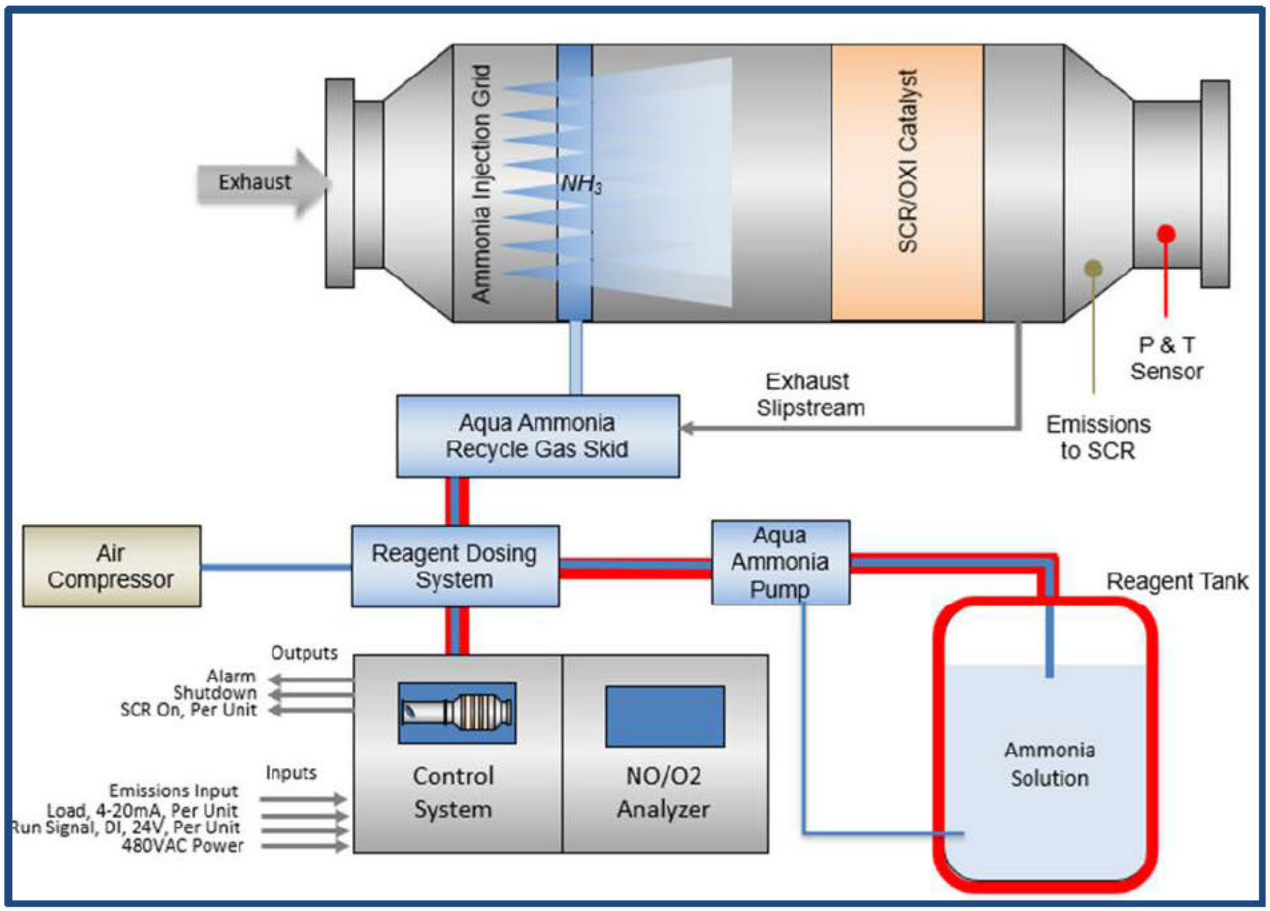
NOx emissions are most efficiently removed from the exhaust by Selective Catalytic Reduction, often referred to as SCR. SCR works by promoting a chemical reaction between the NOx and ammonia gas (NH_3), which is introduced upstream of the SCR catalysts. The ammonia can come from a variety of sources, including directly as a gas (known as anhydrous ammonia), or as an aqueous ammonia solution. It is more common to use aqueous urea solution. Urea is a widespread component of fertilizer, and water-based solutions made from urea are easier to handle than ammonia compounds. Moreover, aqueous urea solutions are readily available in different storage capacities and concentrations.

Commercially, aqueous urea solutions come in two concentrations, either 32.5% or 40%. The lower concentration, 32.5%, has the lowest freezing point of 12°F (-11°C), and is therefore used in colder climates where ambient temperatures can reach this point. The 40% concentration has a higher freezing temperature of 35°F (2°C), but requires less volume of solution to achieve the same degree of NOx reduction. In either case, freezing is to be avoided since injection becomes problematic. When low temperatures are encountered in the application, it is customary to install an immersion heater in the urea storage tank, as well as heat-tracing the urea supply lines to the SCR System. This is true for both concentrations of urea solution.

When the engine is running and the catalyst has warmed up to its normal operating temperature, urea solution is injected into exhaust stream ahead of the SCR catalyst, in combination with high-pressure air, to assist in atomizing the spray. (The air also cools the urea injection nozzle and purges the injector when the engine is no longer running.) Chemically, the heat of the exhaust first vaporizes the water in the urea solution, resulting in the formation of small urea crystals. These crystals further breakdown in the exhaust stream into ammonia and carbon dioxide. Once ammonia is present, the chemical reactions shown below take place over the SCR catalyst, reducing NOx to harmless nitrogen gas and water vapor.

Once ammonia gas is present, the chemical reactions shown below take place over the SCR catalyst, reducing NOx to harmless nitrogen gas and water vapor:

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$6\ NO_2 + 8\ NH_3 \rightarrow 7\ N_2 + 12\ H_2O$$
$$2\ NO + 2NO_2 + 4\ NH_3 \rightarrow 4\ N_2 + 6\ H_2O$$



The SCR Catalyst Technology:

SCR catalysts generally fall into two categories, a vanadia-based catalyst embedded in an extruded ceramic substrate, or a zeolite-based technology coated onto the surface of a ceramic substrate. In the former, the catalyst is actually incorporated into the ceramic structure, and as a result the catalyst is generally more robust to thermal variation. In addition, vanadia-based technologies operate over a wide temperature range, and when combined with its strength advantages and lower cost, are used in many

industrial applications such as large-scale power plants and boiler systems. Vanadia-based catalysts have demonstrated NOx reduction capability of up to 98%, and can operate continuously to temperatures of 510°C (950°F).

Zeolite systems are ideal for higher temperature applications, for example above 510°C, and as such have found wide use in mobile diesel applications such as on-highway trucks. These systems have also demonstrated a capability for high NOx reduction.

The size of the SCR catalyst elements and how they are configured in a catalyst housing (e.g., number of catalyst layers) is determined by factors such as the required NOx reduction, allowable back pressure of the engine, and ammonia slip limits. High levels of NOx reduction (>80%) generally require 2-4 layers of catalyst.

Schematic of a representative [redacted] Emission Control System.

Urea Injection Strategy:

Reducing NOx to N_2 with high levels of chemical conversion efficiency without introducing excess ammonia into the exhaust (known as "ammonia slip") requires precise control of the urea or ammonia injection process. The strategy for urea or ammonia injection depends on the degree of NOx reduction, and the required ammonia slip limits.

The simplest injection strategy links the engine to the SCR system through the engine load. NOx emissions are measured as a function of engine load, creating a "NOx vs. Engine Load" map. From this map, an injection algorithm determines the amount of urea or aqua ammonia necessary to reach the required NOx level, and sends this signal to the dosing control system. Because the amount of urea or ammonia injected is based on the engine load and not on a direct measurement of NOx, such an engine mapping strategy is often referred to as an "open-loop" control strategy. Such an injection strategy has been used successfully when NOx reduction requirements are generally less than 90%. Moreover, the strategy has demonstrated that ammonia slip is minimal, generally far less than typical 10ppm regulatory requirements.

When higher levels of NOx reduction are necessary, it is customary to add a NOx analyzer to the SCR System to directly measure NOx after the SCR catalyst. The signal from the analyzer is then sent to the SCR dosing control system, which then "trims" the injection volume up or down to ensure the required NOx reduction level is reached, without overdosing that could lead to an increase in ammonia slip. As the NOx is measured directly with the NOx analyzer, and the signal is used to control the reagent dosing volume, this strategy is referred to as "closed-loop" control. This strategy has demonstrated up to 98% NOx reduction, with very low levels of ammonia slip (as low as 5ppm in some applications).

Role of the Oxidation Catalyst:

By incorporating an oxidation catalyst into the system, it is possible to reduce carbon monoxide (CO), many hydrocarbon species (HC), volatile organic compounds (VOC) such as formaldehyde, and particulate matter. Placement of the oxidation catalyst depends on the application requirements, such as degree of CO reduction, but also on parameters such as the degree of NOx reduction and maximum levels of ammonia slip. In many cases, the oxidation catalyst can be incorporated directly into the SCR catalyst housing, saving both space and the cost of a separate housing.

Oxidation catalysts are generally precious metals-based systems composed of platinum, or mixtures of platinum, palladium and other precious group metals (PGM). PGM catalysts are highly effective at utilizing the excess oxygen in the exhaust stream of lean-burning engines to convert CO, HC and formaldehyde to water vapor and carbon dioxide, as shown below:

$$2CO + O_2 \rightarrow 2\ CO_2$$
$$HC^* + O_2 \rightarrow H_2O + CO_2$$
$$HCOH + O_2 \rightarrow H_2O + CO_2$$

Oxidation catalysts can be engineered to operate at temperatures similar to SCR catalysts, allowing for reduction of several pollutant emissions within the same system. Moreover, oxidation catalysts are highly effective, reducing emissions as much as 95%.

---

* *The specific reaction depends on HC species, such as CH_4, C_2H_6 etc.*

IV. SCR CATALYST IMPURITY TOLERANCE SPECIFICATION

SCR catalysts, like all catalyst materials, are susceptible to severe performance degradation if certain impurities in the exhaust stream exceed specific levels. These impurities derive from the use of improper or off-spec fuels, certain impurities in landfill or digester gases, lubrication oils, or other additives that could become part of the exhaust gas composition.

In order to maintain the warranty for the SCR quoted in this engineering document, the following impurities and impurity concentrations must be strictly adhered to. Any unexpected performance degradation of the SCR and/or Oxidation catalyst system will result in a chemical analysis of the catalyst system to determine if these impurity tolerances were exceeded.

Impurity	Max. Concentration Limit
Alkaline Metals	5 mg/Nm^3 (wet)
Alkaline Earth Metals	1 mg/Nm^3 (wet)
Hydrochloric Acid; Chloride Compounds	100 mg/Nm^3 (wet)
Hydrofluoric Acid; Fluoride Compounds*	1 mg/Nm^3 (wet)
P_2O_5; Organic Phosphorous Compounds	0.05 mg/Nm^3 (wet)
Mercury & Zinc	0.1 mg/Nm^3 (wet)
Lead & Cadmium	0.1 mg/Nm^3 (wet)
Arsenic; Arsenic Compounds	0.005 mg/Nm^3 (wet)
Organic Silicon Compounds (e.g., Siloxanes); Silicon Halides	0.005 mg/Nm^3 (wet)

**Depending on exhaust gas composition and engine operating condition, a concentration of up to 20 mg/Nm3 may be acceptable. Please contact us for more information.*

Re: Regional Haze – Draft Plan and Rule 20.2.68 NMAC
DCP Operating Company, LP
Linam Ranch Gas Plant
Agency ID: 589

Dear Mr. Jones,

Phillips 66 Company (Phillips 66) is providing this comment on behalf of DCP Operating Company LP (DCP), as it is an indirect subsidiary.

The comment is specific to DRAFT rule 20.2.68.102.A. Table 1 NMAC. On Table 1, Linam Ranch Gas Plant RP Unit 32B is listed with an Emission Limitation of 25 ppmvd @ 15% O2 and a Compliance Deadline of 0 years.

On August 28, 2023, Phillips 66 submitted a letter to Michael Baca of New Mexico Environment Department (NMED) Air Quality Bureau (AQB) responding to outstanding questions for the Linam Ranch Gas Plant from a July 12, 2023 NMED meeting agenda. In the letter Phillips 66 committed that Turbine 32B would be upgraded to be compliant with 20.2.50 NMAC NOx emission limit of 50 ppmvd @ 15% O2. At the time of the August 28, 2023 letter, Turbine 32B did not have a schedule so was committed to be compliant with 20.2.50 NMAC, which would be by January 1, 2028.

On January 24, 2024, you emailed me asking for any updates regarding the schedule. I responded on February 5, 2024 that the bid was out and that there was an expectation, but not a guarantee, to be completed within the second group of the ozone precursor rule [20.2.50 NMAC]. The email indicated that this would have an expectation of the controls being updated by the end of 2025. I followed that up with an expression of regret that I did not have a more definitive schedule, but it was the best that I had at that time.

Based on these communications, Phillips 66 is taken aback by the proposed Emission Limitation and the Compliance Deadline. Since the proposed Emission Limitation for

Turbine 32B has been used in Regional Haze modeling and based on the performance tests of the other turbines at Linam Ranch Gas Plant Phillips 66 does not have a comment on the Emission Limitation, at this time. However, Phillips 66 proposes changing the Compliance Deadline from “0 years”.

When evaluating the Compliance Deadline of all the Units in DRAFT Table 1 of 20.2.68.102 NMAC, there is the following distribution:

- 3 years 80%
- 2 years 7%
- 1 years 0%
- 0 years 14%

While the “3 years” category is necessary for those units that need to start the engineering and purchasing process to meet the proposed Emission Limitation, the “0 years” would imply that the project is complete or at least very near complete. Phillips 66 asserts that while the project to upgrade Turbine 32B has been ongoing, the project does not meet the classification for “0 years”.

For these reasons, Phillips 66 proposes to move the Compliance Deadline for RP Unit 32B, at Linam Ranch Gas Plant, from “0 years” to “1 years”. This should not have an overall negative impact to the NMED Regional Haze State Implementation Plan (SIP).

If you have any questions regarding this notification, please feel free to contact me at the information above.

Sincerely,

Steven R. Torpey, PE (TX)
Sr. Env Air Permitting Engineer

Subject: [EXTERNAL] NM Regional Haze SIP Public Engagement Period
Date: Friday, September 20, 2024 10:08:09 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Hi Mark

Thank you for notifying us that the draft of the New Mexico regional haze state implementation plan (SIP) was posted for informal public comment. We understand from your August 27, 2024, email that this is considered to be an opportunity for informal public engagement rather than a formal public comment period, and that a formal public comment period on the plan and new rule (20.2.68 NMAC – Regional Haze Requirements) will be forthcoming. With that in mind, we have reviewed the updated draft SIP and offer the following informal feedback.

Overall, the updated draft SIP will provide significant reductions in haze-causing emissions, particularly NOx. We appreciate the improvements that NMED has made to the draft SIP in response to comments we submitted during the FLM consultation period earlier this year. In particular, we commend NMED for reevaluating SCR as a control option for NOx at six facilities that were selected four-factor analysis. This identified opportunities to further reduce annual NOx emissions by 1,600 tons.

A few remaining questions and comments that were not addressed in the latest public draft SIP:

- Regarding NOx emission from the Artesia Gas Plant:
  - Were the individual reciprocating engine and boiler unit emissions below NMED's screening criteria for individual units (i.e., potential to emit less than 10 lb/hr or 5 tons/year)? Data from the 2017 National Emissions Inventory (NEI) suggests that several of Artesia's units did report annual emissions of greater than 5 tons.
  - Are the larger engines at the Artesia gas plant subject to NMED's Oil and Gas Sector – Ozone Precursor Pollutants Rule (NMAC 20.2.50.1)? If so, the NPS continues to recommend summarizing any anticipated NOx reductions from Artesia in the SIP.
- The draft FLM consultation SIP stated that application of dry-low NOx (DLN) technology would be required for Linam Ranch Gas Plant turbine 32b, but this is no longer listed as a required measure in the updated draft public SIP. Appendix D seems to suggest that DLN is already being added to turbine 32b for reasons not related to regional haze. Is this correct?
- For Blanco Compressor Station A, NPS continues to recommend that NMED consider engine replacement costs based on facility-wide utilization rates rather than a unit-specific basis.
- For the Cunningham Station Power Plant, the NPS continues to recommend the facility be required to install and operate SCR on units 1 and/or 2 no later than January 1, 2031, if either unit operates beyond the December 31, 2027 end of the second planning period.

Thank you for the opportunity to provide informal feedback on New Mexico's draft regional haze SIP during this informal public engagement period. The NPS finds that the NOx reduction measures identified in this updated regional haze SIP will provide necessary and significant contributions to reducing man-made visibility impairment in NPS-managed Class I areas, including Mesa Verde, Carlsbad Caverns, and Guadalupe Mountains National Parks. We commend NMED for its commitment to protecting these invaluable parks and for its careful consideration of the comments we provided during the FLM consultation period. We look forward to working with you as the plan is further developed. Please do not hesitate to contact us if you have any questions.

Re: Comments on NMED's Draft Regional Haze SIP and Proposed Rule

Dear New Mexico Environment Department ("NMED"),

The Western Environmental Law Center ("WELC"), submits the following comments regarding the New Mexico Environment Department's Draft Regional Haze State Implementation Plan ("Draft SIP") and accompanying proposed rule, 20.2.68 NMAC – Regional Haze Requirements ("NM Haze Rule" or "Proposed Rule."). We appreciate the opportunity to provide feedback on the Draft SIP and Proposed Rule during this informal comment period—and appreciate that NMED is still considering prior comments and analyses submitted by stakeholders (including WELC) in revising the draft and developing a Final SIP.[1] We hope to see those considerations reflected in a Final SIP.

Broadly, we urge NMED to revise its SIP and use its ample authority under the Regional Haze Rule to embrace a more comprehensive approach to haze planning—an approach that improves visibility in Class I areas through more inclusive source identification and stronger emissions controls, *and* better fulfills NMED's environmental justice obligations, promotes public health, and advances statewide air and water quality, climate and just transition efforts.[2] We also offer some suggestions for how NMED can engage in a more robust public participation and consultation process moving forward—in accordance with NM Executive Order 2005-056 and its mandates to provide meaningful opportunities for involvement in decisions that may affect environmental quality and public health.[3]

[1] Prior comments submitted or signed by WELC and included in Appendix E to the SIP are incorporated by reference.
[2] For example, Executive Order 2019-003, "Executive Order on Addressing Climate Change and Energy Waste Prevention," (January 29, 2019), Available at https://www.governor.state.nm.us/wp-content/uploads/2019/01/EO_2019-003.pdf
[3] NM Exec Order No. 2005-056, "Environmental Justice Executive Order." https://www.env.nm.gov/wp-content/uploads/2022/06/EO_2005_056.pdf [Hereinafter NM EO 2005-056]

We also look forward to submitting more detailed, technical comments regarding source identification, four factor analyses, etc., during the formal Notice and Comment period later this year. In the present comments, we emphasize that this Regional Haze SIP, Proposed Rule, and accompanying public engagement processes present an opportunity for New Mexico to set a leading example for other states—not only with respect to air quality and visibility improvements in Class I Areas, but also with respect to climate, health, and environmental justice co-benefits statewide. This Haze SIP and Proposed Rule also represent an opportunity for NMED to enhance and reinforce its existing regulatory scheme, and to harmonize its regulations with those of other state agencies, particularly with respect to curtailing pollution from oil and gas sources. We hope NMED will revise its Draft SIP to seize these opportunities—and fully leverage the power of the Regional Haze Rule not only to protect New Mexico's treasured landscapes and unique ecosystems, but also to promote public health and advance environmental and climate justice for all who call New Mexico home, now and for future generations.

NMED Should Explore Opportunities for its Haze SIP to Strengthen and Reinforce Other State Air Quality and Environmental Regulations, and Vice Versa.

NMED states that the Regional Haze Rule requires consideration of "emissions reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment" in its long-term strategies.[4] These mandatory considerations of ongoing programs do not obviate the need for a strong Haze SIP that could further reduce emissions—instead, they underscore the importance of coordinated, rather than siloed, regulatory processes that strengthen and mutually reinforce one another to ensure the most comprehensive, enduring possible suite of air quality regulations. Coordinated regulatory efforts to address air pollution from oil and gas sources, in particular, should be integral to NMED's Haze SIP, given the WRAP data in the Draft SIP indicating that oil and gas point and non-point sources accounted for almost 80% of anthropogenic haze-causing (and health-harming) SO_2 emissions, almost 40% of anthropogenic NO_x emissions, and over 75% of anthropogenic Volatile Organic Compound (VOC) emissions in New Mexico from 2014-2018.[5]

Unfortunately, after a multi-year delay in issuing a draft SIP, NMED has missed some opportunities to coordinate its Haze SIP and Proposed Rule development directly with other relevant regulatory processes—for example, the state's "Ozone Precursor Rule," 20.2.50 NMAC, discussed in the Draft SIP—for which "pre-petition" outreach and an informal comment period began in 2020, with notice and hearing in 2021 and publication of the final rule in the NM register in July 2022. However, NMED can still identify opportunities for the Haze SIP to reinforce, enhance, and fill gaps in the rule's provisions for reducing or preventing emissions of ozone precursor pollutants such as NO_x and VOCs– pollutants that, as NMED notes, also contribute to visibility impairments in Class I areas[6]—and ensure that the Haze SIP does not *undermine* this and other relevant rules.

[4] NM Draft Haze SIP at 144-145; 40 CFR § 51.308(f)(2)(iv).
[5] *See* NM Draft Haze SIP at 83, Table 5-9. Draft SIP at 84, Table 5-11. Draft SIP at 86, Table 5-15.
[6] *Id.* at 145. The Draft SIP focuses primarily on NO_x and SO_2 emissions as the two largest anthropogenic contributors to visibility impairment. However, is it possible that the comparatively "minimal" contributions of other pollutants to the "Q" value in Q/d may reflect the enormity of NO_x and SO_2 emissions more than the "insignificance" of other emissions?

Moreover, it's not too late for NMED to coordinate its haze planning efforts with other ongoing and upcoming regulatory processes in the state—for example, proposed rules to address PFAS contamination from oil and gas sources, including possible groundwater contamination. As discussed in more detail below, one of the factors NMED must consider when setting reasonable progress goals for Class I areas and selecting reasonable progress measures for sources under the Regional Haze Rule includes "non-air quality environmental impacts." 40 C.F.R. § 51.308(d)(1)(i)(A). And within this broad category, one of the few examples of "non-air quality impacts" that EPA explicitly mentions in its 2019 Guidance is "generation of wastes for disposal and impacts on other environmental media, such as nearby water bodies."[7] Where these considerations in the Haze SIP might overlap with upcoming state rulemakings that seek to address similar impacts, this could present opportunities to harmonize New Mexico's air, land, and water protection rules so that they strengthen and reinforce one another.

NMED Should Analyze the Climate, Health and Environmental Justice Impacts of its Regional Haze SIP, and Incorporate These Considerations Into its Source Selection and Four-Factor Analyses.

The Regional Haze Rule requires states to consider four factors when setting reasonable progress goals for Class I areas, and when selecting reasonable progress measures for sources. These factors include the costs of compliance, the time necessary for compliance, *the energy and non-air quality environmental impacts of compliance*, and the remaining useful life of any potentially affected sources. 40 C.F.R. § 51.308(d)(1)(i)(A), (f)(2)(i) (emphasis added); Clean Air Act Section 169A(g)(1). The third factor directs states to consider the broader environmental implications of their regional haze plans, by requiring an analysis of the "non-air quality environmental impacts of compliance." See, e.g., *id.* § 51.308(d)(1)(i)(A). The Regional Haze Rule does not define "non-air quality and environmental impacts." However, as the U.S. Environmental Protection Agency ("EPA") has explained, the "Best Available Retrofit Technology" (BART) Guidelines—which include "energy and non-air quality environmental impacts of compliance" similar to the third reasonable progress factor—should inform a state's reasonable progress analysis in its haze SIP. 2 U.S.C. § 7491(g)(2); 40 C.F.R. § 51.308(e)(1)(ii)(A); 81 Fed. Reg. 66,332, 66,389 (Sept. 27, 2016). And under those guidelines, "non-air quality and environmental impacts" are to be interpreted broadly, and can be positive or negative. *Id*. EPA's own 2019 Regional Haze Guidance has also explained that "non-air quality environmental impacts" for reasonable progress measures encompass a broad scope of impacts, ranging from "generation of wastes for disposal and impacts on other environmental media, such as nearby water bodies," to "*any* beneficial non-air quality environmental impacts."[8] Moreover, in memoranda and in recent proposed approvals of other states' Haze SIPS, the EPA has stated that "energy and other non-air environmental factors" can include environmental justice and public health considerations.[9]

---

[7] U.S. EPA (August 20, 2019) Guidance on Regional Haze State Implementation Plans for the Second Implementation Period [Hereinafter EPA 2019 Haze Guidance] at 33.
[8] *Id.* at 33, 42 (emphasis added).
[9] *See, e.g.,* Memo from Peter Tsirigotis to Regional Air Directors, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period, at 16 (July 8, 2021), available at https://www.epa.gov/system/files/documents/2021-07/clarifications-regarding-regional-haze-state-implementation-plans-for-the-second-implementation-period.pdf [Hereinafter EPA 2021 Haze Memo]

In short, climate, health, and environmental justice are squarely within the broad scope of the "non-air quality environmental impacts" reasonable progress factor, and NMED has ample authority and discretion to incorporate them into its Haze SIP. Yet the Draft SIP does not even mention climate or environmental justice, and mentions health only in distinguishing it from the visibility protection goals of the Regional Haze Rule and underlying Clean Air Act ("CAA") provisions. Draft SIP at 8, Section 1.3.1. It's true that the National Ambient Air Quality Standards are designed to address human health effects of criteria air pollutants, while the Regional Haze Rule and underlying CAA provisions are designed primarily to "protect visibility in Class I Areas by gradually reducing visibility-impairing anthropogenic air pollutants over time." *Id (citing* 42 U.S.C. §§ 7491 and 7492; 40 CFR §§ 51.300 to 51.309 (haze) and 42 U.S.C. §§ 7408 and 7409; 40 CFR §§ 50.1 to 50.19 (NAAQS). However, nothing in the Regional Haze Rule or the Clean Air Act *precludes* consideration of health impacts in a Haze SIP (or, as EPA has expressly noted, consideration of the environmental justice impacts inexorably linked to health).[10] Indeed according to EPA Region 6 staff, the Regional Haze Rule affords states "prodigious flexibility."[11] And after years of delay in issuing a Draft SIP, NMED's omission of health, environmental justice, or climate considerations— and indeed, the absence of any real discussion of non-air quality environmental impacts at all in the Draft SIP[12]—is particularly unfortunate. We hope NMED will incorporate these considerations into a revised Haze SIP, as discussed further below.

Environmental Justice and Health

The EPA defines environmental justice as "the fair treatment and meaningful involvement of all people, regardless of race, color, national origin, or income, in the development, implementation, and enforcement of environmental laws, regulations, and policies."[13] NMED echoes this definition, and goes on to explain the twin pillars of "fair treatment" and "meaningful involvement" as follows:

> Fair treatment means no group of people should bear a disproportionate share of the negative environmental consequences resulting from industrial, governmental and commercial operations or policies.
>
> Meaningful involvement means:
>
> – People have an opportunity to participate in decisions about activities that may affect their environment and/or health;
>
> – The public's contribution can influence the regulatory agency's decision;

[10] *Id.*
[11] NM Draft Haze SIP at 102 (stating that replacement and electrification requirements are well within the scope of the Regional Haze Rule and NMED's legal authority).
[12] For all sources subject to Four Factor Analyses in the Draft SIP, NMED indicates that there are no significant non-air quality environmental impacts, but does not discuss how it determined this.
[13] *See* U.S. Environmental Protection Agency, *Environmental Justice*, www.epa.gov/environmentaljustice.

– Community concerns will be considered in the decision-making process; and

– Decision makers will seek out and facilitate the involvement of those potentially affected.[14]

New Mexico's own Executive Order 2005-056 ("NM EO 2005-056") directs state agencies to provide opportunities for meaningful involvement, acknowledges the importance of cumulative impacts of exposure to multiple pollutant sources, and directs agencies to use available environmental and public health data —both to address these impacts, and "in determining siting, permitting, compliance, enforcement, and remediation of existing and proposed industrial and commercial facilities."[15]

The mandates of NM EO 2005-056 mirror federal requirements—requirements that EPA must ultimately meet in reviewing and acting on NMED's Haze SIP. Executive Order 12898 (EO 12898) requires each Federal agency to "make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations."[16] Even more recently, President Biden's January 27, 2021 "Executive Order on Tackling the Climate Crisis at Home and Abroad" (EO 14008) explicitly recognizes the inexorable links among climate, health, and environmental justice (which includes social and economic justice), and the corresponding need to address all of them in concert, with a whole-of-government approach.[17] NMED can facilitate EPA's compliance with Executive Order 12898 and Executive Order 14008 —and ensure its own compliance with NM EO 2005-056 — by including an environmental justice analysis in its Haze SIP.

NMED has ample discretion to include an environmental justice analysis—and analysis of associated health risks, impacts, and benefits— in its Haze SIP. EPA has expressly stated that "energy and other non-air environmental factors" for selecting reasonable progress measures can include environmental justice.[18] In a 2021 memorandum, the EPA encouraged states to consider equity and environmental justice impacts in the present haze SIP planning period, and noted that:

[17] *See* Executive Order 14008, 86 Fed. Reg. 7619-7633, Tackling the climate crisis at home and abroad (January 27, 2021), *available at* https://www.whitehouse.gov/briefing-room/presidential-actions/2021/01/27/executive-order-on-tackling-the-climate-crisis-at-home-and-abroad/ Section 201 (Policy), for example, recognizes the threat to public health posed by the climate crisis and the need to "deliver environmental justice in communities all across America." Another part of the EO is expressly dedicated to "Securing Environmental Justice and Spurring Economic Opportunity," and Section 219 expands on the language of EO 12898, directing agencies to make environmental justice part of their mission, to expressly include climate, cumulative impacts, and "accompanying economic challenges." Section 221 creates the "White House Environmental Justice Advisory Council" (WHEJAC), which has since submitted draft recommendations to CEQ on an environmental justice screening tool and on updates to EO 12898.

[18] EPA 2021 Haze Memo, *supra* Note 9

> [T]his consideration could occur in different ways, including undertaking meaningful outreach to environmental justice communities; ensuring adequate opportunity for feedback on states' proposed strategies; and considering equity and environmental justice impacts as part of the technical analyses supporting the SIP, including source selection and four-factor analyses. For example, states could consider environmental justice when they consider the appropriate inclusivity of source selection and the suite of emissions control options that should be analyzed, and when they exercise their discretion in determining what is necessary to make reasonable progress towards the national visibility goal. In general, we encourage states to be aware of where sources of visibility impairing air pollutants are located and impacts they may have on environmental justice communities. *States have discretion to consider environmental justice in determining the measures that are necessary to make reasonable progress and formulating their long-term strategies*...[19] (Emphasis Added).

Oregon's Department of Environmental Quality ("DEQ") has exercised this discretion and incorporated a preliminary environmental justice analysis into its most recent haze SIP, as discussed further below. NMED should similarly exercise its ample authority and discretion to incorporate environmental justice analysis into its Haze SIP—and apply that analysis to its source selection, emissions control options, and reasonable progress determinations. Indeed, polluting facilities and activities, including major sources such as those identified in the Draft SIP, tend to be disproportionately sited in already-overburdened communities.[20] Yet NMED did not undertake any environmental justice analysis in the Draft SIP—or mention environmental justice in the Draft SIP at all. We urge NMED to correct this omission in a revised SIP—consistent with EPA's Guidance, NMED's stated commitments to environmental justice, and its mandates under New Mexico's own Executive Order 2005-056.[21]

In the Draft SIP, NMED *does* recognize its broad legal authority afforded by the Regional Haze Rule.[22]This same flexibility and breadth of legal authority affords NMED an opportunity to advance environmental justice through its Haze SIP. As an example of how NMED can begin to accomplish this, we offer a brief overview of the Oregon DEQ's preliminary environmental justice analysis in its most recent haze SIP. An environmental justice analysis in New Mexico may differ from the DEQ's in its precise parameters and methods, and should be crafted with the meaningful involvement of those who experience environmental justice impacts in the state firsthand. However, Oregon's efforts provide an example of a basic framework, and illustrate the overall feasibility of conducting such an analysis and incorporating it into a state's haze SIP.

[21] NM EO 2005-056

[22] NM Draft Haze SIP at 102.

Environmental Justice in Oregon's Regional Haze SIP

In its haze SIP for 2018-2028, Oregon's DEQ undertook an environmental justice analysis of "communities surrounding the facilities affected by [its] Regional Haze decisions." That analysis informed DEQ's "weight of evidence approach to qualitatively assess potential connections between a facility's emissions and visibility impairment in Class 1 areas, as well as co-benefits to surrounding communities (the non-air impacts [of the Four Factor Analysis]) potentially associated with facility controls."[23] This "weight of evidence" approach to evaluating potential controls succeeded DEQ's required four-factor analysis and helped verify that the agency included the appropriate sources in its reasonable progress determinations—it was *not* used to *eliminate* candidate sources from consideration.[24]

In developing its environmental justice analysis, the Oregon DEQ worked to create an "EJ Score" or "cumulative burden score" for people residing near each source.[25] DEQ first identified the demographic profiles of the communities immediately surrounding the facilities for which it was considering emissions controls. The agency then used data provided in the 2019 version of U.S. EPA's EJSCREEN to calculate the following measures, similar to an "EJ Index" in EJScreen, for each census block group in the state:

- Percent of population identifying as "minority"
- Percent of population living in households making less than 200% of the federal income poverty level
- Percent of the population over the age of 25 without a high school diploma
- Percent of the population self-identified as speaking English "less than well"
- Percent of population under 5
- Percent of population over 64[26]

For each facility, DEQ tallied a "1" for each indicator in the surrounding community (within 2.5 miles of the facility) with a value that exceeded the statewide average, or a "0" if the value was below the statewide average.[27] The analysis showed that most communities surrounding the affected Title V facilities were above the state average combined total score for these indicators.[28] If NMED were to undertake a similar analysis, it may want to consider using slightly different indicators, or another comparison point or threshold in addition to/instead of the statewide average, given the relatively high percentage of New Mexico's population overall that falls within each of the above indicator categories.[29]

While NMED should tailor specific parameters to New Mexico, Oregon DEQ's efforts illustrate how the agency could begin to incorporate environmental justice into its determination of "the emissions reduction measures that are necessary to make reasonable progress." *See* 40 C.F.R. § 51.308(f)(2)(i). NMED should then assess how those measures will either reduce or exacerbate any environmental justice impacts on nearby communities. Incorporating environmental justice and related health impacts into its SIP in this way would help NMED assess the broader environmental implications of NMED's regional haze actions, fulfill its own environmental justice mandates, and maximize the benefits of the regional haze program. *See* 40 C.F.R. pt. 51, app. Y at § (IV)(D)(4)(i)(2). As the Oregon DEQ stated:

> "In considering an EJ score and vulnerable population rank, DEQ can identify locations where facility controls will have the co-benefit of not only improving visibility, but also reducing environmental burden on vulnerable communities. DEQ believes that emission reductions in Oregon should be targeted towards those communities that experience the greatest burden."[30]

Oregon's DEQ did not take the next step and assess specific, potential public health co-benefits of its haze SIP to the communities it identified in the preliminary environmental justice analysis, but did note that it was "confident that public health benefits will arise from PM and NO_x controls, in particular."[31] Indeed, an ever-growing body of peer-reviewed literature supports this assertion, finding tremendous health benefits associated with reduced emissions of PM, NO_x, SO_2, and other haze-causing air pollutants—particularly for those living in close proximity to the source.[32]

Suggestions for Providing Meaningful Opportunities for Involvement in Haze Planning

New Mexico's Executive Order 2005-056 on Environmental Justice emphasizes the importance of meaningful involvement in state agency decisions that may affect environmental quality and public health.[33] To facilitate meaningful involvement, EO 2005-056 directs agencies like NMED to ensure "that all publicly disseminated information, including websites, is available in Spanish and English, at a minimum, and in Tribal languages and dialects as appropriate for areas of the state where these languages are spoken." We urge NMED to develop more linguistically appropriate and accessible materials about its Haze SIP process, and offer some suggestions for removing barriers to meaningful involvement and meaningful Tribal consultation in subsequent meetings and comment processes, particularly for those in frontline communities. Barriers to meaningful involvement that NMED should keep in mind may include, but are not limited to, language barriers, lack of transportation, lack of reliable internet access, a prioritization of written comments over spoken word, lack of appropriate translation and interpretation, and lack of information publicized via linguistically and culturally relevant,

---

focuses on environmental justice in the NEPA process, the guiding principles outlined on pp. 21-28 would likely prove helpful in an environmental justice analysis similar to that undertaken by the Oregon DEQ in its haze SIP.

[30] Oregon Haze SIP. at 38.

[31] *Id*. at 27

[32] See, e.g., Schraufnagel DE, Balmes JR, De Matteis S, Hoffman B, Kim WJ, Perez-Padilla R, Rice M, Sood A, Vanker A, Wuebbles DJ. Health Benefits of Air Pollution Reduction. Ann Am Thorac Soc. 2019 Dec;16(12):1478-1487. doi: 10.1513/AnnalsATS.201907-538CME. PMID: 31774324. (and references therein).

[33] NM Executive Order 2005-056, para. 1, 2.

widely-accessible channels. To address these barriers, NMED should, in public meetings and webinars, offer simultaneous interpretation and translation, and hold meetings in places that are accessible to members of frontline communities (this means accessible locations, and accessible facilities etc. for those individuals with disabilities, the elderly, those without access to transportation, and those with child care needs).

Climate Justice, Greenhouse Gas Emissions, and Climate Change

NMED should analyze how the reasonable progress goals and reasonable progress measures in its Haze SIP could affect greenhouse gas emissions, and in turn, climate change. Doing so would be consistent with the BART Guidelines and EPA's haze guidance and clarifying memorandum, all of which make clear that the "non-air quality environmental impacts" factor is intended to account for broader environmental impacts, such as those caused by climate change. These can include site-specific climate impacts to New Mexico's land, waters, ecosystems, and communities.

The IPCC's recent Sixth Assessment Report (AR6) also underscores the importance of climate *justice* and outlines its main components, stating:

> The term climate justice, while used in different ways in different contexts by different communities, generally includes three principles: distributive justice which refers to the allocation of burdens and benefits among individuals, nations and generations; procedural justice which refers to who decides and participates in decision-making; and recognition which entails basic respect and robust engagement with and fair consideration of diverse cultures and perspectives.[34]

Indeed, as with environmental justice impacts, climate change does not affect every community or region equally. Climate change impacts are often felt far beyond the source of emissions, and tend to fall most heavily on people and communities already overburdened by environmental, social, and structural inequities and harms.[35] Compared to impacts from more localized pollutant emissions, these climate impacts resulting from greenhouse gas emissions tend to be more difficult to trace directly to any one source. However, this does not mean that greenhouse gas emissions shouldn't be considered in Haze SIPs as a "non-air quality environmental impact"—instead, it underscores the cumulative significance of greenhouse gas emissions from every source —and the potential cumulative climate benefits of reducing those emissions from every source—no matter how "incremental" their contributions may seem individually.

When NMED determines "the emissions reduction measures that are necessary to make reasonable progress," it should assess how those measures will either reduce or exacerbate

---

[34] *See* , IPCC AR6, Climate Change 2022: Impacts, Adaptation, and Vulnerability, Summary for Policymakers at 9, 13. *See especially* B.1.4. and B.1.7. *Available at* https://www.ipcc.ch/report/ar6/wg2/downloads/report/IPCC_AR6_WGII_SummaryForPolicymakers.pdf

[35] *See, e.g.,* EPA. 2021. Climate Change and Social Vulnerability in the United States: A Focus on Six Impacts. U.S. Environmental Protection Agency, EPA 430-R-21-003. https://www.epa.gov/system/files/documents/2021-09/climate-vulnerability_september-2021_508.pdf

greenhouse gas emissions. *See* 40 C.F.R. § 51.308(f)(2)(i). For example, engine electrification or retirement of a coal-fired power plant would reduce or effectively eliminate greenhouse gas emissions from that source. If different reasonable progress measures being analyzed and considered for a source would result in different amounts of greenhouse emissions, NMED should use the Social Cost of Carbon/Social Cost of Greenhouse Gas Emissions to analyze and compare the climate impacts of each.[36] As with environmental justice, incorporating climate change into NMED's Haze SIP analysis can help maximize the "non-air quality" benefits of the Regional Haze Rule. *See* 40 C.F.R. pt. 51, app. Y at § (IV)(D)(4)(i)(2).

Conclusion

The Haze SIP presents an opportunity to strengthen and reinforce New Mexico's broader environmental regulatory scheme—and to promote public health and advance climate and environmental justice. However, the Draft SIP takes a more circumscribed approach to haze planning, despite NMED's acknowledgment that the Regional Haze Rule affords the agency "prodigious flexibility."[37] We hope NMED revises its SIP to embrace a more comprehensive and coordinated approach that not only fulfills all of its statutory and regulatory obligations, but also sets a nation-leading example of the powerful co-benefits of a strong haze SIP and accompanying rule. And we hope NMED finds these initial comments helpful in those endeavors.

Thank you for your consideration, and for the opportunity to comment on this Draft SIP. As NMED moves forward with its Haze SIP process, including formal notice and comment, we look forward to providing more detailed, technical comments and otherwise engaging further. Overall, we urge NMED to leverage the full power of the Regional Haze Rule to maximize air quality *and* "energy and non-air quality" benefits—including climate, health, and environmental justice benefits—to all New Mexicans, now and for future generations.

Sincerely,

Allyson Beasley
Attorney
Western Environmental Law Center

El Paso Natural Gas Company, L.L.C.
a Kinder Morgan company

No. EIB 24-49 (R)

Regional Haze State Implementation Plan Revision for the Second Planning Period and Proposed Companion Rule 20.2.68 NMAC – Regional Haze Requirements

Meeting | NMED and EPNG | October 22, 2024

Proposed Agenda

- Introductions
- An introduction to El Paso Natural Gas Company, L.L.C. (EPNG)
- EPNG's Goals
- Proposed Regional Haze SIP revisions applicable to EPNG
- Facility-Specific Discussions
  - Washington Ranch
  - Blanco A
  - Pecos River
- Summary of priority matters for resolution prior to hearing

Introduction: EPNG

- EPNG provides energy transportation services in a safe, efficient, and environmentally responsible manner for the benefit of people, communities, and businesses.
- It supplies natural gas to major utility providers, including Public Service Company of New Mexico, Southwestern Public Service, El Paso Electric, the New Mexico Gas Company, the Navajo Tribal Utility Authority, Zia Natural Gas, as well as the municipal utilities for the cities of Las Cruces, Socorro, Lordsburg and Deming.
- EPNG owns and operates a total of 2,781 miles of pipeline in 15 separate counties in New Mexico.
- In 2023, EPNG paid approximately $2.38 million in taxes to the State of New Mexico.
- In New Mexico alone, EPNG's parent company Kinder Morgan employs approximately 180 individuals, maintains a payroll of over $17 million, and pays approximately $6.8 million annually to local and state taxing bodies.

Introduction: EPNG

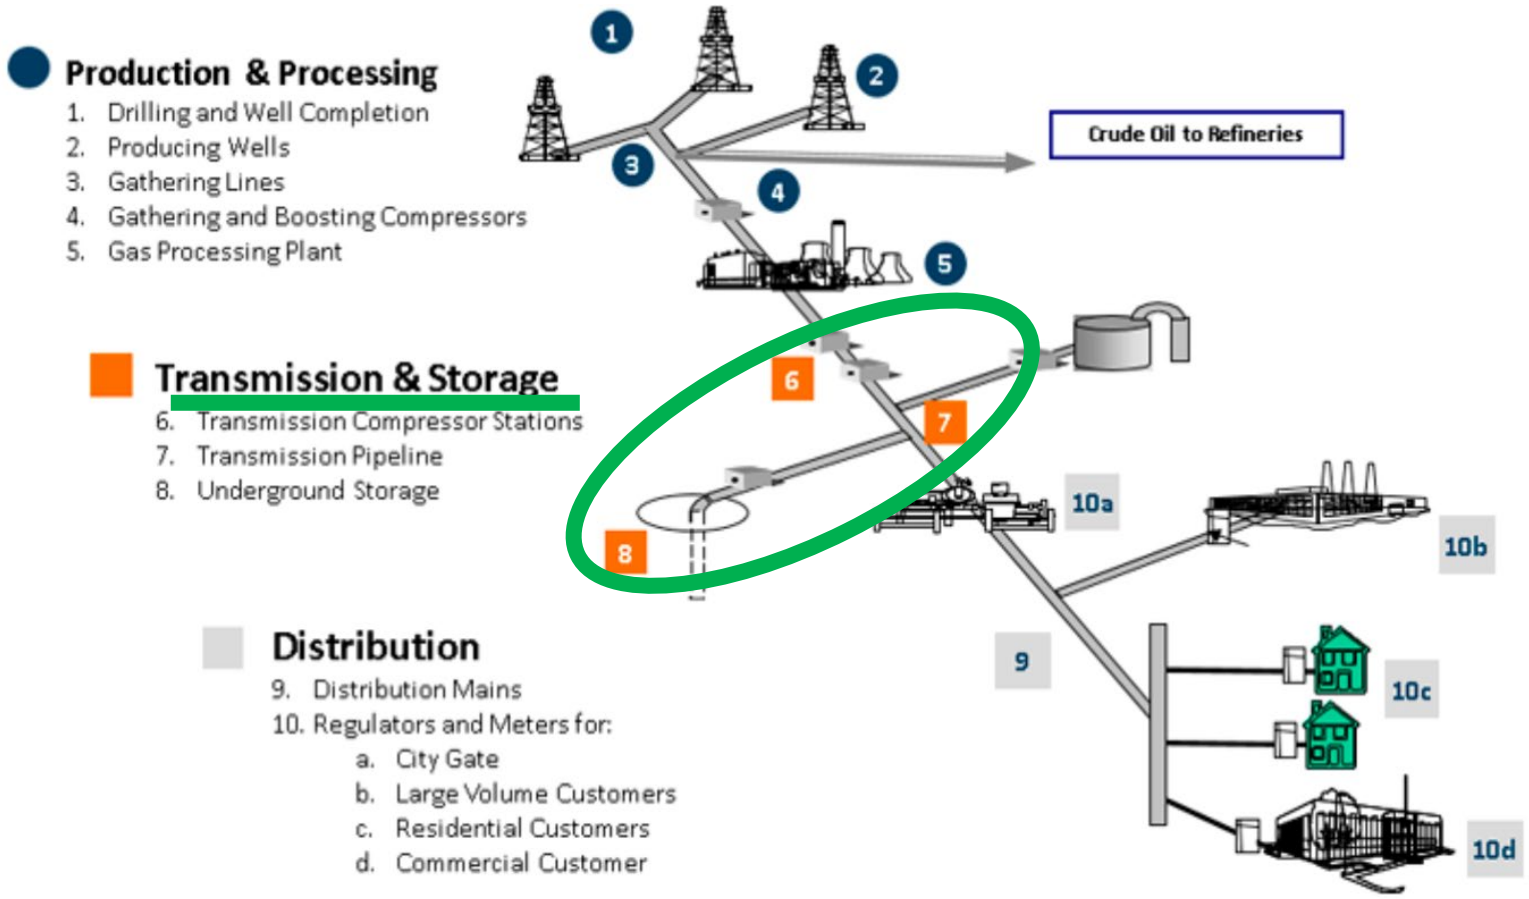

Figure 2. Schematic of the natural gas and petroleum system supply chain.

Source: Adapted from the American Gas Association and EPA Natural Gas STAR Program.

EPNG's Goals

- EPNG is committed to cost-effective and feasible emissions reduction projects as required by the Regional Haze program
- EPNG, and its affiliated entities, have actively participated in EIB rulemakings, collaborated with NMED, and proactively implemented emissions reduction strategies
  - Kinder Morgan, Inc. was a party to the Part 50, ozone precursor rulemaking, and worked closely with all stakeholders (including NMED) to assist in development of the engine and turbine emissions standards, the Alternative Compliance Plan (ACP) and Alternative Emissions Standards (AES) compliance options, as well as other important programs (i.e., LDAR)
  - Under the Part 50 ozone rule, Kinder Morgan's total NOx reduction under both the AES and ACP will be 1149.6 tons per year by 1/1/2027, and that does not even include reductions that have or will be achieved from implementation of the entirety of the Part 50 program
- Shared goal of resolution prior to rulemaking hearing before the EIB

Proposed Regional Haze SIP Revisions – EPNG

- Draft SIP Revision's Proposed Emissions-Rate Limits for EPNG Units

Facility	Unit	Proposed NOx Emissions-Rate Limit	NMED Basis for Limit	EPNG Position
Washington Ranch	1	3 g/hp-hr	Existing LEC	Does not oppose
Washington Ranch	2	3 g/hp-hr	Existing LEC	
Pecos River	A-02	3.64 g/hp-hr	SCR	Oppose based on cost (including past NMED finding), feasibility, and overall visibility impacts
Pecos River	A-03	4.05 g/hp-hr	SCR	
Blanco A	A11	0.5 g/hp-hr	Replacement	Oppose based on cost (including past NMED finding), feasibility, and overall visibility impacts
Blanco A	A13	0.5 g/hp-hr	Replacement	

Issues Applicable Across All EPNG Facilities

Use of *Actual Emissions* is Required

- EPA's 2019 Guidance directs NMED to use actual emissions when calculating cost-effectiveness of controls
  - The use of actuals is also consistent with the approach for BART
- NMED used a potential-to-emit (PTE) type approach for determining baseline emissions for Blanco A and Pecos River
  - This flawed assumption materially skewed results
- An example illustrates the point.
  - Consider engine *A* that runs only 10 hours a year and emits 1 ton of NOx during that operation and an otherwise identical engine, engine *B*, that runs 8760 hours while emitting 100 tons of NOx.
  - Using potential emissions would mean that engine *A* would be assessed to have emissions of 876 tons per year, and would therefore appear far more cost-effective than engine *B*.
  - In reality, however, engine *A* would actually be far more expensive to control based on its actual expected emissions. NMED's four factor analysis should avoid such perverse outcomes.

Use of *Actual Emissions* is Required (cont.)

- For Pecos River, NMED used representative operating hours (no objection), but adjusted turbines' tested NOx emission rates to 100% load assuming a linear relationship between NOx emission rate and percent load.
- For Blanco A, NMED relied on data from one emission test (in lb/hr) from the period of 2022-2023 for units A-2, A-3, A-4, A-9, A-11 AND A-13 and then extrapolated the one data point to 100% load to calculate the Baseline Actual Emissions ("BAE") rate (in lb/hr).
- **Inconsistencies with a proper BAE approach:**
  - All units operate at variable loads, and rarely at 100%.
  - For Blanco A, the look-back period was too short, with too small a data set. Non-representative results.
  - For Blanco A, NMED applied a linear function to engine load percent. This relationship is not linear.
  - For Pecos River, the NOx emission rate for turbines does not increase linearly with percent load; using this approach inflates emissions.

Use of *Actual* Emissions: RECOMMENDATION

- **Recommendation/request prior to rulemaking hearing:**
  - NMED should apply an appropriate measure of emissions baseline through the proper application of the Baseline Actual Emissions ("BAE") concept.
    - This is the approach directed by EPA in authoritative guidance applicable to the Regional Haze Rule: "Guidance on Regional Haze State Implementation Plans for the Second Implementation Period," dated August 20, 2019
    - This approach is consistent with Regional Haze BART analyses – a related and comparable analysis (i.e., statutes must be read together)
    - This is the approach applied in EPA's Prevention of Significant Deterioration ("PSD") program
    - This approach is practical: it is not potential emissions from a source that may affect visibility concerns, but actual emissions
    - This is the approach used in developing cost scenarios in the EIB Part 50 ozone rules rulemaking, and it has continued in implementation, through subsequent AES and ACP approvals. NMED approved an AES for Pecos River turbines that was based in part on a cost showing using actual emissions.

Visibility Impacts Should be Considered

- An overall evaluation of visibility impacts demonstrates NMED can make “reasonable progress” without requiring reductions from Blanco A or Pecos River.
  - Blanco A was selected based on proximity to Mesa Verde, but no reasoned explanation provided for a quantitative “may affect” determination
    - Reasoned explanation and quantification required by the statute, Regional Haze Rule, and EPA 2019 Guidance.
    - The Draft SIP (at 64) punts on this question, instead stating that “it is a challenging exercise to estimate with any degree of certainty what the quantitative impacts of individual point sources are at Class I Areas.”
  - Pecos River was subjected to four-factor analysis because of its proximity to Carlsbad Caverns.
- All Class I areas in New Mexico except Salt Creek Wilderness are projected to be below the glide path to natural visibility by 2028.

Visibility Impacts Should be Considered

- Blanco A and Pecos River emit virtually no SO2, the precursor for ammonium sulfate. Ammonium sulfate dominates visibility impairment on most impaired days at the relevant Class I areas.
  - Ammonium sulfate contributed 3.16 times more than ammonium nitrate to visibility impairment at Carlsbad Caverns on the most impaired days during 2018-2022.
    - Pecos River reported only 1.68 tons of SO2 in 2016 (even using NMED's assumption of emissions at permit limit in lb/hr), the inventory year for screening.
  - Ammonium sulfate contributed 2.75 times more than ammonium nitrate to visibility impairment at Mesa Verde on the most impaired days during 2018-2022.
    - Blanco A reported only 0.12 tons of SO2 in 2016 (again, using permit limit emissions rate), the inventory year for screening.

Visibility Impacts: RECOMMENDATION

- **Recommendation/request prior to rulemaking hearing:**
  - EPA's 2019 Regional Haze guidance provides (at 37) that states have "reasonable discretion to consider the anticipated visibility benefits of an emission control measure along with the other [four] factors when determining whether a measure is necessary to make reasonable progress."
  - Similarly, EPA's 2021 Regional Haze guidance allows (at 13) states to "to choose to require controls at only a subset of those sources that constitute the vast majority of the visibility benefit."
  - Consistent with this guidance, EPNG requests that NMED propose in its technical testimony that no regulation of Pecos River and Blanco A is required on the basis that both facilities were screened in for Class I areas that have projected visibility below the natural visibility glide path and both facilities have *de minimis* levels of SO2 emissions.

Facility-Specific Discussions

Washington Ranch

Facility	Unit	Proposed NOx Emissions-Rate Limit	NMED Basis for Limit	EPNG Position
Washington Ranch	1	3 g/hp-hr	Existing LEC	Does not oppose
Washington Ranch	2	3 g/hp-hr	Existing LEC	Does not oppose

- EPNG does not agree with all the underlying analysis/methodologies applied (see slides relevant to Blanco A and Pecos River)
- However, EPNG agrees with the bottom-line conclusion that additional emission reduction opportunities exceed $10,000/ton reduced
- EPNG also does not oppose an emission rate limit of 3 g/hp-hr based on *existing* controls

Pecos River – Proposed Regional Haze SIP

Facility	Unit	Proposed NOx Emissions-Rate Limit	NMED Basis for Limit	EPNG Position
Pecos River	A-02	3.64 g/hp-hr	SCR	Oppose
Pecos River	A-03	4.05 g/hp-hr	SCR	Oppose

(Summary of basis for opposition on following slide)

Pecos River Must be Excluded

1. **Baseline Emissions Data:** Use of *actual* emissions, not a potential-to-emit (PTE) type approach, is required (discussed above)
2. **NMED Should Consider Projected Visibility Improvements:** An overall evaluation of visibility impacts demonstrates NMED can make "reasonable progress" without requiring reductions from Blanco A or Pecos River (discussed above)
3. **Consistency with Part 50 Ozone Rule:** The Air Quality Bureau recently approved an AES for Pecos River on the basis of cost-ineffectiveness
4. **The Four-Factor Analysis Requires Correction, Resulting in Revised Conclusions:** Corrected site-specific technical four-factor analyses demonstrate costs-per-ton exceed $10,000/ton for all units at each facility

Pecos River: The Broader Context

- **EIB Part 50 – Ozone Rule:**
  - Pecos River Units A-01, A-02, and A-03 are all part of an approved Alternative Emissions Standard (AES) under the New Mexico Ozone Precursor Rule, 20.2.50.113 NMAC, which was conditionally approved on June 26, 2023 by the New Mexico Air Quality Bureau (AQB)
  - These units qualified for an AES based on economic infeasibility because of their high cost-per-ton of emissions reductions, all of which exceeded $10,000/ton based on the assumptions EPNG recommends here
  - NMED's approval, through AQB, of the AES cost assessment just last year represents, per the Ozone Precursor Rule, a finding that "it is not . . . economically feasible for the individual engine or turbine to achieve the emissions standards"
  - NMED should not deviate from this finding now

Pecos River: Critiques of NMED Analysis

- **Capital costs for SCR are under-estimated:**
  - Reliance on SCR workbook (addressing *boilers*) is not applicable to the Pecos River *turbines*
  - The 2019 EPA Guidance directs use of accurate and specific data when available in place of generic information or estimates
  - In the recent Part 50 ozone rulemaking, NMED accepted EPNG-provided vendor quotes for SCR modifications at a similar facility
  - EPNG provided relevant specific cost data (and is working on an updated site-specific cost estimate); NMED has not used EPNG data to date

Pecos River: Critiques of NMED Analysis

- **Allowance for Funds Used During Construction (AFUDC):**
  - AFUDC is a generally accepted regulatory accounting method under which the cost of financing the capital construction projects incurred during the construction phase is added to the cost of the asset
  - AFUDC in construction projects follows the guidelines for accounting in FERC's Uniform System of Accounts, and these are FERC-regulated facilities
  - Importantly, NMED and KMI applied the AFUDC when developing cost-per-ton estimates for the EPNG (and other Kinder Morgan) units in the recent Part 50, Ozone Rulemaking
- **O&M Costs:** NMED relied on outdated default values, while EPNG relied on more accurate vendor quotes

Pecos River: Critiques of NMED Analysis

- **SCR efficiency of 90% is unachievable**
  - NMED cited an SCR efficiency rating of 90% its four-factor analysis calculations
  - This efficiency rating misunderstands EPA's Control Cost Manual, and NMED has presented no data to the contrary
  - The EPA Control Cost Manual is clear that SCR efficiency depends on type of catalyst and flue gas composition
    - As the exhaust temperature decreases below 700F, the reaction rate and resulting NOx removal efficiency begin to decrease
    - From the EPA Control Cost Manual, SCR efficiency in the temperature range for the Pecos River turbines is closer to between 63% and 73%
  - EPNG recommended a 70% reduction efficiency; NMED has not accepted to date

Pecos River: Corrected Four-Factor Analysis

- Correcting the flawed assumptions and data results in costs dramatically exceeding $10,000/ton.
  - A-02 would have costs of $26,790/ton.
  - A-03 would have costs of $28,369/ton.

- **Recommendation/request prior to rulemaking hearing:**
  - EPNG requests that NMED reflect these revised calculations in its submission of technical testimony, which would mean removing all Pecos River units from the proposed SIP for exceeding the cost threshold of $10,000/ton.

Blanco A – Proposed Regional Haze SIP

Facility	Unit	Proposed NOx Emissions-Rate Limit	NMED Basis for Limit	EPNG Position
Blanco A	A11	0.5 g/hp-hr	Replacement	Oppose
Blanco A	A13	0.5 g/hp-hr	Replacement	Oppose

(Summary of basis for opposition on following slide)

Blanco A Must be Excluded

1. **Baseline Emissions Data:** Use of *actual* emissions, not a potential-to-emit (PTE) type approach, is required (discussed above)
2. **NMED Should Consider Projected Visibility Improvements:** An overall evaluation of visibility impacts demonstrates NMED can make "reasonable progress" without requiring reductions from Blanco A or Pecos River (discussed above)
3. **Over-Inclusive Screening:** The established Q/d threshold is over-inclusive; Blanco A should not have been screened into the four-factor analysis
4. **The CAA Only Authorizes Control:** NMED does not have legal authority to require replacement (or electrification) of the Blanco A units. Additionally, replacement presents operational infeasibility issues for this site.
5. **The Four-Factor Analysis Requires Correction, Resulting in Revised Conclusions:** Corrected site-specific technical four-factor analyses demonstrate costs-per-ton exceed $10,000/ton for all units at each facility

Over-inclusive Screening : Q/d

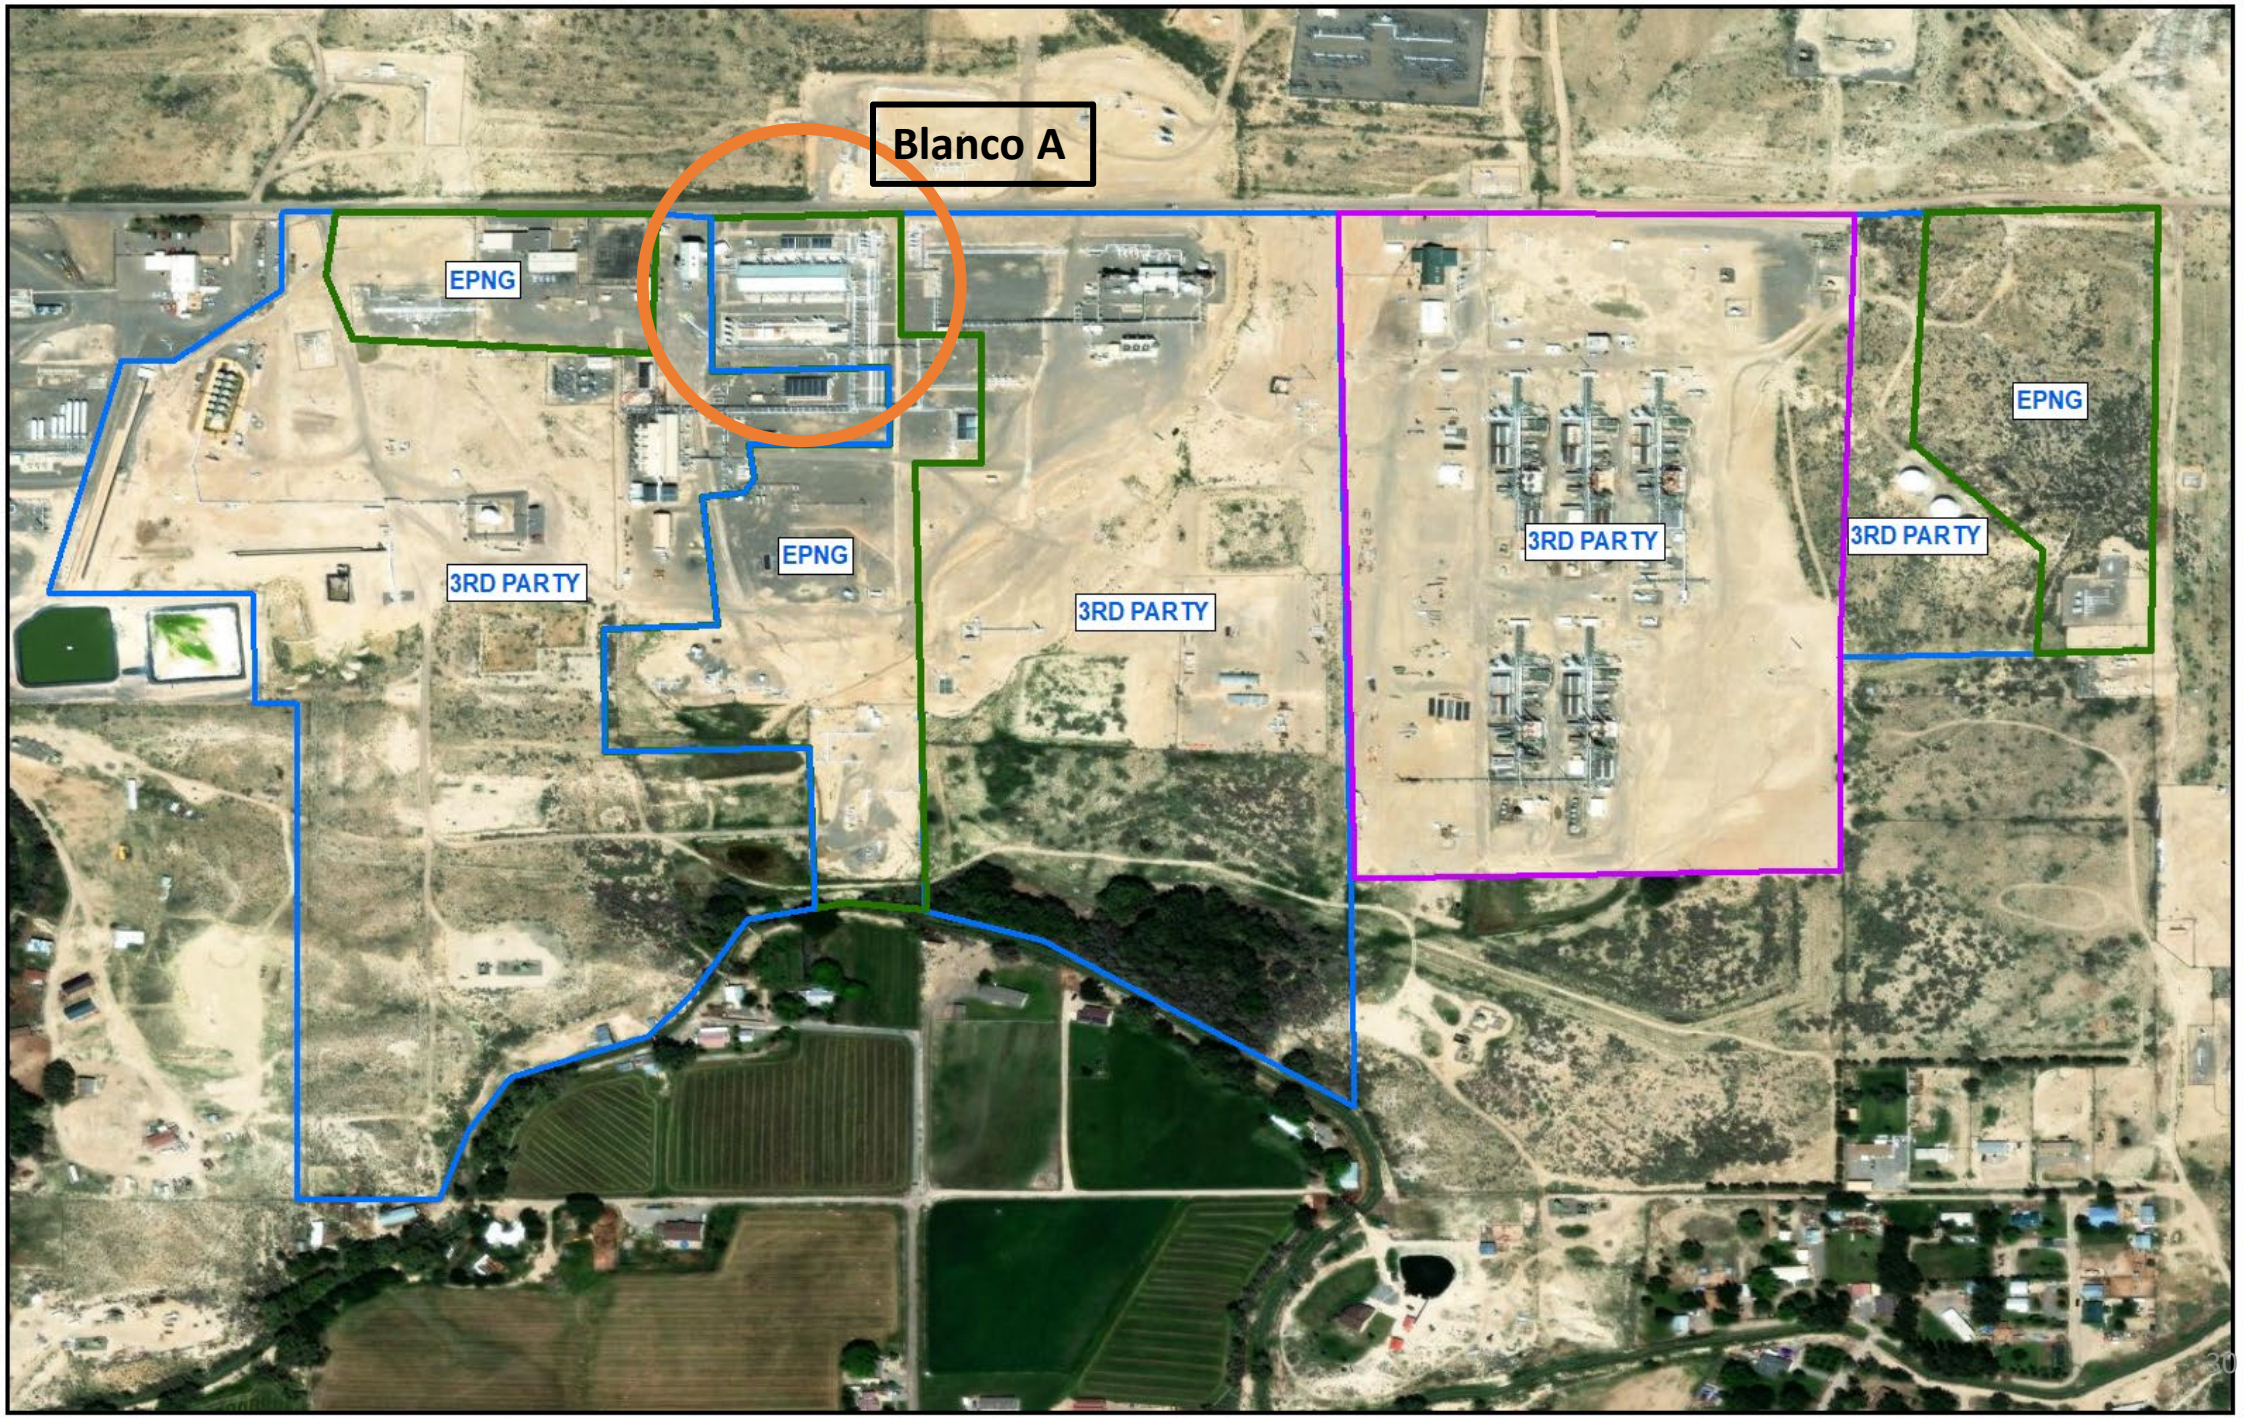
- NMED adopted 5.6 Q/d as the cut-off "necessary to capture 80% of the total NOx and SO2 emissions from all New Mexico Title V facilities combined," citing to the Western Regional Air Partnership (WRAP) Protocol
- Concerns with NMED's approach:
  - WRAP suggest screening in at Q/d > 10, and only if **no sources are selected** does WRAP suggest stepping to a lower Q/d
    - Q/d of 10 captured 13 Title V sources responsible for 70% of the total NOx and SO2 from all Title V facilities in NM
  - WRAP and 2016 EPA Draft Guidance state that the 80% measurement is related to 80% of the visibility impacts, not total emissions (as applied by NMED)
  - Even if 80% was the right target, excluding Blanco A would have still captured sources that emit 79.98% of statewide NOx and SO2 emissions (see Table 6-2 of Draft SIP Revision (meaning, NMED only captures Blanco A by a rounding error)
  - In brief, NMED's screening approach was over-inclusive, not required, and is not technically defensible

Over-inclusive Screening: Q/d (cont.)

- Updated Site-specific information:
  - The Q/d analysis should be done using actual emissions. *See* EPA 2019 Guidance, at 17.
  - The Q/d approach NMED used also used 2016 emissions inventories.
  - These inventories are based on a PTE-like approach where the unit hours of operation were multiplied by the permit limit (in lb/hr) to calculate emissions.
  - Blanco A's units do not run at 100% load, and therefore NMED did not use actual emissions.
    - Whereas NMED's calculation concluded that Blanco A emitted approximately 356 tons of NOx + SO2, the **actual** emissions were approximately 51 tons.
    - Using 51 tons for the Q/d approach would yield a Q/d for Blanco A of 0.8, far below the threshold NMED used, and even farther below the threshold of 10 that WRAP suggests.

Over-inclusive Screening: RECOMMENDATION

- **Recommendation/Request Prior to Hearing**
  - NMED to more closely follow the WRAP Protocol it relies on and use a Q/d score of 10 as the threshold
  - Alternatively, use 7 as a threshold, as that appears to be a break point, after which the percentage of emissions pulled in drops off rapidly
    - As relevant to EPNG, this would eliminate Blanco A from further consideration
  - As another alternative, NMED can round 79.98% up to 80%, consistent with rounding conventions and determine that Blanco A's emissions are not required to hit an 80% threshold of Title V NOx SO2emissions that NMED identified
  - If NMED still applies the arbitrary 5.6 Q/d threshold, based on an accurate calculation of actual emissions, Blanco A's Q/d should be reflected as 0.8, which is well below the 5.6 threshold. At the least, Blanco A should be excluded on this basis.



Replacement: CAA Only Authorizes Control

- NMED's four-factor analyses considered replacement and electrification
- Congress, EPA rules, and EPA Guidance clearly only authorize *control* of existing units.
  - The CAA Regional Haze program does not authorize EPA or any state-delegated agency to eliminate an emissions source (i.e., require replacement or electrification of a source).
- NMED only has flexibility *within* the authority delegated to it under the CAA Regional Haze program

Replacement: Technical Infeasibility Issues

- In addition to the lack of legal authority to require replacement, it is technically and economically infeasible to do so at Blanco A
- EPNG engineer: “This is the most complicated compressor station I’ve ever seen”
- EPNG does not own additional footprint at Blanco A to install replacement engines.
- Even if the existing engines were removed, there still would not be space and facility design is not suited for these types of engines.

[*See diagram on following page*]

Blanco A
EPNG
3RD PARTY
EPNG
3RD PARTY
3RD PARTY
3RD PARTY
EPNG

Replacement: RECOMMENDATION

- **Recommendation/Request Prior to Hearing**
  - Do not conduct four-factor analyses considering replacement of equipment
    - Replacement is not a control technique
    - Note: electrification was already eliminated from NMED's analysis due to feasibility and exorbitant costs, but should have been eliminated as an option entirely.
  - Regardless, replacement would be cost prohibitive (see next slides)
  - This would remove Blanco A from the four-factor analysis

Blanco A: Critiques of NMED Four-Factor Analysis

- **Allowance for Funds Used During Construction (AFUDC):**
  - Should be applied, as discussed above.

- **Replacement Cost Estimates:**
  - At Blanco A – replacement of the units themselves is over $7MM in present dollars, and based on actual vendor quotes (compared to NMED's estimate of $6MM per unit)
  - The prior cost data also do not consider facility-specific limitations and costs, which are now available
  - These costs are based on updated vendor quotes, whereas NMED's cost estimates are based on stale vendor quotes that do not appropriately reflect recent price increases.
  - The 2019 EPA Guidance directs use of specific quotes and data where available. *See id.* at 32 ("We recommend that *states exercise caution before accepting or rejecting controls based on generic cost estimates if adequately documented source-specific estimates are available or can be prepared*.")

Blanco A: Corrected Four-Factor Analysis

- Correcting for some data errors (i.e., inflated baseline emissions, assumed emissions reduction quantities, along with the capital costs shown above), the $/ton using the proper BAE amounts for A-11 and A-13 (of 21.28 tpy and 14.76 tpy, respectively) results in costs dramatically exceeding $10,000/ton.**
  - A-11 would cost > $29,780/ton.
  - A-13 would cost > $44,210/ton.
- **These costs *do not* consider site-specific considerations based on Blanco A's space limitations

- **Recommendation/request prior to rulemaking hearing:**
  - EPNG requests that NMED reflect these revised calculations in its submission of technical testimony, which would mean removing all Blanco A units from the proposed SIP for exceeding the cost threshold of $10,000/ton.

Summary of Recommendations/Requests

1. **Correct calculation methodologies as to Washington Ranch**
   a. Continue to conclude that additional emission reduction opportunities exceed $10,000/ton reduced based on updated calculations
   b. EPNG will not oppose an emission rate limit of 3.0 g/hp-hr based on *existing* controls
2. **Exclude Pecos River units from the proposed Regional Haze SIP on one or more of the following bases**
   a. NMED already found SCR at A-02 and A-03 is not economically feasible for Ozone AES
   b. Update cost-effectiveness calculation methodologies, concluding all control technologies for all Pecos River units exceed the $10,000/ton threshold
   c. SCR cannot feasibly hit 90% removal efficiency at Pecos River exhaust gas temperature
   d. Considering visibility conditions and de minimis SO2 emissions, no regulation required
3. **Exclude Blanco A units from the proposed Regional Haze SIP on one or more of the following bases**
   a. Corrected Q/d assessment would remove Blanco A from screening
   b. Exclude replacement as a consideration from the four-factor analysis
   c. Update cost-effectiveness calculation methodologies, concluding all control technologies for all Blanco A units exceed the $10,000/ton threshold
   d. Considering visibility conditions and de minimis SO2 emissions, no regulation required

Questions & Open Discussion

E.8 Hearing Phase Engagement

Additional comments were submitted to NMED as part of the engagement process after the petition, involving all parties that submitted entries of appearance in the hearing. Comments received during the Party review period from December 15, 2024 - January 7, 2025 are provided below. The following documents are included in this section (in reading order):

- El Paso Natural Gas Company Comments (1/7/2025)
- Enterprise Field Services Comments (1/7/2025)
- Western Environmental Law Center Comments (1/7/2025)

RE: No. EIB 24-49 (R)
El Paso Natural Gas Company, L.L.C.'s Response to the New Mexico Environment Department's December 13, 2024, Revisions to the Draft State of New Mexico Regional Haze State Implementation Plan Revision for the Second Planning Period (2019-2028)

To whom it may concern:

El Paso Natural Gas Company, L.L.C. ("EPNG") provides comment on the December 13, 2024 Revisions to the Draft Regional Haze State Implementation Plan ("SIP") Revision for the Second Planning Period (2019-2028) ("December Draft") prepared by the New Mexico Environment Department, Air Quality Bureau ("NMED"), in partnership with the City of Albuquerque Environmental Health Department ("EHD").[1] The December Draft makes modest changes to the earlier draft dated September 11, 2024 that was originally submitted to the New Mexico Environmental Improvement Board ("EIB") in the rulemaking proceeding EIB 24-49, *In the Matter of Regional Haze State Implementation Plan Revision for the Second Planning Period and Proposed Companion Rule 20.2.68 NMAC – Regional Haze Requirements*.

The December Draft addresses NMED's proposed approach and cost-effectiveness analyses undertaken for developing New Mexico's Regional Haze SIP Revisions for the second planning period. For EPNG in particular, the December Draft continues to include proposed emissions limits for three of EPNG's facilities: Blanco A Compressor Station ("Blanco A"), Pecos River Compressor Station ("Pecos River"), and Washington Ranch Storage facility ("Washington Ranch"), with only minor changes to calculation methodologies.

As discussed herein, NMED's analysis remains deficient and as a result, the EIB cannot require new emissions-rate limits on Blanco A and Pecos River. Given the relatively limited timeline for review, EPNG only provides brief responses on key issues within the December Draft. EPNG will provide a more fulsome response in its notice of intent to present technical testimony. EPNG also cites its September 20, 2024, letter ("September 2024 Letter") provided to NMED in response to

[1] EHD is responsible for CAA compliance within its jurisdiction in Albuquerque. For the sake of simplicity, this comment letter refers to NMED as the author of the Draft SIP Revision.

a public review draft of the September 11, 2024, draft SIP revision, and EPNG maintains the same positions set forth in that letter.

EPNG's responses to the December Draft are organized by facility, beginning with Pecos River, turning to Blanco A, and concluding with Washington Ranch.

I. Pecos River

A. Summary of Changes in the December Draft for Pecos River

It appears that NMED made three changes in the December Draft that are relevant to Pecos River.

1. NMED changed to the Chemical Engineering Plant Cost Index ("CEPCI") instead of the consumer price index ("CPI") to adjust for cost estimates that are denominated in dollars preceding 2023.
2. NMED used an estimate of 80% NOx removal efficiency for selective catalytic reduction ("SCR") rather than the original 90%,
3. NMED modestly increased the operations and maintenance ("O&M") costs for ammonia as a reagent and for catalyst replacement.[2]

As a result, the cost-per-ton of NOx reduction that NMED estimates for Pecos River Units A-02 and A-03 increased by approximately $2,000/ton ($6,000/ton to $8,000/ton for Unit A-02 and $7,000/ton to $9,000/ton for Unit A-03).[3]

B. EPNG's Response to the December Draft's Pecos River Analysis

All three changes in the December Draft for Pecos River were suggested in EPNG's September 2024 Letter. EPNG appreciates NMED's adoption of those important updates; however, NMED did not go far enough in correcting the base data and/or calculation methodologies for Pecos River (as described in detail in the September 2024 Letter). As a result, the cost-effectiveness analysis presented in the December Draft remains inaccurate, and insufficient to support new emissions limits for Pecos River. The September 2024 Letter noted use of the CPI was improper and that the CEPCI must be used, and the letter further urged that an appropriate SCR removal efficiency would be 70%, while also explaining that ammonia reagent costs were higher than NMED had used.[4]

[2] *Compare* December Draft Redline pdf page 807 (ammonia cost of $0.293/gallon and catalyst cost of $227/cubic foot), *with id.* at 808 ($0.529/gallon and $255/cubic foot).

[3] *See id.*, at pdf page 354.

[4] *See* September 2024 Letter, at 23 n.79 (noting that the CEPCI should be used for scaling up SCR costs for cost increases), at 27-28 (discussing range of SCR efficiency from 63% to 73% for the relevant Frame 3 turbine with a regenerator attached, causing the exhaust temperature to be between 500- and 580-degrees Fahrenheit, which is below the 80% NMED used), at 29 (ammonia cost is $1.80/gallon).

Again, EPNG appreciates the changes NMED made. However, EPNG briefly discusses the additional corrections that must be made to have a defensible Regional Haze cost-effectiveness analysis. These additional changes would result in excluding Pecos River from additional regulations under the proposed SIP.

- Pecos River Units A-01, A-02, and A-03 are all part of an approved Alternative Emissions Standard ("AES") under the New Mexico Ozone Precursor Rule, 20.2.50.113 NMAC, which was conditionally approved on June 26, 2023, by the AQB. As recently as 2023, NMED, through the Air Quality Bureau, approved these units for an AES based on **economic infeasibility** because of their high cost-per-ton of emissions reductions.[5] Costs have only increased since then. NMED has made no record showing of why it is appropriate to use different calculation methodologies to reach a different result.

- Even if an 80% removal efficiency is feasible at Units A-02 and A-03, the increased removal efficiency comes at a high capital cost and high operating cost because the SCR system would need to be built in an oversized fashion for additional NOx removal. Oversizing an SCR system in that fashion is expensive.

- Most importantly, the ***actual*** costs of adding a control technology should be used, consistent with the U.S. Environmental Protection Agency's ("EPA") own guidance, as discussed in the September 2024 Letter.[6] NMED has failed to use the ***actual*** cost data supplied by EPNG in its September 2024 Letter. Recognizing that NMED is now proposing an 80% removal efficiency in the December Draft, EPNG is still working with SCR vendors to determine the specific capital cost and feasibility of an SCR system that can achieve an 80% NOx removal efficiency. EPNG plans to include this information in its notice of intent to present direct technical testimony. However, initial estimates indicate that use of the ***actual*** cost data to achieve even the 80% removal efficiency will exceed the proposed $10,000/ton threshold, thereby excluding Pecos River from further regulation under the proposed SIP.

- As also noted in EPNG's September 2024 Letter, the SCR cost estimating tool that NMED used for estimating the costs of SCR installations is for larger ***boilers*** (25 MW, approximately 250 MMBtu/hr) rather than ***turbines***. As discussed in the September 2024 Letter, cost estimates for large boilers are unreliable for turbines, because they are an entirely different piece of equipment with different configurations and exhaust gas

[5] *See* NMED Letter Conditionally Approving AES (June 26, 2023). The approval was conditional "to the extent that, when any turbine is permanently replaced, the replacement turbine shall be considered 'new' pursuant to the rule." *Id.* at 1.

[6] *See id.* at 24 (noting that the EPA's 2019 EPA guidance for regional haze provides that states should use caution before accepting controls based on generic cost estimates if adequately documented source-specific estimates are available or can be prepared and that generic cost estimates are permissible when site-specific cost estimates are ***not*** available).

characteristics.[7] Further, the September 2024 Letter observed that "capital costs do not necessarily scale with unit size because of certain size-invariant capital costs,"[8] meaning capital costs for turbines that are only 56.45 MMBtu/hr (the size of the Pecos River turbines) would not scale down one-for-one. Thus, even the alleged "proxy" data that NMED used in place of the **actual** data is inaccurate and not defensible.

- In addition to capital costs, EPNG also emphasized that the aqueous ammonia needed to run an SCR system is also costly: approximately $1.80 per gallon based on an actual vendor quote.[9] The December Draft uses a value of $0.529 per gallon cost for ammonia, but the September 2024 Letter—**based on an actual vendor quote**—used $1.80 per gallon. In the December Draft, NMED claims to have "check[ed] with vendors for current prices" for these values,[10] but NMED has not provided copies of actual vendor quotes, in contrast with EPNG.[11] The record does not support NMED's position.

- NMED's December Draft also failed to correct its flawed methodology for assessing the baseline level of NOx emissions from Pecos River.[12] Whereas NMED's flawed method calculates baseline emissions of NOx as 116 tons per year ("tpy") and 112.2 tpy for A-02 and A-03, respectively, the actual representative baseline emissions value should be 81.7 tpy and 76.2 tpy, respectively.[13] Without any other changes in NMED's flawed assumptions, this change alone would cause the cost-per-ton of NOx reductions to be $11,386/ton and $12,564/ton, respectively, both of which are above the $10,000 threshold that NMED proposes.[14] NMED has presented no response to why the actual representative baseline emissions values of 81.7 tpy and 76.2 tpy, respectively, should not be used.

- Additionally, 2023 is not the appropriate year on which to base costs for a regulation that will be promulgated in 2025. For this reason, the CEPCI should be used to reflect inflation up to the most up-to-date CEPCI value at the time the December Draft is proposed on the rulemaking docket. This applies to Blanco A and Washington Ranch as well.

- Finally, NMED appears to have made no change in its analyses of SCR's visibility benefits to evaluate the impact of increased ammonia emissions resulting from ammonia slip,

[12] *See id.* at 25-27 (noting flaws in NMED's method for evaluating the NOx emissions rate from Units A-02 and A-03).

[13] *Id.*

[14] Calculations scaling the cost-per-ton figures from the December Draft, at pdf page 754.

which has "the potential to impact visibility."[15] Potential impacts to visibility is the entire reason we are here. As EPNG already noted, "NMED has failed to consider an important aspect of the problem at this stage, which would result in arbitrary and capricious action if left uncorrected and if the final SIP revision requires SCR at Pecos River."[16] NMED must consider visibility impacts that would result from ammonia slip from SCR usage, and doing so through a photochemical model would be the most thorough method for assessing such impacts. For example, ammonia is itself a precursor of fine particulate matter because "it preferentially reacts with sulfuric acid (H_2SO_2) to form ammonium sulfate ($(NH_4)_2SO_2$). If more NH_3 is available, it then reacts with nitric acid (HNO_3) to form ammonium nitrate (NH_4NO_3)."[17] Notably, both ammonium sulfate and ammonium nitrate are the two most significant visibility-impacting substances that the proposed SIP targets.[18]

II. Blanco A

A. Summary of Changes in the December Draft for Blanco A

It appears that NMED made one change in the December Draft that is relevant to Blanco A: NMED uses the CEPCI to adjust for cost estimates that are denominated in dollars preceding 2023. This increased the cost of replacement for Units A11 and A13 to go from approximately $6,000 and $8,000, respectively, to $7,000/ton and $9,000/ton, respectively.[19] Additionally, the change in assumption drove up the cost of two low-emissions combustion projects above the proposed threshold of $10,000/ton for Unit A11.[20]

B. EPNG's Response to the December Draft's Blanco A Analysis

As noted above, EPNG appreciates the change from using the consumer price index to the CEPCI. However, the September 2024 Letter included a variety of other important recommendations that NMED failed to heed. For the reasons discussed below and in the September 2024 Letter, replacement is inappropriate and unsupported for Blanco A Units A11 and A13.

- NMED does not have authority under the Clean Air Act's regional haze provision to require

[15] *See* September 2024 Letter, at 31; *see also id.* at 30-32 (discussing other drawbacks of ammonia, including required safe handling).

[16] *Id.* at 31.

[17] *See* U.S. Dep't of Agriculture Air Quality Task Force, *Ammonia Emissions: What to Know Before you Regulate* at 4 (Oct. 1, 2014) https://www.nrcs.usda.gov/sites/default/files/2022-10/AAQTF-Accomplishments-Ammonia-White-Paper.pdf.

[18] *See, e.g.*, December Draft at xi-xii ("NMED's analysis of monitoring trends shows that ammonium nitrate (NH_4NO_3) and ammonium sulfate ($(NH_4)_2SO_4$) are important contributors to visibility impairment at all Class I Areas on both the most impaired days and clearest days.").

[19] *See* December Draft Redline, at pdf page 355. *See also id.* at pdf page 720 ($7,365/ton and $9,045).

[20] *See id.* at pdf page 365.

replacement. This is explained in more detail in the September 2024 Letter.[21] And to the extent that NMED attempts to rely on the State of New Mexico's authority to require replacement, doing so would run afoul of the federal preemption of interstate natural gas pipelines under the federal Natural Gas Act and regulation subject to the Federal Energy Commission's jurisdiction.[22] Please refer to EPNG's September 2024 Letter for a detailed legal analysis. A failure to regard this threshold issue creates significant legal exposure for the proposed SIP.

- Blanco A should never have been screened in for further evaluation of emissions reductions in the first place. In addition to using a flawed screening methodology that calls into question the reasonableness of the entire proposed SIP,[23] the screening was especially problematic for facilities with low SO_2 emissions, including Blanco A and Pecos River. Blanco A is an especially strong example of the point, and the additional data provided in the December Draft underscores that. The December Draft shows the emissions profiles of facilities that were ***not*** selected for further analysis. Notably, the two facilities immediately following Blanco A on the list of facilities ranked by combined NOx and SO_2 emissions had far higher SO_2 emissions than Blanco A.[24] As noted in the September 2024 Letter, SO_2 has a larger impact on visibility impairment than does NOx.[25] It is therefore especially arbitrary to subject Blanco A to emissions controls when other facilities that very likely have greater visibility impacts were not evaluated for emissions reductions. Finally, and as noted in the September 2024 Letter, even if NMED were to follow its (flawed) approach of using the aggregate 80% combined emissions of NOx and SO_2, NMED should have at the very least rounded 79.98% up by 0.02% to 80.0%, which would have eliminated Blanco A from further consideration.[26] Indeed, within the December Draft, NMED rounded ***down*** $10,138/ton to $10,000/ton to determine that SCR should be required for another operator's unit.[27]

- Proposing to require replacement of units is unlawful, as noted above. Even if it were lawful, replacement at Blanco A is also infeasible. Given the short turn-around time for EPNG to prepare its September 2024 Letter (18 business days), EPNG did not have an opportunity to fully complete an engineering and design evaluation considering

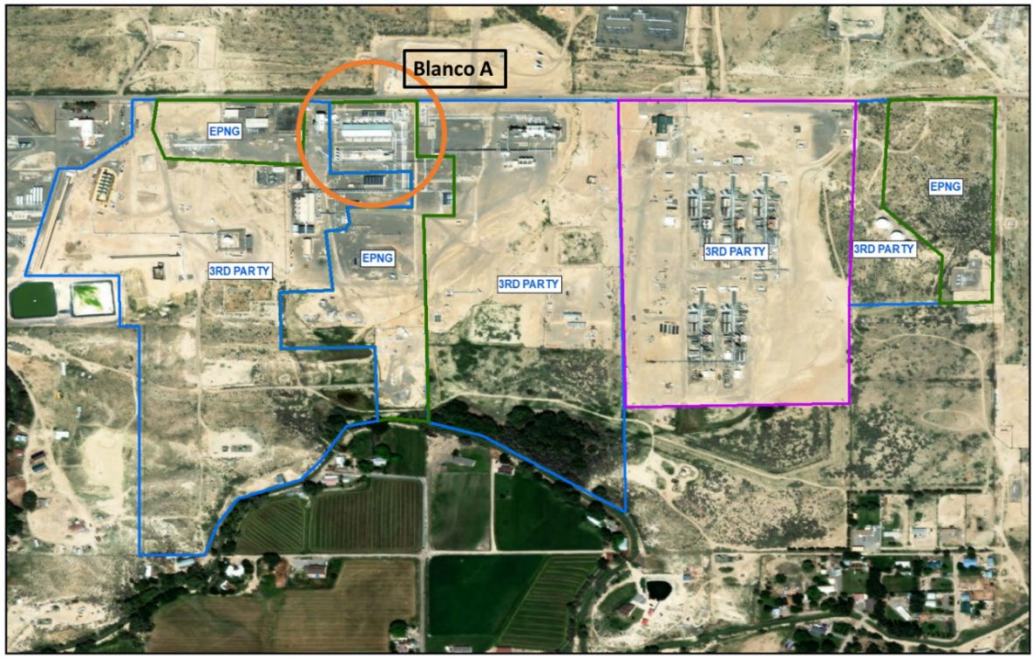
[21] September 2024 Letter, at 6-9.

[22] *See id.* at 10-11.

[23] *See id.* at 11-14. As explained in the September 2024 Letter, the Western Regional Air Partnership ("WRAP") only calls for going below a Q/d of 10 as a screening threshold if no sources are selected or identified at that level, which is clearly not the case. *Id.* at 13.

[24] *See* December Draft, at 94-95 (emissions of 271 and 108 tons of SO_2, for Empire Abo Gas Plant and San Juan River Gas Plant, respectively, compared with 0.12 tons of SO_2 for Blanco A).

[25] September 2024 Letter, at 14 n.59.



[26] *See id.* at 14 (identifying other instances where NMED would round up).

[27] *See* December Draft, at 125-26 (proposing regulation of unit 2), pdf page 1518 (showing cost of $10,138/ton for unit 2).

replacement of engines at Blanco A. However, following submittal of the September 2024 Letter, EPNG continued evaluating the engineering requirements for replacement and identified dramatic feasibility and cost concerns in so doing. Some of this specific data is new to NMED, so we respectfully request NMED carefully review and consider the same. EPNG will be filing additional detailed information regarding infeasibility in its notice of intent to present technical testimony, and EPNG would welcome a discussion with NMED on this particular topic in advance of that submission timeline.

- The existing compressor building (circled in **Figure 1**, below) cannot accommodate replacement engines because it is already filled by 14 existing engines. Additionally, the existing engines are lower speed engines while the new engines would operate at higher speeds, which is an unavoidable feature of modern engine design. These higher-speed engines are incompatible with lower-speed engines due to differing vibration characteristics, which could lead to operational disruptions and costly repairs if they were operated within the same building. In short, this presents a significant safety issue.[28] Moreover, the current emergency shutdown system at the site, which integrates third-party lines due to the site's historical configuration, is illustrated in **Figure 1**. Installing a new engine would render the existing emergency shutdown system inadequate, necessitating the development and implementation of an entirely new system. This would dramatically increase both costs and complexity of the project and require close coordination with other operators, necessarily delaying implementation.

Figure 1 – Blanco A and Surrounding Facilities

[28] *See* **Attachment 1**, at 74-75, 80-82 (discussing vibration issues).

- **Second**, replacement horsepower cannot be installed elsewhere at the Blanco A site. Because there is no existing space in the compressor building where engines are currently housed at Blanco A, EPNG also investigated whether it would be possible to add replacement compression horsepower elsewhere at the Blanco A site. However, **Figure 1** demonstrates that there is no space left at the site that EPNG owns that is directly adjacent to the compressor building at Blanco A. As shown in that figure, the area of the overall parcel where Blanco A is located is fully occupied by the compressor building, piping, and other facilities. That means the only area within the contiguous EPNG-owned site where there could be sufficient space lies to the south. But this would not work either because compressor stations must have an emergency shutdown system that can blowdown piping at a location where the gas will not create a hazard.[29] Further, the emergency system must provide means for the shutdown of gas compressing equipment, gas fires, and electrical facilities in the vicinity of gas headers and in the compressor building. Building compressor station facility components near another entity's equipment would therefore require all third parties to operate under the same emergency shutdown system, which is not feasible, practical, or safe. And even setting these safety concerns aside, running piping to the southern part of the existing parcel would be highly complex and increase costs well beyond the proposed $10,000/ton reduced threshold.[30]

- Finally, as with NMED's estimated baseline emissions for Pecos River, NMED must also correct its assessment of baseline emissions for Units A11 and A13 at Blanco A. NMED assessed baseline emissions of 54.8 tpy and 44.6 tpy for Units A11 and A13, respectively. But this method relied on improperly scaling the engine load up to 100% and using too short of a look-back period that does not capture the full business cycle.[31] NMED should have instead used 21.28 tpy and 14.76 tpy, respectively, as the baseline actual emissions for Units A11 and A13. Even if NMED changed no other additional parameters—and that alone would be an indefensible position given the technical and cost feasibility issues at this facility—using the correct emissions volume in the cost-effectiveness evaluation would make replacement for both units exceed the proposed $10,000/ton threshold, with costs of $18,966/ton and $27,331, respectively.

[29] *See* 49 C.F.R. § 192.167.

[30] Additionally, if NMED considers justifying replacement based on EPNG obtaining rights to *additional* land to get around the infeasibility of on-site replacement, then NMED would also need to show such an approach is even within the EIB's authority and is feasible. And even if NMED (wrongly) concludes that it is legal and feasible to require EPNG to obtain access to lands not owned or leased by EPNG, NMED would still need to show that acquiring rights to another parcel would be cost-effective. It would ***not*** be. The cost of obtaining new land, clearing that land for construction, constructing a new building housing additional compression horsepower, and obtaining all associated permits would add onto the already high capital costs of purchasing a new engine of approximately 2,000 horsepower that EPNG would use to replace the two engines.

[31] September 2024 Letter, at 16-18.

III. Washington Ranch

A. Summary of Changes in the December Draft for Washington Ranch

It appears that NMED made one change in the December Draft that is relevant to Blanco A: NMED uses the CEPCI to adjust cost estimates that are denominated in dollars preceding 2023. This caused the cost estimates for the two units at Washington Ranch to increase from $277,880/ton and $1,000,013/ton to $315,558 and $1,135,609/ton, respectively.[32] None of those costs are at or below the proposed $10,000/ton cost-effectiveness cut-off.

B. EPNG's Response to the December Draft's Washington Ranch Analysis

As discussed in the September 2024 Letter, EPNG does not agree with NMED's Washington Ranch cost-effectiveness calculation methodology, including the overestimation of baseline actual emissions. This methodology flaw should be corrected. However, because NMED does not propose any additional controls be added to Washington Ranch, EPNG does not oppose the ultimate recommendation in the December Draft that Washington Ranch would not be required to undertake any projects and would instead be required to maintain the NOx emissions rate achieved with existing control measures.

IV. Conclusion

NMED must incorporate the recommendations provided in this letter in any updated proposal in the rulemaking matter EIB 24-49.

If you have any questions about our response, please contact Weiwen Daly by email at Weiwen_Daly@kindermorgan.com or by phone at 303-914-7616 or me by email at Tom_Mitchell@kindermorgan or by phone at 713-420-3463.

Sincerely,

/s/ R. Thomas Mitchell

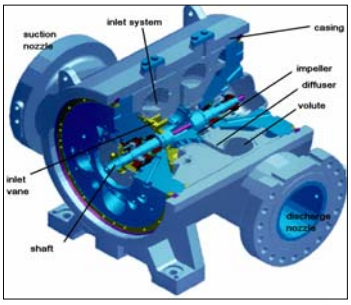
Advanced Topics in Pulsation and Vibration Control

GMC 2020

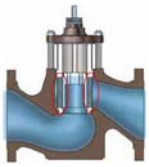
Southwest Research Institute
Benjamin A. White, P.E.
Eugene "Buddy" L. Broerman
Sarah B. Simons

Overview

- **Pulsations / Acoustics Basics**
  - Theory and Equation of State Topics
- **Pulsation Mitigation for Positive Displacement Machinery**
  - Low/Medium/High Pressure Machines
  - Advanced Pulsation Attenuation Devices
    - Commercially Available, In Development, New Research
  - Effect of Changing Operating Conditions/Reverse Flow
  - Pump Pulsation Mitigation
- **Other Advanced Pulsation Topics**
  - Wet Gas Considerations
  - Mixed Compression
  - High Frequency Pulsations—Centrifugal Compressor and Valves
- **Mechanical Design**
  - General Design Guidelines
  - Advanced Topics: Skid and Foundation Analysis, Screw Piles, AIV



Poll #1 - What is your company role?



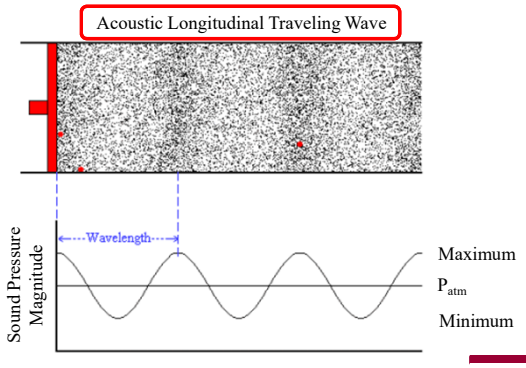
Acoustics / Pulsation Basics

Sources of Pulsations...

Reciprocating Compressors –most common

Piping Dead Leg Stubs

Control elements (e.g., valves & regulators)

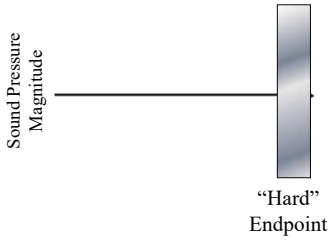


Protrusions into the pipe

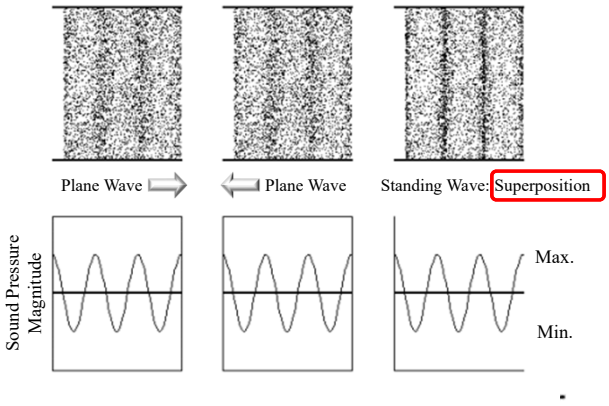
Pulsation: What is it?

(Image courtesy of the Institute of Sound and Vibration Research)

- Pulsation is a periodic fluctuation in both local pressure and velocity at each point along a pipe (Bernoulli's equation).
- Pulsations (a.k.a., acoustic waves) can travel both upstream and downstream from the source - at the speed of sound of the flowing fluid.



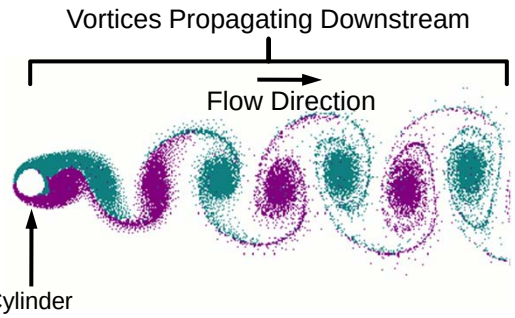
Example of a Positive Pressure Wave originating in cylinder and moves through the piping at the Speed of Sound



Creating Standing Waves from Traveling Waves

(Images courtesy of the Institute of Sound and Vibration Research)

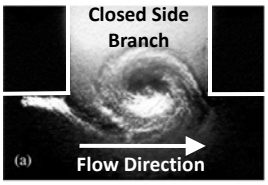
Reflection of a pulsation (pressure) wave off a hard end, such as a blind flange or valve...

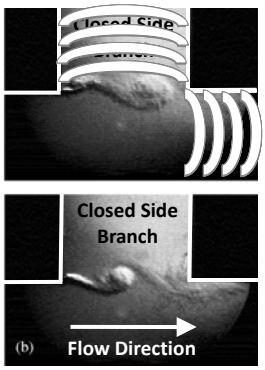


Creating standing waves from traveling waves...

Vortex-Shedding as a Pulsation Source

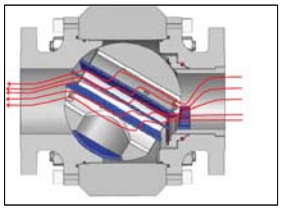
- Interaction of an otherwise steady flow stream with piping features can give rise to substantial unsteady fluctuations.
- Culprits can include:
  - Tees, bends, reducers
  - Flow Restrictions: Valves and orifice plates
  - Obstructions: Struts, instrumentation locations (thermowells), tubes
- Most common source of low frequency pulsations in high flow piping systems is excitation of dead legs or stubs.
- Higher frequency pulsations are associated with thermowells/instrumentation, valves and orifices.





Vortex Shedding: Closed Side Branches or Valve Cavities

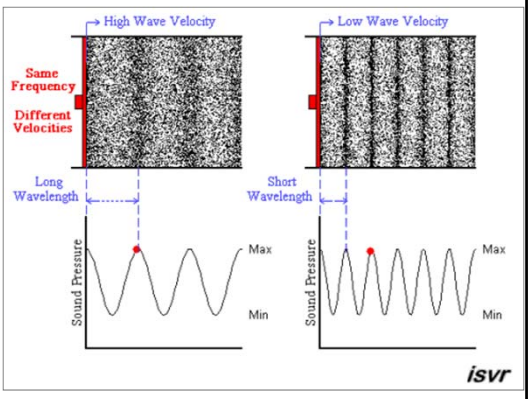
(Images courtesy of S. Dequand, et al.)



- The shear layer of the flow will separate at changes in piping geometry and can shed vortices at periodic intervals, creating areas of high and low velocity (and pressure)
- Closed side branches and valves generate vortices at the fundamental or higher-order modes.
- Excites acoustic natural frequency of cavity
- These can cause excessive pressure drop, audible discrete noise, high amplitude pulsations and vibrations, and distorted pressure signals.

Fundamental mode

Second-order mode



Sound Speed
How Fast Is It Traveling?

- Sound speed: How fast the wave can travel through the medium=elasticity/density
- Sound speed is temperature dependent
  - For an ideal gas, the speed of sound is proportional to $\sqrt{T}$

$$c = \sqrt{\frac{\gamma RT}{M}}$$

c = speed of sound
γ = ratio of specific heats, C_p/C_v
R = ideal gas constant
M = molecular weight

- Sound speed is generally higher for liquids than gasses
  - Depends upon stiffness or compressibility of material
  - Exceptions: Hydrogen, other low density gases

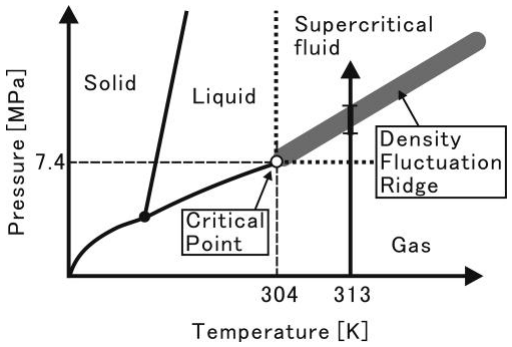
Same forcing frequency, different speed of sound

Image courtesy of the Institute of Sound and Vibration Research

Equation Of State (EOS)

- Various EOS exist to calculate thermo properties in mixtures each using different mixing rules. The implementation of mixing parameters and rules may vary based on the implementation in a particular software.
  - Common EOS: BWR, SRK, Gerg 2008, AGA8, NIST—last three are industry standards
- For gases with significant amounts of unusual components such as CO_2, SO_2, water, heavier hydrocarbons, operating points near critical points or phase changes, and for many refinery mixtures (liquids and gases), equations of state can have significant amounts of error.

If a higher degree of accuracy is needed for measurement or performance it is recommended to:



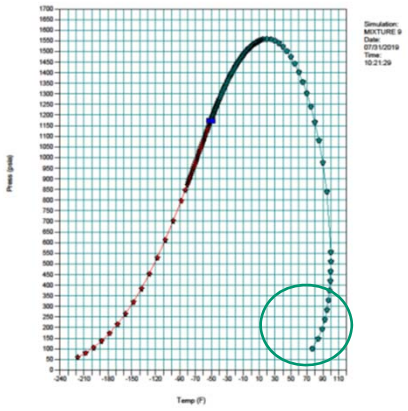
a. Have the mixture evaluated to determine the best EOS for that application and the associated deviations

b. Test the physical properties of that mixture at the planned operating points

Equation Of State (EOS)

- Operating in the supercritical regime
  - Density of a liquid, but SOS or "compressibility" of a gas.
  - Density ridge exists creating widely fluctuating pulsation amplitudes

	Temperature (°C)	Pressure (bar)	Density (kg/m³)	Cp/Cv	Sound Speed (m/s)
1	168.00	42.260	140.34	2.2120	144.13
2	169.00	41.260	127.69	1.9295	150.31
3	169.00	43.260	147.39	2.3242	142.79



- Gas Composition Analysis
  - Must be performed up to C14
  - Small variations in heavier hydrocarbons can shift dewpoint (wet gas) and other thermophysical properties

Dewpoint Calculations
Small Increases in C10+ Components

Mixture 7: 15 ppm C10,C12

Mixture 9: 60 ppm C10, C12

Dewpoint Shifted by 20 deg F

Pulsation Excitation Frequencies

Compressor Excitation Frequency

$$f = n\frac{rpm}{60} \qquad where\ n = 1,2,3,...$$

A 300 rpm unit generates pulsation at 5, 10, 15, 20, ….Hz

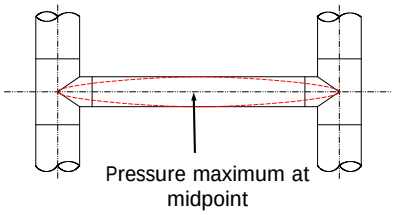
A 900 rpm unit generates pulsation at 15, 30, 45, 60, ….Hz

Vortex-Shedding Excitation Frequency

$$S_t = f_s d/U$$

f_s is the shedding frequency or frequency, d is characteristic dimension of object generating disturbance (such as diameter) and U is flow speed (velocity)

The Strouhal number or range of numbers is determined experimentally generally in the range of 0.10-0.55

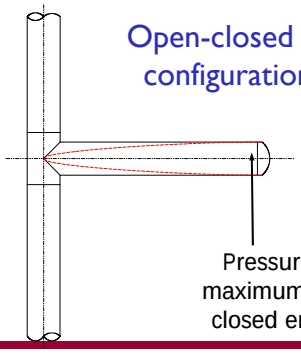


Acoustic Natural Frequencies: Longitudinal Modes

Half-Wave Response

$$f = n\frac{c}{2L}$$

f = Response frequency (Hz)
c = Velocity of sound (ft/sec)
L = Acoustic length of pipe span (ft)
n = 1,2,3,…

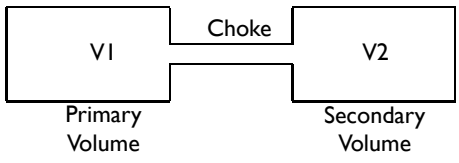


Open-Open configuration

Quarter-Wave Response

$$f = (2n-1)\frac{c}{4L}$$

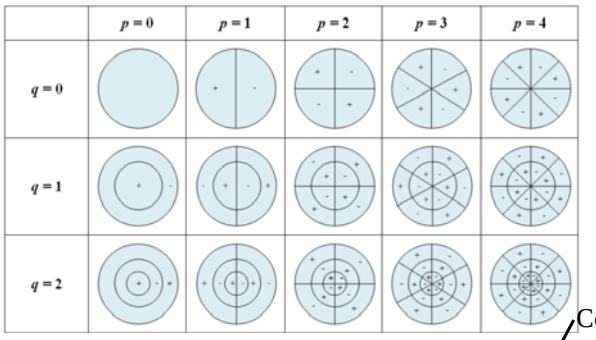
Open-closed configuration



Acoustic Resonance

Natural Frequency: Helmholtz Response

$$f_H = \frac{c}{2\pi}\left(\frac{\mu}{V_1}+\frac{\mu}{V_2}\right)^{\frac{1}{2}} \qquad \mu = \frac{A}{L}$$



f_H = Helmholtz frequency (Hz)
c = Velocity of sound (ft/sec)
V_1 = Volume of or chamber (ft^3)
V_2 = Volume of chamber (ft^3)
A = Cross-sectional area of choke (ft^2)
L = Acoustic length of choke (ft)

Volume-Choke-Volume

Circular Duct Modes

Nodal diameters: p
Nodal circles: q

$$f = \frac{c\alpha_{pq}}{2\pi r}$$

$$r = \frac{D}{2}$$

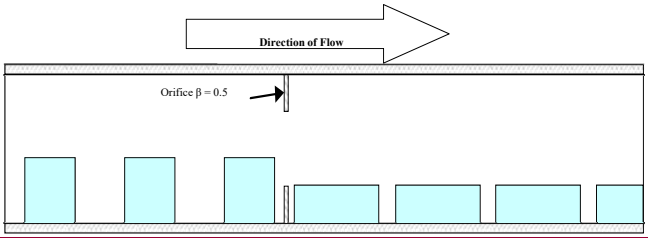
α values are the q^{th} zero of the first derivative of the p^{th} order Bessel function [$J'_p(\alpha_{pq})=0$], which describes radial and circumferential motion.

Constants based on circular geometry

α_{pq}	p = 0	1	2	3	4
q = 0	0.000	1.841	3.054	4.201	5.318
1	3.830	5.331	6.706	8.015	9.282
2	7.016	8.536	9.969	11.346	12.682

f_{pq}	p = 0	1	2	3	4
q = 0	0.00	**332**	551	758	959
1	691	962	1210	1446	1674
2	1266	1540	1798	2047	2288

Below the cut-on frequency, only plane wave propagation exists in pipe

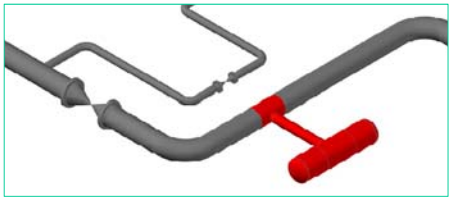


Attenuation Through Choking

Method of Attenuation

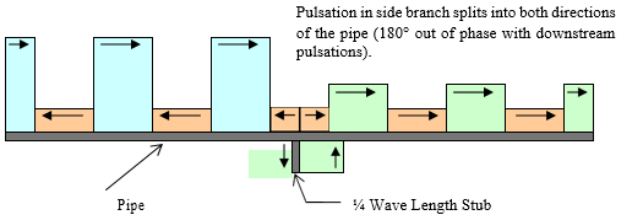
- Area ratio chokes the flow
- Pressure builds upstream of orifice
- Pressure pulse is elongated (decreased) downstream

Caveats



- Creates total static pressure loss
- Must be located at a pressure node
- Does not attenuate low frequencies effectively

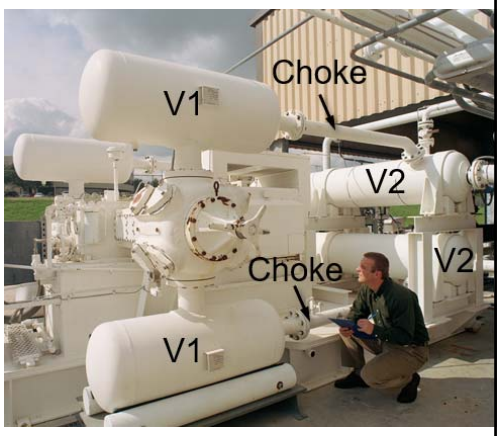
Attenuation Through Shifting



Method of Attenuation

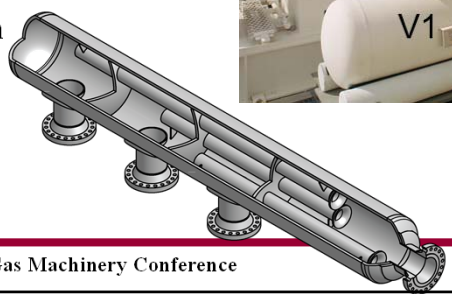
- Portion of the flow diverted to a closed end (pipe or volume) tuned to one frequency
- Pressure pulse travels down closed end and is reflected back 180 deg out of phase with downstream pulsations to attenuate the design frequency
- Very low pressure loss

Caveats



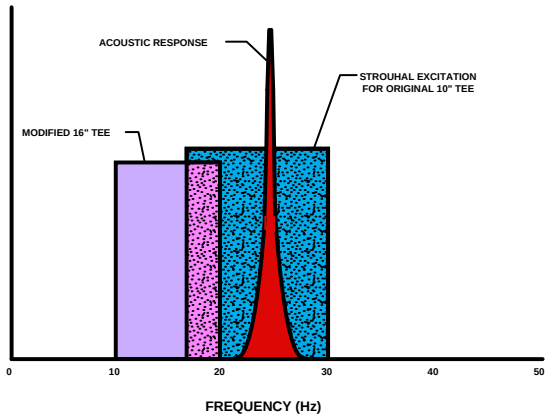
- Only works for one frequency, one per frequency
- Can be very large/long for low frequencies

Attenuation Through Damping or Filtering



Method of Attenuation

- Large volumes damp pulsations
- Damping is most effective and practical when combined with choking
- Wide range of frequency attenuation—most effective method



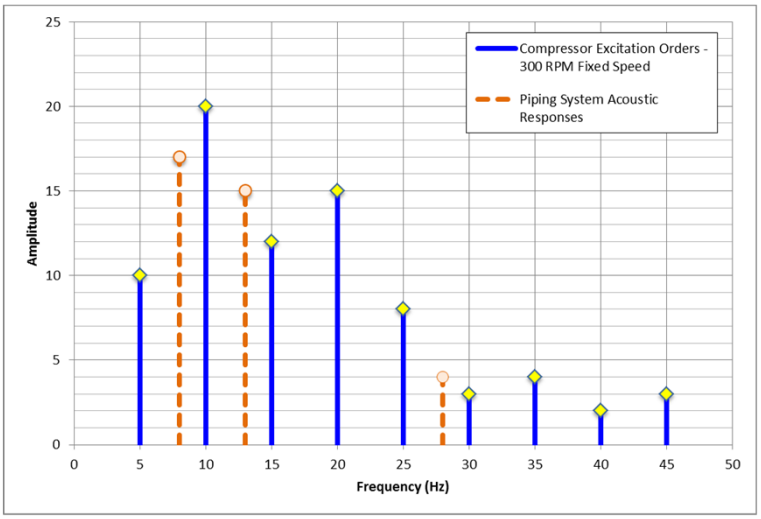
Caveats

- Typically the most expensive option
- Can be very large

Resonance Avoidance: Vortex-Shedding or Hyper Compressors

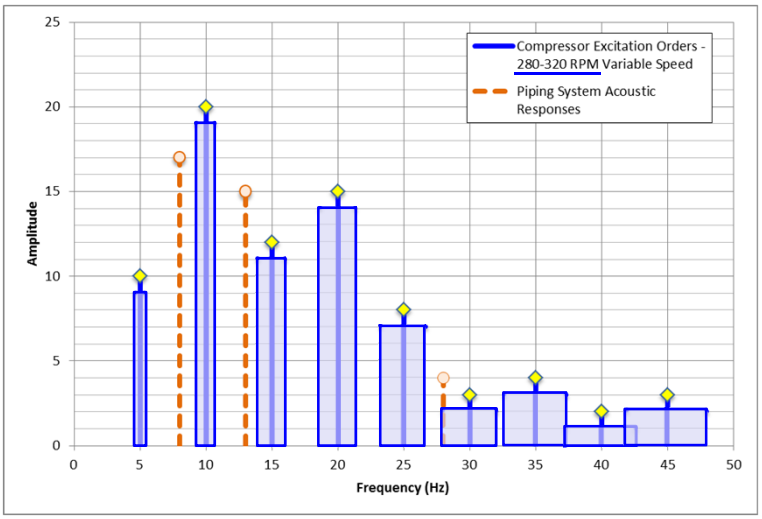
- Primarily used when excitation band is narrow
- Resonance avoidance method: a separation margin is maintained between the calculated excitation frequency and the predicted acoustic and/or mechanical natural frequencies.
- Difficult to predict the amplitude of vortex-shedding pulsations or install pulsation bottles

Pulsation Mitigation for Positive Displacement Machinery



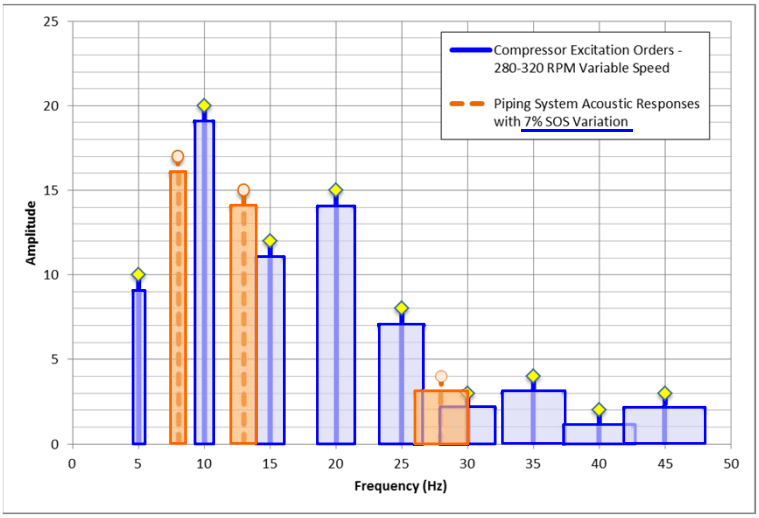
Pulsations Mitigation for Low/Med/High Pressure Machines

1. Low and Medium Pressure Machines (pressure < ~10,000 psi; lower pressure than the typical Hyper compressor)
   - Empty volumes and/or acoustic filters
   - Orifices
   - Timed Pulsation Cancelation – Side Branch Absorbers/Resonators (SBA/SBR) or PAN™
2. High Pressure Machines (pressure > ~10,000 psi; Hyper compressors)
   - Orifice plates
   - Timed Pulsation Cancelation – Cross-overs or PAN™



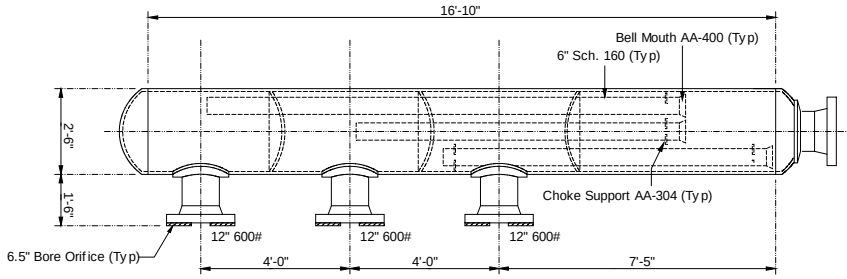
How Do We Control Acoustic Resonances?

1. Avoid acoustic resonances in the piping system, where possible
2. Install well-sized pulsation attenuation bottles
3. Install additional pulsation control devices:
   - Pulsation Damping Devices – pressure loss elements such as orifice plates
   - Acoustic Altering Devices – Side-Branch Absorbers (SBAs) or TSBA or PAN™ or cross-overs

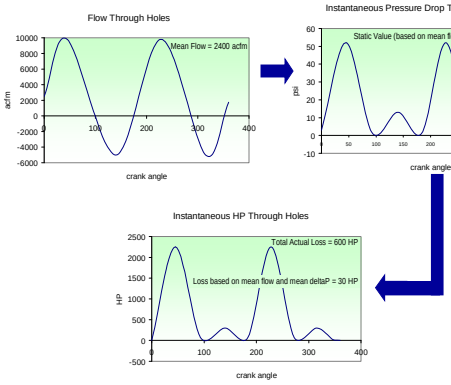


1. Avoid Acoustic Resonances

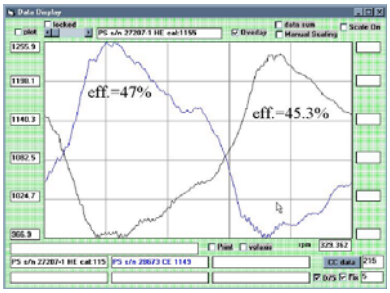
1. Avoid Acoustic Resonances



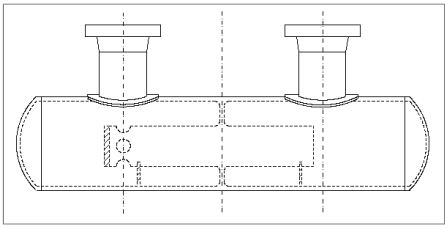
1. Avoid Acoustic Resonances



2. Install Pulsation Attenuation Bottles

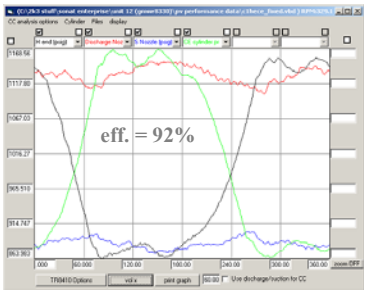


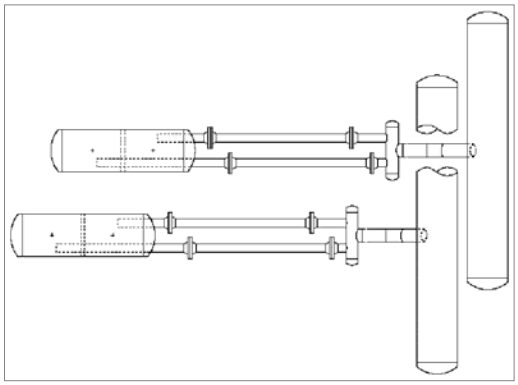
- Attenuate the acoustic Excitation Energy at higher frequencies
- Steady the flow
- Reduce Cylinder-to-Cylinder and Cylinder-to-Pipe interactions



Acoustic Filter Bottle, Single-Bottle System

Why Install Adequate Pulsation Attenuation Bottles?... Consequences of Improper Bottle Design



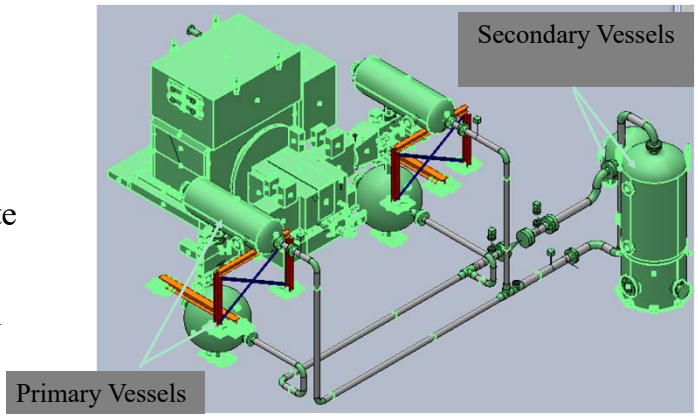


Poor performance of low speed unit in transmission service due to dynamic flow losses through the bottle caused by cylinder interactions.

Achievements of Proper Bottle Design

Improved performance by minimizing cylinder interactions and reducing dynamic flow losses through the pulsation control system.

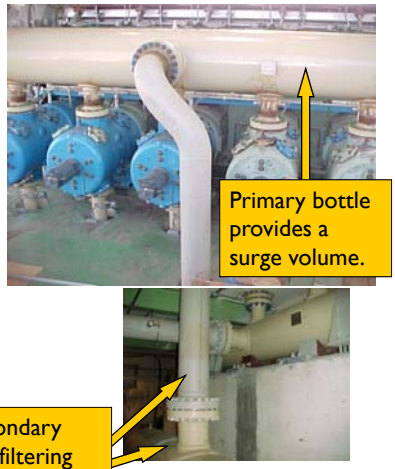
Bottle Design Methodology



- Step 1: Determine the speed of sound variation based on gas composition, expected pressures and temperatures, and equation of state prediction
- Step 2: Select a pulsation bottle design philosophy based on:
  - Sound velocities:
    - >2,000 ft/sec (Lighter gases) ← Type 1: Empty Volume
    - ≤2,000 ft/sec (Typical Natural Gas)
  - Compressor running speed
    - ≤ 500 rpm (low speeds) ← Type 2: Two-Bottle Filter
    - >500 rpm (high speeds) ← Type 3: Single-Bottle Filter
- Step 3: Size the pulsation bottle to attenuate the excitation energy while avoiding acoustic resonances

At this point, the basic dimensions are determined but the bottle design must then be analyzed within the piping system for all acoustic and mechanical responses.

Type 1: Empty Volume
Sound Velocities >2,000 ft/sec (Lighter Gases)



Pulsation Bottle Design

- A bottle volume of ≈20 x PD (Piston Displacement) is generally sufficient - can be refined with modeling.
- Pressure drop restrictions (orifices, line tubes, or alternate low loss technology) often located at bottle inlets and outlets for additional pulsation control.

Type 2: Two-Bottle Acoustic Filter Design
Low Speed Compressors (<500 rpm)

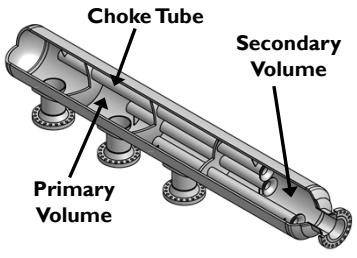
- Symmetry often used to minimize pass bands.
- Helmholtz frequency often placed between 1X and 2X. (Locating Helmholtz well below 1X would require larger volumes and/or smaller chokes.)
- Internal baffles and chokes often used to control bottle shaking forces and to isolate cylinders.

Type 2 & 3: Acoustic Filter Bottles
Sound Velocities ≤2,000 ft/sec (Typ. Natural Gas)

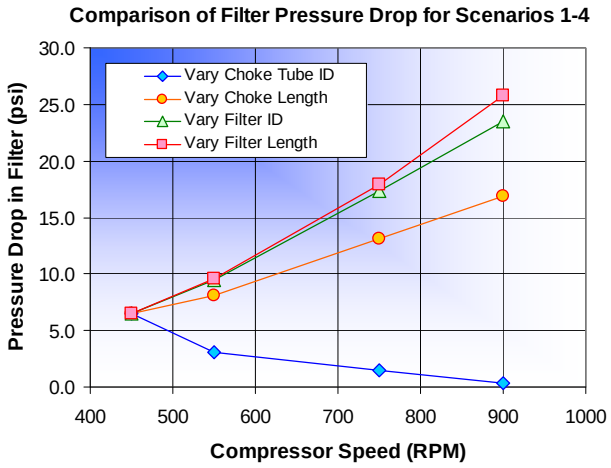
Pulsation bottle design

- Internal elements (baffles and choke tubes) often used to control shaking forces and piping pulsations
- Pressure drop restrictions (orifices) often located in the compressor nozzle for additional pulsation control

Type 2: Two-Bottle Acoustic Filter

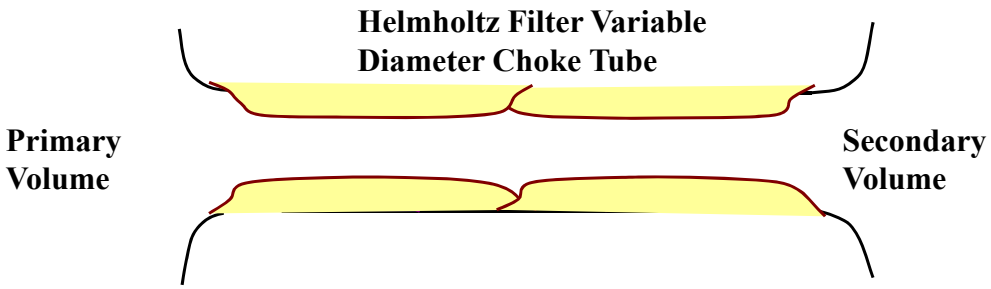


generally appropriate for speeds <500 RPM

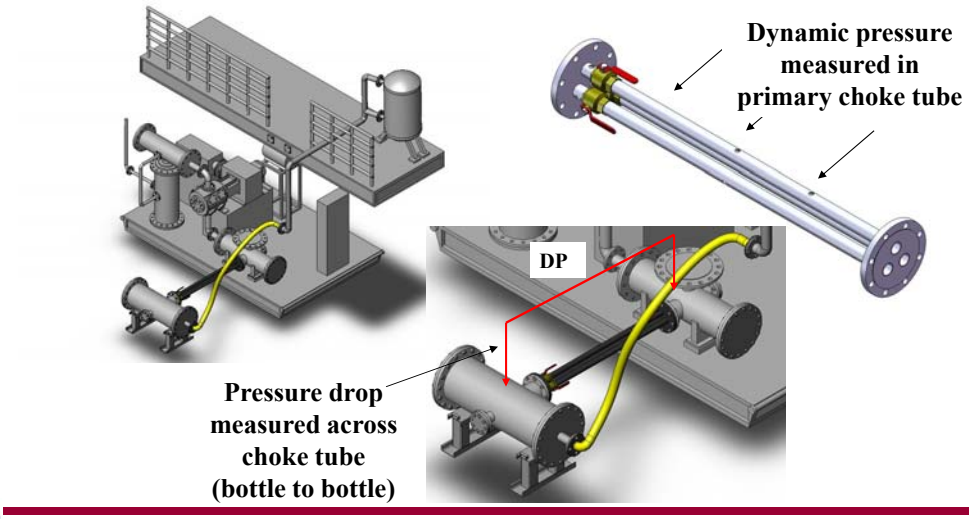


Type 3: Single-Bottle Acoustic Filter

generally appropriate for speeds >500 RPM

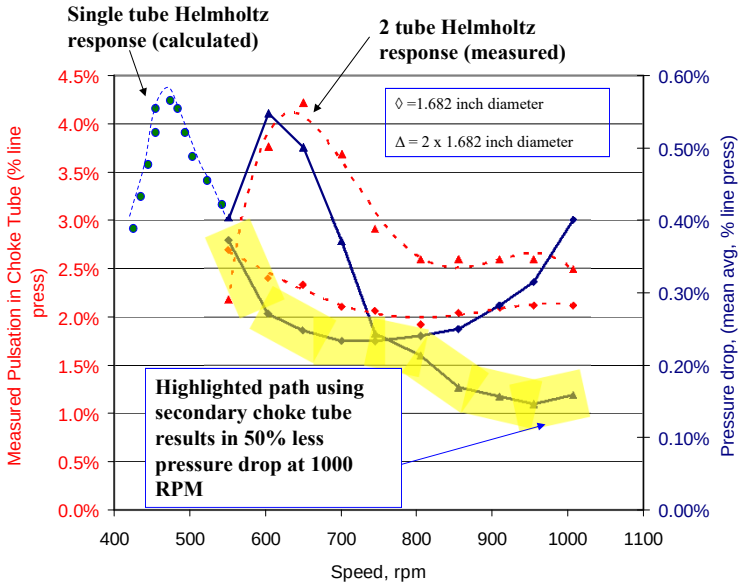


Why not a Tunable Pulsation Filter Bottle? Which Tuning Method Should be Used?



Tunable Filter Concepts after Brainstorming: Discrete Point Methods vs. Continuous Diameter Choke Tube

Continuous Diameter Method



Pinch Valve Method – option

Tunable Choke Tube – Previous Testing

Tunable Choke Tube – Previous Testing (2008)

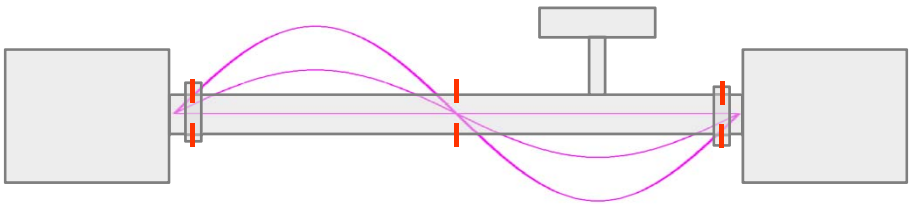
- The concept of varying the choke tube cross-section results in a significant reduction (1/3rd) in pressure drop at high flow rates with the potential of a small reduction in bottle diameter.
- The concept also allows the option of moving the response between the first and second order for cases when this is not an option with fixed, conventional designs.
  - This would allow a significant reduction in bottle diameter (potentially as much as half the bottle diameter).

VERY HIGH PRESSURE: NO VOLUMES

- Typical for hyper compressors and chemical applications
- Vessel walls become too thick and heavy
- Use combination of orifice plates and well placed acoustic natural frequencies
- Results in high pulsations in the system
  - Very robust support types
  - Thick-walled small diameter piping

Hyper Compressor Picture Courtesy of Burkhardt Compression

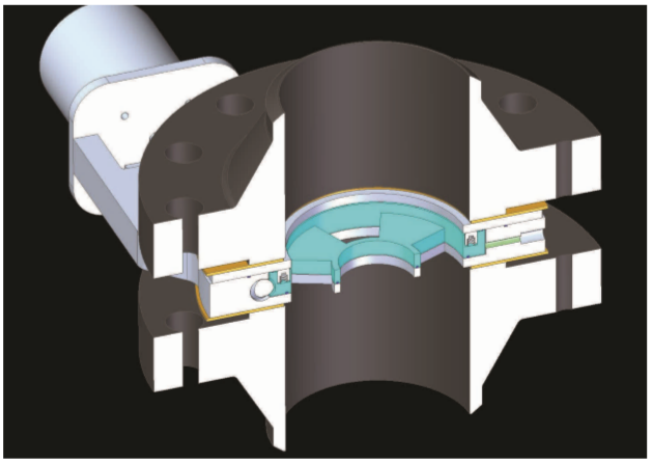
3. What if Additional Pulsation Control is Needed?



- Pressure drop restrictions (Orifices)
  - Restrict flow, add pressure loss, and *can* attenuate pulsations
  - Must be installed at the proper location (based on acoustic mode shape) to be effective
  - Most often provide pulsation damping, but do not significantly alter frequencies
  - Orifices are easy to install, but can reduce peak performance (and raise fuel consumption for the same throughput). Pressure loss increases with flow velocity squared and can be significant.
  - Cost of orifice should be carefully considered & weighted against options.
  - Orifices can increase pulsations at lower harmonics as back pressure is added to the compressor / pump

3. Other Options Beyond Bottles & Orifices?

- Side branch absorbers (SBA or Helmholtz or Quarter-wave resonator) – Low horsepower cost, but targets a small frequency range
- TSBA – Low horsepower cost & targets a larger frequency range
- Piping modifications (swages, length changes)
- Speed lockouts
- Advanced technologies (Low loss devices developed to control pulsations)
  - Pressure Recovery Insert (PRI)
  - Virtual Orifice (VO)
  - Pulsation Augmentation Network (PAN™)



Importance of Understanding the Mode Shape to be able to Apply the Various Acoustic Tools

- The pressure pulsations mode shape is the inverse of the velocity mode shape. – Remembering this can help with the logic behind locating orifices.
- Knowing the mode shape is important to be able to alter or damp the resonance by placing an SBA, orifice, or other system modification at a location where it can be most effective/useful.

Dynamic Variable Orifice (DVO)

- Bore is variable
- If resonance on 1x, then it's probably on 2x, but not as high amplitude – DVO could be smaller when single-acting (lower flow/losses), but larger when double acting (higher flow = don't want the smaller orifice)
- If resonance at low end of speed range, but not problem at higher speed – DVO could be smaller at lower speed/flow, but larger at higher speed/flow

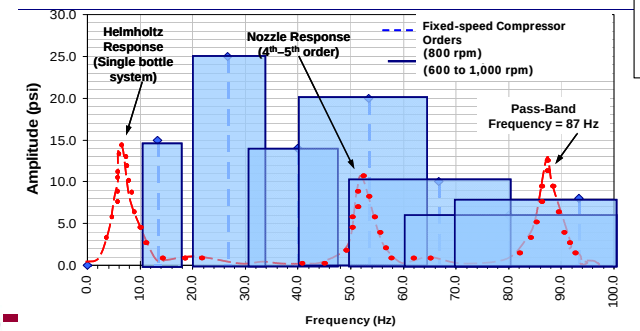
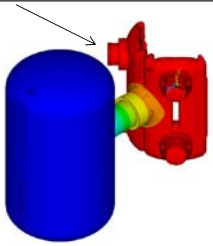
Addressing Nozzle Resonance – A Significant Acoustic Resonance That Should Not Be Ignored During the Bottle Design

- Typically, nozzle resonance in variable speed applications is controlled with pressure drop elements, which significantly affects compressor performance.
- State-of-the-art design tools can be used to optimize losses through orifices used to reduce nozzle pulsations.
- Technologies for controlling nozzle resonance that will minimize pressure drop (pressure recovery insert, virtual orifice) are currently available.

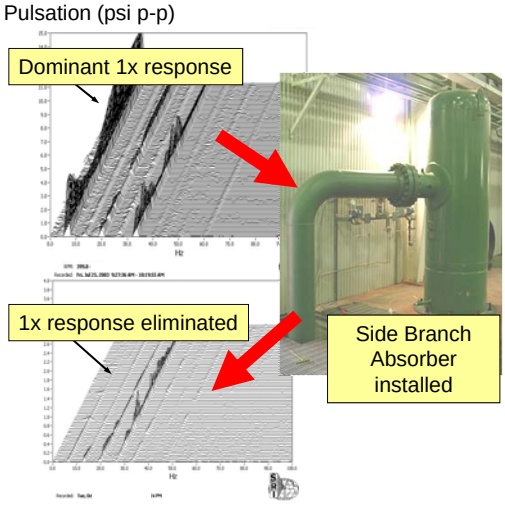




https://aciservices.com/wp-content/uploads/MKT-1244-DVO.pdf

Why Cylinder Nozzle Resonance Exists

- Variable speed, high speed compressors have very little (or non-existent) "windows" between running speeds.
- Often times, the 1-D acoustic representation of the 3-D gas passage is not well matched for accurate frequency prediction.
- NEW 3-D acoustic modal analysis can help to develop a better 1-D model.



Prediction of 66 Hz "cylinder to bottle" nozzle resonance – matched field data exactly (recorded for 825-1000 RPM speed sweep.)

Concept Behind the Virtual Orifice Technology

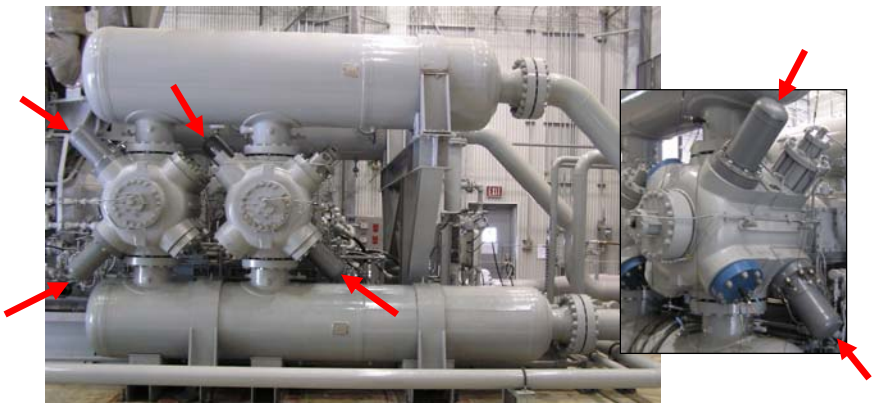
- Use of Helmholtz resonators has been a common practice to absorb dominate frequency in piping system.
- Size of Helmholtz resonators varies according to absorption frequency, SOS, and desired effectiveness. (Low frequency = Large volumes.)
- VO technology is unique in its placement of the SBA on compressor cylinders to reduce the nozzle response, typically at 4x-6x running speed.

Basic Virtual Orifice Design

- Designed to reduce nozzle pulsations with same acoustic performance as an orifice plate (or better performance).
- Recovers pressure losses – 26-32% pressure recovery*
- Efficiency Improvement – 3-9% efficiency improvement*
- Installed in place of a cylinder valve cap.
- Size varies based on cylinder size and operating conditions.

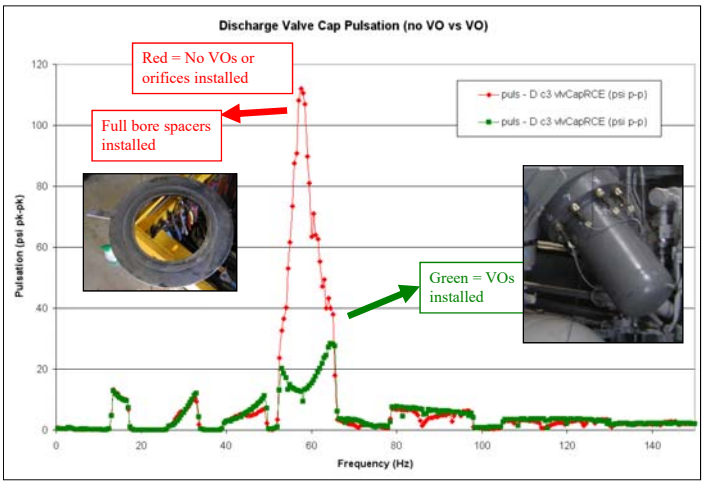
* As compared with the losses of a typically sized cylinder nozzle orifice plate

Virtual Orifice Field Test – Initiated in October 2007



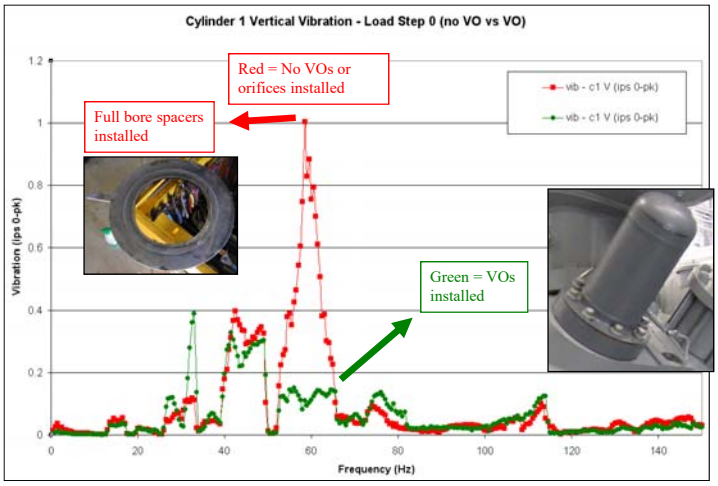
- Installed on suction side of two cylinder Superior MH62 unit at El Paso Baxter Station in Rocksprings, WY.
- Issues prior to VO installation: Vibrations and nozzle failures in the suction bottle due to lack of clamps and cylinder nozzle resonance. Initially, a typical orifice was used to mitigate the effects of high nozzle pulsations.
- VO reduced vibrations significantly and improved horsepower consumption.

VO primary vessel diameter = 5.56" with overall length = 14.75"



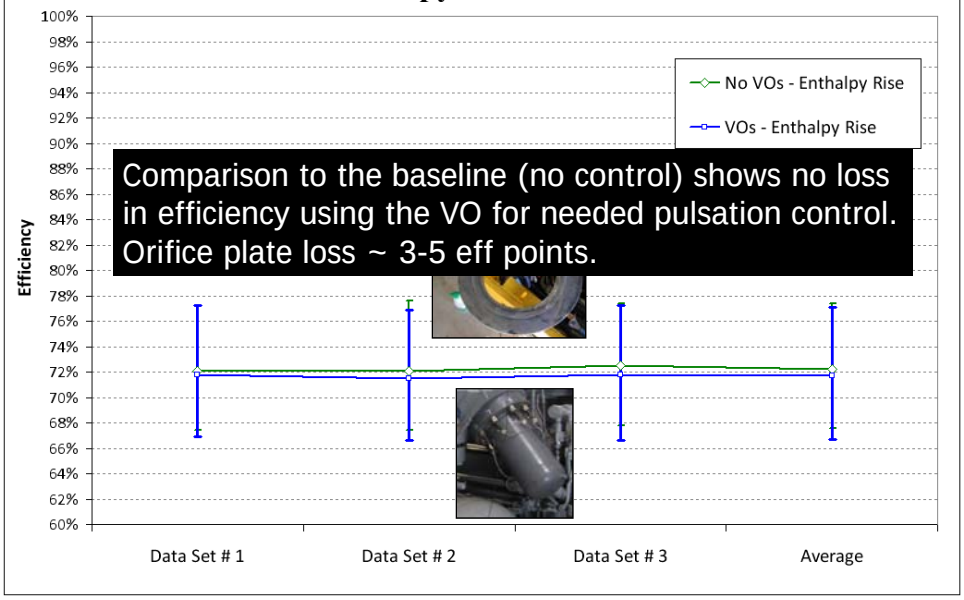
VO Field Testing at Boardwalk Pipeline Destin Station

- **Objective:** To further develop and verify performance of the VO through field testing. Testing to evaluate reliability, mechanical responses, material considerations, and performance.
- Compressor Specifications: Ariel JGC/4, 790-1000 rpm, ~950 to 1080 psig suction pressure, ~1090-1210 psig discharge pressure, all cylinders can SA



VO – Destin Field Testing – Measured Pulsation Data (Discharge)

Similar results were observed on the suction side.

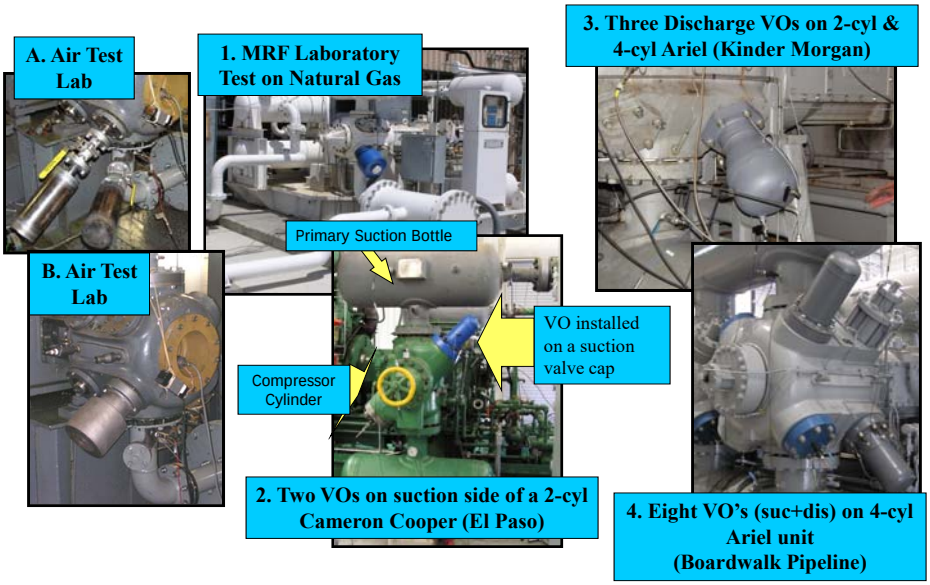


VO – Destin Field Testing – Measured Vibration Data (Vertical)

Similar (but less significant) results were observed in the horizontal direction.

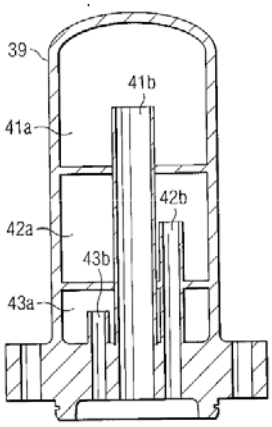
Measured Enthalpy Rise Performance Data

Comparison to the baseline (no control) shows no loss in efficiency using the VO for needed pulsation control. Orifice plate loss ~ 3-5 eff points.

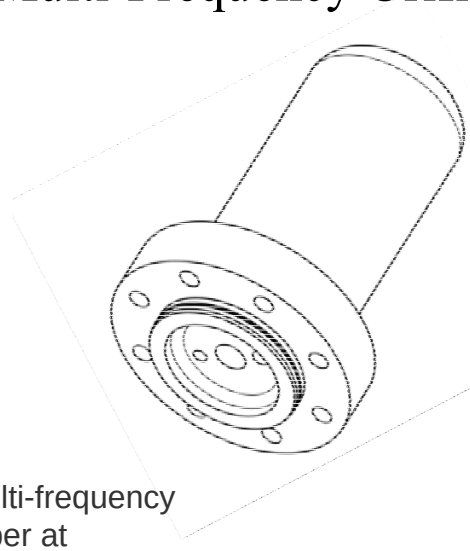


VO – Destin Field Testing – Summary

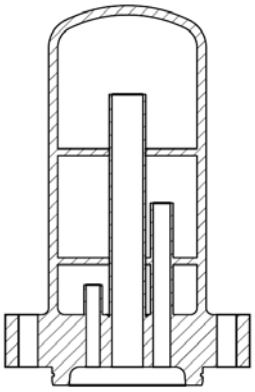
- Cylinder Valve Cap Pulsation Improvement:
  - Suction: 64% (83% at the initial resonance)
  - Discharge: 73% (86% at the initial resonance)
- Cylinder Vibration Improvement:
  - Vertical: 60% (85% at the initial resonance)
  - Horizontal: 16% (77% at the initial resonance)
- Performance Changes – When the VOs were installed (compared with no control):
  - PV Card Measurements indicated comparable performance.
  - Enthalpy Rise measurements indicated only a 0.5% efficiency reduction. *
  - hp/MMSCFD comparisons indicated a 3% improvement



* The measured values were statistically equal when considering the uncertainties associated with the measurements.



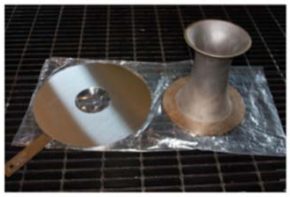
Verified System Changes That Resulted From the Installation of VOs



VO Fabrication Record

M-FOR – Multi-Frequency Orifice Replacement

Patent title: "Multi-frequency pulsation absorber at cylinder valve cap"

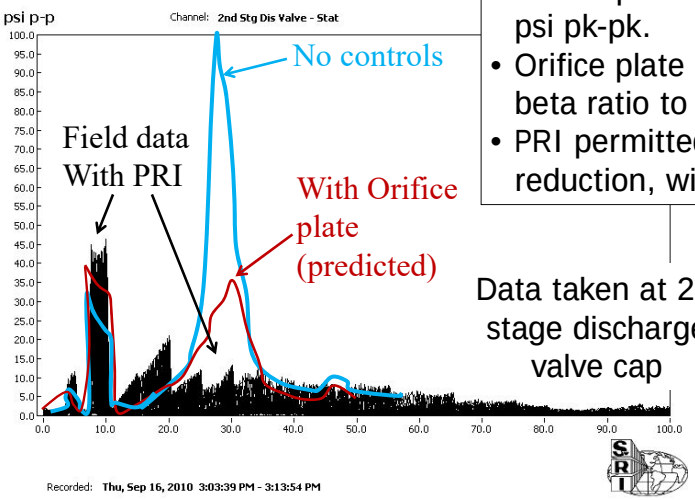


The Pressure Recovery Insert (PRI) Nozzle

- Designed to provide same or better pulsation control as an orifice plate, using a reduction is cross-sectional area to attenuate high pressure peaks.
- Pressure recovery is achieved because of gradual changes in area expansion and contraction
- Less pressure loss, which results in less power lost and reduced fuel cost
- Engineered using CFD studies and test data to provide optimal pulsation reduction at very low pressure drop penalty
- Can be made to fit full-range of pipe sizes and in discharge or suction configurations

Installation of PRI Suction Nozzle at El Paso Elk Basin Station

Orifice vs Nozzle Insert



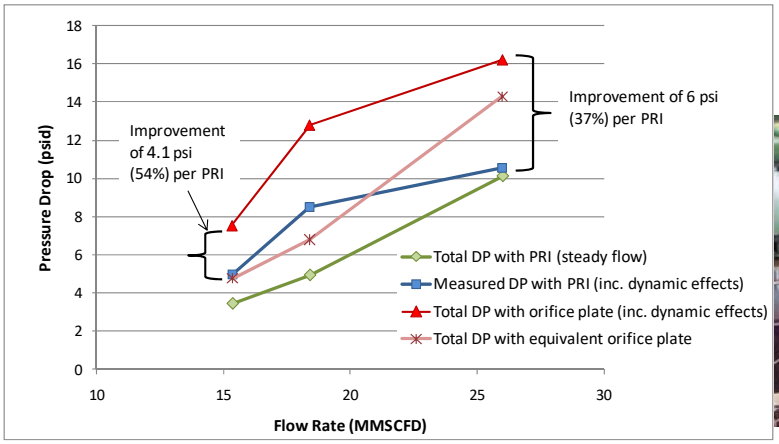
Nozzle Insert & Gasket

*Successful operation since August 2009.

Nozzle Pulsations on 2nd Stage Discharge – Fully Load, Single Stage Operation

- Nozzle pulsations with no control at 100 psi pk-pk.
- Orifice plate DP requirements limited beta ratio to 0.75.
- PRI permitted optimal nozzle pulsation reduction, with less DP.

Data taken at 2nd stage discharge valve cap



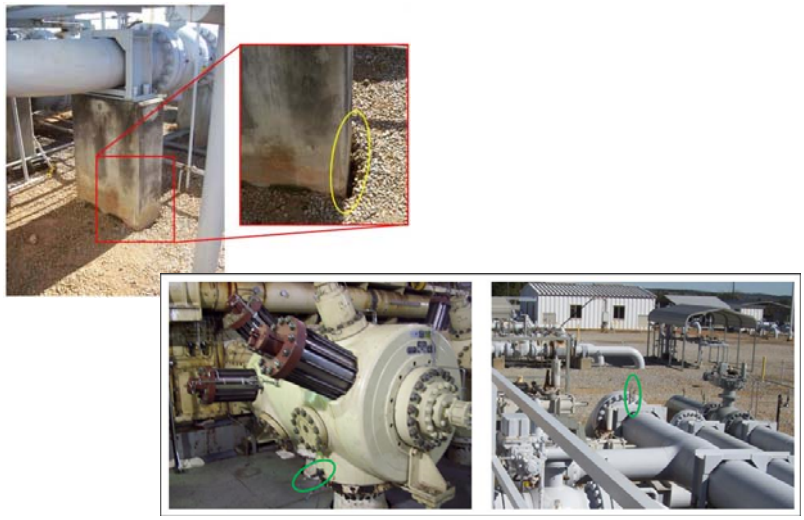
PRI Field data shown in black

In blue = Model data: Baseline nozzle response prediction (no control in place)

In red = Model data: Nozzle response with Beta 0.75 orifice plate

PRI Summary Pressure Loss Data

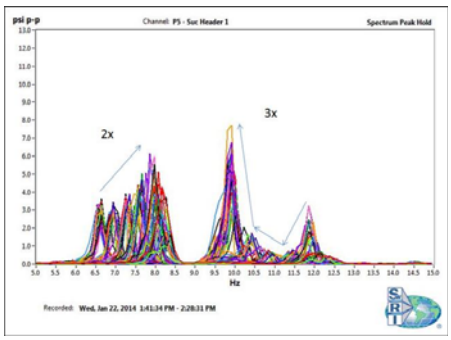
- SwRI analyzed two stage operation with highest flow rates (30-52 MMSCFD) over speed range of 230-300 RPM.
- Measured DP for PRI included dynamic effects and elbow, tee losses between taps.
- PRI showed 37-54% less pressure drop than equivalent orifice plate. (Equivalency based on similar pulsation control.)



Advanced Pulsation Control Conclusions

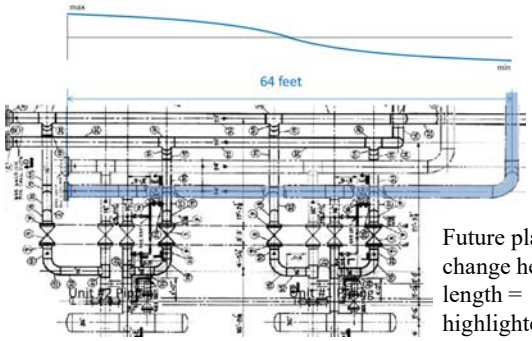
- Tunable Filter Bottle – Pulsations controlled + improved efficiency over the entire speed range
- DVO (Dynamic Variable Orifice) – Can be a significant system efficiency improvement
- PAN (Pulsation Augmentation Network) – Similar to a network of SBA's, but flow-through device
- TSBA (Tunable Side Branch Absorber) – Better than SBA, it's tunable!
- VO (Virtual Orifice) – controls vibration and pulsation in cylinder nozzles through absorption of primary frequency band – No efficiency penalty
- M-FOR (Multi-Frequency Orifice Replacement) – VO with additional pulsation frequency absorption capabilities
- PRI (Pressure Recovery Insert) – PRI offers ability to control nozzle pulsations through attenuation, at lower DP cost than orifice plate.

- 6 of the 7 devices have been field tested
- All devices, when properly designed and implemented, produce significant efficiency and pulsation attenuation improvements



Effect of Changing Operating Conditions: Case History

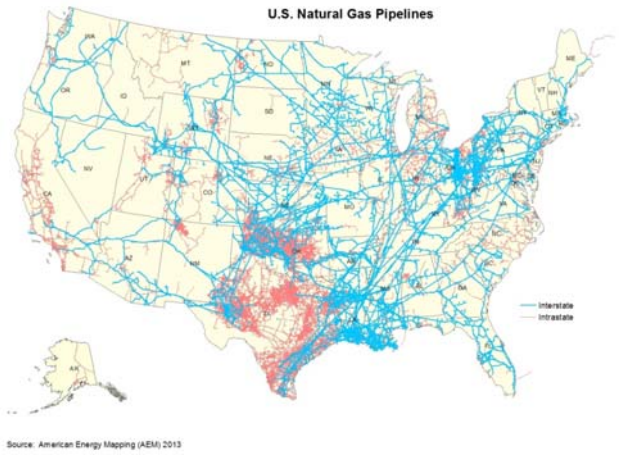
- Pipeline gas compression facility reported excessive vibrations
  - Variable speed reciprocating compressors 200-250 rpm (3.3-4.2 Hz) swept data in 10 rpm (0.2 Hz) increments
- Levels of vibration visibly high in yard piping during previous summer of operation
  - Vibrations developed after recent changes of this piping
  - Current testing done in spring



Effect of Changing Operating Conditions : Results – Pressure Measurements

- Significant increase in pulsations at suction header end near bottom of 3x
- Difference of 20°F would increase SOS

Shape of pulsations suggest acoustic resonance between 8 and 10 Hz

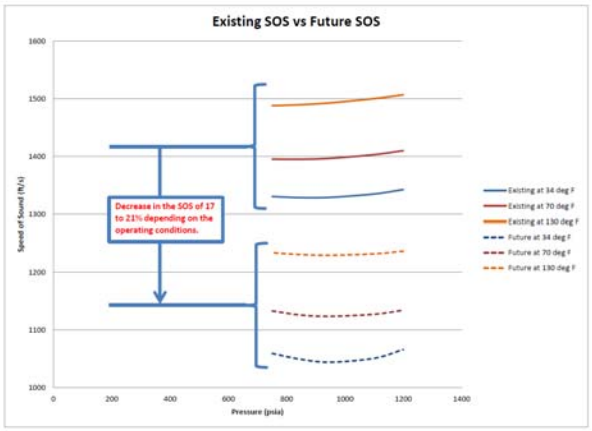


- Acoustic length response of main suction header
- Pulsation force could exceed 3,000 lbf p-p at each end
- Potentially > 12,000 lbf p-p with 0.25 Hz ANF shift

Future plans to change header length = highlighted need for pulsation study

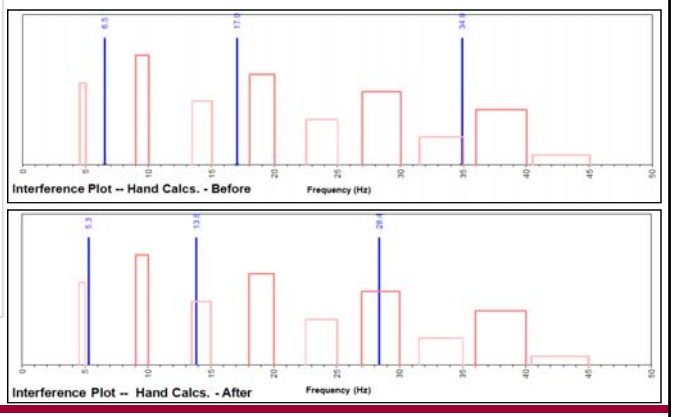
Flow Reversal and/or Gas Change

- Natural gas boom has created a demand for gas flow in different directions.
  - New well productions
  - Higher demand in geographical areas
  - New interconnects throughout piping system
- Many of the stations are built to flow in one direction.
  - Gulf of Mexico stations typically designed to flow North
  - Northern regions now have large quantities of gas entering the pipeline.



Flow Reversal and/or Gas Change

- Many stations have operated at the same conditions for decades with no vibration issues.
  - Initial design conditions:
    e.g. gas composition, pressures
  - Station requirements:
    e.g. flowrates, discharge pressures
- Updates to station equipment might coincide with flow reversal project.
  - Gas scrubbers
  - Piping and valve additions



Existing recip. compressor station planning to operate with new shale gas

	Existing	Future

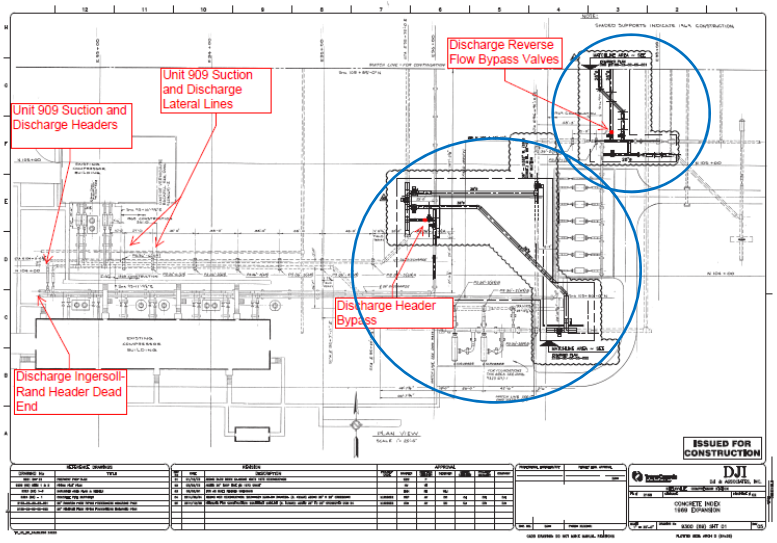
NEW Acoustic Natural Frequencies

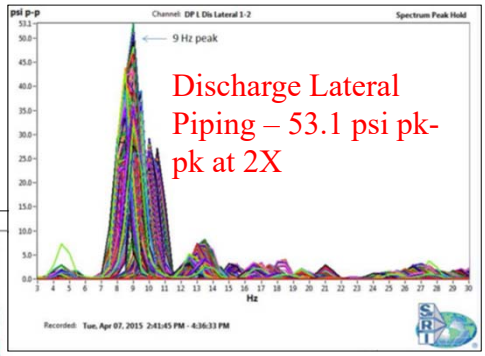


Acoustic Design Consideration

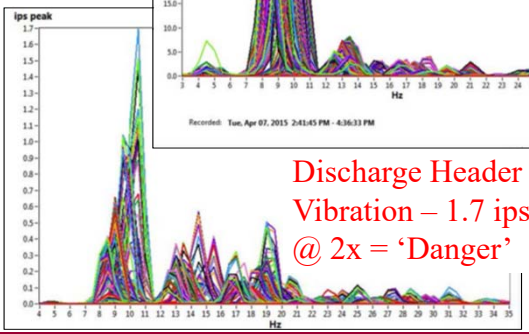
Excitation Frequencies Shift

Flow Reversal Case Study

- TransCanada transmission station
- Station experienced high vibration when reverse flow lines added and while operating in reverse flow mode.
- Original study performed in 1970 – no plans for reverse flow 45+ yrs later

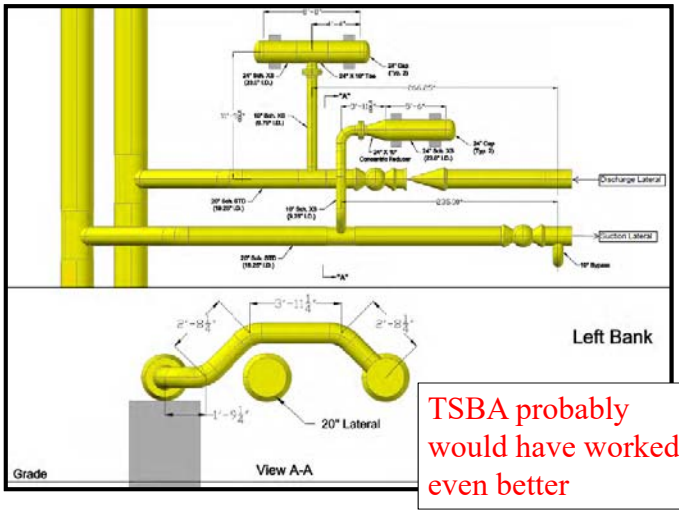


Flow Reversal Case Study – Acoustic Design



- Data collected on suction and discharge bottles, laterals, and header piping system.

Discharge Lateral Piping – 53.1 psi pk-pk at 2X



Discharge Header Vibration – 1.7 ips 0-pk @ 2x = 'Danger'

1.7 ips 0-pk vibration data also collected on the valves implemented for reverse flow.

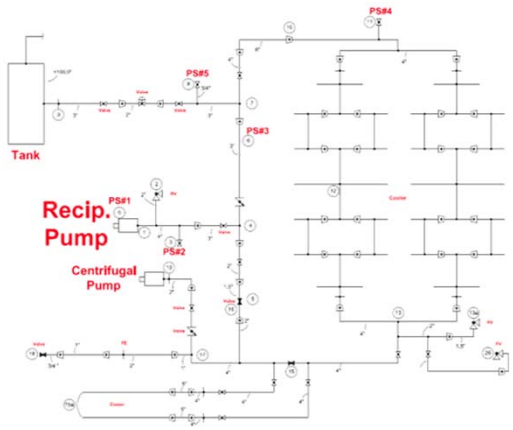
Flow Reversal Case Study – Recommendations for the Left Bank (similar for Right Bank of compressor)

- Possible modifications included:
  - Multiple orifice plate locations
  - Modify existing pulsation bottles in order to filter 2X running speed.
    - Would have needed to add approximately 30 to 40 feet to the bottles.
  - Add additional secondary pulsation bottles.
  - Side branch absorbers (SBAs) tuned to 2X running speed.
- An updated acoustical analysis should be performed prior to operation in reverse flow

TSBA probably would have worked even better

Pump Poll Question (Poll #2)

Pumps – Dampener/Volume or Filter



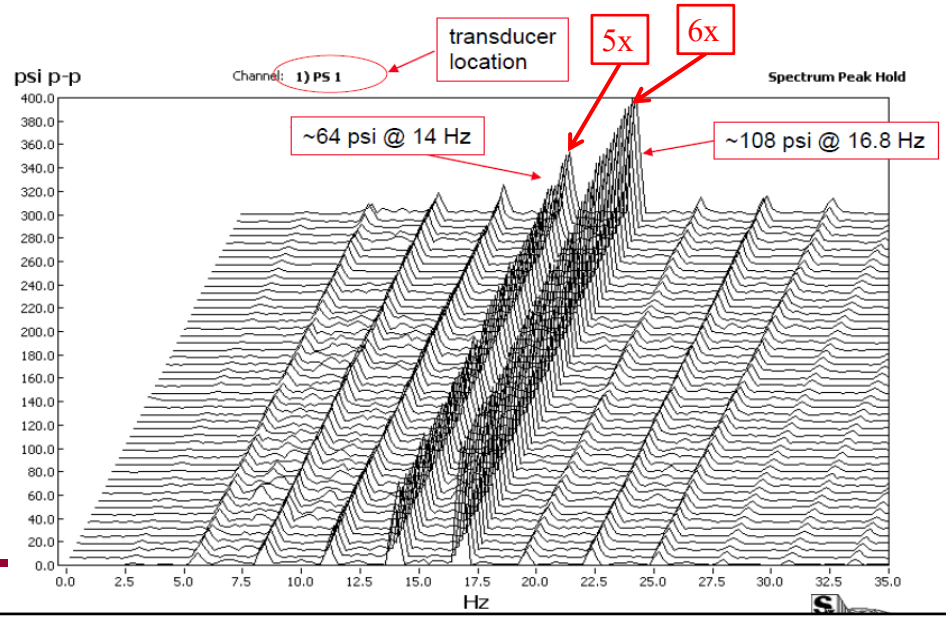
- Case study where dampener caused pulsation problem
- Case study for Filter

CASE STUDY: ON-SITE PROBLEMS— POSITIVE DISPLACEMENT PUMP

- High suction piping vibration causing:
  - Pipe insulation deterioration
  - Pipe restraint damage
  - Shortened pump valve life
  - High noise
- Gas-liquid pulsation dampeners installed years prior to field study – removed due to high maintenance and frequent bladder failures
- Issues above raised safety & reliability concerns

ALL-LIQUID ACOUSTIC DAMPENER – PUMP DESCRIPTION DETAILS

Pump Operating Conditions
30-40 psig (2.1-2.8 barg) Suction Pressure
1000-1250 psig (69-86 barg) Discharge Pressure
210-230°F (99-110°C)

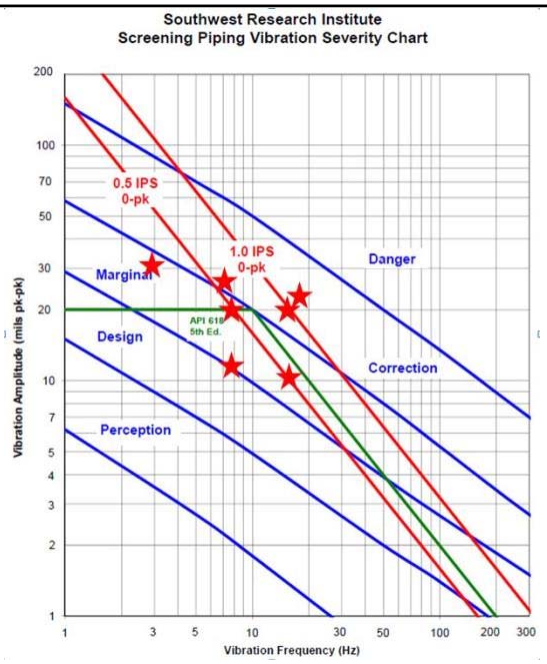


Pumps Details
2 pumps (plunger) Separate piping systems
3 plungers per pump
3.375” bore (8.57 cm)
5” stroke (12.7 cm)
166 rpm

SUMMARY OF FIELD MEASURED PULSATION

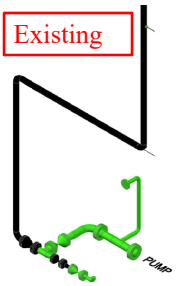
Test Point	Overall Amplitude psi pk-pk	Shaking Force lb_f p-p	3x 8.4 Hz psi p-p	5x 14 Hz psi p-p	6x 16.8 Hz psi p-p	~10x 25 Hz psi p-p
PS 1	110	1749	22	64	108	--
PS 2	143	1820	19	60	96	--
PS 3	---------- No signal ----------					
PS 4	45	573	15	--	95	--
PS 5	80	591	11	--	17	24 / 25

Indicates potential of failed valves



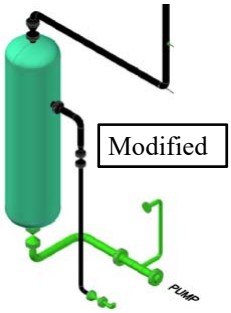
FIELD PULSATION DATA AT PUMP

FIELD VIBRATIONS ON VIBRATION GUIDELINE CHART

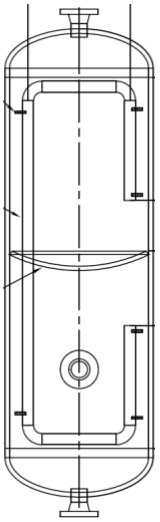


Field measured vibrations in "Marginal" and "Correction" regions

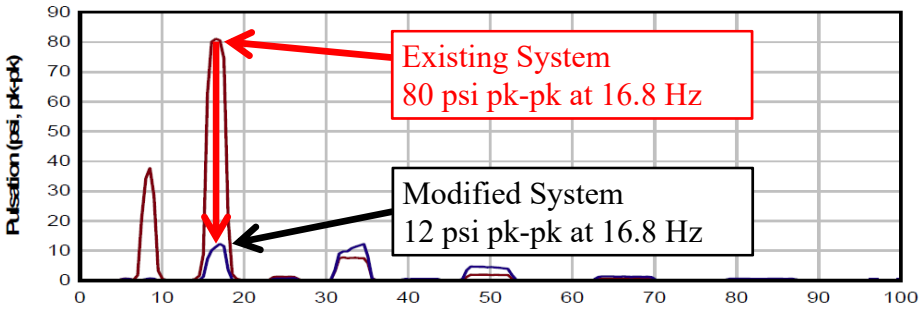
High vibrations coincided with frequency of high pulsations



PULSATION ANALYSIS/MODELING MODIFIED SYSTEM



Existing



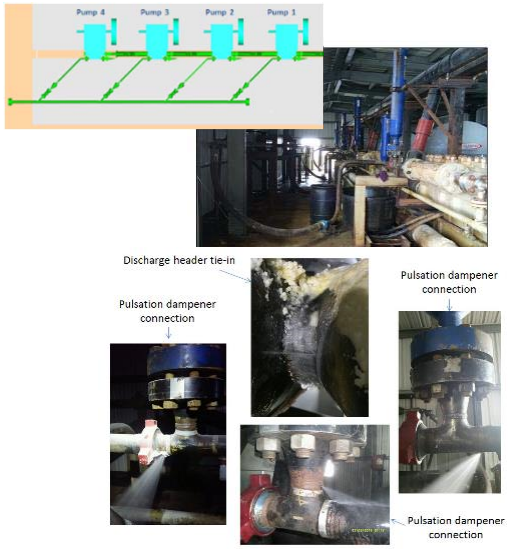
Much lower amplitude pulsations predicted

- Pump manifold (see below)
- Upstream piping 0.1-12 psi pk-pk at 16.8 Hz

VIBRATION MEASURED WITH FILTER INSTALLED

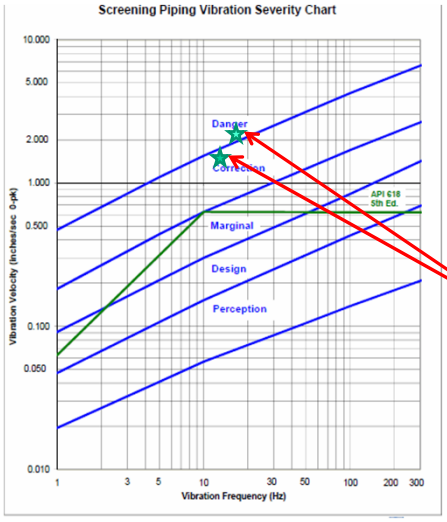
Test Point	Before 3x 8.4 Hz (mils p-p)	After 3x 8.4 Hz (mils p-p)
FV	76	0.73
Pump Suction	34	0.37
Pump Discharge	33	1.25

- Data measured by operating company
- Highest vibration with filter = 1.84 mils pk-pk at 9x



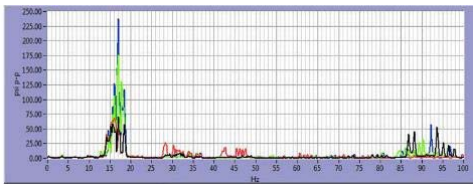
The following is a quote from the client: "Operators saying they have to walk up and touch the motor to make sure it's running, whereas they could hear the pump from the road before the change."

Pump Acoustic Filter Case Study – SUMMARY AND LESSONS LEARNED

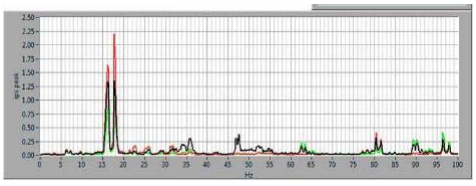


- Pump System Problem
  - High amplitude piping vibrations – insulation and restraint damage
  - Gas-liquid dampener bladder failures
- Steps taken to Solve Problem
  - Field investigation for problem evaluation – vibration & pulsation data measured
  - Pulsation analysis
- Summary & Lessons Learned
  - Well designed acoustic dampener significantly reduces system pulsations, which results in reduced vibration amplitudes

CASE STUDY, Pump System: Gas-Liquid Dampeners

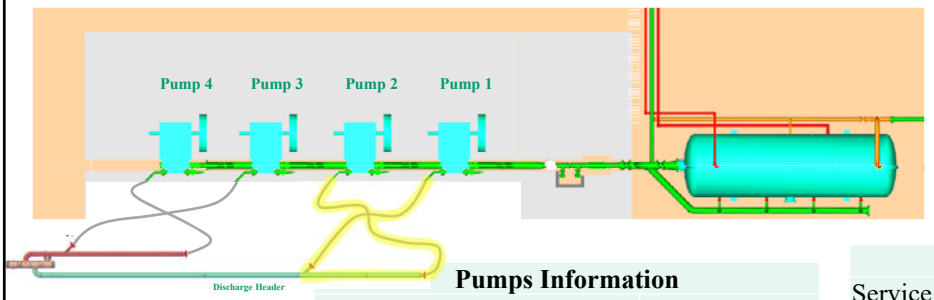


- Four positive displacement quintuplex pumps
- Each pump had dampener installed on discharge line
- Pumps connect to discharge header with flexible lines
- Problems:
  - Numerous failures in piping near pulsation dampeners and at discharge header tie-ins
  - Visibly high levels of vibrations on piping
  - Elevated audible noise



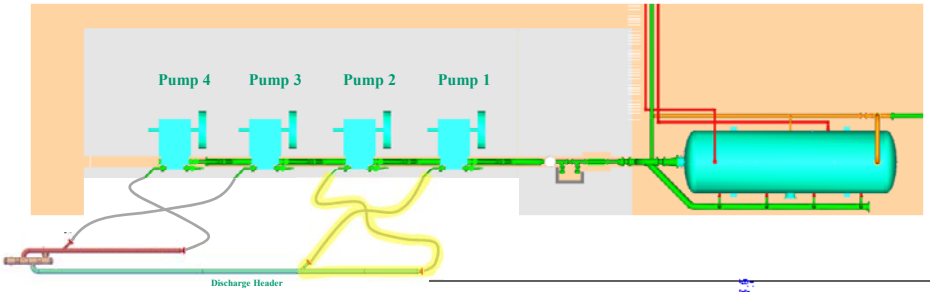
FIELD DATA: DISCHARGE VIBRATION RESUTING FROM PULSATION

Field Data pulsation at 16 - 18 Hz



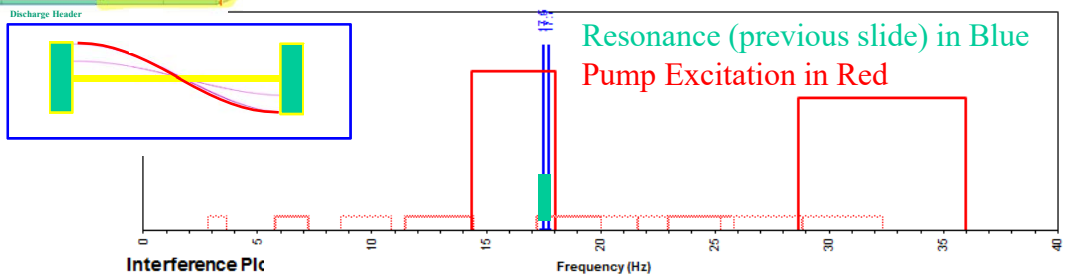
Field Data vibration at 16 - 18 Hz

Field data indicated vibration due to high pulsation levels (acoustic source)



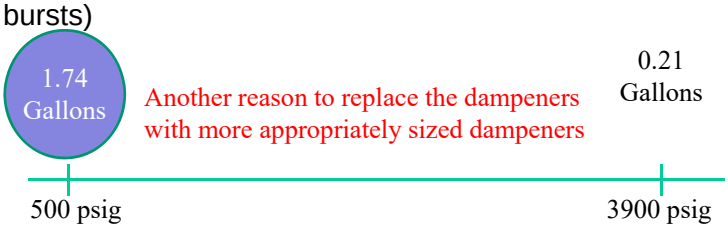
Pulsation/Acoustic Analysis – Model Details

Pumps Information	
Number of Pumps	4
Number of Stages	1
Number of Plungers	5
Pump Speed (rpm)	143-286
Plunger Diameter (in)	2.625
Stroke (in)	7
Capacity at max speed (gpm)	235
Rated Horsepower (BHP)	625



Fluid Information	
Service - Type of Fluid	Well Injection Oil
Suction Pressure (psig)	40
Discharge Pressure (psig)	~1000-3900
Temperature (°F)	110
Specific Gravity	~2.8

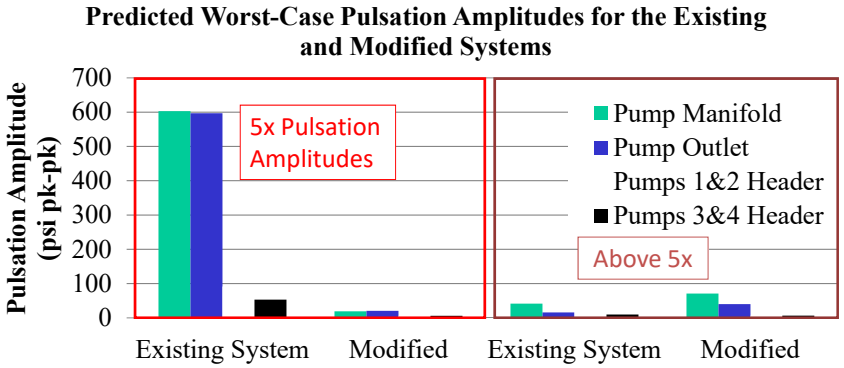
System Acoustic Natural Frequency (ANF)



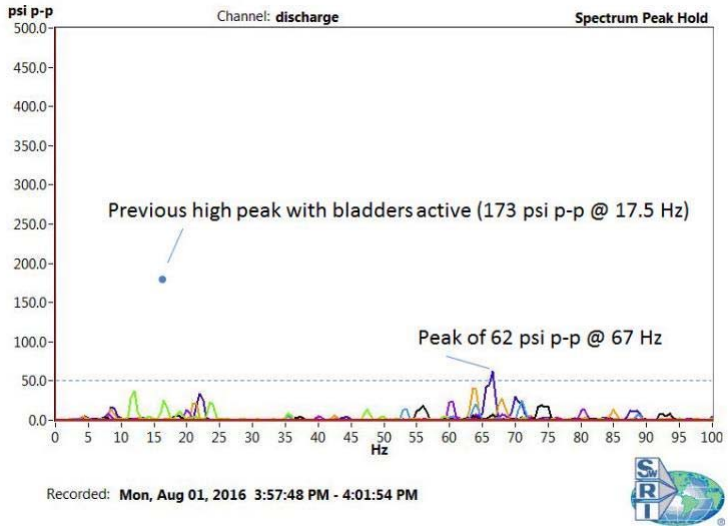
$$f_n = \frac{c}{2\pi}\sqrt{\frac{\mu}{V_1}+\frac{\mu}{V_2}}$$

$$\mu = \frac{A_c}{L_c}$$

Pulsation Analysis – Dampener Size



- Pre-charged original dampener to only 500 psi (MAX)
  - Gas volume decreases at higher pressures (per ideal gas law)
  - 1.74 gallon gas volume at 500 psig becomes 0.21 gallon gas volume when line pressure reaches 3900 psig (or it bursts)



Pulsation Analysis – Before/After Predictions

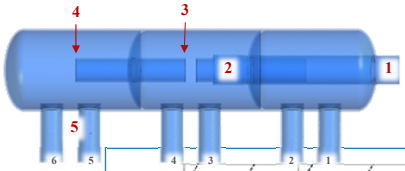
Recommendation - 2.5 gallon dampeners in same location

- Sufficient surge volume at max pressure (when properly pre-charged)
- Sufficient volume to shift acoustic natural frequency down to below 5x

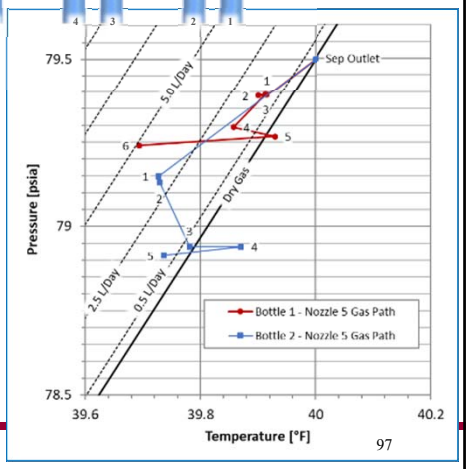
Pump Dampeners Cause Resonance Case Study: Post-Modification Testing

- Pulsations significantly reduced with modifications
- Audible noise and visual vibrations also reduced per station personnel
- Station has been running without incident since modifications in 2016.

Acoustic/Pulsation Attenuation Summary



- Avoid acoustic resonances in the piping system, where possible
- Installing well-sized pulsation attenuation bottles/dampeners is the next best solution for resonance management
- Manifold design must balance pulsation/vibration control and compressor performance and mechanical considerations
- When installing additional pulsation control devices, such as orifices, DVO, SBA, TSBA, PAN, VO, M-FOR, PRI, etc., it is important to understand the system acoustics and how it will interact with the pulsation signature of the PD machinery
- Consider revisiting pulsation analysis when gas comp. changes

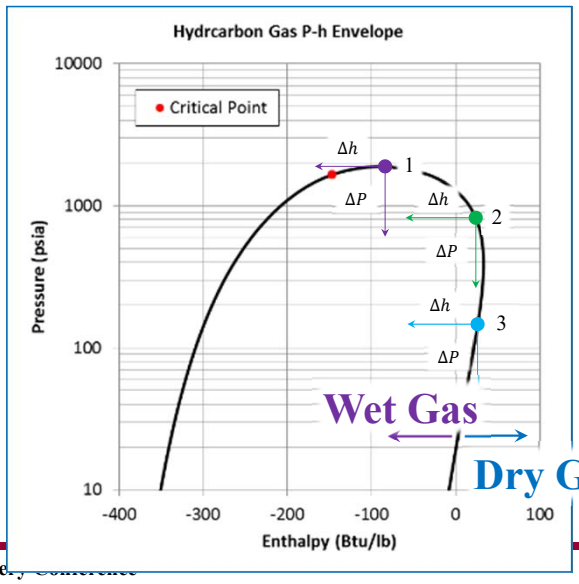


Break

Advanced Topics in Pulsation

Wet Gas Considerations

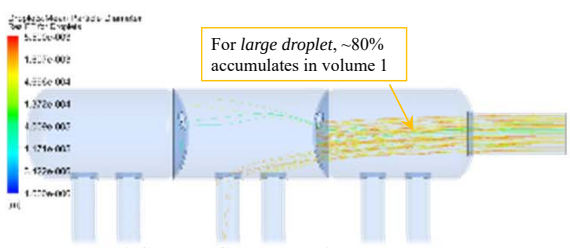
- Pulsating flow and pulsation control systems can move the operating point of the gas resulting in liquid drop-out
  - Pulsations create large changes in pressure
  - Pressure losses create heat losses
- Even small amounts of drop-out can result in significant ingestion of liquid into the compressor
- Problems with liquid accumulation:
  - Filling cylinder end cap resulting in pressure spikes
  - Decrease the effectiveness of the pulsation bottle if not regularly drained
  - Slugging



For a saturated gas, will pressure and heat losses result in liquid dropout?

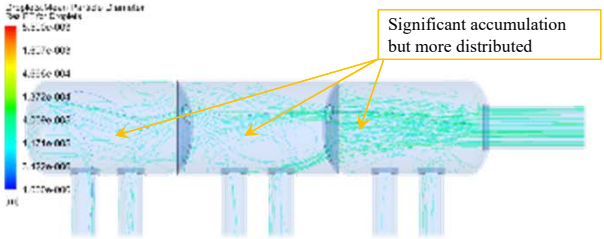
Depending on operating conditions, pressure losses, heat losses, or both can result in condensation.

Operating Point 1: pressure losses move operating point into the wet gas (two-phase) region



Operating Point 2: both pressure and heat losses move operating point into the wet gas region

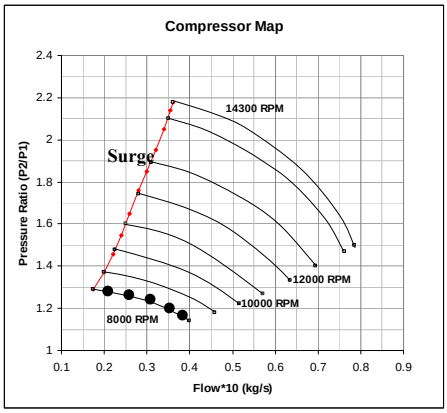
Operating Point 3: heat loss moves operating point into the wet gas region, pressure loss moves into superheated region



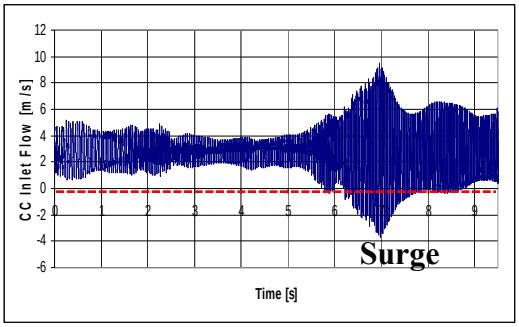
Does It Accumulate: Where and How Much?

- A 1-D screening analysis can be performed in HYSYS enabled pulsation analysis to evaluate whether the dewpoint will be crossed as the gas travels through the piping system and pulsation control system
- A 3-D CFD analysis can be performed to qualitatively and quantitatively compare bottle designs, patters of liquid dropout or liquid distribution

Bottle 1 Steady State Particle Track - Large Droplet



Bottle 1 Steady State Particle Track - Small Droplet



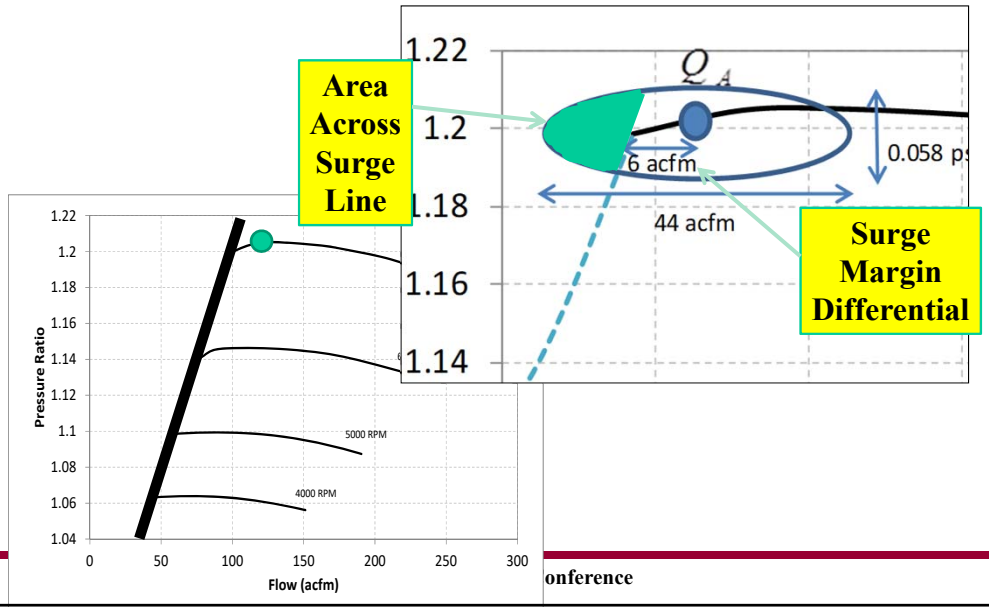
PULSATION INTERACTION IN MIXED COMPRESSION

When reciprocating compressors share common headers with centrifugal compressors, pressure and flow pulsations can severely reduce the centrifugal compressor's surge margin and operating range.

- Low frequency pulsations less than 50 Hz do not decay quickly—it is not sufficient to separate the compressors by several hundred feet of piping.
- Lateral piping of centrifugal compressor can experience severe vibrations
- Pulsating flow requires more horsepower to compress resulting in centrifugal compressor performance degradation
- Pulsations create flow velocity fluctuations which can result in periodic surge events

CENTRIFUGAL COMPRESSOR MAP AND SURGE

Brun et al. 2010



Flow pulsations can cause periodic surge in centrifugal compressor

PROBLEM

- The performance of a centrifugal compressor is defined by its operating map.
- This map is critical in assessing the operating range of a compressor for both steady- state and slow transient system scenarios.
- The compressor map does not provide a complete picture of how the compressor will respond to rapid transients (pulsations) or the affect on its surge margin.
- The response of the compressor to rapid transient events is unique to each system since it is a function of the acoustic and impedance characteristics of the associated piping system.

Unexpected periodic surge has been observed in compressors when pulsations were present.

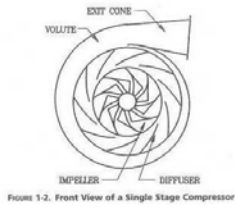
OPERATING MAP ELLIPSE

SOLUTION

- Extend API 618 Pulsation Analysis to centrifugal compressor flanges
- Predict unsteady compressor operating map area taking into account piping impedance
- Determine net effective surge margin reduction
- Use GMRC guideline criteria to determine safe operating ranges,
  - Add margin to surge control line
  - Install additional pulsation control between the two compressor types
    - Orifice plates
    - SBA
    - Filter Bottles

HIGH FREQUENCY PULSATION SOURCES IN TURBOMACHINERY

- fpb = RPM * b / 60; impeller blade pass frequency
- fp = RPM * nb /60 or RPM * nd /60; harmonics
- Variables
  - RPM – impeller rotating speed in revs/min
  - b = Number of Impeller Blades
  - d = Number of Vanes (Diffuser)
  - n = Integer 1, 2, 3, …
- More complex interactions may also be significant
- Normally present at a low amplitude
- When present at several psi or more, they can be problematic



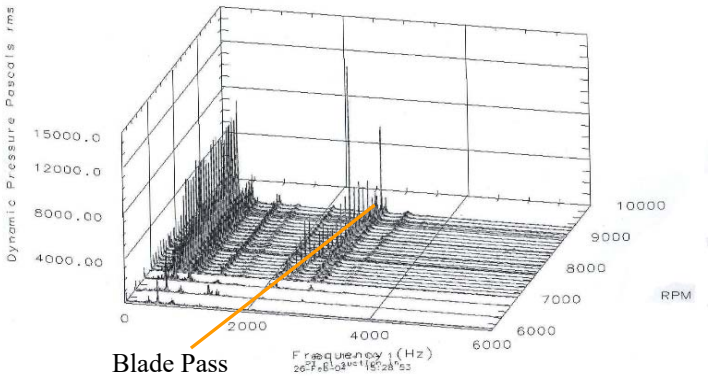


FIGURE 1-2. Front View of a Single Stage Compressor

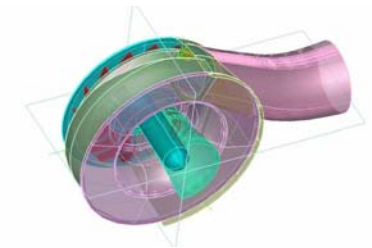
BLADE PASS SIGNATURE IN PULSATIONS

Waterfall plot shows pressure pulsations in compressor discharge piping during speed change.

Blade Pass Frequency



EXAMPLE: EXCITATION FREQUENCIES

Consider a compressor having an impeller with 17 blades and rotating at 9600 RPM.

Rotation Frequency: f_shaft = 9600 RPM/60 = 160Hz

Blade Pass Frequency: 160Hz * 17 blades = 2720 Hz

Rotating Stall: Approx. 1/10 to 1/3 of 160Hz ~ 15 – 50 Hz

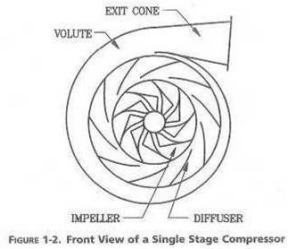


FIGURE 1-2. Front View of a Single Stage Compressor

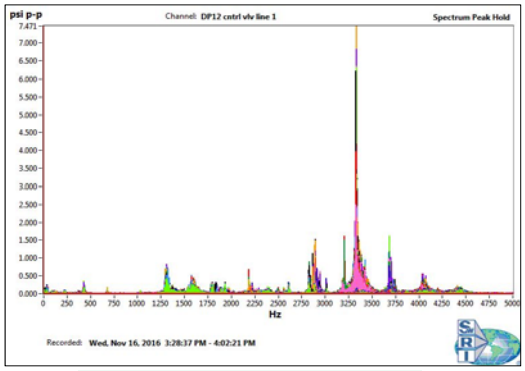
Volute cutwater or "tongue" can be source of pressure pulsation at blade pass frequency

DUCT AND SHELL MODE INTERACTION

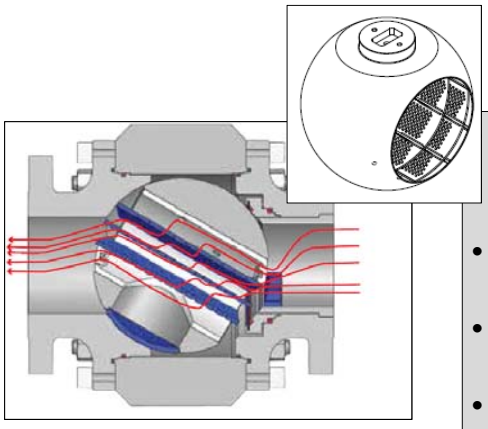
- A duct mode may excite a shell mode if the frequencies are similar and the mode shapes match



- Lightly damped resonance can lead to high stress concentrations at branch connections or other fittings, which can lead to fatigue failures

Valve Related Noise and Vibrations

- Noise
  - Discrete tonal noise from vortex-shedding excitations
  - Broadband noise from turbulence in high energy flow or pressure reduction (AIV)
  - Can have both
- Chatter or Vibrations
  - Acoustic excitation of risers or piping associated with a closed valve creating pulsations and chatter of PSV or check valve (FIV)
  - Discrete acoustic excitation of valve internals excites radial and shell modes of the main piping resulting in vibrations and/or failures (FIV)
  - High amplitude broadband excitation from high mass flows creating vibrations through a pressure reduction and transfer of flow energy (AIV)



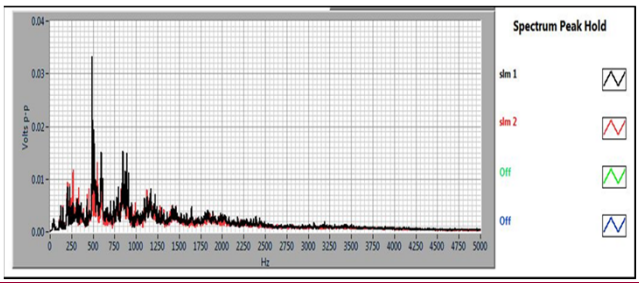
Valve Pulsations: Control Valve Example

- Loud tonal noise created by 3300 Hz pulsation coupling with shell mode of connecting piping
- Approx. 106 dBA
- Below ring frequency (4,000 Hz) of pipe—low transmission losses
- Higher pulsation amplitudes at 4,400 Hz, but not associated with loud external noise since above ring frequency
- Occurred at a metering station near noise sensitive areas (NSAs)

Noise only occurred when valves in partially closed position

Flow Control Valve
Noise Reducing Trim

Examples of a Noise Reducing Trim—Valves in Various Open Positions
Images Courtesy of GE Becker and Flowserve



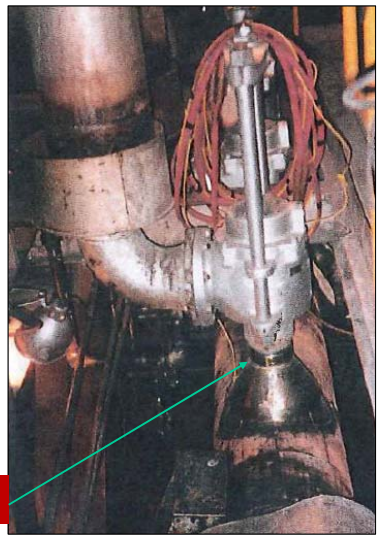
Valve Internal Noise Control Trim Creates Flow Across Cavities

- Can Result in V-S When in Various % Open Positions
- Excites Acoustic and Mechanical Piping Modes
- Noise, Pulsations, and Vibration Problems

Control Valve Solution

- Replaced valve with different noise trim
- High frequency noise peaks virtually eliminated
- All NSAs had an Ldn less than 55 dBA

Location	L_{eq} dBA	L_{dn} dBA
NSA #1	47	53.4
NSA #2	42	48.4
NSA #3	47.5	53.9



PRESSURE SAFETY (RELIEF) VALVES

Problem:

- Vortex-shedding of flow past PSV risers can excite the acoustic and mechanical modes of the piping
- This can cause the valve to lift, chatter or be unable to re-seat after lifting due to high pulsations/vibrations

Solutions:

- New spring stiffness
- Increase piston mass or dome volume
- Add drag rings
- Alter riser geometry
- Orifice
- Side branch absorber

ACOUSTICALLY-INDUCED VIBRATION (AIV)

- Acoustically-Induced Vibration (AIV) refers to high-frequency broadband excitation and high-frequency vibration (typically 100-2000 Hz) in piping downstream of a pressure-reducing device (e.g., a control valve or pressure relief valve)
- Can result in high-cycle fatigue failures at branch connections or welded supports
- First identified in 1983 by Carucci and Mueller
- Often a concern in flare/blowdown piping with thin walls and large diameters

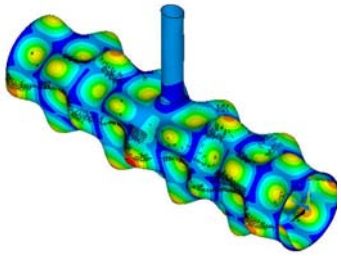


Image Courtesy Tyco Valves & Controls

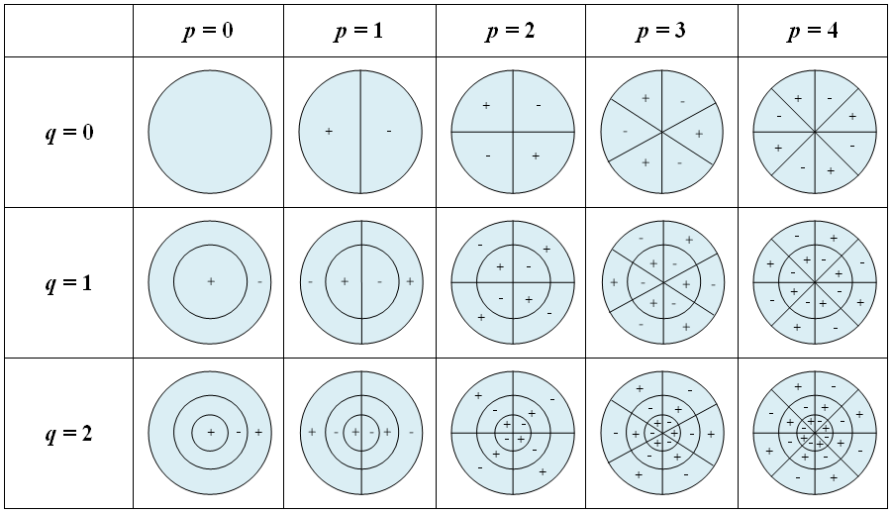

Image Courtesy Chemical & Process Technology

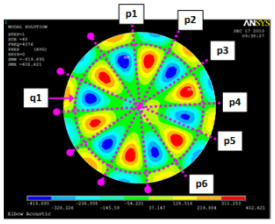
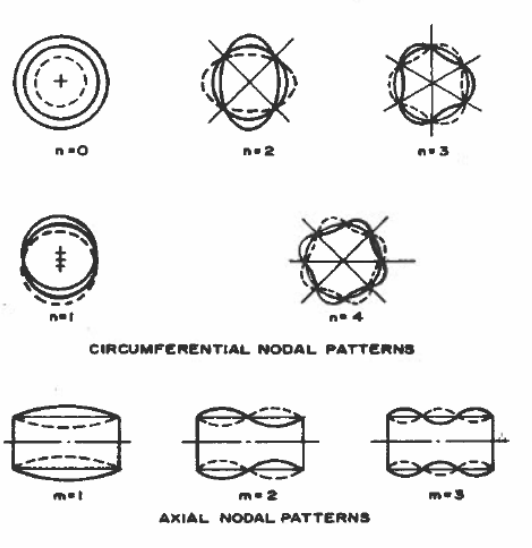
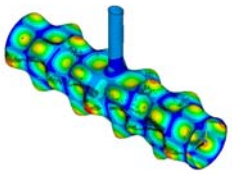


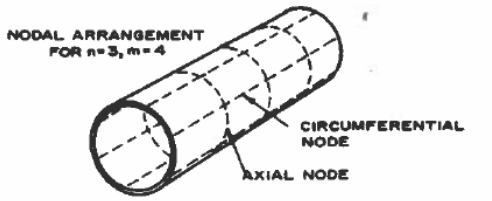
THEORY OVERVIEW

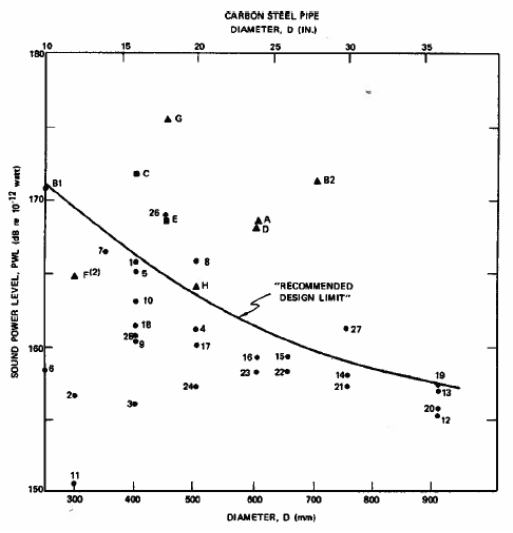
- AIV-related fatigue failures are caused by the following four physical phenomena:
  1. Excitation from a pressure-reducing valve causes high-frequency pressure fluctuations in downstream piping.
  2. These fluctuations excite higher order acoustic modes in the pipe with circumferentially varying pressure mode shapes.
  3. The acoustic pulsations couple to shell modes of the main piping.
  4. Branch connections or other welded discontinuities in the main line serve as stress risers.



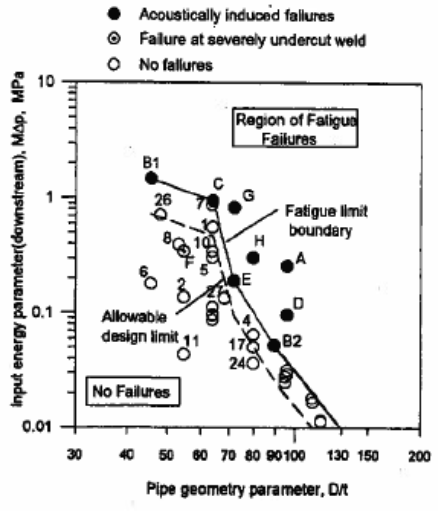


THEORY: ACOUSTIC CROSS MODES

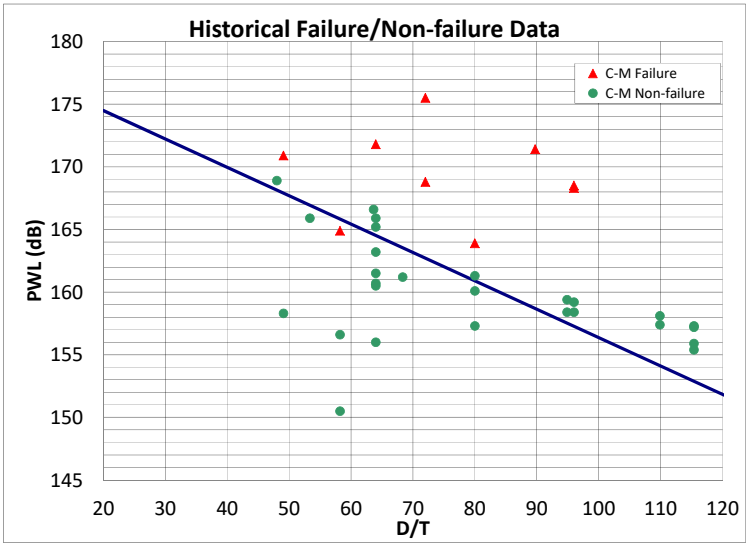




THEORY: PIPE SHELL MODES



EXISTING AIV SCREENING METHODS

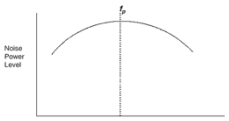


Carucci-Mueller Design Curve

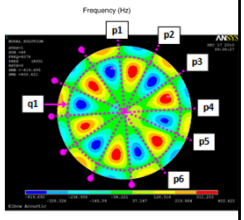
Eisinger Design Curve

EXISTING AIV SCREENING METHODS

Evans, Allison, and Arnett 2012

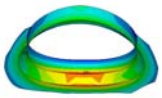


EXISTING AIV SCREENING METHODS

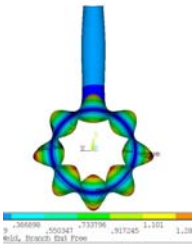


The Energy Institute introduced a screening methodology* for AIV:

- Simple source PWL computation
- PWL decay to branch connection and addition of PWL from multiple sources at each branch
- Estimate of fatigue life from curve-fit data (data from FE models calibrated to historical failure/non-failure data)
- Fatigue life estimation including reduction due to weldolet fittings and small branch diameter to main line diameter ratios
- Likelihood of Failure (LOF) computed from estimated fatigue life



*See "Guidelines for the avoidance of vibration induced fatigue failure in process pipework," Energy Institute, 2nd Ed., Jan. 2008



DETAILED ANALYSIS METHODS

- Valve excitation analysis, acoustic analysis and finite element analysis can be performed to determine coincidence of acoustic and pipe shell modes
- Forced response analysis of FE model at coincident modes can be performed with shell models to determine stresses at fillet weld and resulting fatigue life
  - Excitation from valve amplified by acoustic amplification factor to account for acoustic resonance
  - Stresses evaluated using mesh-insensitive procedure for welded joints in accordance with Section 5.5.5 of the ASME Boiler and Pressure Vessel Code, Section VIII, Division 2
- Can evaluate relative changes better than absolute life

ANALYSIS METHOD COMPARISON

	Carucci-Mueller	Eisinger	Modified C-M	Energy Institute	Finite Element
Calculates PWL	X		X	X	X
Includes pipe diameter	X	X	X	X	X
Uses historical data	X	X	X	X	See (1)

[1]FEA methods must be calibrated with test and historical data

AIV SOLUTIONS

- AIV stresses can be reduced by many design changes or retrofits
  - Changes to valve (low noise trim, multiple valves)
  - Piping changes (increase spacing from noise source, increase wall thickness, change branch connection type or size)
  - Support type changes
  - Reinforcement
  - Weld quality
  - Stiffener rings
  - Damping
  - Other (tuned vibration absorbers, acoustic mode interference) – these are concepts only…

TESTING OF AIV SOLUTIONS AT SWRI

- Tested multiple header geometries and AIV solutions through series of 170 dB Nitrogen blowdown tests:

Test	Configuration	% reduction
1a	36" baseline	-
1b	36" clamps	51.8%
1c	36" damping wrap	11.1%
1d	36" tube bundles	30.1%
2a	20" baseline	-
2b	20" clamps	17.8%
2c	20" damping wrap	17.0%
2d	20" tube bundles	28.2%
3a	12" baseline	-
3b	12" clamps	15.8%
3c	12" damping wrap	8.4%
3d	12" tube bundles	*

AIV SUMMARY

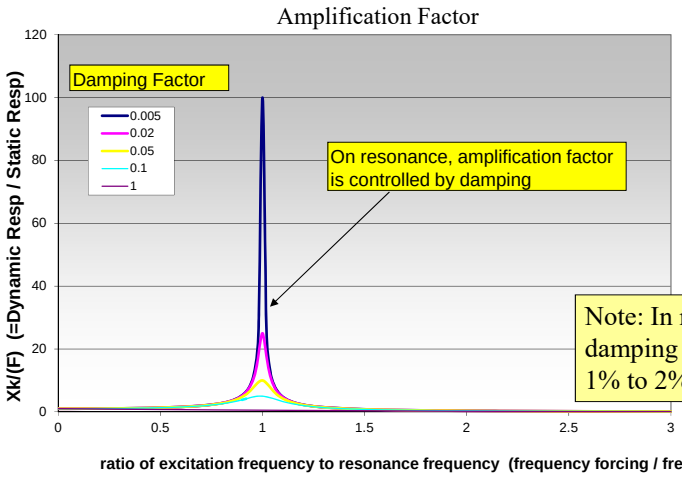
- Acoustic-induced vibration has historically led to many piping failures in piping downstream of pressure-reducing devices
- Multiple screening tools were presented to evaluate the susceptibility of a piping system to acoustic fatigue failures
- Many design options available to reduce the likelihood of an acoustic fatigue failure
- AIV is easiest to catch & prevent at design stage
- Fatigue life analysis for existing systems can be expensive and validated methods are still not available
- Be cautious when selecting thin-wall pipe downstream of noise sources, even if pressures are low!

Mechanical Design

Mechanical Design of Reciprocating Compressors and Piping Systems

- Purpose of Mechanical Design
  - Reduce Vibration Risk – Increase Reliability.
  - Predict Mechanical Characteristics.
  - Mechanical design parameters include support types and locations, structures, pipe routing, vessel design, etc.

Mechanical Analysis of Compressors and Piping



- Two Categories
  - Piping Spans (Simpler Systems)
  - Compressor Manifolds (More Complex Systems)
- API 618 Design Approaches
  - Design Approach 1 – Analytical Acoustical Design
  - Design Approach 2 – Full Acoustical Analysis + Mechanical Piping Review
  - Design Approach 3 – Design Approach 2 + Mechanical Manifold Analysis

Vibrations of Complex Systems

- Complex Systems Have Many Resonant Frequencies.
- For Every Resonant Frequency, a Corresponding Mode Shape (Deflection Pattern) Exists.
- Vibration Amplitudes Are Function of the Force Amplitude, the Frequency Ratio And Damping.
- A System at Resonance Will Have Much Higher Vibration.

Response of a Single Mass System

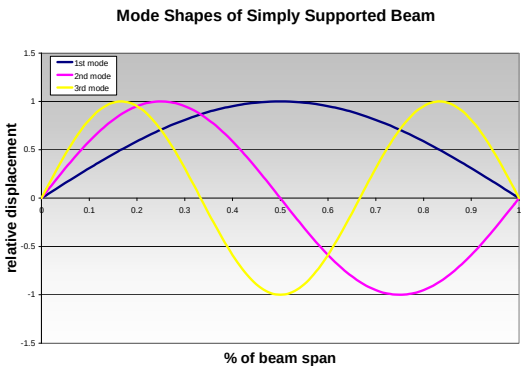
Forced Response of Mass-Spring System
F(t)=F sin (2 π *freq*t)….harmonic....sinusoidal

Key Points

In order to reduce response on resonance, we have several options
1 - add damping (hard)
2 - add mass (lower natural frequency)
3 - add stiffness (increase natural frequency)

Note: In many piping systems, damping will range from 1% to 2% (Q = 25 to 50).

A Simple Beam (or Run of Pipe)



$$\text{Freq_Response} = \frac{1}{2 \cdot \pi}\sqrt{k/m}$$

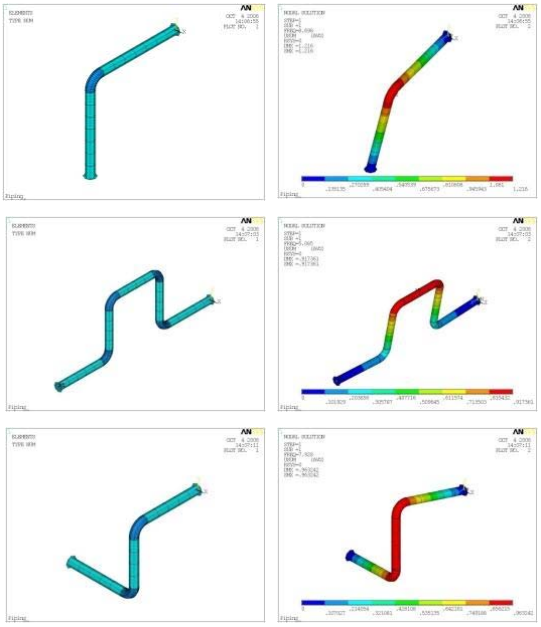
$$\text{Freq_Response} = \frac{\pi \cdot \text{n}^2}{2 \cdot l^2}\sqrt{EI/m}$$

$n = (1,2,3...)$

Note: m= weight (lb_f) per unit length / g

For every resonant frequency, there is a distinct mode shape. The mode shape describes the relative vibration amplitude at that frequency

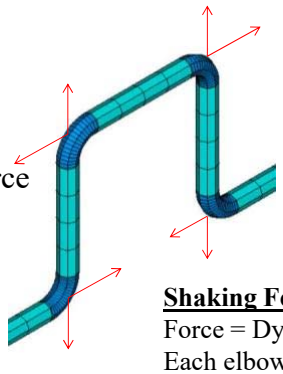
Simply supported beam
(pinned at both ends)



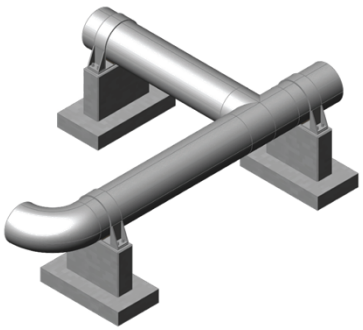
Piping Design for Vibration Control

Main Factors in Piping Design for Vibration Control

- Restraint Locations
- Restraint Types
- Excitation Source (Pulsation Amplitudes & Frequencies)
- Maximize Mechanical Natural Frequencies (Place Above Excitation Frequencies)
- API 618 Minimum MNF = 2.4 * Running Speed/60



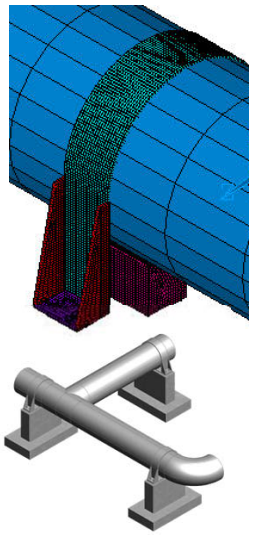
Typical Piping Configurations



- 1st column shows various simple piping layouts.
- 2nd column shows the deflection pattern of lowest mechanical natural frequency.
- Which points have the greatest deflections?

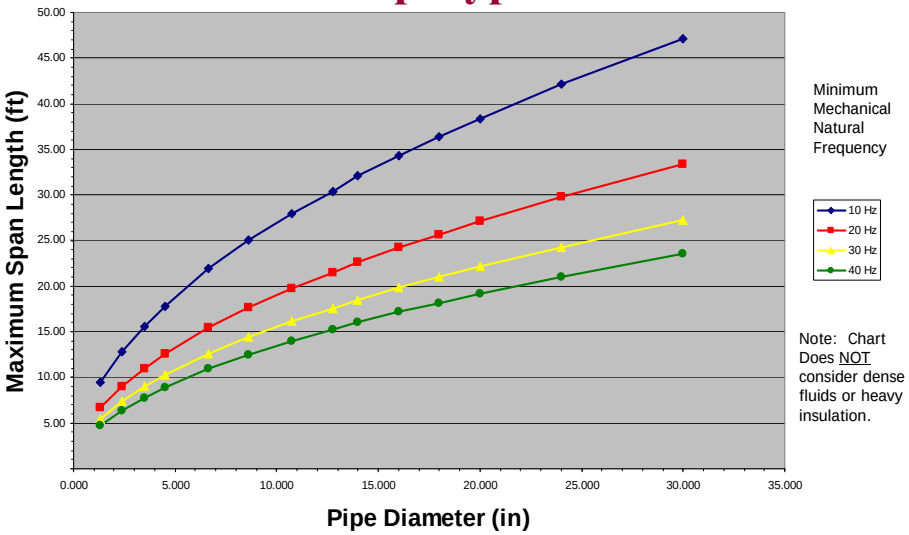
Clamp Locations

- Near Elbows and Tees (Coupling & Flexibility)
- Near Concentrated Masses (Valves)
- On Long Spans (See Following Chart)



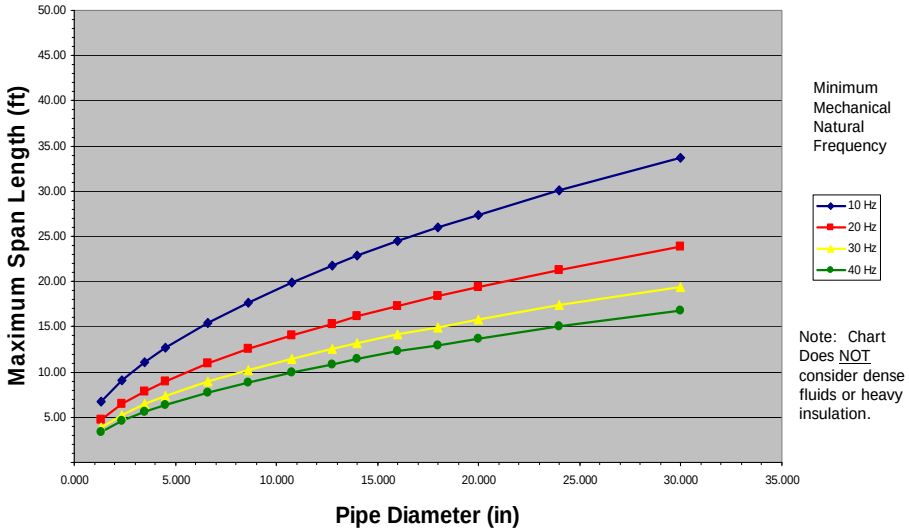
Shaking Forces from Pulsation

Force = Dynamic Pressure * Pipe Cross-Sectional Area



Each elbow has unique pulsation amplitude & phase

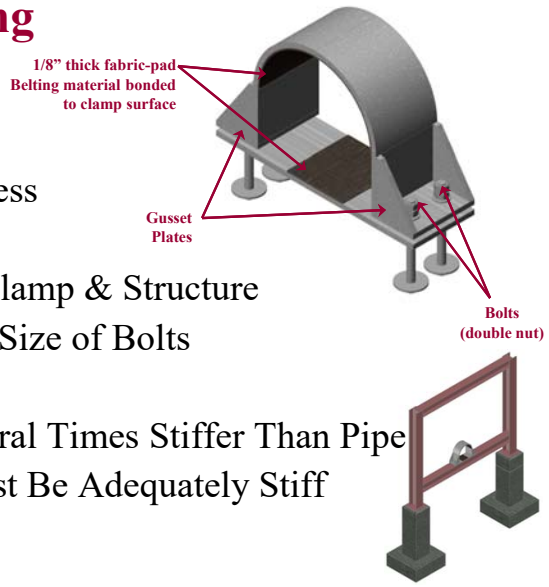
Clamp Locations - Continued



- Design Frequencies
  - Mechanical Responses Above Excitation
  - 2X + 20% for Reciprocating Units
  - Higher Speed Compressors Need Shorter Spans Between Clamps
  - 10 to 15 Hz for Centrifugal Units
- Where are Clamps No Longer Necessary?
  - Depends on Acoustic Analysis (Large Vessels)
- Consider Thermal Expansion

Maximum Straight Span Lengths Between Effective Strap Type Restraints

Maximum Span Lengths Between Effective Strap Type Restraints For Spans with Elbows

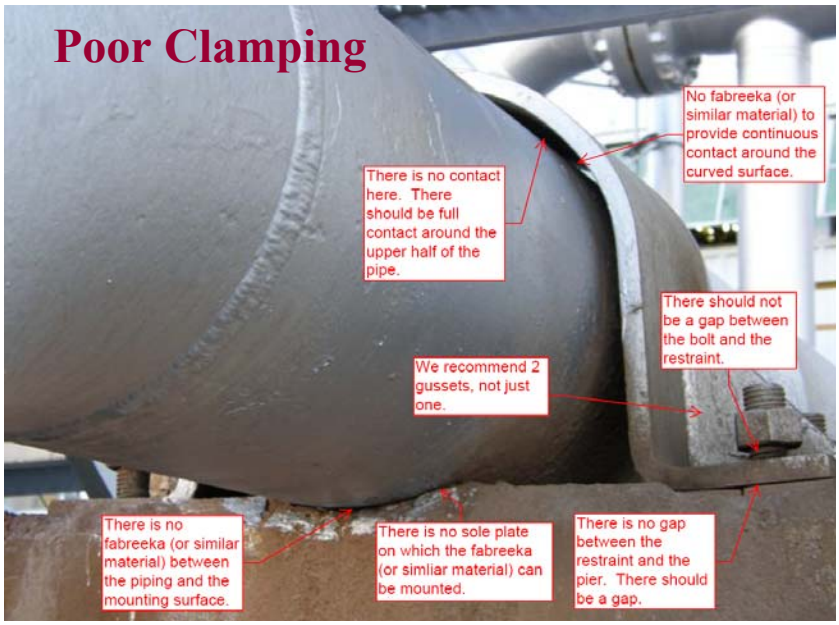


Restraint Types and Stiffness

- Different Restraints Have Different Stiffness Properties

- Simple Weight Supports
- Guides, Stops, Spring Cans and Hangers
- Box Clamps
- U-bolts
- Strap Type Hold-down Clamps (With Or Without Wedges) Are Best For Vibration Control.

- For Accurate Modeling Predictions, It Is Essential to Accurately Estimate Stiffness in All Directions



Effective Clamping

Clamp Characteristics

- Adequate Plate Thickness
- Side Gussets
- ½ Inch Gap Between Clamp & Structure
- Adequate Number and Size of Bolts
- Clamp Liner Material
- Clamp Should Be Several Times Stiffer Than Pipe
- Attached Structure Must Be Adequately Stiff

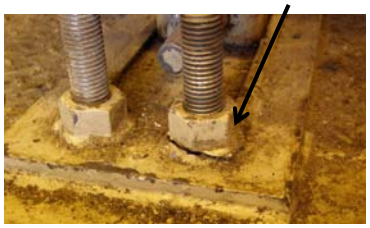
Poor Clamping

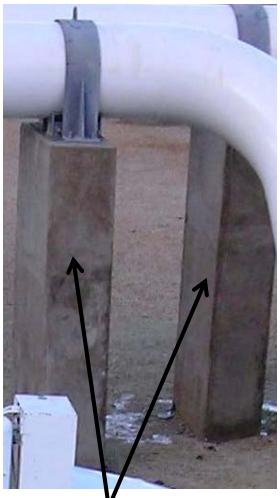
Flexible Structure Under Clamp

Excessive Gap

Stretch Tube Design (good and bad).

Poor Clamping

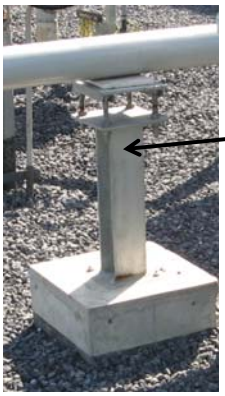




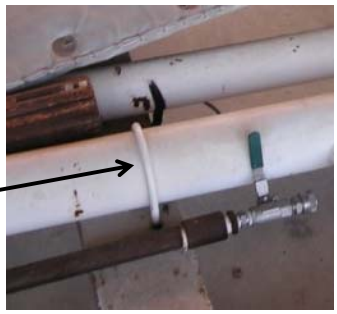
Wedge is Too Tall & No Liner

Poor Clamping

Nuts Welded to Plate - Failed

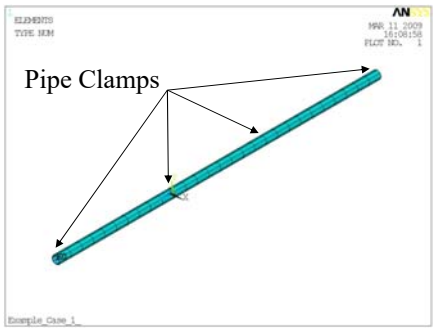


Good Clamp – but Piping is Elevated and Pier is Too Tall

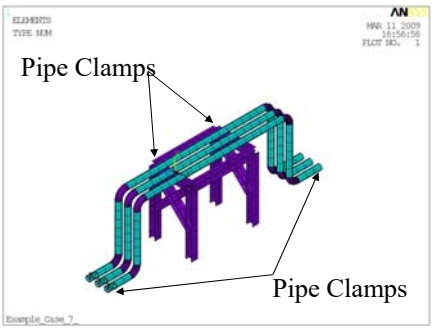


Flexible Dummy Leg

Poor Clamping

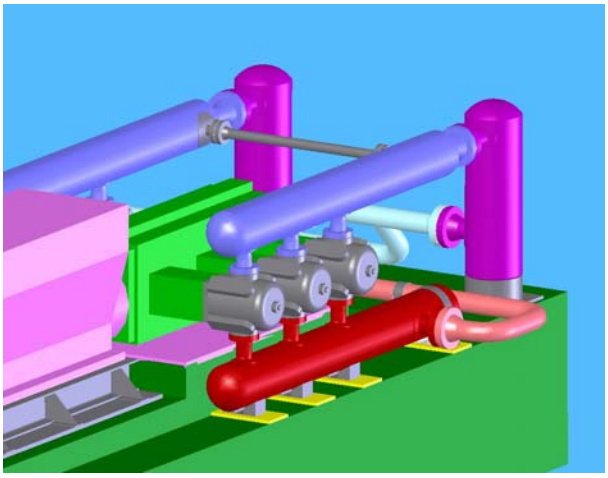


- Slender column
- Weak link at bolts
- No clamp – can lift off

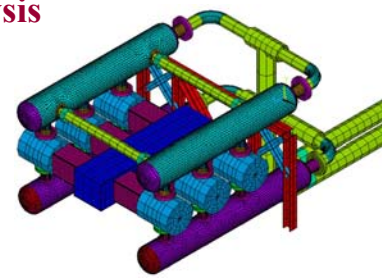


- Simple U-Bolt
- Pipe can easily rotate
- Fretting & wear concern

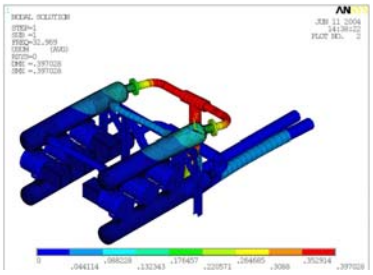
Elevated Piping



- Elevated Piping Will Almost Always Have Higher Vibration
- This Is Due to More Flexible Supports and Piping (More Elbows).
- It Is Easier to Control Vibration on Grade Level Piping.
- If Piping Must Be Elevated, Use Good Pulsation Control, Stiff Support Structures, and Tie Multiple Components Together.

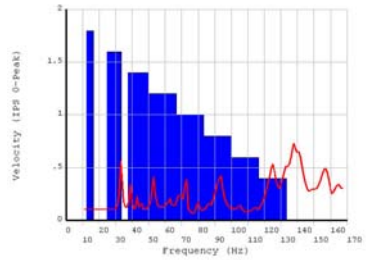


Compressor Manifold Systems

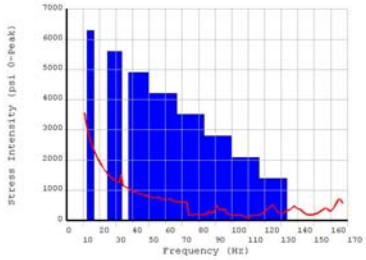


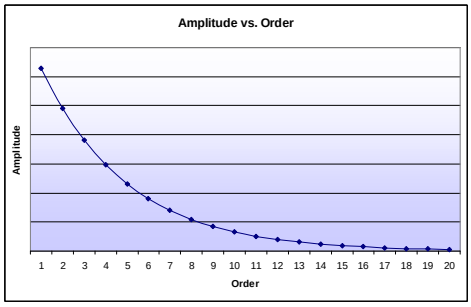
- What: The Cylinders, Bottles, Frame Components, and Attached Piping.
- Why: Lots of Energy and Vibration Potential Near the Compressor Unit.

Modal Analysis

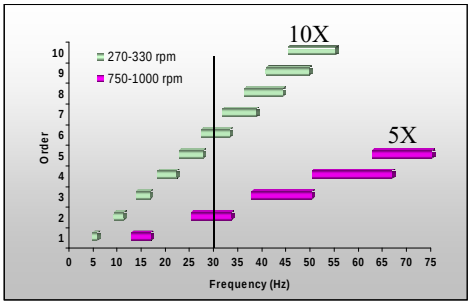


- Predict Mechanical Natural Frequencies of Manifold System.
- Vibration Amplitudes Will Be Significantly Amplified If the System Is Excited at a Natural Frequency.
- Modify the System to Place the Mechanical Responses Where They Are Less Likely to Be Excited.



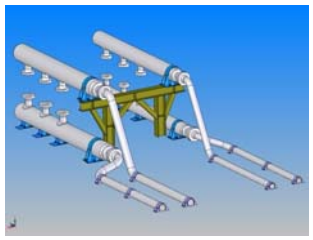


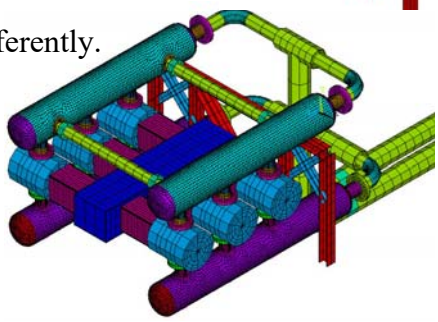
Forced Response Calculations



- Resonance Avoidance is Best
- Not Always Possible with
  - Higher Operating Speeds
  - Wider Speed Ranges
- Forced Response Calculations
  - Verify Acceptable Vibration
  - Verify Acceptable Dynamic Stress

Low Speed vs. High Speed



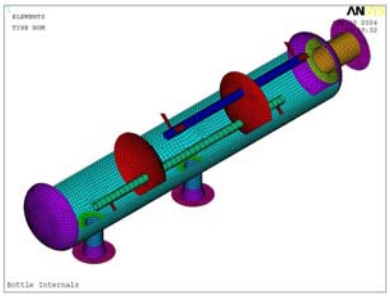


- 120 - 300 RPM (acoustic predominates)
- 300 - 600 RPM (acoustic, cylinder stretch)
- 600 - 900 RPM (acoustic, cylinder stretch, unbalance)
- 900 - 1200 RPM (cylinder stretch, unbalance, shell mechanics)
- > 1200 RPM (cylinder stretch, unbalance, radial acoustics, shell mechanics)

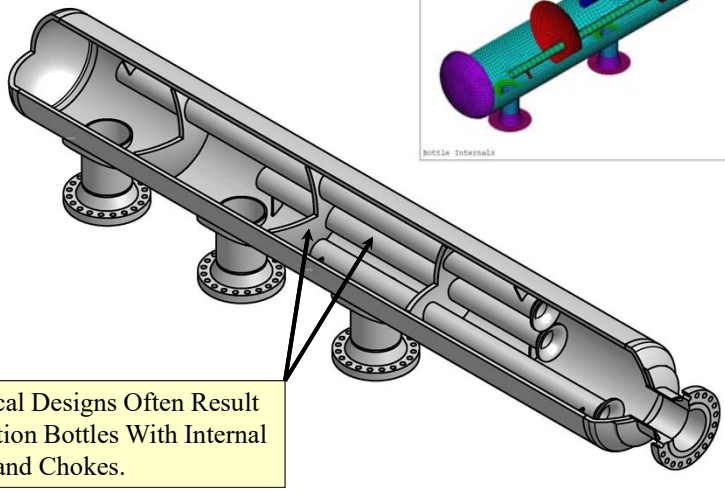
Mechanical Analysis – Typical Modifications

- Pipe Clamp Locations and Types.
- Suction Bottle Support Frame.
- Discharge Bottle Restraints.
- Nozzle and Repad Specifications.
- Suction Bottle Bracing.
- Each System Will Respond Differently.

Inspection Ports And Auxiliary Attachments



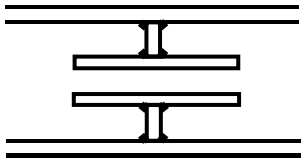
Bottles often have small bore auxiliary attachments for inspection, instrumentation, etc.



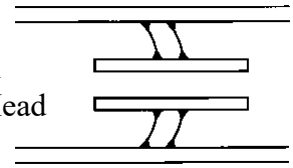
Localized high frequency vibration on ports can result in failures.

Minimize ports in size and quantity as much as possible, especially on high speed reciprocating equipment.

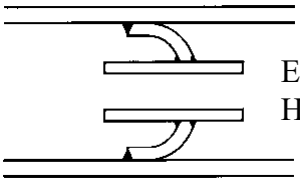
Design Considerations for Internal Baffles & Chokes



- Predict Dynamic Pressure Loads During Pulsation Analysis
- Apply loads to finite element model to predicted stresses

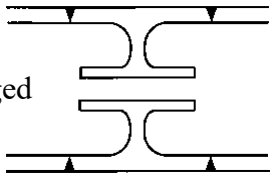


Acoustical Designs Often Result in Pulsation Bottles With Internal Baffles and Chokes.



Baffle Types

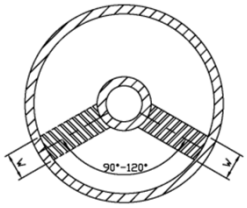
Flat Plate (Not Recommended)

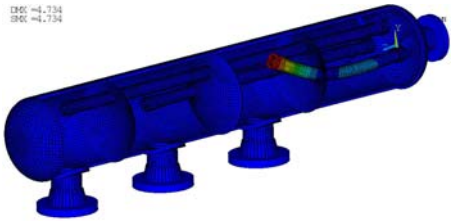


Spherical Dished Head

Ellipsoidal Head

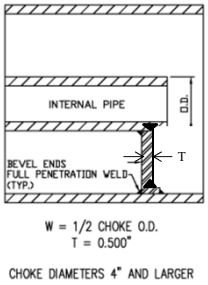
Forged





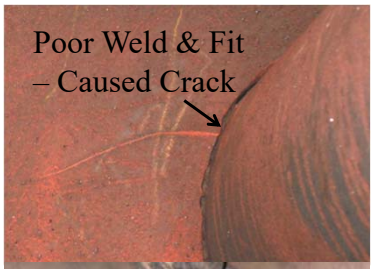
If Baffles stresses are too high:

- Redesign the acoustics / Modify operating conditions.
- Use a thicker baffle (same as bottle shell, up to 1").
- Increase the choke wall thickness.
- Use a different type of baffle.
- Reinforce the choke or vessel wall (wrap)



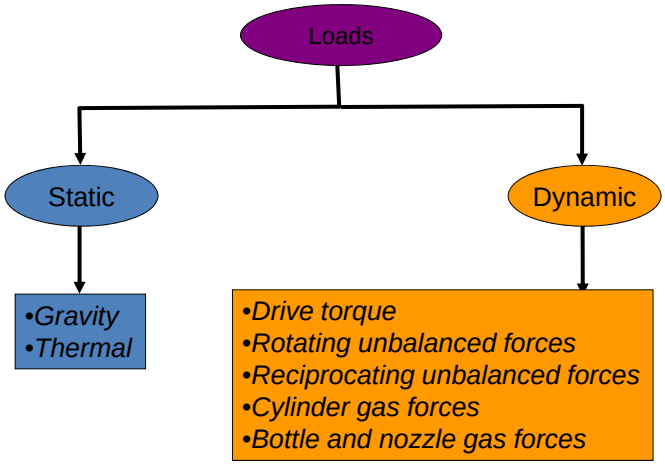
Unsupported Internal Chokes Can Fail

- Unsupported or Under-Supported Chokes Can Vibrate and Fail if their Mechanical Response Coincides with an Excitation Source.
- No more than 2 Pipe Diameter Overhang.



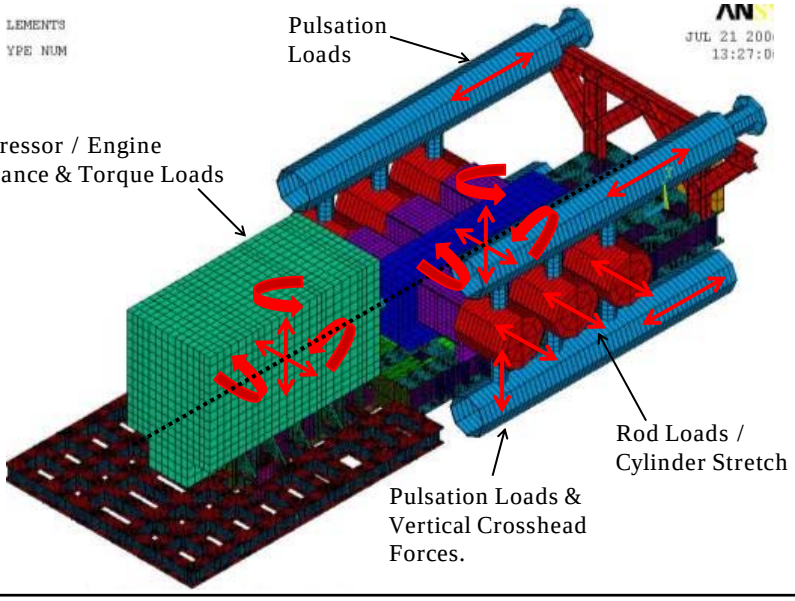
Baffle And Choke Welding / Fabrication

- Many Vessel Internal Failures Due to Poor Welding
- Baffle to Bottle Weld - Full Penetration
- Baffle to Choke Weld
  - Full Penetration on One Side OR
  - Fillet Welds on Both Sides
- All Welds 360° Around
- As Smooth as Possible



SKID AND FOUNDATION DESIGN

SKID AND FOUNDATION LOADS



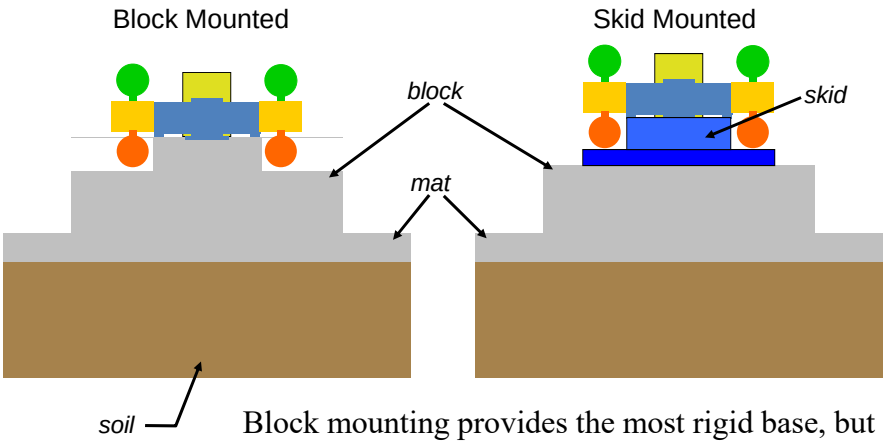
Functions of Skid and Foundation

- Provides Rigidity for the Engine and Compressor
- Sets Position of Machines and Accessories
- Maintains Alignment
- Absorbs and Reacts to Excitation Forces
- Transmits Net Forces to the Foundation / Soil

The machine foundation must provide support of the installed machinery, and react all forces and moments necessary to provide restraint and maintain machine alignment.

PRIMARY DYNAMIC EXCITATION FORCE DIRECTIONS

157



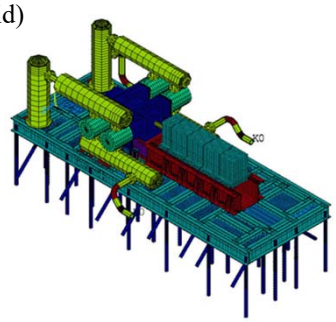
COMPRESSOR LOADS

Reciprocating Machinery
- Inherently Unbalanced
- Forcing Frequencies Near Foundation Resonances
- Foundations Designed to React Shaking Loads
- Transmit Vibration to the Ground

Rotating Machinery
(Turbines, Blowers, Centrifugal Compressors, etc.)
- Relatively Small Dynamic Loads
- Running Speed Above Foundation Resonances
- Foundations Designed to Resist Static Loads

158

FOUNDATION / MOUNTING ALTERNATIVES BLOCK MOUNTED VS. SKID MOUNTED



Block mounting provides the most rigid base, but most modern reciprocating compressors are skid mounted due to cost and packaging issues.

159

FOUNDATION / MOUNTING ALTERNATIVES

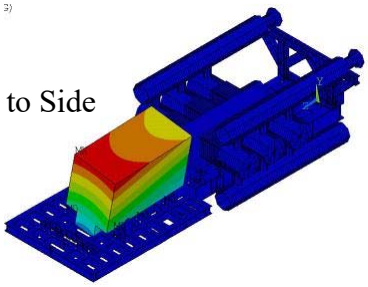
- Compressor skid on block foundation
  - Typically high speed compressors
  - Typically 4-8 feet deep foundation (depends on soil)
- Compressor mounted directly to a block foundation
  - Typically slower speed, higher hp (5000+ hp)
- Concrete block on piles (with or without a skid)
  - Driven piles or screw piles
- Skid on steel pilings (no concrete)
  - Requires a stiffer skid design
  - Typically less damping
- Gravel Pad (less than 1000 hp)

160

SCREW PILES FOR SKID SUPPORT

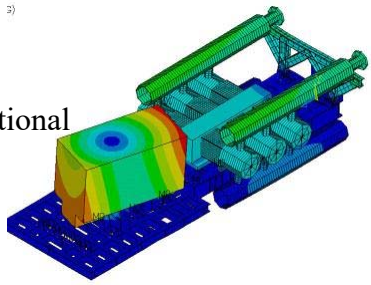
- Screw piles have recently been used to support a variety of reciprocating compressor skid packages.
- One key advantage of screw piles is their faster installation process. However, they must also be able to adequately support the compressor package and all of its inherent dynamic loads to prevent excessive vibration.

Screw pile mounted skid during installation (fill will be added later).

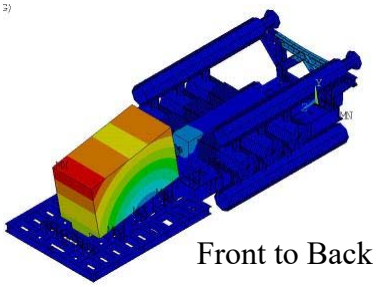


161

COMMON ENGINE MODES



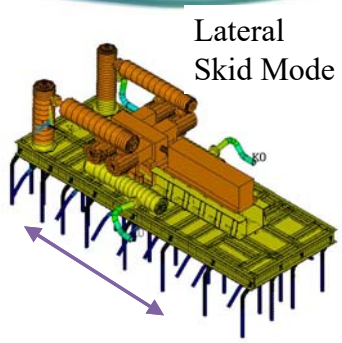
Controlled by engine mass and skid structure underneath.



Should be above rpm range.

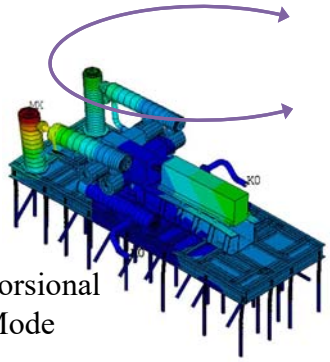
Side to Side

Rotational



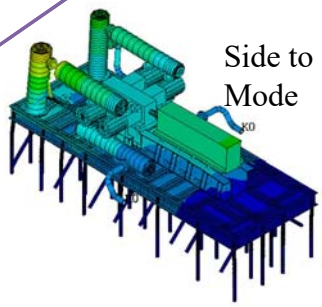
Front to Back

162



COMMON SKID MODES

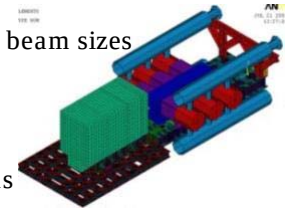
Controlled by skid mass and foundation stiffness.



Can be above or below rpm range.

Lateral Skid Mode

Torsional Mode



Side to Side Mode

DESIGN OBJECTIVE

- Primary concern is excessive vibration
- All compressor skids (whether on a concrete foundation or not) have several low frequency mechanical natural resonances
  - Based on mass and stiffness of system
  - Coincidence with frequencies of excitation can cause excessive vibrations.
- Want to avoid coincidence, especially on or near 1X or 2X orders of the compressor running speed

GENERAL GUIDELINES FOR SKID DESIGN FOR VIBRATION CONTROL

- Keep skid as low and stiff as possible with adequate beam sizes
- Mount discharge bottles off-skid (to keep low)
  - 6-8” from top of concrete to bottom of bottle
- Perform static and dynamic analyses on new designs
- Gusset beams at critical points (bolt and mounting locations, etc.)
- Keep anchor bolts near beam webbing
- Outriggers should be bolted and grouted in place
- Add concrete with rebar under the compressor, engine & scrubbers
- Use sufficiently long anchor bolts internally and externally
- Have direct load transfer paths under key locations

Re: Comments of Enterprise Field Services, LLC on NMED's Revised Draft Regional Haze State Implementation Plan Revision

Dear Mr. Jones:

These are the comments of Enterprise Field Services, LLC ("Enterprise") on the New Mexico Environment Department's ("NMED" or the "Department") revised draft State of New Mexico Regional Haze State Implementation Plan Revision Second Planning Period (2019-2028) and 20.2.68 NMAC – Regional Haze Requirements ("Revised Draft SIP").

Section 169A of the Clean Air Act ("CAA") requires states to develop state implementation plans ("SIPs") containing "emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal" of eliminating visibility impairment in protected Class I federal areas that results from manmade air pollution. 42 U.S.C. § 7491(b)(2). The U.S. Environmental Protection Agency's ("EPA") regional haze rule requires that states meet the CAA's requirement for "reasonable progress" toward the national visibility goal over successive ten-year planning periods. 40 C.F.R. § 51.308(f). NMED's Revised Draft SIP responds to the regional haze program's requirement for SIPs to address regional haze for the program's second planning period, running from 2018 to 2028.

On August 26, 2024, NMED released an initial draft of the state's regional haze SIP, ("August 2024 Draft SIP"). Enterprise is the owner and operator of the following three facilities (collectively, the "Enterprise facilities") that have been subject to these proceedings:

- Blanco C & D Compressor Station ("Blanco") located in San Juan County, New Mexico – approximately 39 miles from the nearest Class I Area
- Chaco Gas Plant located in San Juan County, New Mexico ("Chaco") – approximately 49 miles from the nearest Class I Area

P.O. BOX 4324
HOUSTON, TEXAS 77210-4324
713.381.6500

1100 LOUISIANA STREET
HOUSTON, TEXAS 77002-5227
www.enterpriseproducts.com

- South Carlsbad Compressor Station ("South Carlsbad") located in Eddy County, New Mexico – approximately 26 miles from the nearest Class I Area

Enterprise submitted comments to NMED addressing the August 2024 Draft SIP on September 20, 2024 ("September 2024 Enterprise Comments"). Those comments are included as Attachment A to this submittal. While Enterprise appreciates NMED's efforts to revise the SIP to address one issue—the nitrogen oxides ("NOx") removal efficiency of selective catalytic reduction ("SCR") controls—addressed in the September 2024 Enterprise Comments, Enterprise asks that NMED consider further revisions to the SIP to address *all* of Enterprise's previously submitted comments. Enterprise also submits these additional comments on the Revised Draft SIP for NMED's consideration.

As noted above, Enterprise appreciates the Department's efforts in the Revised Draft SIP to address issues related to the NOx removal efficiency of SCR controls. But as described in greater detail below, the impact of this revision on the control requirements contained in the Revised Draft SIP demonstrates the need to address the other issues raised in Enterprise's previous comments. Even in the absence of substantial further revisions, however, the Revised Draft SIP's new control requirements and emission rate limits highlight the need to provide additional compliance flexibility, should the control requirements and limits in the Revised Draft SIP be retained. To that end, and without conceding that an SCR-based emission rate is appropriate, Enterprise renews its request for facility-wide emission rate limits. Based on the limits in the Revised Draft SIP, Enterprise specifically requests an emission rate limit of 50.58 lbs/hr for the Blanco units and a facility-wide weighted average rate of 15 ppmvd @ 15% oxygen for the units at South Carlsbad. The reasons for these requests are provided in more detail below.

I. The Revised Draft SIP

As NMED notes in the Revised Draft SIP, the Department has made minor corrections to the August 2024 Draft SIP and, most significantly, has revised its cost estimates and cost-effectiveness values to: (1) adopt a different method for adjusting for inflation; and (2) assume a more realistic NOx removal efficiency for sources that provided information justifying such removal efficiencies. Revised Draft SIP at 191. This has resulted, in some instances, in changes to the units subject to new control requirements, the emission control technology such control requirements are based on, and/or the emission rate limits contained in the Revised Draft SIP (and the accompanying draft regulations).

As a result of NMED changes to its cost assessment, NMED has proposed revised control determinations and emission rate limits for the Enterprise facilities.

For Blanco, NMED's August 2024 Draft SIP would have required emission rate limits based on installation and operation of SCR controls, and emission rate limits of 6.52 lb/hr for unit T-C01; 6.66 lb/hr for unit T-C02; and 12.11 lb/hr for unit T-D01. *See* Revised Draft SIP, App. G at 2. The Revised Draft SIP retains the determination that SCR is justified for these units but adjusts

the emission rate limits to 13.04 lb/hr for unit T-C01; 13.32 lb/hr for unit T-C02; and 24.22 lb/hr for unit T-D01. *Id*.

For Chaco, the August 2024 Draft SIP would have required emission rate limits based on SCR, and emission rate limits of 2.62 lb/hr for unit 35; 3.02 lb/hr for unit 36; and 2.97 lb/hr for unit 37. *See id*. The Revised Draft SIP eliminates these requirements. *Id*. NMED also proposed in the August 2024 Draft SIP to require an emission rate limit of 0.5 g/bhp-hr for Chaco unit 14 based on installation and operation of a low emission combustion system ("LEC"). *See id*. The Revised Draft SIP does not alter this proposed requirement. *Id*.

For South Carlsbad, NMED initially proposed in the August 2024 Draft SIP emission rate limits based on SCR and emission rate limits of 1.81 lb/hr for unit 1 and 1.82 lb/hr for unit 2. *See id* at 3. Based on its new cost assessment in the Revised SIP, however, NMED revised the emission rate limits to reflect installation of dry low-NOx combustion ("DLN"), with emission rate limits of 15 ppmvd @ 15% oxygen for each unit. *Id*.

Enterprise appreciates that NMED has responded in this manner to address one significant issue identified in the September 2024 Enterprise Comments—the NOx removal efficiency for SCR. The impact of this revision demonstrates the critical nature of the factors that go into the Department's cost assessment, as well as its consideration of other relevant issues under the CAA and state law. Making this single change to the NOx removal efficiency assumption has resulted in substantially different emission control determinations for the Enterprise facilities. While Enterprise supports the revisions to the SIP and NMED's decision to replace its 90% NOx removal efficiency with 80% removal efficiencies for the Enterprise facilities, it is important to note several important further considerations:

- First, the NOx removal efficiency NMED adopted is at the high end of the 65% to 80% range recommended by Enterprise and its vendor. A more conservative approach, which Enterprise supports, would yield even higher costs.

- Second, additional real-world costs associated with installation of controls, and SCR in particular, will further increase control costs beyond NMED's current estimates.

- Third, consideration of factors beyond cost, including visibility, support further revisions to the SIP and elimination of additional control requirements for the Enterprise facilities.

For these reasons and the reasons stated in the previously submitted September 2024 Enterprise Comments, although Enterprise supports the action taken in the Revised Draft SIP, Enterprise believes additional revisions are nevertheless required. Full consideration of the relevant factors, as required by the CAA, and the most accurate, site-specific information should make clear that additional controls for the Enterprise facilities are not needed to address the CAA's "reasonable progress" requirement for the second planning period of the regional haze program.

II. NMED Should Revise the Emission Rate Limits to Provide Greater Compliance Flexibility for the Enterprise Facilities.

Enterprise explained in its comments on the August 2024 Draft SIP that NMED's proposal would have unnecessarily imposed unit-by-unit emission rate limits for each of the Enterprise facilities. September 2024 Enterprise Comments at 24. Enterprise requested that NMED revise those individual unit limits to allow for facility-wide averaging. *Id*. The Revised Draft SIP, however, continues to apply emission rate limits on a unit-by-unit basis. Revised Draft SIP at 144-46, App. G at 2-3. The Revised Draft SIP does not address Enterprise's request or the possibility of facility-wide averaging.

Despite NMED's revisions, the Revised Draft SIP continues to contain unsupported control determinations for the Enterprise facilities. In particular, for the reasons explained in these comments in the September 2024 Enterprise Comments, Enterprise believes the record does not support imposing emission rate limits for either the Blanco units based on SCR or for the South Carlsbad units based on DLN. Nevertheless, should NMED continue to support such an approach with regard to these units, Enterprise requests that NMED provide a facility-wide emission rate. Such a rate will achieve the same environmental benefits as unit-by-unit rates, while providing for additional, necessary compliance flexibility.

Accordingly, consistent with the current provisions of the Revised Draft SIP, NMED should further revise the emission rate limits applicable to the Blanco units to provide for a facility-wide emission rate limit of 50.58 lbs/hr, which is derived from summing the unit-by-unit rates contained in the Revised Draft SIP. Likewise, for South Carlsbad, a facility-wide weighted average rate of 15 ppmvd @ 15% oxygen (the rate that would be applicable to both South Carlsbad units individually), would allow for additional compliance flexibility without sacrificing overall environmental impact.

As explained in the September 2024 Enterprise Comments, allowing for compliance in this manner is fully consistent with the state's legal authority under the regional haze program, and similar approaches have been adopted in other states and approved by EPA to address reasonable progress requirements in the past. *See* September 2024 Enterprise Comments at 24. Enterprise therefore encourages NMED to adopt this approach.

III. NMED's Revised Cost Calculations for the Enterprise Facilities Are More Reasonable but Still Require Further Adjustment.

The most significant changes contained in the Revised Draft SIP relate to NMED's adjustments to its cost-effectiveness determinations, including its cost-effectiveness findings for the Enterprise facilities. Enterprise supports these changes.

For Blanco, the Revised Draft SIP increases the cost-effectiveness values for water steam injection controls, SCR, and unit replacement for units T-C01 and T-C02, and increases the values for SCR and replacement for unit T-D01. Revised Draft SIP at 120. Using these the revised cost-

effectiveness values, the Revised Draft SIP retains NOx emission control requirements for the Blanco units that are based on SCR. *Id*.

For Chaco, in relevant part, the Revised Draft SIP increases the values for DLN, SCR, and replacement for units 35, 36, and 37.[1] *Id*. at 122. Based on these revised values, the Revised Draft SIP eliminates emission control requirements based on SCR for units 35, 36, and 37. *Id*.

For South Carlsbad units 1 and 2, NMED revised the cost-effectiveness estimate for SCR and unit replacement. *Id*. at 123. As a result of its updated cost-effectiveness determinations, the Revised Draft SIP would require emission reductions based on DLN rather than SCR, based on NMED's finding that DLN would achieve greater emission reductions than SCR for these units. *Id*. at 123-24.

As noted above, the changes in cost-effectiveness values for SCR derive primarily from NMED's changes to the assumed control efficiency for SCR. *See id*. at 148.[2] NMED has included in its Four-Factor Analyses and Control Measures Determinations Technical Support Document (Appendix C to the Revised Draft SIP) a new statement:

> [F]or units that operate intermittently, such as natural gas compressor drivers, NOx removal efficiency may be lower due to decreased efficiency when the system is below the optimum temperature following cold starts. Depending on such a unit's annual operating profile, the average NOx removal efficiency of SCR could reasonably vary from approximately 75 to 85 percent.

Revised Draft SIP at 319.[3] That document further indicates that NMED revised the assumed NOx removal efficiency for the Enterprise facilities from 90% to 80%. *Id*. at 373, 382, 392.

Although Enterprise supports NMED's decision to revise the NOx removal efficiencies for the Enterprise facilities and the corresponding changes to the Revised Draft SIP's control determinations and emission rate limits, this single change to NMED's cost assessment does not adequately capture the full array of real-world costs that the Revised Draft SIP would impose on the Enterprise facilities, nor does this change adequately respond to Enterprise's September 2024 Comments.

---

[1] The Revised Draft SIP also adjusts control costs for units 12, 13, 13, 17, and 18, but NMED's analysis based on these revised control costs did not change the Department's determination that these units do not require additional control requirements. *See* Revised Draft SIP at 122.

[2] Additional changes to the cost-effectiveness values, including those unrelated to SCR systems, appear to result from changes to "the methodology used for adjusting estimated costs from previous year dollars to 2023 dollars based primarily on feedback from industry." *Id*. at 191.

[3] Appendix C of the Revised Draft SIP is not paginated, so these comments refer to the page number of the PDF file containing the complete Revised Draft SIP and its appendices.

In its September 2024 Comments, Enterprise explained that it had received information from a vendor indicating that SCR was likely to be able to achieve NOx removal efficiencies of between 60 percent and 80 percent at the Enterprise facilities. September 2024 Enterprise Comments at 22. Those estimates were consistent with EPA technical guidance that suggests that removal efficiencies for SCR range from 65 to 90 percent across a wide scope of industries. *See id*. NMED's cost-effectiveness values for SCR would increase even further if it adopted a lower removal efficiency assumption, which would be a reasonable and conservative approach.

Moreover, just as adjusting NMED's cost estimates to reflect an 80 percent removal efficiency has had significant impacts on the Department's assessment of the cost-effectiveness of SCR for the Enterprise facilities, including in the analysis the additional costs associated with site complexities would similarly increase costs and impact NMED's cost-effectiveness analysis. Those costs have not been adequately taken into account by NMED in the Revised Draft SIP.

To attempt to address the lack of site-specific information in the record regarding the costs and feasibility of constructing SCR systems at the Enterprise facilities, Enterprise provided preliminary vendor data to NMED in the September 2024 Enterprise Comments. *Id.* at 20-21. As noted at that time, the vendor data Enterprise was able to obtain during the comment period was incomplete and reflected a number of necessarily conservative assumptions. *Id*. Even with those limitations (including those related to site complications and adequate power supplies), the preliminary vendor information submitted by Enterprise indicated that NMED had underestimated costs for the Enterprise facilities in the August 2024 Draft SIP, in some cases substantially.

Enterprise has continued to seek additional, detailed vendor data on costs. As a result of the Revised Draft SIP and its new control requirements, Enterprise will continue to work with vendors to acquire the most detailed and accurate estimates possible. It is all but certain, however, that the data Enterprise will receive will confirm that the Revised Draft SIP's cost estimates and its cost-effectiveness determinations, while improved, remain unrealistic and require further revision. Consistent with section VI of these comments, Enterprise will present the best available information at the time of the hearing on the Revised Draft SIP before the Environmental Improvement Board, or earlier, as appropriate.

IV. The Revised Draft SIP Does Not Correct NMED's Inadequate Evaluation of Visibility Impacts.

Enterprise previously noted that "NMED did not directly consider the visibility benefits of potential control measures when making its control determinations," and instead merely assumed that reductions in sulfur dioxide ("SO_2") and NOx emissions would result in visibility improvements at affected Class I areas. *See* September 2024 Enterprise Comments at 6-7 (quoting August 2024 Draft SIP). As Enterprise explained, the failure to consider visibility impacts violates the CAA, which requires consideration of visibility impacts when states develop SIP measures to address regional haze. *Id*. This failure further violates New Mexico law, which requires the Environmental Improvement Board consider visibility when making control determinations. *See id*.

Unfortunately, as reflected in the Revised Draft SIP, NMED continues to assume – rather than conduct the full evaluation of visibility impacts the CAA and New Mexico law requires – that visibility improvements will occur as a result of its control determinations. Revised Draft SIP at 109-110. While the Department has included limited additional information on visibility in the Revised Draft SIP such as summaries of visibility conditions, expressed in deciviews ("dv"), for the most impaired days in the baseline period, natural conditions, and conditions under the uniform rate of progress, *id*. at 55-62, this additional information does not place the expected visibility improvements of various control options into context, nor does it provide a basis for concluding that the visibility improvements that would be expected from implementation of the SIP will be meaningful, or that the visibility improvements otherwise justify or support the control determinations contained in the Revised Draft SIP.

For the reasons stated in the September 2024 Enterprise Comments, The Revised Draft SIP rests on an unsound and unreasonable approach to assessing visibility. NMED should further amend the Revised Draft SIP to fully assess the visibility impacts of the considered control options. Enterprise believes such an evaluation will support the conclusion that additional controls for the Enterprise facilities are not required to address reasonable progress under the CAA's regional haze program.

V. The Revised Draft SIP Does Not Provide Sufficient Justification for NMED's Q/d Screening Threshold.

NMED continues to rely on a Q/d assessment in the Revised Draft SIP to identify sources with emissions significant enough to warrant further evaluation pursuant to the CAA's four reasonable progress factors. *Id*. at 93. In the September 2024 Enterprise Comments, however, Enterprise explained that the Q/d threshold NMED adopted was unreasonably low and should be revised to be consistent with the actions of most other states and EPA guidance. *See* September 2024 Enterprise Comments at 13-15. NMED has not responded to these comments in the Revised Draft SIP. Instead, NMED has included additional information on the sources that it did not select for analysis based on their Q/d values. *See* Revised Draft SIP at 96-101. It has further included additional calculations intended to demonstrate that NMED's Q/d threshold of 5.6 "captures 80% of the total NOx and SO_2 emissions from all New Mexico Title V facilities." *Id*. at 93. But the NMED Q/d threshold is based on draft EPA guidance that EPA never finalized and decided against recommending when it issued its final guidance. *See* September 2024 Enterprise Comments at 15. The basis for NMED's Q/d threshold therefore remains flawed and unsupported despite the additional information included in the Revised SIP.

Had NMED adopted a more reasonable Q/d threshold, it is likely that at least several of the Enterprise facilities that are addressed in the Revised Draft SIP would not have been selected for additional analysis pursuant to the four reasonable progress factors. Indeed, the Q/d values, as stated in the Revised Draft SIP are: 7.81 dv for Blanco; and 5.91 dv for South Carlsbad. *See* Revised Draft SIP at 97. A screening threshold of 10, as many states have adopted, would have reasonably excluded these facilities. *See* September 2024 Enterprise Comments at 13-14.

The Q/d screening threshold used by NMED in the Revised Draft SIP conflicts with EPA recommendations and the threshold adopted by many states, and NMED does not provide adequate justification to support its use. NMED should further revise the SIP to adopt a Q/d screening threshold consistent with the majority of states and EPA's guidance, and amend the SIP's control requirements accordingly based on the revised Q/d screening threshold.

VI. The Abbreviated Comment Period Has Limited Enterprise's Ability to Develop New Information in Response to the Revised Draft SIP.

As stated above, Enterprise appreciates NMED's decision to adjust the NOx removal efficiency assumption used in its cost assessments for the Enterprise facilities and NMED's efforts to revise the SIP accordingly. Enterprise received notice of the Revised Draft SIP on December 13, 2024, at which time, NMED established a twenty-one-day comment period that ran over the holidays, ending on January 3, 2025. NMED subsequently extended that deadline to January 7, 2025.

Enterprise is continuing to review and assess the Revised Draft SIP. Because of the limited time to review and develop comments, Enterprise reserves its right to present additional information during review of the SIP by the Environmental Improvement Board and will submit this information to NMED once it is available.

CONCLUSION

For the foregoing reasons and the reasons stated in the September 2024 Enterprise Comments included here as Attachment A, the Revised Draft SIP, while improved, will continue to impose unwarranted emission control requirements on Enterprise's facilities if finalized. Although the Revised Draft SIP more reasonably addresses the NOx removal efficiency associated with SCR for the Enterprise facilities, and makes corresponding changes to the SIP's requirements for the Enterprise facilities, additional revisions are nevertheless warranted.

Comments of Enterprise Field Services, LLC on NMED's Draft Regional Haze State Implementation Plan Revision and 20.2.68 NMAC - Regional Haze Requirements

Dear Mr. Jones:

Enterprise Field Services, LLC ("Enterprise") submits herein to the New Mexico Environment Department ("NMED") comments on NMED's draft State of New Mexico Regional Haze State Implementation Plan Revision Second Planning Period (2019-2028) ("Draft SIP") and 20.2.68 NMAC – Regional Haze Requirements ("Companion Rule").

I. Introduction

On August 26, 2024, the NMED announced the release of a Draft SIP to address the Clean Air Act's ("CAA") regional haze requirements for the second planning period of the program (2018-2028). NMED established a comment deadline of September 20, 2024 for these proceedings.[1]

Enterprise is the owner and operator of three facilities that would be subject to the Draft SIP:

- South Carlsbad Compressor Station located in Eddy County, New Mexico (South Carlsbad) – located approximately 26 miles from the nearest Class I Area

[1] *See* NMED, Regional Haze Planning, https://www.env.nm.gov/air-quality/reg-haze/.

- Blanco C & D Compressor Station located in San Juan County, New Mexico (Blanco) – located approximately 39 miles from the nearest Class I Area

- Chaco Gas Plant located in San Juan County, New Mexico (Chaco) – located approximately 49 miles from the nearest Class I Area[2]

Throughout the development of the Draft SIP, Enterprise has engaged with NMED, providing information to support the state's four-factor analyses, responding to information requests, and proposing reasonable regulatory approaches. The Draft SIP, however, takes a very different approach than NMED appeared to be considering during these discussions. Despite indications that NMED agreed with Enterprise that selective catalytic reduction ("SCR") for the control of oxides of nitrogen ("NOx") was not feasible at the Enterprise facilities, the Draft SIP would impose emission limits for eight (8) of the thirteen (13) Enterprise units evaluated that are based on installation and operation of SCR.

NMED has not appropriately evaluated "reasonable progress," as defined by the CAA, for the Enterprise facilities addressed in the Draft SIP. As described in these comments, the Draft SIP is based on an incorrect determination of SCR's technical feasibility and faulty and unrealistic cost assumptions. Further, the SIP would impose control requirements to satisfy the CAA's reasonable progress standard without considering visibility improvement in any meaningful way. Failure to consider visibility and to take all of the statutory factors into account when devising the control requirements for the Enterprise facilities is arbitrary and capricious and contrary to the requirements of the CAA. For all of these reasons, Enterprise requests that NMED withdraw the Draft SIP, reconsider its analysis consistent with these comments, and develop more reasonable and better-supported control requirements for the Enterprise facilities.[3]

II. Background on the Regional Haze Program

The CAA's visibility protection provisions establish as a national goal "the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas[4] which impairment results from manmade air pollution." CAA § 169A(a)(1). The Act directs the U.S. Environmental Protection Agency ("EPA") to issue regulations designed "to assure … reasonable progress toward meeting the national goal" and to require each state to submit a SIP containing "such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal." *Id*. § 169A(a)(4), (b)(2). Accordingly, pursuant to CAA section 169A, the ultimate requirement

[2] Collectively, the "Enterprise facilities."

[3] If NMED plans to proceed to seek approval of the Draft SIP, Enterprise requests, in the alternative, that NMED submit a partial SIP, excluding the Enterprise facilities, to allow Enterprise and NMED to work together to develop a separate SIP submittal that more appropriately addresses the Enterprise facilities.

[4] Class I federal areas are specified units of federal land receiving special protections, such as National Parks and Wilderness areas.

states must satisfy with their regional haze SIPs is to provide for "reasonable progress" towards the national visibility goal.

EPA implements the regional haze program in successive ten-year "planning periods." The first planning period ran from 2008 to 2018. The second planning period of the program covers the period from 2018 to 2028. SIPs to address second planning period control requirements were due to EPA by July 31, 2021. 40 C.F.R. § 51.308(f). As NMED notes in its announcement of the availability of the Draft SIP, EPA "is currently under a September 29, 2024 deadline to approve New Mexico's regional haze plan or promulgate a federal plan for New Mexico satisfying the visibility protection requirements of the Clean Air Act."[5] That deadline, negotiated with environmental groups, is already well past the July 31, 2021 regulatory deadline for second planning period regional haze SIPs. 40 C.F.R. § 51.308(f).

A regional haze SIP has a number of required elements. Most importantly for purposes of these comments, regional haze SIPs must include: (1) technical analyses to inform and support the SIP's control determinations, including calculation of visibility conditions, development of the "uniform rate of progress" ("URP") for each of the state's Class I areas, and interstate and Federal Land Manager ("FLM") consultation demonstrations; (2) a Long-Term Strategy ("LTS"), which includes measures necessary to make reasonable progress toward the national visibility goal; and (3) reasonable progress goals ("RPGs"), which are visibility goals for each mandatory Class I federal area located in the state and which are based on the control measures included in the LTS.

The CAA and EPA's regional haze rule ("RHR") require states to evaluate potential control requirements for sources within their jurisdiction using the four reasonable progress factors: "[1] the costs of compliance, [2] the time necessary for compliance, [3] the energy and non-air quality environmental impacts of compliance, and [4] the remaining useful life of any potentially affected sources." *Id*. § 51.308(f)(2)(i). If a four-factor analysis supports the establishment of new control requirements, those requirements may be appropriate for inclusion in the state's regional haze SIP. Under certain conditions, a state may be required to include existing control measures in their regional haze SIPs to ensure that the state continues to make reasonable progress.

EPA guidance establishes that states may consider visibility alongside the four statutory factors when evaluating controls, stating "EPA has interpreted the CAA and RHR as allowing states to consider visibility alongside the four statutory factors when determining the emission reduction measures that are necessary to make reasonable progress."[6] In fact, EPA "anticipate[s] that the outcome of the decision-making process by a state regarding a control measure may most often depend on how the state assesses the balance between the cost of compliance and the

[5] https://www.env.nm.gov/air-quality/reg-haze/.

[6] EPA, Clarifications Regarding Regional Haze State Implementation Plans for the Second Implementation Period at 12 (July 8, 2021) ("Clarifications Memo").

visibility benefits."[7] Moreover, as discussed above, the CAA requires states to make reasonable progress determinations that are tied by law to consideration of the national visibility goal.

In addition, under the RHR, states must determine and take into account URP, *i.e.*, the rate of progress that would be needed to attain natural visibility conditions by the year 2064, assuming consistent progress is maintained from the baseline to the program's aspirational endpoint. *Id*. § 51.308(f)(3)(ii)(A). Under the RHR, a state may establish an RPG that differs from the URP if the state demonstrates that the URP for the Class I area in question would not be reasonable. A state makes such a showing by conducting a reasonable progress analysis that considers the four reasonable progress factors and makes a "robust" demonstration. *Id*.[8] The RHR also allows states to adjust the URP to account for the effects of international emissions and emission from prescribed fires on wildlands. 40 C.F.R. § 51.308(f)(1)(vi)(B).

States whose emissions may cause visibility impairment in another state's Class I area and states with Class I areas that may experience visibility impairment caused by emissions from other states may be subject to an interstate-consultation requirement. *Id*. § 51.308(f)(2)(ii). The purpose of that requirement is to provide a forum for states to decide collaboratively on reasonable emission reductions and appropriate apportionment of responsibility for reducing emissions during each planning period of the regional haze program. In addition, all states are subject to a requirement to consult with the FLMs in the development of their SIPs. *Id*. § 51.308(i).

III. The New Mexico Environment Department Has Not Adequately Engaged with the Regulated Community.

During the development of the Draft SIP, Enterprise undertook extensive work to assist in the preparation of four-factor analyses for the Enterprise facilities. Enterprise further submitted written materials explaining potential legal and policy justifications to support the state's reasonable progress determinations. To further those efforts, Enterprise met multiple times with NMED staff. Enterprise worked with the state to understand its process, the emission controls under consideration, and the information NMED needed to make informed reasonable progress determinations. As noted in Appendix C, this engagement included:

- The FFA completed by Trinity Consultants for Enterprise Field Services, LLC (Enterprise) and submitted to NMED on 10/30/19 and 11/14/19, respectively.
- Additional information provided by Enterprise on 2/14/20, 2/26/20, 5/19/20, 6/2/20, 9/8/20, 10/1/20, 3/4/21, and 8/30/23.
- Detailed discussions between Enterprise and NMED on 8/28/20 and 7/13/23.

[7] EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period at 37 (Aug. 20, 2019) ("2019 Guidance").

[8] The statutory basis for EPA's "robust" demonstration requirement is, at best, unclear.

• Written comments submitted to NMED regarding Draft Final Cost Evaluations on 1/15/24.[9]

In addition to the engagement described above, Enterprise, in a February 19, 2020 presentation given to NMED, explained using aerial photographs that there was insufficient space available for SCRs at each of the Enterprise facilities.[10] At no time during the many interactions since that presentation did NMED indicate that it was evaluating SCR for the Enterprise facilities or that it had reason to reject Enterprise's assertions as to the problems posed by space constraints. On the contrary, in an email dated December 20, 2023, NMED provided Enterprise with " draft final cost evaluations" for the Enterprise facilities to facilitate Enterprise providing comments on those cost evaluations.[11] Two spreadsheets containing the state's cost analysis were attached to this email and indicated that NMED had concluded that, due to space constraints, other site-specific factors, and costs for other similar facilities in New Mexico, "SCR is cost prohibitive" for the Enterprise facilities.[12]

Despite all of this early engagement, NMED has now released its Draft SIP with vastly different conclusions as to the feasibility of SCR and would impose especially stringent emission rate limits on the Enterprise facilities as a result. Had NMED shared with Enterprise that it was considering a significant change in course, Enterprise would have worked to provide the state with additional information to further assist in its assessment of SCR. Unfortunately, Enterprise did not have that opportunity. Similarly, NMED has now provided only a 25-day period for comment on the Draft SIP. Although Enterprise understands that the regulatory process in New Mexico will provide additional opportunities to participate, by failing to transparently engage with Enterprise during development of the Draft SIP, NMED has substantially limited Enterprise's ability to develop and provide much-needed information to correct the record in these proceedings.

In the limited time available, Enterprise has developed the analysis presented here, which further demonstrates the significant costs of SCR for the Enterprise facilities. Because NMED is using SCR as the basis of the NOx limits, as expressed in the Companion Rule, and due to the limited time available to evaluate SCR, Enterprise has not been able to quantify the full scope of facility modifications, with their attendant cost, complexity, and uncertainty, that would be needed to attempt to achieve the proposed NOx limits. This would have required a full constructability evaluation as well as an analysis of infrastructure reconfiguration and potential electrical upgrade requirements. Enterprise appreciates that NMED has committed to considering any additional information that may be developed subsequent to the close of the current

[9] Draft SIP, App. C at 65. For ease of reference, Citations to NMED Appendices refer to the PDF pagination rather than the pagination of the individual reports contained therein.

comment period and to reasonably accommodate the need for additional time that may be needed to complete complex analyses and to obtain information from third parties.

The information that is available makes clear that SCR is not necessary to make reasonable progress when considered in light of the four factors and the limited visibility improvement that could be achieved through installing these controls. Accordingly, just as Enterprise has worked diligently in very short time to provide NMED with information that necessitates revising the Draft SIP's requirements for the Enterprise facilities, NMED must revise the Draft SIP before submitting it for review by the state's Environmental Improvement Board ("EIB"). Indeed, proceeding to seek approval of the Draft SIP after consideration of the information provided in these comments would be unreasonable and unsupported by the record. Accordingly, NMED should withdraw the Draft SIP or substantially revise it based on these comments before proceeding with EIB review.[13]

IV. New Mexico Has Unreasonably Refused to Consider Visibility in Violation of the CAA.

As explained above, section 169A of the CAA imposes one overarching requirement on states: they must include in their SIPs "such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal." 42 U.S.C. § 7491(b)(2). The national goal that states must ensure "reasonable progress" towards is a visibility goal: "the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution." *Id*. § 7491(a)(1). While states must consider the four reasonable progress factors when assessing the level of progress that is reasonable, plainly, states cannot make a determination as to the measures needed to ensure reasonable progress without considering the overall goal of the program.[14] Thus, as should be clear, a regional haze SIP must be based on consideration of visibility to satisfy the CAA.

In describing how it selected control requirements for sources subject to the SIP, NMED says:

> NMED did not directly consider the visibility benefits of potential control measures when making its control determinations. EPA has

[13] If, in spite of these comments, NMED intends to proceed with finalizing the Draft SIP without appropriate revisions, Enterprise requests that NMED provide Enterprise with the opportunity to respond to any of the Department's remaining questions and to provide any necessary additional information. As noted above in footnote 3, addressing the Enterprise facilities in a separate SIP submittal could provide NMED with additional time to respond to these comments (as well as any additional information that is developed) while still proceeding with approval of the remainder of the Draft SIP.

[14] In its Clarifications Memo, EPA appears to assert that states may only consider visibility in certain ways or for certain purposes. Clarifications memo at 13. For instance, EPA says visibility should not be used to "summarily dismiss" cost-effective controls, but that it could be used to select among different cost-effective controls. *Id*. EPA has presented no principled basis for limiting consideration of visibility. Moreover, as described above, the CAA must be interpreted to require consideration of visibility in support of measures needed to make reasonable progress under the regional haze provisions of the Act.

> consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making control determinations. NMED's approach is based on the assumption that substantial reductions in emissions of NOx and SO_2 will translate into visibility benefits.

Draft SIP at 104-05. According to NMED, therefore, the state did not consider visibility other than to assume that emission reductions would translate to visibility benefits, essentially failing to consider visibility at all. This is an unreasonable approach to developing a regional haze SIP, and it is inconsistent with the requirement that states develop SIPs that ensure reasonable progress toward the national visibility goal. In short, failure to consider visibility is a failure to consider a factor Congress intended states to take into account when developing regional haze SIPs. NMED has therefore failed to consider "an important aspect of the problem," which renders the Draft SIP arbitrary and capricious under the law. *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43, (1983) ("Normally, an agency rule would be arbitrary and capricious if the agency has relied on factors which Congress has not intended it to consider, entirely failed to consider an important aspect of the problem, offered an explanation for its decision that runs counter to the evidence before the agency, or is so implausible that it could not be ascribed to a difference in view or the product of agency expertise.")

In addition, New Mexico law requires that the EIB consider visibility when taking action. NM Stat § 74-2-5(f) (2023). The EIB is tasked with weighing visibility improvements against "the public interest, including the social and economic value of the sources and subjects of air contaminants;" as well as "technical practicability and economic reasonableness of reducing or eliminating air contaminants from the sources involved and previous experience with equipment and methods available to control the air contaminants involved." *Id*. The EIB cannot fulfill its statutory obligations without an assessment of visibility by NMED. On the contrary, in the absence of a visibility assessment in support of the Draft SIP, the EIB will have no choice but to disapprove it for failure to comport with the CAA minimal requirements.[15]

NMED must correct this shortcoming in the Draft SIP before proceeding to seek approval from the EIB. A proper consideration of visibility, moreover, as described in the next section, demonstrates that existing controls at the Enterprise facilities are sufficient to address the CAA's reasonable progress requirement for the second planning period and that SCR cannot be justified.

V. Any Reasonable Assessment of Visibility Demonstrates that Additional Controls, Including SCR, Cannot Be Justified for the Enterprise Facilities.

All evidence in the record supports a finding that visibility conditions in Class I areas potentially affected by the Enterprise facilities are already achieving reasonable progress. The evidence in the record further establishes that any new emission control requirements for the

[15] While the technical information included in the Draft SIP on visibility conditions is useful information, without analysis of visibility impacts and an assessment of how such impacts should figure into control determinations by NMED in the first instance, the EIB will not have an adequate basis on which to evaluate the Draft SIP.

Enterprise facilities will result in, at most, imperceptible visibility impacts. In short, considered by every metric, the visibility effects that would result from the requirements of the Draft SIP cannot support the imposition of costly new control requirements. As such, the Draft SIP should be revised to recognize that existing controls at the Enterprise facilities are sufficient to ensure reasonable progress.

The progress achieved to date and projected for the future without requiring additional controls, including SCR, at the Enterprise facilities should be deemed sufficient to address the reasonable progress requirement for the second planning period. The Draft SIP acknowledges, for instance, that all Class I areas affected by New Mexico sources "have shown visibility improvement over the monitoring period." Draft SIP at 42. This improvement, when compared to the URP, demonstrates that the areas affected by New Mexico sources are generally improving faster than the URP metric. The Draft SIP explains:

> NMED's glidepath checks show that eight of New Mexico's nine Class I Areas are projected to fall below the URP glidepath in 2028, which is indicative of a faster rate of improvement than the URP. Only Salt Creek Wilderness Area in Chaves County is projected to be above the glidepath, indicating a slower rate of improvement than the URP.

Draft SIP at xiii. Despite devoting a chapter of the Draft SIP to describing the results of its comparison of the URP to visibility conditions, NMED fails to draw any conclusions or present any analysis of how it took the performance of these Class I areas relative to the URP into account in evaluating requirements for the Draft SIP. Indeed, it does not appear that NMED actually took the URPO into account in any way. NMED must include such an analysis to satisfy the requirements of the RHR and to provide a well-supported SIP. Any reasonable assessment of the URP, moreover, supports the conclusion that additional controls for the Enterprise facilities, including SCR, are not needed for reasonable progress.[16]

In each of the four-factor assessments that Enterprise submitted to NMED to assist in the development of the Draft SIP, Enterprise's consultant included an assessment of likely visibility impacts that would result from controls at the Enterprise facilities. For Blanco, Enterprise reported:

> The Blanco C&D Compressor Station is located approximately 50 miles from the Mesa Verde Class I areas at a wind vector range of approximately 155 degrees to 165 degrees (SSE). According to 2015 meteorological data collected in Bloomfield, NM . . . wind blows from this direction range at a frequency of only 2.4%.

[16] As explained below, although Salt Creek Wilderness Area is not yet projected to be below the URP glidepath, a Q/d assessment for South Carlsbad using recent emissions data shows that its emissions would have minimal impacts on visibility that fall below NMED's screening threshold for bringing sources forward for four-factor analysis.

> Moreover, when the wind direction is within this range, the wind speed is typically relatively low; the frequency of wind speeds greater than 3.09 m/s (or ~7 mph) is only 0.3%, or about 25 hours per year. Higher wind speeds would be needed to effectively transport emissions from Blanco to the Mesa Verde Class I area. Moreover, over the 50 miles of transport, pollutants undergo significant dispersion. While full dispersion and photochemical modeling would be needed to more robustly evaluate Blanco's impact, based on this evidence, Blanco's impact on visibility is likely insignificant.

See Draft SIP, App. D. at 488.

Similarly, for Chaco, Enterprise reported:

> The Chaco Gas Plant is located approximately 50 miles from the Mesa Verde Class I area at a wind vector range of approximately 155 degrees to 165 degrees (SSE). According to 2015 meteorological data collected in Bloomfield, NM . . . wind blows from this direction range at a frequency of only 2.4%. Moreover, when the wind direction is within this range, the wind speed is typically relatively low; the frequency of wind speeds greater than 3.09 m/s (or ~7 mph) is only 0.3%, or about 25 hours per year. Higher wind speeds would be needed to effectively transport emissions from Chaco to the Mesa Verde Class I area. Moreover, over the 50 miles of transport, pollutants undergo significant dispersion. While full dispersion and photochemical modeling would be needed to more robustly evaluate Chaco's impact, based on this evidence, Blanco's impact on visibility is likely insignificant.

Id. at 581.

For South Carlsbad, Enterprise reported:

> The South Carlsbad Compressor Station is located approximately 16.2 miles [sic][17] from the Carlsbad Caverns Class I area at a wind vector range of approximately 60 degrees to 70 degrees (NE). According to 2017 meteorological data collected in Carlsbad. . . wind only blows from this direction at a frequency of 1.4% or approximately 120 hours per year. Moreover, over the 16 miles of transport, pollutants would undergo significant dispersion. While

[17] The distance is 25.88 km (16.1 miles) according to SIP table 6-1. Draft SIP at 96.

> full dispersion and photochemical modeling would need to be conducted to more accurately evaluate South Carlsbad's impact, based on this evidence, the facility's impact on visibility is likely insignificant.

Id. at 644.

As explained above, NMED has not conducted any additional visibility assessment or reached any conclusions about the impact of the Enterprise facilities on visibility in Class I areas. Accordingly, the only information in the record supports the conclusion that the impacts from the controls under evaluation are not likely to be meaningful. NMED cannot nevertheless impose emission control requirements without even considering this crucial information, much less carefully weighing it.

Since preparation of the NMED and Enterprise four-factor assessments, additional data has become available to demonstrate that visibility impacts from Chaco and South Carlsbad—and any benefit that would result from further controlling their emissions—have grown even smaller. As shown in the table below, since 2016, emissions from Chaco and South Carlsbad have generally fallen, with resulting Q/d values falling appreciably as well. Most significantly, the Q/d values for South Carlsbad for four of the last five years have been below the state's adopted Q/d threshold of 5.6. This is adequate grounds in itself to remove control requirements for South Carlsbad from further consideration.

	Blanco		Chaco		South Carlsbad	
Year	Q	Q/d	Q	Q/d	Q	Q/d
2014	513.2	8.1	2250.0	28.0	149.5	5.8
2015	528.3	8.3	2175.6	27.1	160.3	6.2
2016	494.8	7.8	2270.7	28.3	153.0	5.9
2017	515.0	8.1	1943.9	24.2	156.5	6.0
2018	512.6	8.1	1976.2	24.6	160.0	6.2
2019	573.7	9.1	1829.2	22.8	133.8	5.2
2020	883.1	13.9	1861.0	23.2	135.6	5.2
2021	591.5	9.3	1826.9	22.8	140.2	5.4
2022	456.9	7.2	777.1	9.7	121.6	4.7
2023	658.7	10.4	707.6	8.8	156.7	6.1

Q = Sum of reported annual NOx and SO2 emissions (tons)

d = distance from Class I area (km) per Table 6-1 of draft SIP

Blanco =	63.4	km
Chaco =	80.2	km
S. Carlsbad =	25.9	km

Finally, the lack of a visibility assessment obscures the truly de minimis nature of the visibility impacts from the Enterprise facilities further demonstrating why refusing to consider visibility is unreasonable and inconsistent with the CAA. When EPA promulgated a Federal Implementation Plan ("FIP") to address regional haze for New Mexico during implementation of the first planning period of the program, EPA conducted a full visibility assessment to evaluate whether SCR could be justified. *See* 76 Fed. Reg. 491 (Jan. 5, 2011) (Proposed FIP for New Mexico). In determining that SCR could be justified for the San Juan Generating Station, EPA determined that the installation and operation of SCR would result in a visibility improvement of 21.69 deciviews across 16 different Class I areas. *Id*. at 503. Improvements within individual Class I areas ranged from 0.31 deciviews to 3.11 deciviews. *Id*. To put this context, EPA says that a 0.5 deciview impact "contributes" to visibility impairment, a 1.0 deciview impact "causes" visibility impairment, and a 1.0 deciview impact is generally the threshold for human perception of a change in visibility conditions. To further put this into perspective, to achieve this level of visibility improvement, EPA projected that the FIP would eliminate 17,518 tons per year of NOx. *Id*. at 502, Table 7.

By contrast, the Draft SIP's tons per year NOx reductions estimated for Blanco are 974.4 tons. Draft SIP at 115. For Chaco, they are 363.6 tons. *Id*. at 116. For South Carlsbad, they are 138.7. *Id*. at 118. The visibility benefits that might result from these reductions would be a mere fraction of those previously deemed sufficient to justify requiring SCR. Accordingly, the minimal visibility impacts that may result from emissions from the Enterprise facilities cannot reasonably serve as the basis for imposing the enormously costly, if not infeasible, emission controls contemplated in the Draft SIP.

A full and reasonable evaluation of visibility, as required by the CAA and New Mexico law, demonstrates that the Draft SIP's control determinations for the Enterprise facilities are unsound and must be revised. The only information in the record supports the conclusion that the visibility impacts of the Enterprise facilities, and the visibility improvements that could be achieved with additional controls, do not support requiring additional costly requirements to address reasonable progress at this time. NMED is obligated to consider this information and to revise the requirements of the Draft SIP to better align the Draft SIP's requirements with the requirements of the CAA.

VI. New Mexico Has Failed to Justify Its Decision to Pursue Reductions in Nitrogen Oxides.

The Draft SIP explains that visibility impairment is overwhelmingly dominated by "ammonium sulfate, organic mass, and coarse mass on both the Most Impaired Days and the Clearest Days." Draft SIP at 53.[18] EPA guidance makes clear that it is appropriate for states to evaluate controls for the most significant visibility-impairing pollutants:

[18] The only exceptions are Salt Creek Wilderness and San Pedro Parks Wilderness, "when ammonium nitrate was one of the top three contributors instead of either organic mass or coarse mass." Draft SIP at 53. None of the Enterprise facilities is located near these areas or could reasonably be expected to influence their visibility conditions. Blanco is 471.14 kilometers ("km") from Salt Creek and 89.47 km from San Pedro. Chaco is 461.68 km

> When selecting sources for analysis of control measures, a state may focus on the PM species that dominate visibility impairment at the Class I areas affected by emissions from the state and then select only sources with emissions of those dominant pollutants and their precursors. Also, it may be reasonable for a state to not consider measures for control of the remaining pollutants from sources that have been selected on the basis of their emissions of the dominant pollutants.

2019 Guidance at 11. Had NMED followed this guidance and focused on the greatest pollutants of concern, the Enterprise facilities would not have even been considered for additional controls. This is itself an adequate basis for removing the Enterprise facilities from further consideration for reasonable progress controls.

EPA's guidance goes on to provide one pertinent example:

> For example, organic mass by carbon (OMC) light extinction might be dominant in the IMPROVE data for a western Class I area on the average of the 20 percent most anthropogenically impaired days, even though days heavily affected by fires will tend not to be included in the 20 percent most anthropogenically impaired days. This may cause sulfate to account for only a small percentage of total light extinction. However, it could be clear that most of the OMC is natural and that sulfate dominates anthropogenic light extinction. In this situation, we recommend that a state consider SO_2 sources and SO_2 control measures.

This is the situation facing New Mexico. Yet instead of focusing on SO_2 controls, as the data suggests would be appropriate and a*s EPA guidance calls for*, the state has unreasonably focused on the negligible impacts that might result from NOx emissions, including the relatively small NOx emissions from the Enterprise facilities.

New Mexico rationale for pursuing NOx reductions is that "[t]he largest haze reductions over time (i.e., the largest reduction in individual species' contributions to light extinction) are generally associated with ammonium sulfate and ammonium nitrate, which have likely occurred due to reduced SO_2 and NOx emissions since EPA first promulgated the Regional Haze Rule in 1999." Draft SIP at 53. Although significant reductions in NOx in the past may have been associated with commensurate reductions in haze, there is no basis for concluding that eliminating minor amounts of NOx will have a significant effect on visibility at this time.

---

from Salt Creek and 99.97 km from San Pedro. South Carlsbad is 141 km from Salt Creek and 477.04 km from San Pedro.

Indeed, as described above, EPA's FIP for New Mexico for the first regional haze planning period would have eliminated 17,518 tons per year of NOx. *Id*. at 502, Table 7 and improved visibility by an appreciable 21.69 deciviews across 16 different Class I areas. 76 Fed. Reg. at 502-03. EPA withdrew that FIP and approved a subsequently submitted regional haze SIP for New Mexico that achieved *even greater* emission reductions and visibility improvements than the FIP. See Approval and Promulgation of Implementation Plans; New Mexico; Regional Haze and Interstate Transport Affecting Visibility State Implementation Plan Revisions, 79 Fed. Red. 60,985 (Oct. 9, 2014). The Draft SIP achieves nothing approaching this level of visibility improvement from its proposed NOx controls.

For all of these reasons, NMED has "offered an explanation for its decision [to focus on NOx] that runs counter to the evidence before the agency." *Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43, (1983). New Mexico, consistent with EPA guidance, should elect to focus the current regional haze SIP on the visibility impairing pollutants of most significance. It should not continue to pursue NOx controls for this planning period. For that reason, NMED should revise the Draft SIP to acknowledge that existing controls at the Enterprise facilities are adequate to ensure reasonable progress.

VII. NMED Has Adopted an Unreasonable Q/d Screening Threshold.

The Draft SIP explains that NMED performed Q/d assessment to identify sources with emissions significant enough to warrant further evaluation pursuant to the four factors. Draft SIP at 93. NMED adopted a Q/d screening threshold of 5.6. *Id*.

This screening threshold is significantly out of step with the thresholds used by other states, including those that have previously been approved as reasonable for use in the regional haze program by EPA. Indeed, every state to adopt such a screening threshold appears to have adopted one substantially higher than New Mexico:

- Air Plan Partial Approval and Partial Disapproval; Wyoming; Regional Haze Plan for the Second Implementation Period, 89 Fed. Reg. 63,030, 63,042 (August 1, 2024) (screening threshold of Q/d > 10).

- Air Plan Partial Approval and Partial Disapproval; Utah; Regional Haze State Implementation Plan for the Second Implementation Period; Air Plan Disapproval; Utah; Interstate Transport of Air Pollution for the 2015 8-Hour Ozone National Ambient Air Quality Standards, 89 Fed. Reg. 67,208, 67,220 (August 19, 2024) (screening threshold of Q/d ≥ 6).

- Air Plan Approval; Wisconsin; Second Period Regional Haze Plan, 89 Fed. Reg. 65,492, 65,503 (August 9, 2024) (screening threshold of 10).

- Approval and Promulgation of Air Quality Implementation Plans; State of Florida; Regional Haze State Implementation Plan, 77 Fed. Reg. 31,240, 31,253

(May 25, 2012) (screening threshold of 50).

- Partial Approval and Disapproval of Air Quality Implementation Plans; Arizona; Regional Haze State Implementation Plan for the Second Implementation Period and Prong 4 (Visibility) for the 2015 Ozone and 2012 Particulate Matter Standards, 89 Fed. Reg. 47,398, 47,412 (May 31, 2024) (screening threshold of 10).

- Promulgation of Air Quality Implementation Plans; State of Texas; Regional Haze and Interstate Visibility Transport Federal Implementation Plan: Proposal of Best Available Retrofit Technology (BART) and Interstate Transport Provisions, 83 Fed. Reg. 43,586, 43,596 (Aug. 27, 2018) (screening threshold of 10).

- Approval and Promulgation of Air Quality Implementation Plans; Montana; Regional Haze Federal Implementation Plan, 82 Fed. Reg. 17,948, 17,955 (Apr. 14, 2017) (screening threshold of 10).

- Approval and Promulgation of Implementation Plans; South Dakota; Regional Haze State Implementation Plan, 76 Fed. Reg. 76,646, 76,661 (Dec. 8, 2011) (screening threshold of 10).

- Approval and Promulgation of Implementation Plans; State of Colorado; Regional Haze State Implementation Plan, 77 Fed. Reg. 18,052, 18,078 (Mar. 26, 2012) (screening threshold of 20).

The vast majority of similarly situated states have adopted screening threshold of 10 or higher. Such a threshold is consistent with EPA's BART Guidelines,[19] which provide:

> Based on our analyses, we believe that a state that has established 0.5 dv as a contribution threshold could reasonably exempt from the BART review process sources that emit less than 500 tons per year of NO—T2X or SO—T22 (or combined NO—T2X and SO—T22), as long as these sources are located more than 50 kilometers from any Class I area; and sources that emit less than 1000 tons per year of NO—T2X or SO—T22 (or combined NO—T2X and SO—T22) that are located more than 100 kilometers from any Class I area."

40 C.F.R. 51, appendix Y, section III, How to Identify Sources "Subject to BART." According to the BART Guidelines, therefore, a facility with minimal impacts such as these can reasonably be excluded from the regional haze program. As EPA explained in another final regional haze rule,

[19] Although the BART Guidelines are not binding in setting reasonable progress requirements, the BART Guidelines nonetheless provide useful precedent.

"[t]he values described [in the BART Guidelines] equate to a Q/D of 10." 82 Fed. Reg. at 17,955 n.53.

Had New Mexico adopted such a threshold, based on review of the most recent Q/d calculations, presented above, at least two of the three the Enterprise facilities (Chaco and South Carlsbad) should have screened out of further evaluation. For this reason alone, NMED should revise the Draft SIP to impose no additional control requirements for Chaco and South Carlsbad on this basis.

NMED has not offered a valid rationale for adopting such a low screening threshold. The explanation contained in the Draft SIP is that the threshold was intended:

> to capture 80% of the total NOx and SO_2 emissions from all New Mexico Title V facilities combined. NMED and EHD chose this 80% threshold based on guidance in the WRAP Source Selection Protocol. The Protocol noted draft guidance from EPA recommending an 80% threshold applied to emissions from all stationary sources.

Draft SIP at 92 (citation omitted). The draft guidance recommending an 80% threshold was never adopted by EPA. EPA instead issued the 2019 Guidance, which did not adopt the 80% threshold. Accordingly, NMED has adopted an extreme outlier screening threshold on the basis of guidance that was never adopted as formal EPA policy.

NMED should withdraw the Draft SIP and apply a more reasonable screening threshold, consistent with the actions of its sister states. It should further revise the Draft SIP to recognize that the visibility impacts of the Enterprise facilities are too small to justify imposing additional controls and are indeed, small enough to reasonably be screened out from a four-factor assessment.

VIII. NMED Has Failed to Adequately Consider Each of the Four Factors.

Under the CAA, states must consider four factors to determine reasonable progress: "the costs of compliance, the time necessary for compliance, and the energy and nonair quality environmental impacts of compliance, and the remaining useful life of any existing source subject to such requirements." 42 U.S.C. § 7491(g)(1). Rather than fully consider each of the four factors, NMED has focused almost exclusively on cost, contrary to the CAA. The Draft SIP explains, "[c]ost effectiveness was the predominant factor in NMED's decision-making regarding necessary control measures, with the remaining factors either being subsumed into the cost of compliance or not being major considerations." Draft SIP at 104.

Although states have considerable discretion as to how they weigh the four statutory reasonable progress factors, states must, at a minimum, give reasonable consideration to each one. *See Nat'l Parks Conservation Ass'n v. McCarthy*, 816 F.3d 989, 992 (8th Cir. 2016) (states "must consider four factors").

NMED has not considered the disbenefits of SCR. Specifically, in evaluating SCR or any other control, the state must take into account "the energy and nonair quality environmental impacts of compliance" to satisfy the CAA's requirements. Operation of SCR will have at least four such impacts.

First, a disbenefit of SCR is ammonia ("NH_3") emissions. Based on approximate exhaust rates for the 8 Enterprise turbines for which NMED has proposed to require SCR, and an estimated 10 ppmv NH_3 slip, aggregate annual NH_3 emissions would be approximately 196 tons assuming no restriction in operating hours.

NH_3 Emissions (Annual)

Facility	Estimated NH_3 Emissions
Blanco	86.6 tons
Chaco	87.6 tons
S. Carlsbad	21.8 tons

Emissions of ammonia have a range of environmental impacts. *See generally* U.S. EPA. Integrated Science Assessment (ISA) for Oxides of Nitrogen, Oxides of Sulfur and Particulate Matter Ecological Criteria (Final Report, 2020). NMED has not considered this disbenefit.

Second, the SCR system will involve the use of hazardous materials. SCR can use either aqueous or anhydrous ammonia for the reduction reaction. Anhydrous ammonia is classified as a hazardous material and often requires special permits as well as additional procedures for transportation, handling and storage. Aqueous ammonia, on the other hand, requires more storage capacity than anhydrous ammonia. Both pose environmental and safety risks. Again, NMED has not considered this.

Third, operation of SCR requires power. Due to the limited amount of time to evaluate SCR as a control option for the Enterprise facilities, a feasibility and constructability evaluation has not been completed at the time of submittal. It is therefore unknown if existing electrical power is sufficient or if upgrading or adding electrical infrastructure would be required. NMED has not considered these energy impacts either.

Fourth, operation of SCR could impact engine performance by creating additional working load on the engine. A detailed engineering study could not be performed in the limited time available for public comment. It is therefore not known issue will impact the ability of the Enterprise facilities to meet commercial throughput requirements. This is also an energy impact that NMED is obligated to consider.

Before NMED can lawfully propose its reasonable progress and related emission control determinations, it must present an assessment of each of the four factors evaluating the use of the controls under consideration. NMED has not done that in support of its proposed SCR requirements for the Enterprise facilities. A proper and complete evaluation of "the energy and nonair quality environmental impacts of compliance" would, moreover, provide further support

for the conclusion that SCR is not needed to achieve reasonable progress and that the existing controls at the Enterprise facilities ensure that reasonable progress will be achieved during the second planning period of the regional haze program.

IX. NMED Has Unreasonably Concluded SCR Is Technically Feasible.

According to EPA's 2019 Guidance, "[t]he first step in characterizing control measures for a source is the identification of technically feasible control measures for those pollutants that contribute to visibility impairment." 2019 Guidance at 28. EPA's regulatory BART Guidelines for the regional haze program provides further information on the methodology for assessing control to address visibility. In the BART Guidelines, EPA explained:

> You should clearly document a demonstration of technical infeasibility and should show, based on physical, chemical, and engineering principles, that technical difficulties would preclude the successful use of the control option on the emissions unit under review. You may then eliminate such technically infeasible control options from further consideration….
>
> Alternatively, a demonstration of technical infeasibility may involve a showing that there are unresolvable technical difficulties with applying the control to the source (e.g., size of the unit, location of the proposed site, or operating problems related to specific circumstances of the source).

Proposed Guidelines for Best Available Retrofit Technology (BART) Determinations Under the Regional Haze Regulations, 66 FR 38108, 38,123-24 (July 20, 2001).

During development of the Draft SIP, Enterprise demonstrated to NMED that SCR was not a technically feasible control for the Enterprise facilities. Enterprise communicated to NMED that it had eliminated consideration of SCR as a feasible technology due to the current configuration and available space.[20] Enterprise provided vendor-supplied SCR dimensions as CBI to NMED in support of that assessment.[21] Maps were also provided in this response that overlayed the area required for SCR showing existing facility infrastructure.

NMED has not explained its reason for changing course with respect to the technical feasibility of SCR for the Enterprise facilities. All that NMED says in this regard is the following:

[20] *See* Draft SIP, App. D at 481-82, 494-502, 574, 589-598, 639, 651-661 (Various Enterprise four-factor analysis submittals).

[21] *Id*. (providing CBI materials to NMED).

> Enterprise asserted that limited physical space precludes the option of installing SCR and provided an aerial image with measurement overlays to support this assertion. However, the image provided suggests there is physical space for SCR if building modifications are made.

Draft SIP, App. C at 80. This minimal level of assessment is not sufficient to serve as a basis for finding that SCR is technically feasible. NMED must revise the Draft SIP to reflect this reality.

X. New Mexico's Cost Evaluation for the Enterprise Facilities Is Substantially Flawed.

To support its proposed control requirements for the Enterprise facilities, NMED focused predominately on costs. Draft SIP at 102 ("To characterize the cost of compliance, which was the predominant factor in NMED's decision-making regarding control measures…."). NMED considered a single cost metric: "cost effectiveness of each control, expressed in terms of cost per ton of emissions reduced." *Id*.

The regional haze program is intended to evaluate real-world, site-specific costs. NMED says that it made use of such information in a limited fashion:

> NMED utilized source-specific cost estimates provided by the facilities in its calculations whenever possible. In cases where facilities failed to provide source-specific cost estimates or NMED found estimates provided by facilities to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including -four-factor analyses developed for similar facilities in New Mexico and other states, to estimate costs.

Id. There are substantial flaws in NMED's consideration of costs that necessitate reevaluation of and modifications to the Draft SIP's proposed control requirements for the Enterprise facilities.

A. NMED Has Not Considered Relevant Cost Metrics.

NMED has only considered cost-effectiveness on a simple dollar-per-ton basis. Such limited consideration does not fully evaluate costs and has resulted in Draft SIP requirements that go beyond what is needed to make reasonable progress. In the body of the Draft SIP, for instance, NMED presents only $/ton cost-effectiveness values for SCR. Draft SIP at 114-118. Appendix C, which contains additional narrative explaining NMED's four-factor analysis confirms that the $/ton metric was the only manner in which NMED considered costs. Draft SIP, App. C, at 68-91.

According to EPA's 2019 Guidance, a cost assessment in furtherance of a reasonable progress assessment "will typically produce estimated values of capital costs, annual operating and maintenance costs, annualized costs, and cost per ton of emission reductions, as well as

multiple values for daily visibility benefits." 2019 Guidance at 38. NMED has calculated annualized costs, but does not appear to have considered them. NMED has not considered a $-per-deciview or dollar-per-inverse megameter metric at all. These factors have been determinative in the regional haze proceedings of other states.

- Approval, Disapproval and Promulgation of Implementation Plans; State of Nebraska; Regional Haze State Implementation Plan; Federal Implementation Plan for Best Available Retrofit Technology Determination, 77 Fed. Reg. 40,150, 40,151, 40,156 (July 6, 2012) (EPA partially disapproving Nebraska's SIP after recalculating Nebraska's cost effectiveness analysis for BART using $/dv. Additionally, EPA defended its use of $/dv in response to a comment: "We believe that dollars per deciview is one of several metrics that can be used to analyze cost of visibility improvement, and reaffirm our position that the calculation is more meaningful if cumulative visibility benefits are accounted for.")

- Environmental Protection Agency: Rules and Regulations: Approval and Promulgation of Implementation Plans; State of Oregon; Regional Haze State Implementation Plan and Interstate Transport Plan, 76 Fed. Reg. 38997, 38999 (July 5, 2011) (EPA approving and promulgating Ohio's Regional Haze SIP for the first implementation period based on a dollars/dv threshold of $10 million per deciview; the EPA responded to a comment challenging the threshold by stating that the threshold was "consistent with EPA's review of dollars/dv cost effectiveness data…").

NMED's failure to consider cost metrics in addition to its dollar-per-ton calculations has left NMED with an incomplete picture of the costs of the controls it has proposed. New Mexico must further evaluate all potentially informative cost metrics to ensure that the state has met its obligation to weigh the four factors in determining reasonable progress. Failure to consider this information—which Congress intended the states to take into account—is arbitrary and capricious. *See Motor Vehicle Mfrs. Ass'n of U.S., Inc. v. State Farm Mut. Auto. Ins. Co.*, 463 U.S. 29, 43, (1983).

B. NMED's Cost-Estimates Are Unrealistic and Result in Unreasonable Control Determinations for the Enterprise Facilities.

NMED's assessment of the costs of SCR is incomplete, lacks site-specific information, and understates the costs associated with this control option. For each of the Enterprise facilities, the NMED spreadsheet presenting its SCR cost assessment indicates that NMED relied on default values from EPA's Control Cost Manual and its SCR cost calculation tool. Draft SIP, App. D at 455, 460 (Blanco), 536, 540 (Chaco), 622 (South Carlsbad).

Because Enterprise and NMED had previously concluded that SCR was not technically feasible at the Enterprise facilities due to space constraints, Enterprise did not seek vendor quotes or other information prior to release of the Draft SIP. Enterprise maintains that the site-specific

impediments to construction of SCR should be considered sufficiently onerous to render SCR technically infeasible at the Enterprise facility sites.

In the short time provided for public comment on the Draft SIP, Enterprise has not been able to develop the sort of detailed engineering studies that would be needed to fully assess the true costs of installing and operating SCR at the Enterprise facilities. Such information is needed for a true and accurate cost assessment. Accordingly, NMED should pause its efforts to seek approval of the Draft SIP and ensure that an adequate cost assessment, including site-specific information and vendor quotes, if available, is included in the record and comprises the basis for the SIP's requirements. Proceeding on the basis of NMED's more generic cost assessment when better data could have been obtained is arbitrary and capricious. *Conservation Cong. v. Finley*, 774 F.3d 611, 620 (9th Cir. 2014) ("Agencies 'must support their conclusions with accurate and reliable data'"). If Enterprise is able to obtain additional information further characterizing SCR costs, we will provide it to NMED as expeditiously as possible.

In the time provided, Enterprise has obtained two preliminary vendor quotes that demonstrate the values NMED has relied on are unrealistic. It is first important to emphasize that the quotes Enterprise has received significantly understate likely actual costs. Because of limited time, these quotes were developed without taking into account factors that will significantly impact costs:

1) No SCR feasibility or constructability walk-downs were performed to prepare these estimates.
2) Costs assume no relocations of existing infrastructure would be required; however, as explained further below, substantial relocation and additional construction will be required.
3) Costs are not based on detailed engineering studies.
4) The quotes assume sufficient electricity is available and do not include costs associated with upgrading or adding electrical infrastructure.

Even with these limitations, the vendor quotes indicate that NMED's cost estimates are too low.

Facility	Unit No.	Unit Type	NMED's Proposed NOx Control Measure	NMED's Total Capital Investment Estimate	NMED Cost Effectiveness	Enterprise Capital Investment Estimate	Enterprise Cost Effectiveness (Using NMED Methodology)
	35	Solar Mars T-15000	SCR (90% Reduction)	$5.3 MM	$9,000/ton	$6.8 MM	$10,107/ton
	36	Solar Mars T-15000	SCR (90% Reduction)	$5.3 MM	$9,000/ton	$6.8 MM	$10,713/ton
	37	Solar Mars T-15000	SCR (90% Reduction)	$5.3 MM	$10,000/ton	$6.8 MM	$12,062/ton

South Carlsbad Compressor Station	1	Solar Centaur T-4700	SCR (90% Reduction)	$2.5 MM	$5,000/ton	$7.2 MM	$13,617/ton
	2	Solar Centaur T-4700	SCR (90% Reduction)	$2.5 MM	$5,000/ton	$7.2 MM	$13,670/ton

Thus, even using marginally more accurate cost information substantially affects the outcome of a cost-effectiveness analysis. Without accounting for the complications and additional costs needed to address relocation of existing infrastructure and adequate power supplies, preliminary vendor information provided to Enterprise indicates that NMED has generally underestimated costs, in some cases substantially. Indeed, Enterprise's more accurate cost information establishes clearly that three of the units at Chaco and both units at South Carlsbad would exceed NMED's threshold for cost-effectiveness, even based on incomplete cost data. Enterprise is working to develop additional, more complete cost data for al of the Enterprise facilities and will seek to supplement the record as appropriate.

At least two additional factors excluded from NMED's and Enterprise's cost information will further increase costs significantly: (1) the costs associated with site-specific retrofit complications; (2) the use of an unsupported 90% NOx removal efficiency assumption.

First, costs associated with retrofitting the Enterprise facilities, including moving existing structures and equipment, will considerably affect cost-effectiveness. NMED explains that it attempted to account for the additional costs associated with retrofit complexity at the Enterprise facility sites by using a retrofit factor in EPA's cost calculation tool:

> A retrofit factor of 1.1 was used in the EPA SCR Tool to account for the additional capital costs anticipated to create physical space for the SCR system. This factor was selected based on Enterprise's recurring assertion that the current layout of the existing building cannot accommodate the physical space needed for SCR. Aerial photos provided by Enterprise suggest there is space for SCR if building modifications are made[.]

Draft SIP, App. D at 455. There is no explanation in the Draft SIP, however, as to how this factor affected costs or why it was the appropriate value to select. According to NMED documentation, EPA's SCR cost tool suggests a range of retrofit factors of "between 0.8 and 1.5 based on the level of difficulty" with a value of 1 being "for projects of average retrofit difficulty." *See id*. at 463. At the very least, to provide adequate support for its Draft SIP, NMED must explain why it has selected its chosen retrofit factor and why its choice is reasonable. A full analysis is likely to find that this figure does not fully capture the costs likely to be incurred to install and operate SCR.

Second, both the NMED and Enterprise cost effectiveness values are also overinflated due to the assumption by NMED, which Enterprise replicated in its assessment of the vendor information, that SCR can achieve a 90 percent removal efficiency at the Enterprise facilities.

The basis for that assumption appears to be that 90 percent is a default value in EPA's SCR cost tool. Draft SIP, App. D at 460. The Draft SIP provides no other explanation than the value is an assumption: "Emissions limitations for selective catalytic reduction are based on current actual emissions and an assumed 90% control efficiency." Draft SIP at 140.

This assumption may be appropriate for some industries under certain conditions, but it is not likely applicable to the Enterprise facilities. As explained in the attached letter from Solar Turbines to Enterprise, a much lower removal efficiency is more likely to apply to at least some the Enterprise units. A 60% to 80% NOx reduction may be a more realistic range of NOx reduction achievable with SCRs placed on certain Enterprise units.[22]

The reduction efficiencies Solar Turbines supports are consistent with EPA's analysis. In its AP-42: Compilation of Air Emissions Factors from Stationary Sources, EPA explains that "[t]he removal efficiency of an SCR system in good working order is typically from 65 to 90 percent." AP-42 at § 3.1.4.3. NMED should, at the least, assume a more realistic removal efficiency. NMED should further conduct a full assessment of removal-efficiency achievability for the Enterprise facilities. Such a change will further increase the cost-effectiveness values.

Enterprise believes that the best available information indicates that SCR is not cost-effective. Just as importantly, however, NMED has not made an adequate demonstration that SCR is cost-effective. Because that burden falls upon the state, NMED should withdraw its Draft SIP, conduct a more fulsome cost analysis, consistent with these comments, and propose a substantially revised Draft SIP.

C. NMED's Cost-Estimates Threshold is Too High.

NMED has adopted a "cost effectiveness threshold value (CETV) to remove control measures deemed not cost-effective from further consideration." Draft SIP at 102. NMED set its CETV at $10,000/ton NOx removed. *Id*. This threshold is too high and an outlier among states.

- Partial Approval and Disapproval of Air Quality Implementation Plans; Arizona; Regional Haze State Implementation Plan for the Second Implementation Period and Prong 4 (Visibility) for the 2015 Ozone and 2012 Particulate Matter Standards, 89 Fed. Reg. 47,398, 47,429 (May 31, 2024) (Cost-effectiveness threshold of $6,500/ton for point sources).
- Disapproval and Promulgation of Air Quality Implementation Plans; Texas and Oklahoma; Regional Haze State Implementation Plans; Federal Implementation Plan for Regional Haze; Completion of Remand, 88 Fed. Reg. 48,152, 48,167 (July 26, 2023) (cost-effectiveness threshold of $2,700/ton).

[22] Letter from Solar Turbines, Re: Solar Compressor Sets - NOx Reductions per NM Regional Haze Rule Requirements (Sept. 9, 2024) (Attachment C).

- Approval, Disapproval and Promulgation of Implementation Plans; State of Nebraska; Regional Haze State Implementation Plan; Federal Implementation Plan for Best Available Retrofit Technology Determination, 77 Fed. Reg. 40,150, 40,159 (July 6, 2012) (cost effectiveness threshold of $5,000 incremental cost per ton).

In addition to relying on much lower cost-effectiveness thresholds, several of these states failed, in EPA's view, to adequately support their chosen cost-effectiveness thresholds. *See, e.g.*, *id*. NMED has likewise failed to explain why its threshold is reasonable.

In one recent rulemaking action addressing the regional haze SIP for Missouri, EPA reviewed cost-effectiveness thresholds used in the regional haze context. In that action, EPA notes that Missouri selected cost-effectiveness thresholds of $3,658 per ton for SO_2 controls and $5,370 per ton for NOx controls. Air Plan Partial Approval and Partial Disapproval; Missouri; Regional Haze, 89 FR 55140, 55154 (July 3, 2024). Although EPA proposed to find those values were too low, EPA instead found costs in the range of $5,000/ton to $6,000/ton for SO_2 control would be more appropriate. *Id*.

EPA further explained that the regional planning organization for Missouri had recommended cost-effectiveness thresholds in a range from $4,000 to $5,000/ton (in 2005 dollars) which becomes $6,060 to $7,600/ton in 2021 dollars. *Id*. EPA provided another example with its own cost-effectiveness threshold of $4,200 to $5,100/ton range (escalated to 2020 dollars) for a Texas regional haze federal implementation plan. EPA further noted that, in 2021 dollars, this range is $5,300/ton to $6,500/ton. *Id*.

The one thing all of these values have in common is that they are much lower than NMED's cost-effectiveness threshold. If NMED were to adopt a threshold more in line with the practice of other states and EPA itself, it is likely that none of the Enterprise facilities would be deemed to have additional cost-effective control options, and SCR would certainly not be deemed cost-effective.

D. NMED Should Provide Enterprise an Opportunity to Address Specific Cost Items.

In the Draft SIP, NMED says that it excluded certain cost items provided by Enterprise or relied on default values where information was not available:

> In cases where Enterprise failed to provide source-specific cost estimates or NMED found estimates provided by Enterprise to be unreliable, NMED utilized EPA's Control Cost Manual or other reliable sources of information, including FFAs developed for similar facilities in New Mexico and other states, to estimate costs.

Draft SIP, App. C at 69. Enterprise believes the information it has provided is reliable, and requests that NMED identify gaps in information that it deems crucial or that might otherwise address any shortcomings NMED perceives with the information Enterprise has provided. Enterprise will work with the Department to provide the more reliable possible information.

XI. In the Alternative, NMED Should Provide Enterprise With Additional Compliance Flexibility.

As drafted, NMED's proposed regulation would impose unit-by-unit emission rate limits for each of the Enterprise facilities. NMED can achieve the same emission reductions and the same improvements in visibility (minimal as they may be) while providing for greater operational flexibility for the Enterprise facilities.

Specifically, if NMED proceeds to seek final approval of its Draft SIP without changing course on requiring emission limits based on SCR for the Enterprise facilities—which it should not—Enterprise requests that NMED allow for facility-wide averaging. Allowing this additional compliance flexibility will ensure that each facility meets an overall emission rate limit while allowing Enterprise to operate the respective emissions units at each facility in the most efficient manner possible.

Allowing for averaging in this manner is fully consistent with the state's legal authority under the regional haze program and similar approaches have been adopted to address reasonable progress requirements in the past.

- Approval and Promulgation of Air Quality Implementation Plans; New Hampshire; Regional Haze, 77 Fed. Reg. 11,809 11,818 (Feb. 28, 2012) (placing two unit within a regulatory "bubble" for compliance purposes).

- Approval, Disapproval and Promulgation of Air Quality Implementation Plans; Arizona; Regional Haze State and Federal Implementation Plans, 77 Fed. Reg. 72,512, 72,527 (Dec. 5, 2012) (applying a compliance "bubble" across multiple units)

Enterprise further requests that NMED reevaluate the emission rate limits contained in the Companion Rule. Those limits are likely too stringent even with installation of SCR, although Enterprise will continue to evaluate this issue. Emission rate limits in the SIP should instead be based on the existing controls at the Enterprise facilities.

CONCLUSION

For all of the foregoing reasons, NMED's Draft SIP would impose unwarranted emission control requirements on Enterprise's facilities. The Draft SIP's requirements are based on a flawed cost assessment and a failure of the Department to fully consider the four reasonable progress factors and the visibility implications of its proposed emission control requirements. NMED should withdraw the Draft SIP and propose regional haze requirements for the Enterprise facilities consistent with the site-specific analysis Enterprise has provided and the CAA's goal that states make reasonable progress toward the national visibility goal.

Should you have any questions regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828 (bjcooley@eprod.com).

Sincerely,

Aaron M. Flynn

Subject:	[EXTERNAL] Revised Regional haze cost evaluations for Blanco C&D and Chaco Gas Plant
Date:	Wednesday, December 20, 2023 10:54:16 AM
Attachments:	2023-12-19_Corrected Draft Final NMED Cost Evaluation_Enterprise - Blanco C and D Compressor Station.xlsx 2023-12-19_Corrected Draft Final NMED Cost Evaluation_Enterprise - Chaco Gas Plant.xlsx

[Use caution with links/attachments]

Dear Mr. Jacobson,

After sending you NMED's draft final cost evaluations for Enterprise Field Services, LLC's Blanco C&D Compressor Station, Chaco Gas Plant and South Carlsbad Compressor Station last Thursday (12/14), our Regional Haze planning team discovered a formula error in the following sheets:

- Sheet "Eval – EMD" of the Blanco C&D Compressor Station workbook, resulting in an incorrect 2023$ cost effectiveness value for Unit T-C02
- Sheet "EMD1" of the Chaco Gas Plant workbook, resulting in an incorrect 2023$ cost effectiveness value for Unit 18
- Sheet "EMD2" of the Chaco Gas Plant workbook, resulting in incorrect 2023$ cost effectiveness values for Units 36 and 37
- Sheet "EMD3" of the Chaco Gas Plant workbook, resulting in incorrect 2023$ cost effectiveness values for Units 13 and 14

The errors have been corrected in the attached workbooks. Please disregard the Blanco C&D Compressor Station and Chaco Gas Plant workbooks we provided last week and review the sheets in the attached, corrected versions instead. As a reminder, the deadline to submit review comments is Jan. 15, 2024.

Regards,
Kirby Olson

This email is intended to serve as general guidance and is in no way a formal statement of Department policy. Unique operating conditions may result in different determinations and may require a site specific analysis to accurately determine requirements and applicability.

Methodology/Note
Enterprise provided a cost estimate for electrification using EPA Cost Control Manual Section 5.2, which pertains to acid gas scrubbers. As this is not applicable to replacement with EMD, a Total Capital Cost metric of $2,084 (2023$/hp) was calculated using detailed cost information provided by other facilities. The TCI figure assumes no costs associated with substation or distribution line upgrades. This assumption underestimates costs given that Enterprise indicated in its August 2023 update that utility infrastructure upgrades would be needed to support electrification at all three of its facilities.

osts associated with replacement with an equivalent/like-kind unit

Enterprise indicated in its initial 2019 FFA submittal, 2020 follow-up and 2023 update that there is insuff
accommodate SCR. In support of its assertion, it indicated (2020 follow up) that CECO-Peerless stated th
approximately 40' x 20' is required for an SCR unit" and a copy of the correspondance was provided. An
facility was provided in the 2020 follow up which suggests that new buildings (or substantial extensions
building) would be required to house an SCR. The associated costs of building construction coupled with
exhaust system modifications would be costly. Considering the calculated cost effectiveness of SCR for
Mexico, it is reasonable to conclude that SCR is cost prohibitive for the Blanco C/D units.

Solar Turbines
A Caterpillar Company

Solar Turbines Incorporated

9330 Sky Park Court
San Diego, CA 92123
Tel: (858) 694-1616

Submitted Electronically

September 9, 2024

Subject: **Solar Compressor Sets - NOx Reductions per NM Regional Haze Rule Requirements**

There are very few gas turbine compressor sets in the world equipped with SCR systems. While a 90% NOx reduction rate is generally applicable to base-loaded generator sets producing electrical energy usually in combined cycle or cogeneration configurations, the same NOx reduction cannot be assumed for compressor sets which operate in simple cycle mode and experience variable loads swings as part of normal operations.

For reference, there are two compressor stations in Virginia with Solar Turbines equipped with SCR systems. NOx limits for these stations are based on approximately a 60% reduction from the SCR systems. 60-80% NOx reduction is a more realistic range of NOx reduction achievable with SCRs placed on gas turbine compressor sets.

The Solar Centaur 40 and Mars 100 gas turbines at South Carlsbad Station and the Chaco Gas Plant, respectively are of the vintage diffusion flame version of gas turbines which have higher NOx emissions than modern dry-low emissions (DLE) gas turbines sold today. Solar offers upgrades for these turbines to DLE versions (termed 'SoLoNOx' – Solar's DLE system) which will reduce NOx emissions greater than SCR systems with the added benefit of avoiding NH3 emissions which are produced by the SCR process. The SoLoNOx upgrades will also be less costly and require much less unit downtime than SCR installation.

Specifically, Solar offers SoLoNOx upgrades on these units to levels of 15 ppm NOx for the Centaur 40 and to 9 ppm NOx for the Mars 100. The SoLoNOx levels represent NOx reductions of greater than 90% from the existing diffusion flame configurations.

In summary, upgrading the existing Solar turbines at South Carlsbad Station and the Chaco Gas Plant to modern SoLoNOx combustion systems is a more cost-effective and environmentally beneficial solution than retrofitting to SCR.

Please call me at 858.505.8554 if you have any questions.

Sincerely,

Anthony Pocengal

Re: Revisions to the New Mexico Environment Department's Regional Haze Draft State Implementation Plan and Companion Rule 20.2.68 NMAC.

Dear Ms. Chavez and Mr. Hirsch,

The Western Environmental Law Center, on behalf of Citizens Caring for the Future, Conservation Voters New Mexico, Diné C.A.R.E., National Parks Conservation Association, New Mexico Interfaith Power and Light, Sierra Club, and San Juan Citizens Alliance (Conservation Groups), respectfully submits the following comments on and recommendations for the New Mexico Environment Department's (NMED) draft revisions to the Regional Haze State Implementation Plan (SIP) for the second planning period and companion rule, 20.2.68 NMAC.

While Conservation Groups generally support the revised draft SIP, we urge NMED to address the issues raised below. Specifically, while we do not oppose NMED's changes to the control efficiency for selective catalytic reduction (SCR) controls at intermittently operated sources and use of the Chemical Engineering Plant Cost Indices (CEPCI), NMED must further revise its control cost analyses to correct other control cost parameters that affect the cost-effectiveness of controls analyzed. NMED adopted shortened remaining useful lives for a number of the controls analyzed even though the revised SIP does not indicate that there are federally enforceable requirements that justify the use of a shortened useful life. NMED also used interest rates that are higher than the current bank prime rate of 7.5%. Thus, many of the controls analyzed are likely

much more cost-effective than NMED's analyses in the revised SIP currently show. Additionally, NMED's use of 90% control efficiency for SCR on gas-fired combustion turbines was well supported, and NMED must provide additional source-specific information to support the reduction in control efficiency for each facility for which it reduced the SCR control efficiency. In accordance with the discussion below, we request that NMED amend its control cost analyses to accurately reflect the cost-effectiveness of controls analyzed.

I. NMED Should Use a Longer Remaining Useful Life for Controls Analyzed.

When determining the reasonable progress measures for a source, NMED must consider four factors: the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of the source.[1] As EPA has explained, "[t]he remaining useful life factor is closely related to the cost of compliance factor, with the calculated cost of compliance generally increasing with a shorter remaining useful life."[2] Thus, to assume a shortened remaining useful life, the state must provide a federally enforceable requirement for the facility to shutdown or some other enforceable requirement to justify the shortened remaining useful life.[3]

Here, NMED assumed a shorter remaining useful life for a number of the controls analyzed than what other agencies, including EPA, and facilities use to assess these controls. For example, NMED adopted a 20-year remaining useful life when assessing selective catalytic reduction (SCR) controls for gas-fired combustion turbines. However, EPA has found that SCR on gas-fired turbines in an industrial setting has a remaining useful life of 25 years.[4] NMED similarly assumed a 20-year remaining useful life for dry low NOx burners (DLN) on combustion

[3] *Id.* at 34 (explaining that, "[i]n the situation of an enforceable requirement for the source to cease operation before the end of the useful life of the controls under consideration, a state may use the enforceable shutdown date as the end of the remaining useful life," as long as the SIP includes the shutdown date (citing 40 C.F.R. § 51.308(f)(2)); Memorandum from Peter Tsirigotis, Dir., Env't Prot. Agency, to Reg'l Air Dirs., Regions 1-10 at 10 (July 8, 2021), https://www.epa.gov/system/files/documents/2021-07/clarifications-regarding-regional-haze-state-implementation-plans-for-the-second-implementation-period.pdf (explaining that, if a state relied on a source shutdown or retirement to, for instance, "shorten the remaining useful life of a source," then that source retirement is "necessary to make reasonable progress and must be included in a SIP").
[4] Vicki Stamper & Megan Williams, Oil and Gas Sector Reasonable Progress Four-Factor Analysis of Controls for Five Source Categories at 76 (March 6, 2020) [hereinafter "Oil and Gas 4FA Report"] (citing Envtl. Prot. Agency, Air Pollution Control Cost Manual, Section 4: NOx Controls, Chapter 2: Selective Catalytic Reduction at PDF 80 (2019), https://www.epa.gov/sites/default/files/2017-12/documents/scrcostmanualchapter7thedition_2016revisions2017.pdf [hereinafter "CCM SCR Chapter"). The Oil and Gas 4FA Report is attached to these comments as Exhibit 1.

turbines, but these controls should have a 25-year remaining useful life.[5] For gas-fired lean burn reciprocating internal combustion engines (RICE) with low emission combustion (LEC), NMED used a remaining useful life of 20 years when these controls should have a useful life of 25 years.[6] At the very least, NMED must assume a useful life that is equivalent to RICE without LEC. Finally, NMED adopted a short 20-year remaining useful life for gas-fired boilers with SCR at the Cunningham Station Power Plant, despite the fact that there is ample support for a 30-year useful life for SCR on these sources, including EPA's Control Cost Manual (CCM).[7]

Yet, nothing in the revised SIP indicates that any federally enforceable requirements justify the use of a shortened remaining useful life for these controls at any of the sources analyzed. NMED must revise the remaining useful life used in its control cost analyses to accurately reflect the expected and proven useful life of these controls. By correcting the remaining useful life for controls considered, NMED would likely find that the controls are much more cost-effective than the revised SIP currently shows.

II. NMED's Use of an 8.5% Bank Prime Interest is Inappropriate.

Conservation Groups urge NMED to revise its calculations to reflect a more current bank prime interest rate. Throughout its analysis, NMED applies a default interest rate of 8.5%, unless a different rate is specified by an operator. Although this rate was appropriate when NMED initially performed its analysis,[8] the bank prime interest rate has dropped by a full percentage point,[9] rendering capital investment markedly more cost effective than it would have been a year ago. NMED should adopt a default interest rate of 7.5% and revise its calculations accordingly.

Additionally, for the facility-provided interest rates, NMED must ensure that the facilities have adequately documented and supported the claimed interest rates to support the control cost analyses. The Regional Haze Rule requires that NMED "must document the technical basis, including . . . cost, engineering, and emissions information, on which the State is relying to determine the emission reduction measures that are necessary to make reasonable progress."[10] Some of the facility-specific interest rates on which NMED relies in the revised SIP are

[6] Notably, several New Mexico sources assumed a 25-year remaining useful life in their facility-submitted four-factor analyses for LEC, demonstrating that LEC can achieve a longer useful life than NMED assumed in its analyses. *See, e.g.*, NM Env't Dep't, State of New Mexico Revised Proposed Reginoal Haze State Implementation Plan Revision Second Planning Period (2019-2028) at PDF 1264, 1268-69, 1271, 1299 (revised Dec. 13, 2024) (Clean) [hereinafter "Clean Revised SIP"] (Mountainair Compressor Station No. 7 four-factor analysis stating that LEC controls have a 25-year remaining useful life); *id.* at 1318, 1326, 1368 (Roswell Compressor Station four-factor analysis stating that LEC controls have a 25-year remaining useful life).

[7] CCM SCR Chapter at PDF 80 (noting a 30-year remaining useful life for SCR on power plant turbines).

[8] NMED states that this rate was current on Oct. 31, 2023.

[9] *See, e.g.*, https://www.wsj.com/market-data/bonds/moneyrates.

[10] 40 C.F.R. § 51.308(f)(2)(iii).

significantly higher than the current bank prime interest rate,[11] which also significantly affects the cost effectiveness of the controls analyzed. Thus, NMED must ensure that the facility-specific interest rates are adequately documented, as required by the Regional Haze Rule, and if the facility rate is not properly supported, NMED must use the bank prime rate, in accordance with EPA's CCM.

III. NMED's Assumption of a 90% NOx Removal Efficiency for SCR Was Reasonable.

Although Conservation Groups do not oppose NMED's reduction of the assumed NOx removal efficiency for SCR to 80%, NMED's initial assumption of 90% was reasonable and would have resulted in greater progress towards the Regional Haze Program's natural visibility goal. Ample evidence supports that SCR can achieve up to 90% or higher control efficiency for NOx on gas-fired combustion turbines.[12] However, NMED's assumption of 80% control may be valid if a facility is operated intermittently, as incomplete combustion during start up or shut down periods can result in higher NOx emissions. Thus, to justify reducing the assumed control efficiency for SCR on gas-fired turbines to 80%, NMED must provide more information about facilities' operations to support that efficiency. Specifically, NMED must demonstrate that the gas turbines for which it switched to 80% control are, indeed, operated only intermittently based on plant-specific operating conditions for each unit.[13] Data reported by facilities indicate variability in operating hours, which may indicate intermittency, but also show that some turbines have operated at 8,000+ hours in a year,[14] which is inconsistent with intermittent operation.[15] Moreover, lower operating hours are not necessarily indicative of highly intermittent operation, as the critical variable is the time during which a facility is starting up or shutting down. Accordingly, NMED must further justify and provide adequate documentation to support its

[15] *See, e.g.*, Clean Revised SIP: App. C: Four-Factor Analyses Supporting Documentation at PDF at 330 (showing that turbine 29 at the Linam Ranch Gas Plant operated for more than 8,000 hours in all but one year from 2016 to 2022 and that turbine 31 operated for more than 8,000 hours in all years from 2016 to 2022); *id.* at PDF 362 (showing that all turbine units at the Blanco C&D Compressor Station have operated for more than 8,000 hours in the years from 2016 to 2022); *id.* at PDF 370-71 (showing that multiple turbine units at the Chaco Gas Plant operated for more than 8,000 hours for multiple years from 2016 to 2022); *id.* at PDF 381 (showing that both turbines at South Carlsbad Compressor Station operated for more than 8,000 hours in all years from 2016 to 2022); *id.* at PDF 413 (showing that multiple turbine units at the San Juan Basin Gas Plant operated for more than 8,000 hours for multiple years from 2016 to 2022).

reduction to 80% efficiency,[16] and oppose any further weakening of the NOx removal efficiency figure.

IV. Conclusion.

Conservation Groups appreciate the opportunity to comment on this revised draft SIP. We encourage NMED to apply an appropriate remaining useful life of controls and bank prime interest rate, and we oppose any further weakening of the NOx removal efficiency figure.

Sincerely,

Morgan O'Grady

March 6, 2020

EXECUTIVE SUMMARY

States are required to revise and submit revisions to their regional haze state implementation plans to make reasonable progress toward the national visibility goal, with the next revision due to the U.S. Environmental Protection Agency by July 31, 2021. In this second round of regional haze plans, each state needs to look broadly at the sources of visibility-impairing emissions within its state and determine the sources or source categories for which to conduct a four-factor analysis of emission reducing measures. Oil and gas development is a significant source of visibility-impairing emissions in many states, including emissions of nitrogen oxides (NOx), volatile organic compounds (VOCs), sulfur dioxide (SO_2), and particulate matter (PM).

This report conducts a four-factor analysis of reasonable progress controls for five air emission source categories within the oil and gas development industry: natural gas-fired reciprocating internal combustion engines (RICE), natural gas-fired combustion turbines, diesel-fired RICE, natural gas-fired heaters and boilers, and flaring. This report includes a compilation of information on available pollution control options for visibility-impairing pollutants, provides cost of controls (where available) and documents the cost effectiveness of controls for various size units and a range of operating levels. The report also provides information for specific pollution controls regarding the three other reasonable progress factors: the time necessary for compliance to install the controls, the energy and non-air quality environmental impacts of the controls, and the remaining useful life of both the source category and the pollution control in question, if it differs from that of the source category.

With respect to the cost of controls, the authors used control cost data that were relied upon by federal, state, and local air agencies. Also, capital costs of control were amortized based on the expected useful life of the unit unless a shorter useful life of the specific pollution control was expected, all of which is documented in the report. The authors did not escalate costs to current dollars, because in many cases, the cost information was more than five years old, and EPA's Control Cost Manual cautions against attempting to escalate costs more than five years from the original cost analysis. Last, the authors compiled information on federal, state, and local air emission limitations that were required to be met by existing sources and thus required a retrofit of pollution controls to the source category. This assessment includes an evaluation of the lowest emission limits required of existing sources by state and local agencies and correlates those emission limits to specific pollution controls. Looking to state regional haze plans, the authors note that determinations of cost effectiveness for a particular source category should be based on the costs that similar sources have had to incur to meet Clean Air Act requirements.

Although the authors attempted to identify the pollution control methods that were both cost effective and the most effective at reducing visibility-impairing emissions and evaluated varying levels of operation, it is recognized that air pollution control determinations to retrofit existing sources cannot always be implemented via a "one-size-fits-all" approach. Thus, in some cases, a few different options for retrofit pollution controls are recommended for a source category, with the primary reasons for differentiating recommended pollution controls being based on size of the unit and/or operating capacity factor. Below the authors summarize the pollution controls that are presumed to be the best control options for each source category, with a focus on NOx pollution controls.

Summary of Cost Effective Control Options for Air Emissions Sources of the Oil and Gas Sector

SOURCE CATEGORY	NOx POLLUTION CONTROL	NOx COST EFFECTIVENESS ($/TON)	PERCENT NOx REMOVAL, AND EMISSION RATES	OTHER POLLUTION CONTROLS
Natural Gas (NG)-Fired RICE Compressors	Replace with Electric Compressors	$1,228–$2,766/ton (2011 $)	100% Removal of NOx and All Other Pollutants	Power Compressors with Renewable Energy
NG-Fired RICE Rich Burn >50 hp	Nonselective Catalytic Reduction (NSCR) and Air Fuel Ratio Controller (AFRC)	$44–$3,383/ton (2009$)	94–98% 11–67 ppmv 0.16–1.0 g/hp-hr	VOC Controls integrated into NSCR.
NG-Fired RICE Lean Burn >50 hp	Low Emission Combustion (LEC)	$47–$941/ton (2001$)	87–93% 75–150 ppmv 1.0–2.0 g/hp-hr	Oxidation Catalyst for VOC Emissions
	Selective Catalytic Combustion (SCR)	$628–$13,567/ton (1999$–2001$)	90–99% 11–73 ppmv 0.15–1.0 g/hp-hr	
NG-Fired Combustion Turbines	SCR (alone or with Dry Low NOx Combustion)	$566–$13,238/ton (1999–2000$)	80–95+% 3-15 ppmv	Oxidation Catalyst for VOC Emissions
	Dry Low NOx Combustion	$208–$2,140/ton (1999$–2000$)	80–95% 9-25 ppmv	
Diesel-Fired RICE	Use Electric Engines and Tier 4 Gen Sets ---------- OR Replace Older Engines w/ Tier 4	$564–$9,921/ton (2010$)	94% 0.5 g/hp-hr ---------- 49%–96% 0.3-3.5 g/hp-hr	Catalytic Diesel Particulate Filter For PM (81%-97.5% control) Use of Ultra-Low Sulfur Diesel Fuel
	Replace w/ NG RICE	Implemented by several companies	85–94%	
	Retrofit with SCR	$3,759–$6,781/ton	90%	
Heaters/Boilers >20 MMBtu/hr	Ultra-Low NOx Burners (ULNB)	$545–$3,270/ton (2018$)	93% 6 ppmv	Other Options: Lower heater-treater temperatures Install insulation on separators
	SCR	$1,025–$6,149/ton (2018$)	97% 2.5 ppmv	
Heaters/Boilers >5 and ≤20 MMBtu/hr	ULNB	$727–$5,232/ton (2018$)	93% 6 ppmv	
Heaters/Boilers ≤5 MMBtu/hr	Replacement of Heater with New Unit with ULNB	$4,055-$10,809/ton (2005$)	82–89% 9-20 ppmv	

Note: The range of cost effectiveness for each control reflects a range of capacities of emission units and also reflects a wide range of operating hours per year. Refer to the report for more details.

As shown in the table above, there are technically feasible and cost effective options to control NOx, VOCs, PM, and SO2 from these four source categories of combustion-related emissions from the oil and gas sector and, in most cases, there are many examples of state and local air agency rules that require these or similar levels of control for existing sources. While many of these state and local rules were adopted to address the National Ambient Air Quality Standards (NAAQS), cost effectiveness of controls is generally part of the rulemaking process under reasonably available control technology (RACT) and best available retrofit control technology (BARCT – which applies in California) determinations. Given that state and local air agencies have found the costs of these controls to be reasonable for imposition of various pollution control requirements, these costs should be considered reasonable to impose to meet other Clean Air Act requirements including under the Regional Haze Program.

For flaring of waste gases, the following control options are recommended:

- Prevent flaring of excess gases through capture and use requirements instead of flaring
- Prevent flaring at gas sweetening and other processing plants by proper maintenance, training, installing duplicative equipment to minimize upsets
- Require documentation of flaring episodes with all relevant info to estimate emissions and to assess causes and actions to mitigate
- Thermal incineration should be considered in lieu of flaring due to ability for improved VOC destruction and available NOx and SO2 controls (if sour/acid gas is being combusted)

The ultimate goal to reduce VOC, NOx, PM, and SO2 emissions from excessive flaring should be to eliminate or minimize flaring to the maximum extent possible and to use, and not waste, excess gas produced.

I. BASIS FOR REASONABLE PROGRESS CONTROLS

Under the Regional Haze Rule (RHR), states are required to revise and submit periodic comprehensive revisions to their regional haze plans, with the next revision due to be submitted to the U.S. Environmental Protection Agency (EPA) by July 31, 2021.[1] This next round of regional haze plans is referred to as the regional haze plan for the second implementation period. States' regional haze plans address regional haze in all Class I areas within the state and in all Class I areas located outside the state that may be affected by emissions from within the state.[2] Each state's plan and plan revision must include, among other things, a long term strategy which is to be determined as follows:

> Each State must submit a long-term strategy that addresses regional haze visibility impairment for each mandatory Class I Federal area within the State and for each mandatory Class I Federal area located outside the State that may be affected by emissions from the State. The long-term strategy must include enforceable emissions limitations, compliance schedules, and other measures that are necessary to make reasonable progress, as determined pursuant to [40 C.F.R. § 51.308] (f)(2)(i) through (iv). In establishing its long-term strategy for regional haze, the State must meet the following requirements:
>
> (i) The State must evaluate and determine the emission reduction measures that are necessary to make reasonable progress by considering the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment. The State should consider evaluating major and minor stationary sources or groups of sources, mobile sources, and area sources. The State must include in its implementation plan a description of the criteria it used to determine which sources or groups of sources it evaluated and how the four factors were taken into consideration in selecting the measures for inclusion in its long-term strategy. In considering the time necessary for compliance, if the State concludes that a control measure cannot reasonably be installed and become operational until after the end of the implementation period, the State may not consider this fact in determining whether the measure is necessary to make reasonable progress.
>
> . . .

40 C.F.R. § 51.308(f)(2)(i).

The requirement for evaluation of emission reduction measures quoted above is generally referred to as a "four-factor analysis" or a "reasonable progress analyses" of controls. To reiterate, the four factors that must be considered when evaluating reasonable progress controls for a source are (1) cost of compliance, (2) time necessary for compliance, (3) the energy and non-air quality environmental impacts of compliance, and (4) the remaining useful life of the source. In the first round of regional haze plans, States were required to evaluate and impose emission limitations that reflect "best available

[1] 40 C.F.R. § 51.308(f).
[2] *Id.*

retrofit technology" (BART) at all BART-subject sources (which were clearly defined by regulation). States also were required to identify sources to control in order to make reasonable progress towards the national visibility goal; for these sources states tended to focus on the larger single sources of emissions, as was also the focus of BART controls. In the second round of regional haze plans, each state needs to look more broadly at the sources of visibility-impairing emissions within its state and determine the sources or source categories for which to conduct a four-factor analysis of controls. Each state must adopt emission-reduction measures in its regional haze plan developed for the second implementation period to make reasonable progress towards the national visibility goal. The Clean Air Act (CAA) mandated that regional haze plans must address sources of "emissions from which may reasonably be anticipated to cause or contribute to ***any*** impairment of visibility" (emphasis added)).[3]

Air emissions from oil and gas development, production, treatment, and transmission represent a significant quantity of regional haze-impairing emissions in many states. Air emissions from oil and gas development that can impact visibility include nitrogen oxides (NOx), sulfur dioxide (SO_2), directly emitted particulate matter (PM), volatile organic compounds (VOCs), and ammonia. NOx, SO_2, VOCs, and ammonia, initially emitted as gases, often convert into fine (i.e., less than 2.5 micrometers in diameter) particulate matter ($PM_{2.5}$) in the atmosphere, which can travel far and which are very efficient in scattering light and impacting visibility. Oil and gas development often occurs on federal, state, and/or private lands near or even adjacent to Class I areas. Oil and/or gas development tends to be clustered in certain areas where such fossil fuels are found. Many of the air emissions sources associated with gas and/or oil production are minor sources, not large enough in emissions to trigger new source review permitting. However, such sources collectively are often significant contributors to visibility impairment in Class I areas due to sheer numbers of emission sources or proximity to Class I areas, or both.

In the United States, oil and gas production has been increasing and is projected to continue to increase in the future. States with significant increases in oil production since 2013 include Colorado with almost a tripling of production since 2013, New Mexico with more than a doubling of production since 2013, Texas with a 73% increase in production since 2013, and North Dakota with a 48% increase since 2013.[4] States with significant increases in gas production include, among others, Ohio with annual gas production in 2018 that is more than 14 times higher than it was in 2013, West Virginia with a 143% increase in gas production since 2013, North Dakota with a doubling of production in 2018 compared to 2013, Pennsylvania with a 91% increase in gas production since 2013, and New Mexico with a 27% increase in gas production since 2013.[5] The U.S. Energy Information Administration (EIA) currently projects crude oil production in the United States to be 25% higher in 2021 than it was in 2018[6] and marketed gas production in the United States to be 13% higher in 2021 than it was in 2018.[7] In many areas of the country, these increases in production are projected to continue well into the future. For

example, the New Mexico Oil and Gas Association recently presented a report to state lawmakers indicating that there will be "solid growth for the next decade or so" in the Permian Basin.[8]

There are several combustion-related sources of visibility-impairing emissions associated with oil and gas development. Various engines, typically fired by natural gas or diesel, are used in the drilling and completion phase, in the processing of natural gas, and at compressor stations. On-site power sources are often used, in the form of natural gas-fired engines, diesel generators, and/or combustion turbines. Natural gas-fired boilers and heaters are also used throughout the oil and gas production and process segments of the industry, to generate power, and to create steam and process heat. Those engines and combustion turbines emit significant quantities of NOx and VOCs and also of SO_2 and PM for diesel-fired engines. Flaring of excess and waste gas can be a significant source of SO_2 and NOx emissions.

This report presents a four-factor analysis of reasonable progress controls for NOx and VOCs, and SO_2 and PM as appropriate, for five significant air emissions source categories associated with oil and gas development: natural gas-fired reciprocating internal combustion engines (RICE), natural gas-fired combustion turbines, diesel-fired RICE, natural gas-fired boilers and heaters, and flaring/incineration of waste or excess gas. This report (1) proposes pollution controls and/or measures for such sources considering the control technology available and the most effective controls; (2) compiles cost data with a focus on data relied upon by federal, state, and local air agencies in regulatory decisions; (3) evaluates non-air quality environmental and energy impacts of controls; and (4) considers the remaining useful life of the equipment.

It is important to note that, while New Source Performance Standards (NSPS) exist for these source categories, the existence of an NSPS does not negate the need for a four-factor analysis of controls to achieve reasonable progress towards the national visibility goal for several reasons. First, it has been many years since the NSPS standards for RICE units, gas turbines, and small boilers have been re-evaluated. Although EPA correctly states in its 2019 Regional Haze guidance that "[t]he [CAA] requires EPA to review, and if necessary, revise NSPS every 8 years,"[9] EPA has not always updated the NSPS emission standards for a source category in accordance with this timetable. Second, the NSPS emission standards only apply to a facility if it is constructed, modified, or reconstructed after the applicability date.[10] The applicability date of an NSPS (or of a revised NSPS emission standard) is set as either the date of publication of any proposed or of any final rulemaking establishing the standard. Third, when EPA adopts or revises NSPS for a source category, EPA is establishing an emission standard applicable to all of the source types and variable fuels, operating conditions, etc. that exist for that source category. Thus, the NSPS are generally applicable emission standards and not a source-specific evaluation of controls.

Further, while EPA's Regional Haze guidance states that, if a new or modified unit is subject to and complying with an NSPS promulgated or reviewed since July 31, 2013, it is unlikely that new or existing controls are available or more effective, no such assumption should be made without considering the

[8] As discussed in Report: New Mexico oil, gas boom to continue, by Susan Montoya Bryan/Associated Press, September 3, 2019, Albuquerque Journal, *available at:* https://www.abqjournal.com/1361629/report-new-mexico-oil-gas-boom-to-continue.html.

[9] EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, August 20, 2019, at 23, note 44.

[10] *See* 40 C.F.R. § 60.1(a); *see also* definitions in § 60.2 and regulations on "modification" and "reconstruction" in §§ 60.14 and 60.15.

specific emission and operational characteristics of the source in question. EPA's statements are problematic and need clarification. One cannot simply determine the last time the NSPS for a source category was amended and assume that if the amendments occurred within the last eight years, the NSPS is up to date. Section 111(b)(1)(B) of the CAA requires EPA to review and revise each NSPS at least every eight years, to essentially determine if the NSPS currently reflect the "degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated."[11] EPA amends its NSPS for various reasons (e.g., changes in test methods or protocols, clarifications), but thorough reviews and revisions generally occur much less frequently — in many cases less frequently than every eight years as required by the CAA. Table 1 below shows the NSPS applicable to RICE units, turbines, and small boilers and provides the most recent date of EPA's comprehensive review and revision. The NSPS rules applicable to RICE units and gas turbines were last subject to a comprehensive revision to reflect the best-demonstrated technology well before July 31, 2013.

Table 1. NSPS Categories that Address RICE, Natural Gas Turbines, and Small Boilers

NSPS Subpart in 40 C.F.R. Part 60	Emission Source(s)	Date of Promulgation of Most Recent Revisions
Dc	Small Industrial-Commercial-Institutional Steam Generating Units	2/27/06 (reflects most recent review of the emission standards)
GG	Stationary Gas Turbines	9/20/79 (first promulgation of NSPS for gas turbines and revised standards promulgated at Subpart KKKK)
IIII	Stationary Compression Ignition Internal Combustion Engines	6/28/11 (reflects most recent adoption of emission standards for this source category)
JJJJ	Stationary Spark Ignition Internal Combustion Engines	1/18/08 (NSPS for source category first promulgated, and reflects most recent review of emission standards)
KKKK	Stationary Combustion Turbines constructed, reconstructed or modified after 2/18/05	7/6/2006 (first promulgation of NSPS Subpart KKKK, and reflects most recent review of emission standards)
OOOO	Crude Oil and Natural Gas Production, Transmission, and Distribution for which Construction. Modification, or Reconstruction Commenced after 8/23/11 and on or before 9/15/15	6/3/2016 (reflects most recent review the emission standards)
OOOOa	Crude Oil and Natural Gas Production, Transmission, and Distribution from which Construction. Modification, or Reconstruction Commenced after 9/18/15	6/3/2016 (NSPS Subpart first promulgated)

[11] *See* Section 111(a)(1) of the Clean Air Act, 42 U.S.C. § 7411(a)(1).

Thus, while the NSPS may be a place to start in evaluating pollution controls for air emissions sources associated with the oil and gas industry, it is also necessary to evaluate if more stringent requirements and pollution controls have been required in state rules or local air rules, air permits, or other requirements. Review of state regulations and state implementation plans, particularly to address national ambient air quality standards (NAAQS) which requires reductions in emissions from existing sources, is necessary to fully evaluate controls for emission sources associated with oil and gas development to achieve reasonable progress towards the national visibility goal.

The information provided below reflects a comprehensive review of the pollution controls and techniques and associated emissions levels applicable to each of the source categories, along with data on cost of controls where available, non-air quality environmental and energy impacts, and the reasonable useful life of the emission source being evaluated.

II. CONTROL OF NOx EMISSIONS FROM NATURAL GAS-FIRED RECIPROCATING INTERNAL COMBUSTION ENGINES

Reciprocating internal combustion engines (RICE) are used in a variety of applications, including gas compression, pumping, and power generation. RICE can either be: (1) spark-ignited and fueled by natural gas, propane, or gasoline; or (2) compression-ignited and fueled by diesel. Spark-ignition engines fueled by natural gas, propane, and gasoline can operate lean (i.e., with a higher air-to-fuel ratio) or rich (i.e., with a lower air-to-fuel ratio). Compression-ignition diesel-fueled engines operate lean. A rich-burn engine operates with excess fuel during combustion, whereas a lean-burn engine operates with excess air.

Natural gas-fired RICE are the focus of this section and are used throughout the oil and gas industry, as described by EPA:

> Most natural gas-fired reciprocating engines are used in the natural gas industry at pipeline compressor and storage stations and at gas processing plants. These engines are used to provide mechanical shaft power for compressors and pumps. At pipeline compressor stations, engines are used to help move natural gas from station to station. At storage facilities, they are used to help inject the natural gas into high pressure natural gas storage fields. At processing plants, these engines are used to transmit fuel within a facility and for process compression needs (e.g., refrigeration cycles). The size of these engines ranges from 50 brake horsepower (bhp) to 11,000 bhp. In addition, some engines in service are 50–60 years old and consequently have significant differences in design compared to newer engines, resulting in differences in emissions and the ability to be retrofitted with new parts or controls.
>
> At pipeline compressor stations, reciprocating engines are used to power reciprocating compressors that move compressed natural gas (500–2000 [pounds per square inch gauge (psig)]) in a pipeline. These stations are spaced approximately 50 to 100 miles apart along a pipeline that stretches from a gas supply area to the market area. The reciprocating compressors raise the discharge pressure of the gas in the pipeline to overcome the effect of frictional losses in the pipeline upstream of the station, in order to maintain the required

> suction pressure at the next station downstream or at various downstream delivery points. The volume of gas flowing and the amount of subsequent frictional losses in a pipeline are heavily dependent on the market conditions that vary with weather and industrial activity, causing wide pressure variations. The number of engines operating at a station, the speed of an individual engine, and the amount of individual engine horsepower (load) needed to compress the natural gas is dependent on the pressure of the compressed gas received by the station, the desired discharge pressure of the gas, and the amount of gas flowing in the pipeline. Reciprocating compressors have a wider operating bandwidth than centrifugal compressors, providing increased flexibility in varying flow conditions. Centrifugal compressors powered by natural gas turbines are also used in some stations and are discussed in another section of this document.[12]

Natural gas-fired reciprocating engines are also used at well sites across the oil and gas industry in various applications including, e.g., reciprocating compressors and pump engines used to lift oil out of a well.

Natural gas-fired RICE can be classified as two-stroke or four-stroke engines. In a two-stroke engine, the power cycle occurs in a single crankshaft revolution and two strokes: an intake/compression stroke; and a power/exhaust stroke. In a four-stroke engine, the power cycle is completed with two crankshaft revolutions and four strokes: an intake stroke; compression stroke; power stroke; and exhaust stroke. Natural gas-fired RICE units encompass three engine types or classes:

1. Two-stroke lean-burn (2SLB)
2. Four-stroke lean-burn (4SLB)
3. Four-stroke rich-burn (4SRB)

NOx emissions from RICE are highly dependent on combustion temperature, with higher temperatures resulting in more NOx emissions. Rich-burn engines operate with an air-to-fuel ratio (A/F) that is rich with fuel resulting in higher fuel use, increased combustion temperatures, increased engine power, and decreased engine efficiency relative to a lean-burn engine. Lean-burn engines operate with an A/F that is lean with fuel resulting in less fuel use, decreased combustion temperatures, decreased engine power, and increased engine efficiency relative to a rich burn engine.

UNITS

NOx emissions from RICE are generally expressed as emission rates in grams per brake horsepower hour (g/bhp-hr) or as a concentration in parts per million by volume (ppmv or ppmvd). All concentrations expressed in ppmv are on a dry basis and corrected to 15% oxygen. Emission rates expressed in g/bhp-hr and grams per horsepower-hour (g/hp-hr) are assumed to be roughly equivalent for the RICE applications in this section. The following conversion factors from EPA's Updated Information on NOx Emissions and Control Techniques document* are used in this section:

[12] EPA, AP-42, Fifth Edition, Volume 1, Chapter 3: Stationary Internal Combustion Sources.

Uncontrolled rich-burn Spark-Ignition (SI) engines and rich-burn engines controlled with nonselective catalytic reduction (NSCR)……..67 ppmv = 1 g/bhp-hr Uncontrolled lean-burn engines, lean-burn engines controlled with selective catalytic reduction (SCR), and rich-burn engines controlled with prestratified charge™ (PSC) technology……73 ppmv = 1 g/bhp-hr Lean-burn engines controlled with Low Emission Combustion (LEC) Technology……..75 ppmv = 1 g/bhp-hr * EPA, Stationary Reciprocating Internal Combustion Engines Updated Information on NOx Emissions and Control Techniques, September 2000 (EPA-457/R-00-001)

A. RICH-BURN RICE: COMBUSTION CONTROLS

Emission control technologies for RICE depend on the A/F and therefore different controls apply to different engine types. NOx emissions reductions from these engines can be achieved through combustion controls or through post-combustion (add-on) controls. The following retrofit combustion control technologies for rich-burn RICE are described by EPA in its *Alternative Control Techniques Document – NOx Emissions from Stationary Reciprocating Internal Combustion Engines*, and EPA's descriptions are reprinted below:[13]

Rich-Burn A/F Adjustments

> Adjusting the A/F toward fuel-rich operation reduces the oxygen available to combine with nitrogen, thereby inhibiting NOx formation. The low-oxygen environment also contributes to incomplete combustion, which results in lower combustion temperatures and, therefore, lower NOx formation rates. The incomplete combustion also increases [carbon monoxide (CO)] emissions and, to a lesser extent, [hydrocarbons (HC)] emissions. Combustion efficiency is also reduced, which increases brake-specific fuel consumption (BSFC). Excessively rich A/F's may result in combustion instability and unacceptable increases in CO emissions.
>
> The A/F can be adjusted on all new or existing rich-burn engines. Sustained NOx reduction with changes in ambient conditions and engine load, however, is best accomplished with an automatic A/F control system.
>
> The achievable NOx emission reduction ranges from approximately 10 to 40 percent from uncontrolled levels. Based on an average uncontrolled NOx emission level of 15.8 g/hp-hr (1,060 ppmv), the expected range of controlled NOx emissions is from 9.5 to 14.0 g/hp-hr (640

[13] EPA-453/R-93-032 *Alternative Control Techniques Document – NOx Emissions from Stationary Reciprocating Internal Combustion Engines* (July 1993), *available at*: https://www3.epa.gov/airquality/ctg_act/199307_nox_epa453_r-93-032_internal_combustion_engines.pdf [hereinafter referred to as "EPA 1993 Alternative Control Techniques Document for RICE"].

> to 940 ppmv). Available data show that the achievable NOx reduction using A/F varies for each engine model and even among engines of the same model, which suggests that engine design and manufacturing tolerances influence the effect of A/F on NOx emission reductions.[14]

NOx Removal Efficiency:	*10-40%*
Controlled NOx Emission Rates:	*9.5 to 14.0 g/hp-hr*
	640 to 940 ppmv

Rich-Burn Ignition Timing Retard (IR)

> Ignition timing retard delays initiation of combustion to later in the power cycle, which increases the volume of the combustion chamber and reduces the residence time of the combustion products. This increased volume and reduced residence time offer the potential for reduced NOx formation. . . .
>
> Ignition timing can be adjusted on all new or existing rich-burn engines. Sustained NOx reduction with changes in ambient conditions and engine load, however, is best accomplished using an electronic ignition control system.
>
> The achievable NOx emission reduction ranges from virtually no reduction to as high as 40 percent. Based on an average uncontrolled NOx emission level of 15.8 g/hp-hr (1,060 ppmv), the expected range of controlled NOx emissions is from 9.5 to 15.8 g/hp-hr (640 to 1,060 ppmv). Available data and information provided by engine manufacturers show that, like AF, the achievable NOx reductions using IR are engine-specific.[15]

NOx Removal Efficiency:	*0-40%*
Controlled NOx Emission Rates:	*9.5 to 15.8 g/hp-hr*
	640 to 1,060 ppmv

A/F adjustment and IR can be employed together to reduce NOx emissions from rich-burn RICE. According to EPA, the achievable emissions reductions are similar to that for A/F adjustments (i.e., 10-40%) but may offer the potential to minimize some of the adverse impacts of other operating parameters (e.g., CO emissions, engine response, fuel consumption).[16]

Limited cost data indicate that combustion controls for rich-burn RICE costs between $400 to $1,000 per ton of NOx reduced for engines greater than 500 horsepower (hp).[17]

---

[14] *Id.* at 2-5.
[15] *Id.* at 2-5 and 2-9.
[16] *Id.* at 2-9.
[17] *Id.* at 2-30. *See also* California Air Resources Board (CARB) Determination of Reasonably Available Control Technology and Best Available Retrofit Control Technology for Stationary Spark-Ignited Internal Combustion Engines, November 2001, Table V-2 at V-3, *available at*: https://ww3.arb.ca.gov/ractbarc/rb-iceall.pdf [hereinafter referred to as "CARB 2001 Guidance"]. The CARB cost effectiveness analysis assumes the engines are run at 100% load for 2,000 hours per year, annualized costs are figured based on an interest rate of 10% over a 10-year life.

B. RICH-BURN RICE: PRESTRATIFIED CHARGE (PSC)

Prestratified charge (PSC) is a combustion modification that converts rich-burn engines to lean-burn engines by retrofitting the air injectors to make a leaner A/F ratio. PSC is described by EPA in its Alternative Control Techniques Document for RICE, as follows:

> This add-on control technique facilitates combustion of a leaner A/F. The increased air content acts as a heat sink, reducing combustion temperatures, thereby reducing NOx formation rates. Because this control technique is installed upstream of the combustion process, PSC® is often used with engines fueled by sulfur-bearing gases or other gases (e.g. sewage or landfill gases) that may adversely affect some catalyst materials.
>
> Prestratified charge applies only to four-cycle, carbureted engines. Pre-engineered, "off-the-shelf" kits are available for most new or existing candidate engines, regardless of age or size. According to the vendor, PSC® to date has been installed on engines ranging in size up to approximately 2,000 hp.
>
> The vendor offers guaranteed controlled NOx emission levels of 2 g/hp-hr (140 ppmv), and available test data show numerous controlled levels of 1 to 2 g/hp-hr (70 to 140 ppmv). The extent to which NOx emissions can be reduced is determined by the extent to which the air content of the stratified charge can be increased without excessively compromising other operating parameters such as power output and CO and HC emissions. The leaner A/F effectively displaces a portion of the fuel with air, which may reduce power output from the engine. For naturally aspirated engines, the power reduction can be as high as 20 percent, according to the vendor. This power reduction can be at least partially offset by modifying an existing turbocharger or installing a turbocharger on naturally aspirated engines. In general, CO and HC emission levels increase with PSC®, but the degree of the increase is engine-specific. The effect on BSFC is a decrease for moderate controlled NOx emission levels (4 to 7 g/hp-hr, or 290 to 500 ppmv), but an increase for controlled NOx emission levels of 2 g/hp-hr (140 ppmv) or less.[18]

PSC NOx Removal Efficiency:	*87% (85-90%, EPA 2000)*[19]
Controlled NOx Emission Rates:	*2 g/hp-hr*
	140 ppmv

PSC NOx reduction efficiency depends on how much the air content can be increased without adversely affecting the performance of the engine; achieving lower NOx rates with PSC will result in sacrifices in engine power output. PSC, generally, can only achieve a NOx emission rate as low as 2 g/bhp-hr. EPA re-affirmed the limitations of PSC in its 2000 Updated Information on NOx Emissions and Control Techniques for RICE, stating:

---

[18] EPA 1993 Alternative Control Techniques Document for RICE at 2-9 to 2-10.

[19] EPA-457/R-00-001 *Stationary Reciprocating Internal Combustion Engines Updated Information on NOx Emissions and Control Techniques,* September 2000, *available at*: https://nepis.epa.gov/Exe/ZyPDF.cgi/P100V343.PDF?Dockey=P100V343.PDF [hereinafter referred to as "EPA 2000 Updated Information on NOx Emissions and Control Techniques"].

> The 1993 ACT document found that the achievable NOX emission level for PSC is 2.0 g/bhp-hr, based on the vendor's guarantees. This value is generally consistent with the information gathered for this project and is a representative value for the NOX emission level that can be achieved using PSC control technology.[20]

Limited cost data indicate that PSC achieving 80% NOx reduction efficiency costs between $200 to $800 per ton of NOx reduced for engines ranging in size from 50–1,500 hp.[21]

Even the best-case NOx emissions reductions for PSC are generally lower than the emissions reductions that can be accomplished with the nonselective catalytic reduction (NSCR) technologies discussed below. And NSCR also generally costs less, with capital and annual costs less than PSC for almost all engine sizes, according to data from EPA.[22] However, for fuels with higher sulfur content (e.g., waste gases), PSC technology can be effective at achieving NOx emissions reductions where higher sulfur fuels would adversely impact catalyst material used in post-combustion control technologies such as NSCR.

C. RICH-BURN RICE: NONSELECTIVE CATALYTIC REDUCTION (NSCR)

The use of NSCR technology began in the 1970s with the application of 3-way catalysts to gasoline-fueled motor vehicles in order to simultaneously control carbon monoxide, VOCs, and NOx emissions. In automobiles, the technology is known as a "catalytic convertor." Since then, NSCR has been widely applied to stationary engines. NSCR is usually also accompanied by an air/fuel ratio controller (AFRC), which is used to adjust the combustion parameters across the operating range of the engine in order to maintain the conditions needed for the efficient operation of the NSCR system (e.g., sufficient excess oxygen in the exhaust gas).

NSCR is described by EPA in its Alternative Control Techniques Document for RICE, as follows:

> Nonselective catalytic reduction is essentially the same catalytic reduction technique used in automobile applications and is also referred to as a three-way catalyst system because the catalyst reactor simultaneously reduces NO_X, CO, and HC to water (H_2O), carbon dioxide (CO_2), and diatomic nitrogen (N_2). The chemical stoichiometry requires that O_2 concentration levels be kept at or below approximately 0.5 percent, and most NSCR system require that the engine be operated at fuel-rich A/F's. . . .
>
> Nonselective catalytic reduction applies only to carbureted rich-burn engines and can be retrofit to existing installations. Sustained NOx reductions are achieved with changes in ambient conditions and operating loads only with an automatic A/F control system. . . .

[20] *Id.* at 4-21.

[21] *See* CARB 2001 Guidance at Table V-2 at V-3. The CARB cost effectiveness analysis assumes the engines are run at 100% load for 2,000 hours per year, annualized costs are figured based on an interest rate of 10% over a 10-year life.

[22] *See* EPA's 1993 Alternative Control Techniques Document for RICE Table 2-12 at 2-30.

> Catalyst vendors quote NOx emission reduction efficiencies of 90 to 98 percent. Based on an average uncontrolled NOx emission level of 15.8 g/hp-hr (1,060 ppmv), the expected range of controlled NOx emissions is from 0.3 to 1.6 g/hp-hr (20 to 110 ppmv). . . .
>
> The predominant catalyst material used in NSCR applications is a platinum-based metal catalyst. The spent catalyst material is not considered hazardous, and most catalyst vendors accept return of the material, often with a salvage value that can be credited toward purchase of replacement catalyst.[23]

NSCR NOx Removal Efficiency:	*90-98%*
Controlled NOx Emission Rates:	*0.3 to 1.6 g/hp-hr*
	20 to 110 ppmv

According to EPA, when California air district standards were tightened to 96% NOx reduction and emission limits of 25 ppmv (0.37 g/bhp-hr), facilities shifted from PSC to NSCR to meet the standard.[24] This level of NOx control can be met with an NSCR retrofit to an existing unit. For example, retrofit installations of NSCR on five Caterpillar rich burn engines in Texas achieved a NOx reduction of 96% or greater on all of the engines.[25] On two of those engines, testing conducted after more than 4,000 hours of operation with NSCR indicated the NSCR controls were still achieving a 95% NOx reduction.[26] Employing NSCR to reduce NOx emissions from EPA's uncontrolled emission rate of 15.8 g/bhp-hr to 1.0 g/bhp-hr corresponds to a NOx emission reduction efficiency of 94%. Unless otherwise noted, the analyses provided further below in this section assume a 94% NOx reduction efficiency to meet a 1 g/bhp-hr emission rate. Lower NOx emission limits have been required by some states and local agencies that reflect a higher NOx removal efficiency (see Section II.G., below).

NSCR can effectively reduce CO, HC, VOCs (include formaldehyde), as well as NOx emissions, if properly optimized for control of all these pollutants. Such systems must control the A/F carefully to provide enough oxygen to ensure that CO and VOCs are oxidized but also limit oxygen enough to ensure the NOx is effectively reduced. The oxygen content of the exhaust gas needs to be within a narrow window to ensure effective control of all three pollutants, and thus an AFRC is necessary along with an oxygen sensor to provide feedback to the AFRC to ensure the proper fuel-rich operation.

HOURS OF OPERATION FOR RICE

Stationary RICE are used in a variety of applications throughout the oil and gas sector, from providing on-site power, driving pumps or compressors, and drilling operations at well sites to driving pipeline compressor stations to powering pumps, compressors, and refrigeration at gas processing plants. Because of the varying uses for RICE units, RICE units used in the oil and gas sector cover the full

[25] OTC Technical *Information Oil and Gas Sector Significant Stationary Sources of NOx Emissions* October 17, 2012, *available at*: https://otcair.org/upload/Documents/Meeting%20Materials/Final%20Oil%20%20Gas%20Sector%20TSD%2010-17-12.pdf at 45.
[26] *Id.*

range of operating schedules. In providing cost estimates herein, this report presents cost effectiveness analyses to reflect operating as few as 2,000 hours per year and as high as 8,000 hours per year. For example, compressor stations typically operate continuously, although not all compressor engines at a compressor station operate continuously. On the other hand, RICE units used for backup onsite electrical generation may not operate much at all in a year. Thus, a low-end operating capacity factor and a high-end capacity factor were assumed to reflect a range of costs across varying levels of operation.

A cost effectiveness analysis of NSCR was performed in 2010 for EPA, to help determine national impacts associated with EPA's final rule for Reciprocating Internal Combustion Engine National Emission Standards for Hazardous Air Pollutants (RICE NESHAP).[27] The analysis, performed by E^C/R Incorporated, was based on 2009 cost data for retrofitting NSCR on existing 4SLB engines from industry groups, vendors, and manufacturers of RICE control technology. E^C/R Incorporated performed a linear regression analysis[28] on the data set to determine the following linear equation for annual cost, which includes annual operating and maintenance costs plus annualized capital costs based on a 7% interest rate and 10-year life of controls:

NSCR Annual Cost = $4.77 x (hp) + $5,697 (2009$)

The capital cost equation for retrofitting an AFRC and NSCR on a 4SRB engine was determined by E^C/R Incorporated to be, as follows:

NSCR Capital Cost = $24.9 x (hp) + $13,118 (2009$)

These relationships are derived from a data set that includes engines ranging in size from 50–3,000 hp.

The E^C/R document does not explain why it assumed a 10-year life of controls for estimating the annualized capital costs. The life of a RICE unit is generally much longer than ten years, and is often at least thirty years.[29] The assumed 10-year life was not based on the catalyst replacement timeframe, because the E^C/R operating costs took into account the cost for replacing the catalyst every three years, as well as replacing the thermocouple every 7.5 years, the crankcase filters every three months, the oxygen sensor on a quarterly basis, and rotating the catalyst for cleaning annually.[30] Thus, the assumed 10-year life of an NSCR system seems arbitrary. In cost analyses done in 2000 for EPA, an equipment life of NSCR of fifteen years was assumed.[31] The state of Colorado also recently assumed a 15-year life of

[27] Memo from E^C/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010), *available at*: https://www.epa.gov/sites/production/files/2014-02/documents/5_2011_ctrlcostmemo_exist_si.pdf.

[28] *Id.* The report notes that the linear equation has a correlation coefficient (R) of 0.7987, concluding that it "shows an acceptable representation of cost data."

[29] *See, e.g.*, EPRI, 20 Power Companies Examine the Role of Reciprocating Internal Combustion Engines for the Grid, *available at*: https://eprijournal.com/start-your-engines/. The authors also note that, in reviewing permits for gas processing facilities and compressor stations in New Mexico, it is not uncommon to have engines that were constructed from the 1950's to 1970's still operating at such facilities.

[30] Memo from E^C/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010), at 4 and at 11, 13, and 15.

[31] *See* August 11, 2000, E.H. Pechan & Associates, Inc., NOx Emissions Control Costs for Stationary Reciprocating Internal Combustion Engines in the NOx SIP Call States, at 5 and at A-2, *available at*: https://www3.epa.gov/ttn/ecas/regdata/cost/pechan8-11.pdf. *See also* EPA, Regulatory Impact Analysis for the NOx SIP Call, IP, and Section 126 Petitions, September 1998, at 5-5 (Table 5-3).

NSCR for RICE units.[32] Given that EPA assumed a selective catalytic reduction (SCR) system at an industrial fossil fuel-fired boiler has a life of 20-25 years,[33] it seems very likely that NSCR would have a useful life of at least fifteen years if not longer. For the purpose of the NSCR cost analyses presented herein, a 15-year life of the NSCR system was assumed.

In addition, a lower interest rate than 7% is assumed in determining annualized costs of controls for this report, to be consistent with EPA's Control Cost Manual which recommends the use of the bank prime interest rate.[34] The bank prime rate fluctuates over time, and the highest it has been in the past five years is 5.5%.[35] In its cost calculation spreadsheet for SCR provided with its Control Cost Manual, EPA also used an interest rate of 5.5%.[36] Thus, a 5.5% interest rate has been used for the revised cost calculations presented herein.

Table 2 shows the cost effectiveness of NSCR and an AFRC achieving 94% NOx reduction efficiency and operating at 2,000 hours per year and 8,000 hours per year, based on these cost equations from EPA's 2010 RICE NESHAP, adjusted to reflect a 5.5% interest rate and 15-year life of controls.

Note that lower NOx emission limits have been required by some states and local agencies that reflect a higher NOx removal efficiency than the 94% assumed in the table below (see Section II.G.) and the costs of employing NSCR to meet these lower limits will be even more cost effective than what is shown here.

Table 2. Cost Effectiveness to Reduce NOx Emissions from Rich-Burn RICE with NSCR and an AFRC, Based on EPA RICE NESHAP Cost Equations for Existing Stationary Spark-Ignition (SI) Engines[37]

ENGINE TYPE	SIZE, hp	ANNUALIZED COSTS OF NSCR AND AFRC, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 2,000 HR/YR, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 8,000 HR/YR, 2009$
RICH-BURN	50	$5,303	$3,251/ton	$813/ton
	200	$5,859	$898/ton	$224/ton
	500	$6,971	$427/ton	$107/ton
	1,000	$8,824	$270/ton	$68/ton
	2,500	$14,382	$176/ton	$44/ton

TABLE NOTES:

- Cost data are assumed to be in 2009$, based on E^C/R Incorporated analysis of vendor and industry group data for engines ranging from 50–3,000 hp (EPA RICE NESHAP, 2010).
- Recalculated for 15-year life of controls and 5.5% interest rate.
- Assumes 94% NOx removal efficiency.

Colorado requires emissions from rich-burn RICE greater than 500 hp be controlled using NSCR with an AFCR. This requirement applies statewide to engines for which control costs are below $5,000 per ton of NOx reduced.[38] In its initial regional haze plan, Colorado completed a Reasonable Progress Evaluation for the RICE Stationary Source Category, including a NOx emission 4-Factor analysis for reasonable progress toward the national visibility goal.[39] In its evaluation, Colorado reported that, "[f]ew of the statewide rich burn RICE demonstrated control costs exceeding the $5,000 cost off-ramp. Consequently, the state concluded that such NSCR controls are installed on the majority of rich burn RICE over 500 HP statewide."[40] Colorado further reports that "[n]one of the operators of rich burn RICE outside the [Denver] metro-area ozone non-attainment area submitted information demonstrating control costs in excess of $5,000 per ton cost threshold, consequently, the majority of natural-gas fired RB RICE over 500 HP must operate an NSCR with an AFR controller."[41]

Colorado's Reasonable Progress Evaluation for RICE listed the capital and annual operating costs for retrofitting existing engines with NSCR and an AFCR, which are reiterated in Table 3.

[37] *See* Memo from E^C/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010). Annualized costs of control were calculated using a capital recovery factor of 0.099626 (assuming a 15-year life of controls and a 5.5% interest rate). Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032) and a 94% NOx removal efficiency.

[41] *Id.* at 8.

Table 3. Capital and Operating Costs of NSCR with AFCR[42]

SOURCE CATEGORY	CAPITAL COSTS, 2003$*	ANNUAL OPERATING AND MAINTENANCE COSTS, 2003$*
RICH-BURN RICE > 500 hp	$35,000	$6,000
TABLE NOTES: *Colorado's cost estimates are from its "Denver Early Action Compact Analysis of Stationary Sources," dated 2003. Colorado does not specify, but it is assumed the cost data are from the 2003 timeframe.		

Colorado determined the annualized costs of control assuming a 15-year life of controls and indicating that, "[g]enerally the operational life of a catalyst is approximately 5 to 15 years, depending on factors such as how it is maintained and the particular duty cycle of the engine."[43] Colorado's use of a 15-year life of controls is also consistent with previous EPA analysis.[44] The annualized capital cost in Colorado's analysis of $4,851 appears to assume roughly a 10% interest rate, with total annualized costs – i.e., annualized capital costs plus annual operating and maintenance costs – of $10,851.[45] To be consistent with EPA's Control Cost Manual, which recommends the use of the bank prime interest rate, a lower interest rate than 10% is assumed in determining annualized costs of controls for this report.[46] As previously discussed, it is more appropriate to use a lower interest rate of 5.5%.[47] Thus, the cost data were revised to be consistent with the EPA's Control Cost Manual in assuming a 5.5% interest rate in amortizing the capital costs. [48]

Colorado presented the cost effectiveness of retrofitting RICE greater than or equal to 500 hp with NSCR and an AFCR based on 2008 NOx emissions reductions for 305 RICE units located outside the nonattainment area of the state. However, the more generalized approach used in this report of assuming 94% control effectiveness is consistent with Colorado's requirement that these engines – controlled with NSCR and an AFCR – meet an emission limit of 1 g/hp-hr.[49] Again, using EPA's uncontrolled emission rate of 15.8 g/bhp-hr, the NOx emissions reduction efficiency of meeting a 1 g/hp-hr NOx limit for these engines is approximately 94%.[50]

The following table shows the cost effectiveness of a 500 hp RICE unit operating at 2,000 hours per year and at 8,000 hours per year and employing NSCR and an AFRC to meet a 1 g/hp-hr NO_x limit, based on a 15-year life and 5.5% interest rate.

Table 4. Cost Effectiveness to Reduce NOx Emissions from Rich-Burn RICE with NSCR and an AFRC To Meet a 1 g/hp-hr NO_x Limit [51]

ENGINE TYPE	SIZE, hp	ANNUALIZED COSTS OF NSCR AND AFRC, 2003$	COST EFFECTIVENESS OF NSCR AND AFRC AT 2,000 HR/YR, 2003$	COST EFFECTIVENESS OF NSCR AND AFRC AT 8,000 HR/YR, 2003$
RICH-BURN	500	$9,487	$582/ton	$145/ton

TABLE NOTES:

- Cost data are assumed to be in 2003$, based on Colorado's Reasonable Progress Evaluation for the RICE Source Category.
- Analysis assumes 15-year life of controls and 5.5% interest rate.
- Analysis assumes 94% NOx removal efficiency.

NSCR for Smaller Rich-Burn RICE and Cyclically-Loaded RICE (< 500 hp)

California Air Districts have long been regulating NOx emissions from RICE, including engines smaller than 500 hp, and the California Air Resources Board (CARB) issued guidance to Air Districts in 2001 on the best available retrofit technologies for controlling NOx emissions from a broad range of stationary RICE.[52]

In the 1990s, when EPA first issued its Alternative Control Techniques document for stationary RICE, over 90% of all natural gas-fueled RICE were well pumps with an average size of 15 hp operating, on average, 3,500 hours per year.[53] Today, these smaller well pump engines likely make up a smaller share of nationwide RICE applications across the oil and gas industry, with continued growth in gas production and associated compression and processing applications. However, NOx emissions from these smaller pumping engines, on a regional scale, can be significant. For example, NOx emissions from artificial lifts (e.g., beam pumping used to push oil to the surface) in the New Mexico counties of the Permian Basin make up 13% of all NOx emissions.[54] The average rated horsepower of these engines is 21 hp and the magnitude of these NOx emissions – inventoried in 2014 – was close to 4,000 tons.

[51] *See* CDPHE RP for RICE. Annualized costs of control were calculated using a capital recovery factor of 0.099626 (assuming a 15-year life of controls and a 5.5% interest rate). Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032) and a 94% NOx removal efficiency.
[52] CARB 2001 Guidance.
[53] EPA 1993 Alternative Control Techniques Document for RICE Table 3-1 at 3-14.
[54] IWDW 2014 Oil and Gas Emissions Inventories, *available at:* http://views.cira.colostate.edu/wiki/wiki/9170/2014-oil-and-gas-emissions-inventories.

CARB's 2001 guidance discusses RICE units derated[55] to less than 50 hp, indicating that, "[o]ne of the largest categories of the derated engines are cyclically-loaded units used to drive reciprocating oil pumps."[56]

Two specific concerns with respect to the applicability of NSCR to certain types of smaller pump engines used in the oil and gas sector include: (1) the impact that moisture and sulfur in the fuel have on the catalyst; and (2) the impact that variable engine loading has on maintaining sufficient temperatures. Some fuel gases contain high amounts of moisture and sulfur which can result in damage to (deactivation of) the catalyst. The sulfur content of pipeline-quality natural gas is low but some oil field gases can contain high sulfur concentrations. And in applications where engines are periodically idle or where the load is cyclical, it can be more difficult to maintain an adequate exhaust gas temperature. For example, for an oil well pump, the engine may operate at load for a time-period lasting from several seconds to around 20 seconds, followed by an equal amount of time idle. These limitations can generally be minimized through design and maintenance activities, e.g., by treating the field gas to reduce the moisture and sulfur content, heating the catalyst to avoid deactivation, thermally insulating the exhaust pipe and catalyst to maintain a proper temperature, etc.[57]

CARB recognized that these characteristics (e.g., cyclic loads and variable fuel composition) would, "tend to discourage the use of catalysts with air-to-fuel controllers." But CARB specifically noted that, "a review of source test data in [CARB's 2001 Guidance] indicates that there have been instances where these engines have been successfully controlled in the past by cleaning up the field gas, and 'leaning-out' the engine or installing a catalyst in some cases."[58]

Specifically, cyclic engines that drive certain oil pumps (e.g., beam- or crank-balanced pumping engines) fueled by oil field gas operate in a way that may adversely impact the effectiveness of NSCR control. Following are specific pump engine types, as defined in Santa Barbara County Air Pollution Control District (APCD) Rule 333 Control of Emissions from Reciprocating Internal Combustion Engines:[59]

> "Air-balanced pumping engine" means a noncyclically-loaded engine powering a well pump, with the pump using compressed air in a cylinder under the front of the walking beam to offset the weight of the column of rods and fluid in the well, eliminating the need for counterweights.

---

[55] CARB describes a derated engine as, "one in which the manufacturer's brake horsepower rating has been reduced through some device which restricts the engine's output." CARB 2001 Guidance at IV-1.
[56] *See* CARB 2001 Guidance at IV-1.
[57] *Id.*; *also see* South Coast Air Quality Management District Preliminary Draft Staff Report for Proposed Amended Rule 1110.2 – Emissions from Gaseous- and Liquid-Fueled Engines (July 2019), D-4, *available at:* http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/1110.2/rule-1110-2-pdsr_07172019.pdf?sfvrsn=6.
[58] *See* CARB 2011 Guidance at IV-1.
[59] Santa Barbara County APCD Rule 333 CONTROL OF EMISSIONS FROM RECIPROCATING INTERNAL COMBUSTION ENGINES, 333.C at 333-2, *available at:* https://ww3.arb.ca.gov/drdb/sb/curhtml/r333.pdf.

"Beam-balanced pumping engine" means a cyclically-loaded engine powering a well pump, with the pump counterweight on the back end of the walking beam. The counterweight is moved mechanically without a cylinder supplying air pressure.

"Crank-balanced pumping engine" means a cyclically-loaded engine powering a well pump, with the pump counterweight attached to a gearbox which is attached to the walking beam with a pitman arm. The counterweight is moved mechanically, in a circular motion, without a cylinder supplying air pressure.

"Cyclically-loaded engine" means an engine that under normal operating conditions has an external load that varies by 40 percent or more of rated brake horsepower during any load cycle or is used to power a well reciprocating pump including beam-balanced or crank-balanced pumps. Engines powering air-balanced pumps are noncyclically-loaded engines.

In Santa Barbara County APCD, cyclic rich-burn engines (beam- and crank-balanced pump engines) greater than 50 hp are expected to meet a NOx limit of 300 ppmv, corrected to 15% oxygen, by adjusting the A/F mixture (to operate lean) and properly tuning and maintaining the engines; these engines are not required to install add-on NSCR control. However, according to CARB's guidance, cyclic rich-burn engines have met emission limits as low as 50 ppmv (< 1 g/bhp-hr) by "using NSCR or by leaning the air/fuel mixture in conjunction with treating the field gas to reduce moisture and sulfur content."[60] Specifically, the following engine test data demonstrate emission rates under 50 ppmv (corrected to 15% oxygen) for pump engines:

Table 5. Pump Engine Test Data[61]

CA AIR DISTRICT	ENGINE TYPE	ENGINE SIZE[62]	CONTROL TECHNOLOGY	# OF TESTS	NOx EMISSIONS [ppmv corrected to 15% oxygen]
Santa Barbara	Air-balanced oil pumps	195 hp	NSCR	18	2-14
Santa Barbara	Beam- and crank-balanced oil pumps	131 hp	Leaning of A/F mixture	4	12-35
Santa Barbara	Beam- and crank-balanced oil pumps	39-46 hp	Leaning of A/F mixture	16	8-28
Santa Barbara	Beam- and crank-balanced oil pumps	39-49 hp	Leaning of A/F mixture	18	7-33
Ventura	Beam- and air-balanced oil pumps	Not specified	NSCR	5	50

[60] *See* CARB 2001 Guidance at IV-5.

[61] *Id.*at IV-5 to IV-6.

[62] Oil pump engines, sometimes derated, are typically less than 50 hp, however there do appear to be some engines used for oil pumping applications that are larger, as shown in this table. And in addition, the underlying source test data in CARB's 2001 Guidance from Santa Barbara County and Ventura County also include a few data points for rich-burn engines less than 50 hp with NSCR, e.g., four 48 hp engines in Santa Barbara County with NSCR, and a 48 hp engine and 25 hp engine in Ventura County with catalyst control. *See* CARB 2001 Guidance Tables D-2 and D-3.

CA AIR DISTRICT	ENGINE TYPE	ENGINE SIZE[62]	CONTROL TECHNOLOGY	# OF TESTS	NOx EMISSIONS [ppmv corrected to 15% oxygen]
Ventura	Beam- and air-balanced oil pumps	Not specified	NSCR	3	25
TABLE NOTE: the field gas used in these engines was either naturally low in sulfur or treated to pipeline-quality natural gas					

CARB concluded that, "[b]ecause of the demonstrated success of meeting the 50 ppmv NOx limit for cyclic rich-burn engines fueled by low-sulfur or treated field gas, we recommend that the districts consider the cost effectiveness of field gas treatment and emission controls in setting limits for these engines on a site-specific basis."[63] Essentially, CARB guidance proposed considering in its cost effectiveness analysis, the additional cost of field gas treatment including the material and labor costs of piping the treated fuel from the gas processing unit to the engine.

As of January 1, 2017, the San Joaquin Valley Air Pollution Control District (SJVAPCD) requires emissions from rich-burn RICE meet the following NOx limits:

Table 6. NOx Emission Limits for All Rich-Burn Non-Agricultural Operations Engines Rated at > 50 bhp[64]

ENGINE TYPE		NOx LIMIT [ppmvd corrected to 15% O2]	EQUIVALENT NOx LIMIT Converted to g/bhp-hr
4SRB	Cyclic Loaded, Field Gas Fueled	50	0.7
	Limited Use	25	0.4
	All other	11	0.2
TABLE NOTES: Conversions to g/bhp-hr limits are based on: 67 ppmv = 1 g/bhp-hr (per EPA's 1993 Alternative Control Techniques Document, page 4-11)[65]			

SJVAPCD completed a cost effectiveness analysis for the second phase of its internal combustion engine rule (Rule 4702) in 2003.[66] The District analyzed a broad array of control scenarios to meet these NOx limits including installing NSCR on both cyclic and non-cyclic rich-burn RICE of wide-ranging power output and capacity utilization.

[63] *See* CARB 2001 Guidance at IV-6.
[64] SJVAPCD Rule 4702 Internal Combustion Engines, Tables 1 and 2, *available at*: https://www.valleyair.org/rules/currntrules/r4702.pdf.
[65] SJVAPCD Rule 4702 Cost Effectiveness Analysis (July 17, 2003), at B-3, *available at*: https://ww3.arb.ca.gov/pm/pmmeasures/ceffect/reports/sjvapcd_4702_report.pdf.
[66] *Id.*

SJVAPCD found that the costs to install and operate NSCR at cyclically-loaded RICE units to meet the limit in Table 6 above were cost effective, with costs ranging from $394/ton to $20,272/ton (1999$), which reflected costs of NSCR assuming a 10-year life and a 10% interest rate.[67]

To use more current data on NSCR costs applied to cyclically-loaded units, the E^c/R cost equations provided in Section II.C. above were used to estimate cost effectiveness for cyclically-loaded RICE units. As previously stated, the E^c/R cost equations take into account the addition of an AFRC as well as the costs of the NSCR. It was assumed that the NSCR system would achieve 90% control of NOx at cyclically-loaded engines as is required by the Santa Barbara emission limit.[68] To reflect varying levels of operation, emission reductions were based on operating 2,000 hours per year, 4,500 hours per year, and 8,000 hours per year. Texas Commission on Environmental Quality (TCEQ) data for artificial lifts operating in the Permian Basin indicates that such units operate 4,380 hours per year, although a much higher annual hours of operation of 7,106 has been assumed for artificial lift engines in the Greater San Juan Basin.[69] Thus, to give a range of cost effectiveness of NSCR at cyclically-loaded units, cost effectiveness of NSCR was determined for a low, medium, and high number of operating hours per year. As with other NSCR cost effectiveness analyses, a 15-year life and a 5.5% interest rate were assumed. The results of this cost effectiveness analyses are presented in Table 7.

[67] *Id.* at B-2 and at Table 3.

Table 7. Cost Effectiveness to Reduce NOx Emissions from Rich-Burn Cyclically-Loaded RICE Units with NSCR and AFRC, Based on EPA RICE NESHAP Cost Equations for NSCR[70]

ENGINE TYPE	SIZE (hp)	ANNUALIZED COSTS OF NSCR, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 2,000 HR/YR, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 4,500 HR/YR, 2009$	COST EFFECTIVENESS OF NSCR AND AFRC AT 8,000 HR/YR, 2009$
RICH-BURN	50	$5,303	$3,383/ton	$1,504/ton	$846/ton
	75	$5,396	$2,295/ton	$1,020/ton	$574/ton
	100	$5,489	$1,751/ton	$778/ton	$438/ton
	250	$6,045	$771/ton	$343/ton	$193/ton
	500	$6,971	$445/ton	$198/ton	$111/ton

TABLE NOTES:

- Cost data are assumed to be in 2009$, based on E^C/R Incorporated analysis of vendor and industry group data (EPA RICE NESHAP, 2010).
- Recalculated for 15-year life of controls and 5.5% interest rate.
- Assumes 90% NOx removal efficiency.

CARB's 2001 Guidance and the cost effectiveness analysis in this section for RICE units smaller than 500 hp show that application of NSCR to engines less than 500 hp can be cost effective. For RICE units used in oil pumping applications CARB describes situations where NSCR has been applied to cyclic rich-burn RICE to meet limits as low as 50 ppmv, citing certain types of "grasshopper" oil well pumps in Santa Barbara County.[71] And for oil pumping RICE units less than 50 hp CARB identified electrification (discussed in Section II.F, below), in addition to A/F adjustments and catalytic control, as technically feasible approaches to reducing NOx emissions from engines of this size.[72]

Further, SJVAPCD Rule 4702 for Internal Combustion Engines has a provision for RICE units at least 25 bhp, up to, and including 50 bhp that requires units that are sold after July 2012 to meet the applicable requirements and emission limits of EPA's NSPS for spark-ignition internal combustion engines in 40 CFR Subpart Part 60, JJJJ, for the year in which the ownership of the engine changes.[73] In the response to comments on its NSPS Subpart JJJJ rulemaking,[74] EPA provides many examples of the successful application of NSCR on small rich-burn engines and variable-load engines (noted as pumpjack engines or

[70] *Id*. Annualized costs of control were calculated using a capital recovery factor of 0.099626 (assuming a 15-year life of controls and a 5.5% interest rate). Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032) and control efficiency of 90%.

[71] CARB 2001 Guidance at IV-5. "Source tests of NSCR-equipped cyclic engines in Santa Barbara County have shown that these engines can be effectively controlled with or without air/fuel controllers provided the oil well pumps are air-balanced units."

[72] CARB 2001 Guidance at II-1.

[73] SJVAPCD Rule 4702 Internal Combustion Engines Section 5.1

[74] 73 Fed. Reg. 3,568-3,614 (Jan. 18, 2008).

compressor engines) that justify its standards as achievable and demonstrated for very small rich-burn RICE.[75]

Application of NSCR to rich-burn RICE is cost effective for a wide range of engine sizes and types.

While the cost estimates and cost algorithms in this section are of a cost basis that is from the 1999–2009 timeframe, it is important to note that, from at least 2001, several state and local air agencies have found that the costs of control to achieve NOx emission limits of 1 g/bhp-hr (67 ppmvd) and even lower NOx emission limits were cost effective to require such a level of control on existing rich-burn RICE. This will be discussed further in Section II.G. below. It is not possible to accurately escalate these costs to 2019 dollars. The Chemical Engineering Plant Cost Index (CEPCI) has been used extensively by EPA for escalating costs, but EPA states that using the CEPCI indices to escalate costs over a period longer than five years can lead to inaccuracies in price estimation.[76] Further, the prices of an air pollution control do not always rise at the same level as price inflation rates. As an air pollution control is required to be implemented more frequently over time, the costs of the air pollution control often decrease due to improvements in the manufacturing of the parts used for the control or different, less expensive materials used, etc.

The environmental and energy impacts of NSCR for rich-burn RICE include the following:

- 0 to 5% increase in fuel consumption resulting in increased CO_2 emissions[77]
- 1 to 2% reduction in power output[78]
- Increased solid waste disposal from spent catalysts.[79]

The impacts on increased fuel consumption and increased solid waste disposal are taken into account in the cost effectiveness analysis. Further, NSCR has been installed extensively on RICE units in the United States, and these non-air quality environmental and energy impacts are not generally considered to be impediments to implementing the control.

NSCR can be installed fairly quickly. The Institute of Clean Air Companies indicates that "off-the-shelf" NSCR converters can be installed in six to eight weeks. For NSCR installations that are more site-specific, NSCR can be installed in approximately fourteen weeks.[80]

D. LEAN-BURN RICE: LOW EMISSION COMBUSTION (LEC)

Low emission combustion (LEC) retrofit kits are designed to achieve extremely lean A/F in order to minimize NOx emissions. The various retrofit technologies can include:

- Redesign of cylinder head and pistons to improve mixing (on smaller engines)
- Precombustion chamber (on larger engines)
- Turbocharger
- High energy ignition system
- Aftercooler
- AFRC[81]

According to EPA, "[n]ew spark-ignition engines equipped with LEC technology are, by definition, lean-burn engines."[82] A wide range of emission rates are achievable with LEC technology, with emissions generally no higher than 2 g/hp-hr and often significantly lower. EPA's updated information on stationary RICE NOx emissions and control technologies concludes, for lean-burn engines, an emission rate of 2.0 g/bhp-hr is achievable for "new engines and most engines retrofitted with LEC technology."[83] LEC is described by EPA in its Alternative Control Techniques Document, as follows:

> Low-emission combustion designs are available from engine manufacturers for most new SI engines, and retrofit kits are available for some existing engine models. For existing engines, the modifications required for retrofit are similar to a major engine overhaul, and include a turbocharger addition or upgrade and new intake manifolds, cylinder heads, pistons, and ignition system. The intake air and exhaust systems must also be modified or replaced due to the increased air flow requirements.
>
> Controlled NOx emission levels reported by manufacturers for [LEC] are generally in the 2 g/hp-hr (140 ppm) range, although lower levels may be quoted on a case-by-case basis. Emission test reports show controlled emission levels ranging from 1.0 to 2.0 g/hp-hr (70 to 140 ppmv). Information provided by manufacturers shows that, in general, BSFC decreases slightly for [LEC] compared to rich-burn designs, although in some engines the BSFC increases. An engine's response to increases in load is adversely affected by [LEC], which may make this control technique unsuitable for some installations, such as stand-alone power generation applications. The effect on CO and HC emissions is a slight increase in most engine designs.[84]

LEC NOx Removal Efficiency:	*87%*
Controlled NOx Emission Rates:	*1-2 g/hp-hr*
	70 to 140 ppmv

[81] EPA, Final Technical Support Document for the Cross-State Air Pollution Rule for the 2008 Ozone NAAQS, Docket ID EPA-HQ-OAR-2015-0500-0508, Assessment of Non-EGU NOx Emission Controls, Cost of Controls, and Time for Compliance, August 2016, Appendix A at 5-3, *available at:* https://www.regulations.gov/document?D=EPA-HQ-OAR-2015-0500-0508 [hereinafter referred to as "2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls"].
[82] EPA 2000 Updated Information on NOx Emissions and Control Techniques at 4-3.
[83] *Id.* at 4-12.
[84] EPA 1993 Alternative Control Techniques Document for RICE.

In its Updated Information on NOx Emissions and Control Techniques Document for RICE, EPA states the following test data for LEC:

> In all, the sources of NOx emission test data [] include the results of 476 individual tests conducted on 58 engines. (This count does not include the aggregated data in some of the sources discussed [], such as the May 2000 EPA memo and the AP-42 sections.) In these tests, NOx emissions ranged from 0.1 g/bhp-hr to 4.8 g/bhp-hr. Ninety-seven percent of these tests (460) found emissions less than or equal to 2 g/bhp-hr. Almost 75 percent (356) of the tests found emissions less than or equal to 1 g/bhp-hr, and 25 percent (120) found emissions of less than or equal to 0.5 g/bhp-hr. Only two tests measured NOx emissions greater than or equal to 4 g/bhp-hr.[85]

EPA also indicates that, "LEC is expected to be the most common control method for meeting the [1991 CARB Best Available Retrofit Control Technology (BARCT) for Stationary IC Engines], although SCR may be used as an alternative if LEC is unsuitable for a particular model engine."[86]

And according to the Interstate Natural Gas Association of America (INGAA), "LEC is the preferred approach to reduce lean-burn engine NOx emissions, but EPA or states may consider additional controls such as selective catalytic reduction (SCR)."[87]

EPA further states in its Updated Information on NOx Emissions and Control Techniques for RICE:

> Low-emission combustion retrofit equipment and services are generally available, particularly for the most plentiful engine models. Cooper Energy Services, maker of Cooper-Bessemer, Ajax, Superior, and Delaval engines provides CleanBurn™ retrofits for all of its larger models and offers these services for engines manufactured by other companies, as well. Dresser-Rand, manufacturer of Ingersoll-Rand, Clark, and Worthington engines also offers retrofit services for its lean-burn engines. The Waukesha Engine Division of Dresser Industries manufactures two engine families that are available either in rich-burn or LEC configurations. The company offers LEC retrofit services for those engines originally sold in the rich-burn configuration. At least three third-party vendors (Diesel Supply Company; Enginuity, Inc.; and Emissions Plus, Inc.) offer retrofit services for a wide variety of engine makes and models. These vendors will work with any model engine, although economies of scale can reduce capital costs for plentiful engines. For other engines, customized precombustion chambers can result in somewhat higher costs.[88]

[87] INGAA, Availability and Limitations of NOx Emission Control Resources for Natural Gas-Fired Reciprocating Engine Prime Movers Used in the Interstate Natural Gas Transmission Industry (July 2014), *available at*: https://www.ingaa.org/File.aspx?id=22780.
[88] EPA 2000 Updated Information on NOx Emissions and Control Techniques at 4-4.

California Air Districts have long been regulating NOx emissions from RICE, including lean-burn RICE. CARB issued guidance to Air Districts in 2001 on the reasonably available control technologies (RACT) and the best available retrofit control technologies (BARCT) for controlling NOx emissions from a broad range of stationary RICE.[89] In its analysis, CARB determined that LEC was a RACT level of control, and CARB set a NOx RACT limit of 125 ppmv.[90] CARB established a BARCT NOx limit for two- and four-stroke lean-burn engines rated at or higher than 100 hp of 65 ppmv or 90% reduction in NOx emissions.[91] CARB indicated that this lower NOx BARCT limit could also be met with LEC for many engines, although some engines might require some supplemental measures such as ignition system modifications and engine derating and others might require SCR to meet the BARCT NOx limit.[92] LEC can achieve 80 to 90% NOx reductions or even higher.[93]

The only exemptions CARB proposed from the NOx BARCT limit were for lean-burn engines rated less than 100 hp. With respect to these smaller engines, CARB determined that there are a relatively small number of such two-stroke lean-burn engines that cannot cost effectively install LEC or other NOx controls necessary to meet the NOx limits set for lean-burn RICE (both RACT and BARCT limits).[94] CARB described these engines as "located in gas fields statewide and [] used to drive compressors at gas wells."[95] CARB determined that, "the only cost effective way to control emissions from the[se] small two-stroke engines is by properly maintaining and tuning these engines which includes replacing oil-bath air filters with dry units and periodically cleaning the air/fuel mixer and muffler."[96] CARB ultimately recommend that the air districts, "require the replacement of these engines at the end of the two-stroke engine's useful life with prime movers having lower NOx emissions."[97]

CARB conducted cost effectiveness analyses for LEC on lean-burn RICE at a wide variety of engine power output ratings. CARB's analyses of capital and annual operating costs for retrofitting existing engines with LEC (and other NOx controls) were based on, "a mixture of quotes and extrapolations of cost from information provided by industry sources, associations, local governments, and the U. S. EPA."[98] CARB's cost data for LEC are presented in the table below.

[89] CARB 2001 Guidance.
[90] *Id.* at IV-6.
[91] *Id.* at IV.9.
[92] *Id.* at II-2, IV-10.
[93] EPA has said NOx reductions with LEC could be as high as 93%. *See* EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032) at 5-67.
[94] *Id.* at II-2.
[95] *Id.* at IV-7.
[96] *Id.*
[97] *Id.*
[98] *Id*. at V-2.

Table 8. Capital Costs of LEC, 2001$[99]

POWER OUTPUT (hp)	LEC CAPITAL COSTS
50-150	$14,000
151-300	$24,000
301-500	$42,000
501-1,000	$63,000
1,001-1,500	$148,000

CARB calculated cost effectiveness for LEC assuming 80% NOx control, a 10-year life of the controls, and a 10% interest rate.[100] As previously discussed, to be consistent with EPA's Control Cost Manual which recommends the use of the bank prime interest rate, it is more appropriate to use a lower interest rate of 5.5%.[101] Thus, the CARB LEC cost data were revised to be consistent with the EPA's Control Cost Manual in assuming a 5.5% interest rate in amortizing the capital costs. It must be noted that CARB's assumed 10-year life of LEC controls seems unreasonably short, as EPA has assumed a 15-year life of all controls for stationary internal combustion engines in other cost analyses.[102] Thus, the CARB LEC cost data were revised to assume a 15-year life of LEC controls.

CARB's cost analysis also assumed that the engines are run at rated power (100% load) for only 2,000 hours annually, which is equivalent to a capacity factor of roughly 25%. To reflect the cost effectiveness values for a range of operating hours, CARB's cost analysis was revised to reflect costs at 91% capacity factor, or 8,000 operating hours per year.

Last, CARB's cost effectiveness analysis only assumed an 80% NOx removal efficiency with LEC. As discussed above, an 80% NOx control efficiency is the low-end of NOx removal rates that can be achieved with LEC at lean-burn engines. CARB's BARCT limit is based on 90% NOx reduction. Thus, CARB's cost analyses were also revised to include cost effectiveness for 90% NOx control as well as 80% NOx control. These revised cost effectiveness calculations—assuming a 5.5% interest rate, 15-year life of LEC, capacity factors of 2,000 operating hours and of 8,000 operating hours, and both 80% NOx control and 90% NOx control—are presented in Table 9 below.

[99] *Id.* Note that the cost basis is not identified, and it is assumed to be 2001 dollars based on the date of the analysis. Also note that for engines with power output of 1,001-1,500 hp, a mid-range cost of $148,000 was assumed, similar to the assumption made by EPA when using CARB's cost data in its 2016 CSAPR TSD.
[100] CARB 2001 Guidance at V-4.
[101] *See, e.g.*, https://fred.stlouisfed.org/series/DPRIME.
[102] EPA, Regulatory Impact Analysis for the NOx SIP Call, IP, and Section 126 Petitions, September 1998, at 5-5 (Table 5-3).

Table 9. Cost Effectiveness to Reduce NOx Emissions by 80%–90% from Lean-Burn RICE with LEC Operating at 2,000 and 8,000 Hours per Year[103]

ENGINE TYPE	SIZE, hp	ANNUALIZED COSTS OF LEC, 2001$	COST EFFECTIVENESS OF LEC TO REDUCE NOx BY 80%–90%, 2,000 HOURS/YEAR, 2001$	COST EFFECTIVENESS OF LEC TO REDUCE NOx BY 80%–90%, 8,000 HOURS/YEAR, 2001$
LEAN-BURN	50	$1,857	$941/ton-$837/ton	$235/ton-$209/ton
	200	$3,184	$403/ton-$359/ton	$101/ton-$90/ton
	500	$5,572	$282/ton-$251/ton	$71/ton-$63/ton
	1,000	$8,358	$212/ton-$188/ton	$53/ton-$47/ton
	1,500	$19,635	$332/ton-$295/ton	$83/ton-$74/ton

The above analyses demonstrate that, with the exception of lean-burn engines rated at 50 hp that only operated 2,000 hours per year, the cost effectiveness of LEC at lean-burn engines is essentially between $80–$400/ton for a wide range of engine sizes and a wide range of operating hours.

In its Technical Support Document for Non-EGU NOx emissions for the CSAPR rule, EPA presented an equation for estimating the capital cost of LEC on natural gas lean-burn engines, based on cost calculations for engines of varying size and annual capacity factor from CARB's 2001 Guidance:[104]

$$\text{Capital cost} = \$16{,}019\ e^{0.0016 \times (hp)}$$

Thus, the above equation can be used to estimate capital costs for LEC based on the hp rating of the unit. CARB did not identify any operating expenses with LEC, and thus the appropriate capital recovery factor can be multiplied by the results of the equation above for any size lean-burn engine to estimate annual costs of control with LEC.

CARB's cost estimates for LEC are relatively consistent with EPA's prior cost analyses of LEC lean-burn engines. For example, EPA's 1993 Control Techniques Document for RICE found the cost effectiveness for medium-speed engines operating at a 91% capacity factor was in the range of $310–$590/ton (1993$, assuming a 7% interest rate and a 15-year life).[105] EPA subsequently updated the cost information on LEC technology for lean-burn SI engines because "developments in LEC technology have brought retrofit costs down in recent years."[106] Specifically, in EPA's Updated Information on NOx

[103] Cost information for LEC from CARB 2001 Guidance at Tables V-1 and V-2. Annualized cost of control assumed a capital recovery factor of 0.099626 (assuming a 15-year life of controls and a 5.5% interest rate). Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques for RICE (EPA-453/R-93-032).
[104] 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls, Appendix A at 5-5. Note that the CSAPR TSD also presented an equation for annual costs, but it reflected annualized capital costs assuming a 7% interest rate and a 10-year life. Thus, the annualized cost equation is not provided here because it is not reflective of the current recommended interest rate for cost calculations of 5.5% or a 15-year life of controls.
[105] *See* EPA 1993 Alternative Control Techniques Document for RICE, Table 2-13 at 2-36.
[106] EPA 2000 Updated Information on NOx Emissions and Control Techniques at 4-33.

Emissions and Control Techniques for RICE, its analysis of LEC retrofit for lean-burn SI engines showed, "cost effectiveness below $500 per ton of NOx reduced [in 1997$] for all engines larger than 2,000 bhp," which reflected an 80% capacity factor, 88% control, and a 7% interest rate. [107]

The 2001 CARB cost analyses for LEC is the most current comprehensive analyses for the costs of LEC available. It is recommended that the CARB cost data, as reflected in the equation given above (from EPA's CSAPR TSD), be used to calculate capital costs based on horsepower rating of an engine, assuming a 15-year life, 5.5% interest rate, and 90% NOx control. CARB's BARCT NOx limit of 125 ppmv should be considered as an achievable NOx emission limit with LEC at a lean-burn engine.

Application of LEC to lean-burn RICE is cost effective for a wide range of engine sizes and types.

While the cost estimates and cost algorithms in this section are of a cost basis that is close to twenty years old, it is important to note that, from at least 2001, several state and local air agencies have found that the costs of control to achieve NOx emission rates reflective of LEC at lean-burn engines (<2 g/bhp-hr (150 ppmv)) have been considered as cost effective to require such a level of control on existing lean-burn RICE over 100 hp. This will be discussed further in Section II.G. below. For the reasons previously discussed in this report, it is not possible to accurately escalate these costs from 2001 to a current dollar basis. Nonetheless, the fact that numerous state and local agencies have imposed NOx limits that reflect the application of LEC demonstrates that it is a control that has been extensively retrofitted to existing lean-burn engines.

The environmental and energy impacts of LEC for lean-burn RICE are minimal and include the following:

- A decrease in fuel consumption of 0 to 5% resulting in decreased CO_2 emissions, as well as a corresponding decrease in emissions of other air pollutants[108]
- No effect on power output.[109]

E. LEAN-BURN RICE: SELECTIVE CATALYTIC REDUCTION (SCR)

Selective catalytic reduction (SCR) is an add-on (post combustion) NOx reduction technology that has been in use as early as the 1970s and has been applied to numerous source categories including stationary RICE units. In its 1993 Alternative Control Techniques Document for Stationary RICE, EPA described SCR systems as follows:

> Selective catalytic reduction is an add-on control technique that injects ammonia (NH3) into the exhaust, which reacts with NOx to form N2 and H20 in the catalyst reactor. The two primary catalyst formulations are base-metal (usually vanadium pentoxide) and zeolite. Spent catalysts containing vanadium pentoxide may be considered a hazardous material in some areas, requiring special disposal considerations. Zeolite catalyst formulations do not contain hazardous materials.

[107] *Id.* at 5-9.
[108] *See* EPA 1993 Alternative Control Techniques Document for RICE, Table 2-7 at 2-15.
[109] *Id.*

> Selective catalytic reduction applies to all lean-burn SI engines and can be retrofit to existing installations except where physical space constraints may exist. There is limited operating experience to date, however, with these engines. A total of 23 SCR installations with lean-burn SI engines were identified in the United States from information provided by catalyst vendors, in addition to over 40 overseas installations. To date [1993] there is also little experience with SCR in variable load applications due to ammonia injection control limitations. Several vendors cite the availability of injection systems, however, designed to operate in variable load applications. Injection systems are available for either anhydrous or aqueous ammonia. As is the case for NSCR catalysts, fuels other than pipeline-quality natural gas may contain contaminants that mask or poison the catalyst, which can render the catalyst ineffective in reducing NOx emissions. Catalyst vendors typically guarantee a 90 percent NOx reduction efficiency for natural gas-fired applications, with an ammonia slip level of 10 ppm or less. One vendor offers a NOx reduction guarantee of 95 percent for gas- fired installations. Based on an average uncontrolled NOx emission level of 16.8 g/hp-hr (1,230 ppmv), the expected controlled NOx emission level is 1.7 g/hp-hr (125 ppmv). Emission test data show NOx reduction efficiencies of approximately 65 to 95 percent for existing installations. Ammonia slip levels were available only for a limited number of installations for manually adjusted ammonia injection control systems and ranged from 20 to 30 ppmv. Carbon monoxide and HC emission levels are not affected by implementing SCR. The engine BSFC increases slightly due to the backpressure on the engine caused by the catalyst reactor.[110]

There have been many advances in SCR systems and catalysts since EPA's 1993 Alternative Control Techniques Document. In 2012, the Ozone Transport Commission (OTC) issued a Technical Information Document on significant stationary sources of NOx emissions in the Oil and Gas Sector (hereinafter referred to as the "2012 OTC Report").[111] The OTC is a multi-state organization created under the CAA to address ozone problems in the Northeast and Mid-Atlantic U.S.[112] According to the 2012 OTC Report, many of the issues with variable load operation have been addressed by catalysts that have been designed to operate over a wide range of exhaust temperatures and for combustion devices with variable loads.[113] For example, in the 2012 OTC Report,[114] several vendors were listed that could provide such SCR systems and catalysts effective for the NOx control issues of lean-burn engines, such as Johnson Matthey,[115] Miratech Corporation which offers an SCR system for lean-burn engines used in natural gas compression,[116] CleanAir Systems which offers a lean-burn SCR called "E-Pod SCR" that is advertised to achieve up to 95% NOx reduction and reduce particulates, HC, and CO[117], and Caterpillar

which offers SCR systems for several of its engines.[118] Although EPA's 1993 Alternative Control Techniques Document indicates achievable NOx emission rates of 1.7 g/hp-hr, the OTC identified NOx rates achievable with SCR at lean-burn engines of 0.2 to 1.0 g/bhp-hr, with the lower NOx rates achievable at four-stroke lean-burn engines and/or engines that also have some combustion control upgrades.[119] Moreover, two air districts in California—South Coast Air Quality Management District (SCAQMD) and SJVAPCD—have adopted NOx emission limits of 11 ppmv, which equates to 0.15 g/hp-hr, for lean-burn engines.[120] Based on this more recent information, the NOx reduction efficiency and achievable NOx emission rates are:

- *NOx Removal Efficiency:* *90-95+%*
- *Controlled NOx Emission Rates:* *0.15 to 1.0 g/hp-hr (11 to 73 ppmv)*

SCR can be applied to lean-burn spark-ignition engines, diesel compression-ignition engines, and dual-fuel compression-ignition engines. And while diesel engines are the most prevalent applications of SCR at RICE units, SCR has also been applied at lean-burn spark-ignition engines fired with natural gas, including at natural gas pipeline compressor stations.[121] Outside of the U.S., EPA stated in its 2000 update that "there are over 700 IC engines controlled with SCR systems in Europe and Japan, including approximately 80 to 100 2-stroke engines."[122] Thus, for those engines for which effective LEC retrofits are not available, SCR is available to achieve high levels of NOx control.

As previously stated, CARB issued guidance to California Air Districts in 2001 on the best available retrofit technologies for controlling NOx emissions from a broad range of stationary RICE.[123] For two- and four-stroke lean-burn engines greater than 100 hp, CARB set a BARCT limit 65 ppmv or 90% reduction in NO_x emissions.[124] CARB indicated that "[i]t is expected that the most common control method used to meet the BARCT emission limit [] will be the retrofit of low-emission combustion controls. Other techniques may also be used to supplement these retrofits, such as ignition system modifications and engine derating. For engines that do not have low-emission combustion modification

[118] *See* https://www.cat.com/en_GB/search/search-results.html?search=selective+catalytic+reduction&pagePath=%252Fcontent%252Fcatdotcom%252Fen_GB%252Fproducts%252Fnew%252Fpower-systems%252Foil-and-gas.
[119] *See* 2012 OTC Report at 27-28 and 40-41.
[120] *See* SQAQMD Rule 1110.2, Table I and SJVAPCD Rule 4702, Table 2. The SCAQMD 11 ppmv limit applies to engines at facilities that are not in the Regional Clean Air Incentives Market (RECLAIM) as of January 5, 2018, and SCAQMD has indicated there are 18 engines currently meeting the 11 ppmv limit. *See* http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/1110.2/par1110-2-wg2-final.pdf?sfvrsn=6 at Slide 32. The SJVAPCD 11 ppmv limit does not apply to lean-burn engines used for gas compression, or those engines of limited use operation (less than 4,000 hours per year), or those engines that are waste gas-fuel—a higher limit of 65 ppmv applies to these engines.
[121] *See, e.g.,* EPA 2000 Updated Information on NOx Emissions and Control Techniques at 4-13.
[122] *Id.* at 4-13 (EPA notes, "[f]rom the context, we believe that the source of this last data meant 2-stroke lean-burn SI engines fired with natural gas, although it is not explicit in the reference.").
[123] *See* CARB 2001 Guidance.
[124] *Id.*

kits available, SCR may be used as an alternative to achieve the BARCT emission limits."[125] Thus, CARB envisioned that some RICE units would need to install SCR.

The SJVAPCD requires that emissions from lean-burn RICE meet the following NOx limits:

Table 10. SJVAPCD NOx Emission Limits for All Lean-Burn Non-Agricultural Operations Engines[126]

ENGINE TYPE		**NOx LIMIT [ppmvd corrected to 15% O2]**	**EQUIVALENT NOx LIMIT [g/bhp-hr]**
2SLB	Gaseous Fueled; >50 hp and <100 hp	75	1.0
4SLB	Limited Use	65	0.9
	Used for gas compression	65 or 93% reduction	0.9
	All other	11	0.15

TABLE NOTES:

- Conversions to g/bhp-hr limits are based on EPA's Stationary Reciprocating Internal Combustion Engines Updated Information on NOx Emissions and Control Techniques (September 2000), where the conversion for uncontrolled lean-burn engines and lean-burn engines controlled with SCR is: 73 ppmv = 1 g/bhp-hr

The 11 ppmv limit is clearly more stringent than CARB's recommended BARCT limit and thus presumably requires SCR to achieve at lean-burn RICE, possibly along with combustion modifications. SCAQMD adopted an 11 ppmv NOx limit for all RICE units unless located at a Regional Clean Air Incentives Market (RECLAIM) Facility, and thus SCAQMD has applied this lower NOx limit more broadly than the SJVAPCD.

The SJVAPCD completed a cost effectiveness analysis for the emission limits in the above table in 2003.[127] The District analyzed a broad array of control scenarios including installing SCR on lean-burn RICE of wide-ranging power output and capacity utilization and multiple applications (e.g., limited use, gas compression, etc.). SJVAPCD's report indicated that "[d]istrict staff feels that the annual compliance costs are reasonable for [all] five cases analyzed [including installation of a SCR system for a lean-burn engine]."[128] The report further concluded that "[a]lthough a few of the results indicated a high cost effectiveness, such results are due to the low emission reductions and not from high annual costs."[129]

SJVAPCD used the capital and annual operating costs for retrofitting existing engines with SCR based on CARB's 2001 guidance—which are based on installation of the more advanced parametric emissions

monitoring systems (PEMS) feedforward system controls, the use of urea as the reducing agent, and a catalyst sized to achieve 96% reduction in NOx emissions—as presented in the table below.

Table 11. Capital and Operating Costs of SCR[130]

POWER OUTPUT (hp)	INSTALLED SCR CAPITAL COSTS, 1999$	ANNUAL OPERATING AND MAINTENANCE COSTS, 1999$
50	$45,000	$20,102
200	$45,000	$26,102
500	$60,000	$35,102
1,000	$149,000	$78,102
1,500	$185,000	$117,102

TABLE NOTES:

- The cost for the SCR is based on urea injection, with PEMS, and catalyst sized for 96% NOx conversion.

SJVAPCD determined the annualized costs of control assuming a 10-year life of controls and a 10% interest rate.[131] As previously discussed, to be consistent with EPA's Control Cost Manual, a lower interest rate of 5.5% should be used for current cost effectiveness calculations.[132] With respect to the SCR equipment life, SCR systems can likely last much longer than 15 years. EPA states that SCRs at boilers, refineries, industrial boilers, etc. have a useful life of 20-30 years.[133] To be consistent with EPA's statements on SCR, this report will assume a 20-year life for SCRs at lean-burn engines. Thus, a 5.5% interest rate and 20-year life of controls has been used for the revised SCR cost calculations presented herein.

SJVAPCD presented the cost effectiveness of retrofitting RICE with SCR based on reducing NOx emissions from a NOx rate of 740 ppmv to the proposed (and ultimately adopted) emission limit of 65 ppmv, which reflects a 91% control efficiency across the SCR. For RICE not already meeting NOx limits of 740 ppmv, employing SCR to reduce NOx emissions from what EPA considers to be the uncontrolled NOx emission rate of 1,230 ppmv (16.8 g/bhp-hr) to 65 ppmv corresponds to a NOx emissions reduction efficiency of 95%.[134] Such removal rates are achievable with SCR at lean-burn RICE, as discussed above.[135] However, the lower NOx rate of 11 ppmv that SJVAPCD has adopted for lean-burn engines not

[130] *Id.* Table 5.

used for compression and not operated at limited use (less than 4,000 hours per year) would also be achievable with SCR alone or with combustion controls plus SCR. A NOx limit of 11 ppmv reflects 99% control from uncontrolled levels.

SJVAPCD claimed to present cost effectiveness data for two different operating capacity factors: 25% and 75%. However, SJVAPCD also cited to CARB's cost analyses as the basis for SJVAPCD's assumed costs.[136] In the underlying cost effectiveness analysis, CARB assumed that the engines are run at rated power (100% load) for 2,000 hours annually, which is equivalent to a capacity factor of roughly 23%. It does not appear that SJVAPCD accounted for increased operating costs in its evaluation of costs at the higher capacity factor. Operating expenses at higher operating capacity factors would increase approximately by the ratio of the higher capacity factor (or operating hours) to the originally assumed capacity factor (or operating hours) in the original cost analysis.[137] The following table shows the cost effectiveness of retrofitting SCR to an uncontrolled lean-burn RICE operating at 2,000 hours per year and at 8,000 hours per year and meeting a 65 ppmv NO_x limit, based on a 20-year life and 5.5% interest rate. For the cost analyses shown in Table 12, SJVAPCD's operational costs were increased by a factor of four to more accurately reflect operational expenses at an operating capacity of 8,000 hours per year.

Table 12. Cost Effectiveness to Reduce NOx Emissions by 95% from 4SLB RICE with SCR Operating at 2,000 and 8,000 Hours per Year[138]

ENGINE TYPE	SIZE, hp	ANNUALIZED COSTS OF SCR, 1999$	COST EFFECTIVENESS OF SCR, 2,000 HOURS PER YEAR, 1999$	COST EFFECTIVENESS OF SCR, 8,000 HOURS PER YEAR, 1999$
4SLB	50	$24,585	$13,567/ton	$3,392/ton
	200	$30,585	$4,244/ton	$1,061/ton
	500	$41,080	$2,281/ton	$570/ton
	1,000	$92,946	$2,574/ton	$644/ton
	1,500	$135,533	$2,512/ton	$628/ton

As previously stated, the cost effectiveness presented in Table 12 above reflects compliance with the 65 ppmv NOx emission limit with SCR, which corresponds to a NOx emissions reduction efficiency of

[136] *See* SJVAPCD Rule 4702 Cost Effectiveness Analysis (July 17, 2003), Table 5, notes F and H.

[137] This is based on an analysis of varying hours of operation in EPA's SCR Cost Calculation Spreadsheet (06/2019) available on its Control Cost Manual website at https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution. While this spreadsheet is designed to estimate costs of SCR for fossil fuel-fired boilers, it can be used to estimate the increased in operational costs with increases in operating hours for any SCR system given that the SCR components are the same whether for a gas-fired boiler or a gas-fired RICE unit.

[138] *See* SJVAPCD Rule 4702 Cost Effectiveness Analysis (July 17, 2003), Table 5. Annualized costs of control were calculated using a capital recovery factor of 0.083679 (assuming a 20-year life of controls and a 5.5% interest rate). NOx emission reductions are based on SJAPCD's assumed 91% removal efficiency. Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032).

95%.[139] However, the lower NOx rate of 11 ppmv that SJVAPCD has adopted for lean-burn engines not used for compression and not operated at limited use (less than 4,000 hours per year) would also be achievable with SCR alone or with combustion controls plus SCR. A NOx limit of 11 ppmv reflects 99% control from uncontrolled levels.

More recently, EPA's 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls developed the following cost equations for SCR on natural gas four-stroke lean-burn engines, based on cost calculations for engines of varying size and annual capacity factor from SJVAPCD's 2003 cost effectiveness analysis:

Capital cost = $107.1 x (hp) + $27,186

Annual cost = $83.64 x (hp) + $14,718

The annual cost equation given above includes capital costs amortized assuming a 7% interest, which as discussed above is too high, and a 10-year equipment life, which should be 20 years as discussed above.[140] In the table below, the cost effectiveness of SCR based on these cost equations from EPA's 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls but revising the annual costs to reflect a 5.5% interest rate and a 20-year life of SCR and reflecting operations at 2,000 hours per year and at 8,000 hours per year. EPA's cost equations given above are based on an assumed 90% NOx reduction across the SCR, [141] so the same level of NOx control was assumed in the revised cost calculations presented in Table 13. Higher levels of NOx reduction and lower emission limits can be met with SCR alone or in combination with combustion controls. However, because higher levels of NOx reduction could also increase the operational expenses of SCR (unless some of the NOx reductions were achieved with combustion controls), the same 90% level of NOx control was assumed in the revised cost effectiveness analyses presented below to be consistent with the basis of EPA's cost equations.

[141] *Id.*

Table 13. Cost Effectiveness to Reduce NOx by 90% from 4SLB RICE with SCR Operating at 23% and 91% Capacity Factors, Based on EPA's 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls[142]

ENGINE TYPE	SIZE, hp	ANNUALIZED COSTS OF SCR, 2001$	COST EFFECTIVENESS OF SCR, 2,000 HOURS PER YEAR, 2001$	COST EFFECTIVENESS OF SCR, 8,000 HOURS PER YEAR, 2001$
4SLB	50	$17,509	$10,194/ton	$2,548/ton
	200	$29,368	$4,289/ton	$1,072/ton
	500	$53,086	$3,108/ton	$777/ton
	1,000	$92,617	$2,714/ton	$679/ton
	1,500	$132,148	$2,583/ton	$646/ton

Application of SCR to lean-burn RICE is cost effective for a wide range of engine sizes and types.

While the cost estimates and cost algorithms are of a cost basis that is twenty years old, the cost data have been relied on extensively.[143] And, from at least 2001, it is important to note that several state and local air agencies have found that the costs of control to achieve NOx emission limits of 1 g/bhp-hr (65 ppmvd) and even lower (as low as 11 ppmvd as required by SJVAPCD and SCAQMD) were cost effective to require such a level of control on existing lean-burn RICE rated greater than 100 hp. This will be discussed further in Section II.G. below. It is not possible to accurately escalate these costs to 2019 dollars. The CEPCI has been used extensively by EPA for escalating costs, but EPA states that using the CEPCI indices to escalate costs over a period longer than five years can lead to inaccuracies in price estimation.[144] Further, the prices of air pollution control do not always rise at the same level as price inflation rates. As air pollution control is required to be implemented more frequently over time, the costs of air pollution control often decrease due to improvements in the manufacturing of the parts used for the control or different, less expensive materials used, etc.

The environmental and energy impacts of SCR for lean-burn RICE include the following:

- 0.5% increase in fuel consumption resulting in increased CO_2 emissions
- 1 to 2% reduction in power output[145]

[142] *See* 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls, Appendix A at 5-12. Note that EPA assumes the cost basis is 2001$. Annualized costs of control were calculated using a capital recovery factor of 0.083679 (assuming a 20-year life of controls and a 5.5% interest rate). Uncontrolled NOx emissions are based on EPA's 1993 Alternative Control Techniques Document for RICE (EPA-453/R-93-032).

[143] EPA relied on the 2003 SJVAPCD Cost Effectiveness Analysis for Rule 4702 (which, in turn, relied on the 2001 CARB Guidance for Stationary SI Engines) in its 2016 EPA CSAPR TSD for Non-EGU NOx Emission Controls (Appendix A at 5-10 through 5-12).

[144] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017, at 19.

[145] *See* EPA 1993 Alternative Control Techniques Document for RICE, Table 2-7 at 2-15.

- Increased solid waste disposal from spent catalysts[146]
- If ammonia is used instead of urea (which is assumed to be the reagent used in the SCR cost analyses presented above), there would be an increased need for risk management and implementation and associated costs.[147] If urea or aqueous ammonia is used as the reagent, the hazards from the use of pressurized anhydrous ammonia do not apply.

Regardless of these impacts, SCR technology is widely used at many industrial sources. There are typically not overarching non-air quality or energy concerns with this technology, and many of the concerns are addressed in the cost analysis.

In terms of length of time to install SCR at a lean-burn RICE unit, EPA has estimated that it takes 28–52 weeks to install SCR at a diesel-fired RICE unit.[148] It is reasonable to assume a similar time for the installation of SCR at a lean-burn natural gas-fired RICE unit.

F. RICE ELECTRIFICATION

Replacement of RICE with an electric motor is another pollution control option. In its 2001 guidance to California Air Districts, CARB indicated that electrification would be a NOx control option for RICE, with the potential to significantly reduce NOx emissions.[149] *Replacement of on-site engines with electric motors will reduce on-site NOx and other pollutant emissions by 100%.* Depending on the power source used for providing electricity to the site, air emissions may increase from the power generating site (i.e., if the power generating source is fueled by fossil fuels, rather than renewable energy such as wind or solar). However, even if the power is produced by a fossil fuel-fired power plant, it is likely more cost effective to a fossil fuel-fired power plant than it is to apply air pollution controls to individual engines.

CARB indicated in its 2001 guidance that "the majority of beam-balanced and crank-balanced oil pumps in California are driven by electric motors."[150] Thus, it stands to reason that electrification of such oil pumps is cost effective, given the widespread implementation.

CARB also found that electrification of RICE that fall within a size range from 50 to 500 hp would be a cost effective NOx control, but CARB stated that beyond the range of 50 to 500 hp, "modification and installation costs may become so extensive that this approach may not be cost effective."[151] However, on a cost per ton of NOx removed basis, CARB found that the electrification of engines in the 500 to 1,000 hp size range was as cost effective as the electrification of engines in the 50–150 hp size range –

[146] *See* CDPHE RP for RICE at 10 (citing EPA (2002), EPA Air Pollution Control Cost Manual, 6th ed., EPA/452/B-02-001, EPA, Office of Air Quality Planning and Standards, RTP).
[147] Anhydrous ammonia is a gas at standard temperature and pressure, and so it is delivered and stored under pressure. It is also a hazardous material and typically requires special permits and procedures for transportation, handling, and storage. *See* EPA Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, June 2019, at pdf page 15.

[151] *Id.* at V-2.

that is, $1,100/ton in 1999 dollars.[152] For engines in the size range of 150 to 500 hp, electrification of engines was somewhat more cost effective at $900/ton in 1999 dollars.[153] CARB indicated that Air Districts in California should consider the replacement of engines with electric motors as a control option "whenever it is feasible in order to maximize emission reductions."[154]

It is important to note that CARB's cost effectiveness calculations were based the assumption of only 2,000 hours per year operation, and CARB assumed capital costs would be amortized over a 10-year period and at a 10% interest rate.[155] There is no basis for assuming such a short lifespan for an electric internal combustion engine. As discussed further above, gas-fired RICE units have a useful life of at least 30 years, and many have been in operation much longer than 30 years.[156] Had CARB assumed a 30-year life of controls, the annualized cost of a new electric compressor over 30 years would be significantly lower than CARB's assessment of those costs over 10 years. Further, for an engine that operates more than 2,000 hours per year, replacement with an electric engine will reduce more NOx emissions, which would also make the replacement of an engine with an electric engine more cost effective.

More recently, EPA's Natural Gas STAR Program issued a Fact Sheet which evaluated the methane-reduction benefits of replacing gas-fired reciprocating compressors with electric compressors.[157] According to EPA, "[t]he EPA's Natural Gas STAR Program provides a framework for Partner companies within U.S. oil and gas operations to implement methane reducing technologies and practices and document their voluntary emission reduction activities."[158]

The Fact Sheet documents the costs of replacing five existing gas-fired reciprocating compressors with four electric compressors.[159] This Fact Sheet was made available in 2011, and thus the cost basis is assumed to be either from 2010 or 2011. Specifically, the Fact Sheet indicates that a partner replaced two 2,650 hp reciprocating compressors, two 4,684 reciprocating compressors, and one 893 hp reciprocating compressor with four 1,750 hp electric compressors.[160] The Fact Sheet states that the total cost of the replacement was $6,050,000, including the cost of the motor and compressor.[161] The Fact Sheet calculated the cost of electricity as the primary operating expense, and the electricity costs assuming continual operation of the compressors throughout the year were estimated to be $6,800,000

[160] *Id.* at 2.
[161] *Id.*

per year.[162] For electric compressors that operated less than every hour of the year, these operating costs can be scaled back by multiplying the projected electricity cost for continual operation by the ratio of the number of hours operated per year to 8,760 hours per year. Maintenance costs were assumed to be approximately 10% of the capital costs, and the maintenance costs would be lower than apply to gas-fired engines.[163] The Fact Sheet also presents the fuel gas savings for not having to pay for the natural gas to fire the reciprocating compressors based on three prices for natural gas ($3.00 per thousand cubic feet (MCF) of gas, $5.00 per MCF, and $7.00 per MCF).[164] The amount of natural gas saved by changing to electric compressors was estimated to be 1,700,000 MCF, assuming continual (8,760 hours) operation throughout the year and 20% efficiency of the gas-fired reciprocating compressors.[165] Because this analysis was focused on reducing methane emissions, no calculations of cost effectiveness of this control was done for NOx or any other pollutant.

With these data, the cost effectiveness of replacing similar-sized existing reciprocating compressor engines with similar-sized electric compressor engines as a NOx control measure can be calculated. For these calculations, it is assumed that the existing gas-fired reciprocating compressor engines are uncontrolled for NOx and thus emitting NOx at 16.8 g/bhp-hr.[166] To reflect compressor engines operating at varying hours per year, cost effectiveness calculations were done for replacing compressor engines operating at 2,000 hours, 4,000 hours, and 8,000 hours per year. The capital costs of the new electric compressors were amortized over a 30-year expected life of the new electric compressor engines, assuming a 5.5% interest rate consistent with EPA's Control Cost Manual methodology. The results of this analysis are provided in Table 14 below.

[162] *Id.* This assumed that the four 1,750 hp compressor engines had 50% efficiency, operated 8,760 hours per year, and electricity cost $0.075/kW-hr.
[163] *Id.*
[164] *Id.*
[165] *Id.* A heating value of natural gas of 1,020 British Thermal Units (BTU) per standard cubic feet (SCF) of gas was also assumed.
[166] *See* EPA 1993 Alternative Control Techniques Document for RICE, Table 2-1 at 2-3.

Table 14. NOx Cost Effectiveness to Replace Natural Gas-Fired RICE Units with Electric Compressor Engines[167]

	Costs at Operating Hours per Year (2011 $)		
	2,000 hours/yr	**4,000 hrs/yr**	**8,000 hrs/yr**
Annualized Capital Costs of New Electric Engines	$506,385	$506,385	$506,385
Annual Operating Costs of New Engines and Excluding Costs of Gas for Replaced Engines	$992,940	$1,380,880	$2,156,761
Total Annual Costs	$1,887,265	$1,887,265	$2,663,146
NOx Removed, tpy	542 tpy	1,084 tpy	2,168 tpy
NOx Cost Effectiveness at Stated Hours/Year	$2,766/ton	$1,741/ton	$1,228/ton

Assumptions

- Existing Gas-Fired Reciprocating Compressor Engines: 2–2,650 hp, 2–4,684 hp, 1–893 hp
- Replacement Electric Compressor Engines: 4–1,750 hp
- Efficiency of Existing Gas-Fired Engines: 20%
- Efficiency of Electric Engines: 50%
- 30 Year Life of Electric Engines, 5.5% Interest Rate
- Cost of Electricity: $0.075 per kilowatt-hour; Cost of Natural Gas: $3.00/MCF[168]
- Annual Maintenance Costs: 10% of Capital Costs of New Electric Engines

The above cost effectiveness analysis does not take into account the increased emissions that may occur from the electric power generation that will power the new electric compressor engines, which will depend on the source of that power for the new electric engines. If the energy is provided by renewable sources, there will be no NOx, greenhouse gas, or other air pollution increase associated with the energy production. To take into account the increase in NOx from a fossil fuel-fired power plant providing the electricity to the electric compressor engines, a high-end estimate of the increase in NOx from fossil-fuel fired power plant would mean that the switch to electric engines would result in an overall NOx emission reduction of about 97% of the NOx emitted by the gas-fired reciprocating compressor engines (i.e., a power plant providing the electricity for the new electric compressor engines might increase NOx by 15 to 59 tons per year depending on the hours of operation of the new electric compressor

[167] The basis for the capital and operating costs are from EPA's PRO Fact Sheet No. 103 Install Electric Compressors.
[168] The $3.00/MSCF estimated cost of natural gas may overestimate natural gas prices. The EIA reported the Henry Hub Spot Price for 2019 to be $2.66/MCF and has projected the cost to stay similar or decrease slightly in 2020-2021. However, the Henry Hub spot price was higher ($3.27/MCF) in 2018. Further, the EIA lists the 2019 Industrial Sector price of natural gas to be $3.90. It is not clear which of these two prices would apply, and thus the assumed $3.00/MCF price of natural gas is a middle ground between these two prices. *See* https://www.eia.gov/outlooks/steo/report/natgas.php.

engines).[169] From the perspective of cost effectiveness, the potential increase in NOx emissions from the power generating source would not significantly impact cost effectiveness of replacing gas-fired engines with electric engines.

The costs in Table 14 assume that the engines are located relatively close to the power grid and thus do not take into account any costs to bring electricity to the site. For a site that is not relatively close to the power grid, CARB estimated it could cost $5,000 to $10,000 (in 1999 dollars) to set up the site for electric motor operation and states that some utilities may waive or refund those costs if monthly energy usage matches the cost to connect to the grid.[170]

There are many benefits associated with replacing gas-fired reciprocating compressor engines with electric compressor engines. Those benefits include: [171]

- Reduced maintenance requirements and costs.
- Electric engines are more efficient than gas-fired engines.
- Lower noise levels with electric motors compared to gas-fired engines.
- No on-site emissions of other air pollutants.

An additional benefit of replacing gas-fired engines with electric engines is the greenhouse gas reductions that would be achieved. With renewable energy accounting for a larger share of electricity production over time, there could be significant reductions in greenhouse gases by using electrified engines powered by renewable energy. In the EPA's Natural Gas STAR Program Fact Sheet for electric compressors, the gas savings by electrifying the compressors is stated to be 32,800 MCF per year.[172] With that amount of gas not being combusted in the compressor engines and the power for the compressor engines being supplied by renewable energy, there would be a decrease in greenhouse gas emissions of almost 2,000 tons per year.[173] With electric compression engines used, there also will be less methane released from compressor blowdowns. Compressors must be taken offline at times due to emergency upsets and due to maintenance. As previously stated, the maintenance requirements with an electric compressor engine are significantly less with electric compressor engines.[174] It also seems likely that an electric engine would be less prone to upsets that cause the engine to go offline, compared to a gas-fired reciprocating engine. Moreover, with no gas used in the compressor engine, fugitive emission leaks due to fuel gas are also eliminated. EPA's Natural Gas STAR Program Fact Sheet provided an estimate that methane emissions savings from replacing the five gas-fired compressor engines with electric engines could be as high as 16,000 MCF per year, based on a methane emission factor of 2.11

[169] A NOx rate of 1.4 pounds per megawatt-hour was assumed for these calculations to represent a high-end estimate of the increase in NOx emissions if a fossil fuel-fired power plant provided the electricity for the electric engines. This reflects a NOx limit of 0.15 lb/MMBtu for a coal-fired power plant, which reflects a plant burning subbituminous coal with combustion controls. A natural gas-fired power plant would likely have a lower NOx rate, particularly if equipped with SCR.

MCF per horsepower.[175] Using the 100-year global warming potential identified by EPA,[176] that equates to roughly 10,000 tons per year of CO_2 equivalent emissions that would be avoided with no natural gas releases due to blowdowns with electric compressor engines. Thus, the total CO_2 equivalent emissions that could be reduced by replacing the five gas-fired engines with electric compressors powered with renewable energy would be about 12,000 tons per year.

There are several examples of electric engines being used in the oil and gas industry for compression, both at the wellhead and in compressor stations,[177] for drill rigs,[178] and in oil pumps.[179] Ambient air quality concerns have typically been the driver for electrification of engines in the past. Electrification of RICE units can be a very cost effective way to eliminate NOx and other air emissions, including greenhouse gas emissions, for the oil and gas industry and thus should be given serious consideration as an effective pollution control to address regional haze.

G. NOx EMISSION LIMITS THAT HAVE BEEN REQUIRED FOR EXISTING NATURAL GAS-FIRED STATIONARY RICE UNITS

The NSPS standards applicable to stationary spark ignition gas-fired RICE units were last reviewed and revised in 2008.[180] The most stringent NOx limit of those standards currently in effect for new and modified spark ignition RICE units is 1.0 g/hp-hr for rich burn engines greater than 100 hp and for lean-burn engines between 100 hp and 1,350 hp.[181] In considering reasonable progress controls for gas-fired spark-ignition RICE units, the applicable NSPS standards should be considered the "floor" of potential NOx controls to consider for an existing RICE unit.

Numerous states and local air agencies have adopted similar or more stringent NOx limits for existing spark-ignition gas-fired RICE units to meet, many of which have been in place for 10–20 years. In Table 15 below, we summarize those state and local air pollution requirements. Some of this information was initially obtained from EPA's 2016 CSAPR TSD,[182] which provided a summary of state NOx regulations for gas engines.[183] The current state/local requirements for those CSAPR states were confirmed by a review of the state and local rules. The CSAPR TSD focused on the rules applicable in the CSAPR states. A review of California Air District rules was also done for this report, because several of those air districts have adopted the most stringent NOx emission limitations for existing gas-fired engines. We reviewed many of the remaining states' regulations to determine whether there were NOx limitations for existing natural gas-fired stationary RICE units.

Table 15 is a summary of the NOx emission limits required of existing gas-fired stationary RICE units in states and local air districts across the United States. It is important to note that these are limits that, unless otherwise noted, currently apply to existing RICE. Unlike the NSPS standards of 40 C.F.R. Part 60, Subpart JJJJ, the RICE did not have to be modified to trigger applicability to these emission limits. Instead, these emission limits apply to existing natural gas-fired stationary RICE units and generally required an air pollution control retrofit. These state and local NOx limits were most likely adopted to address nonattainment issues with the ozone NAAQS and possibly also the $PM_{2.5}$ NAAQS. However, Colorado adopted a NOx limit for lean-burn RICE of 1 g/hp-hr as part of its initial regional haze plan to achieve reasonable progress towards the national visibility goal.[184] Regardless of the reason for adopting the NOx emission limits, what becomes clear in this analysis is that numerous states and local governments have adopted NOx limitations that require NSCR at rich burn RICE units and either LEC or SCR at lean-burn RICE units. The lowest, most broadly applicable NOx limits are those recently adopted by SCAQMD which require gas-fired RICE units greater than 50 hp in size to meet a 11 ppmvd (equivalent to 0.15 g/hp-hr) NOx limit.

These limits were adopted generally to meet reasonably available control technology (RACT) and best available retrofit control technology (BARCT — applies in California), and costs are taken into account in making these RACT and BARCT determinations. However, RACT is not necessarily as stringent as BARCT. RACT is generally defined as: "devices, systems, process modifications, or other apparatus or techniques that are reasonably available taking into account: (1) The necessity of imposing such controls in order to attain and maintain a national ambient air quality standard; (2) The social, environmental, and economic impact of such controls."[185] BARCT, on the other hand, is defined as "an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy, and economic impacts by each class or category of source."[186] BARCT is like a best available control technology (BACT) determination under the federal prevention of significant deterioration (PSD) program, but it evaluates controls to be retrofit to existing sources, rather than applying to new or modified sources.

Table 15. State/Local Air Agency RICE Rules for Natural Gas-fired Stationary RICE Units[187]

State/Local	Regulation	Rich-Burn (RB) or Lean- Burn (LB) or Both	Applicability	NOx Limit and units (equivalent g/hp-hr)
CA-Antelope Valley AQMD[188]	Rule 1110.2	Both	50–500 hp	45 ppmvd (0.67 g/hp-hr (RB) or 0.62 g/hp-hr (LB))
			>500	36 ppmvd (0.54 g/hp-hr (RB) or 0.49 g/hp-hr (LB))

State/Local	Regulation	Rich-Burn (RB) or Lean- Burn (LB) or Both	Applicability	NOx Limit and units (equivalent g/hp-hr)
		>3/16/79 and facility PTE NOx >25 tpy		
UT[213]	R307-510	Gas-fired engine at a well site that began operations, installed new engines or made modifications to existing engines after 1/1/16	≥100 hp	1.0 g/hp-hr

Most stringent NOx Limit of State/Local Rules:
11 ppmvd (0.15–0.16 g/hp-hr) applicable to either rich-burn or lean-burn RICE units greater than 50 bhp

In addition to the state and local air agency rules requiring NOx emission limits that clearly reflect highly effective NOx controls, some states have BACT or similar requirements that are required of new or modified sources regardless of whether or not such sources or modifications are major and subject to the major source PSD permitting programs. In some cases, states have issued guidelines on what is essentially considered BACT for these non-PSD new and modified sources, in the form of guidance and/or general permit or permit by rule requirements for RICE units. Table 16 below summarizes some of these state requirements which, when imposed in a permit would become binding emission limits.

[213] https://rules.utah.gov/publicat/code/r307/r307-510.htm.

Table 16. Other NOx Limits Applicable to Natural Gas-fired Stationary RICE Units

State	Determination	Applicability [hp]	NOx Limits and Engine Type Applicability [RB, LB or BOTH]
NEW JERSEY[214]	State of the Art (SOTA) Emission Performance Levels	NO SIZE SPECIFIED	0.15 g/hp-hr (BOTH)[215]
PENNSYLVANIA [216]	Best Available Technology (BAT) Emission Limits for new SI RICE permitted on or after 8/8/18	≤100	1.0 g/hp-hr
		>100 TO ≤500	0.7 g/hp-hr (LB) 0.25 g/hp-hr (RB)[217]
		>500	0.5 g/hp-hr (LB) 0.2 g/hp-hr (RB)
		≥2,370	0.3 g/hp-hr uncontrolled (LB) **or** 0.05 g/hp-hr with control (LB)[218]
PENNSYLVANIA [219]	Best Available Technology (BAT) Emission Limits for existing SI RICE permitted on or after	≤100	2.0 g/hp-hr
		>100 TO ≤500	1.0 g/hp-hr (LB)

[214] NJ DEP State of the Art Manual for Reciprocating Internal Combustion Engines (2003), *available at*: https://www.state.nj.us/dep/aqpp/downloads/sota/sota13.pdf.

[215] Generally applied controls to meet State of the Art Emission Performance Levels:

Rich-burn: NSCR

Lean-burn: SCR or LEC

Basis: "In determining SOTA performance levels for RICE engines, permitting agencies, industry associations, manufacturers of RICE and manufacturers of emissions control equipment were contacted to obtain updated information on emissions and control technologies. Databases for recent permitted and tested engines from New Jersey, California and USEPA were reviewed." *Id.* at 8.

Rubart Station was determined to be SCR with a NOx BACT limit equivalent to 0.07 g/hp-hr for loads of 50% or higher.[224]

As Table 15 shows, twenty-three state and local air pollution control agencies have adopted NOx emission limits for existing gas-fired stationary RICE units that reflect the application of NSCR to rich-burn natural gas-fired RICE units greater than 50 hp and LEC and/or SCR for lean-burn natural gas-fired RICE units greater than 50 hp. These air agencies have thus found that the levels of NOx control listed in Table 15, including NOx limits as low as 11 ppmvd, are cost effective for existing natural gas-fired RICE units, providing relevant examples of one measure for states to consider in their second round haze plans to help make reasonable progress towards remedying existing visibility impairment. Further, several states have adopted essentially presumptive BACT NOx limits for new or modified RICE engines that are at least as stringent as the most stringent NSPS limit and/or apply to smaller units than the NSPS. The fact that these limits could apply to modified units means that the states consider retrofit controls to meet the emission limits in Table 15 above to be cost effective. Table 16 above also provides relevant examples of one measure for states to consider to prevent future impairment of visibility due to oil and gas development.

H. SUMMARY – NOx CONTROLS FOR EXISTING RICH-BURN AND LEAN-BURN NATURAL GAS-FIRED RICE

The above analyses and state/local rule data demonstrate that numerous state and local air agencies have found that NSCR is a cost effective NOx control for rich-burn natural gas-fired RICE units with costs ranging from $44/ton to $3,383/ton (2009$). NSCR not only reduces NOx, but can also be optimized with the use of an AFRC and an oxygen sensor to effectively reduce CO and HC and VOCs.

Further, numerous state and local air agencies have found that LEC is cost effective for lean-burn natural gas-fired RICE units with costs ranging from $74/ton to $941/ton (2001$). For the lowest NOx limit of 11 ppmvd applicable to lean-burn engines under rules adopted by SCAQMD and SJVAPCD, SCR was presumably necessary to meet these limits with costs ranging from $650 to $3,500 per ton of NOx removed or even higher for engines that operate 2,000 hours per year.

As states evaluate regulation of NOx emissions from natural gas-fired RICE units, there are several factors to consider, such as how the units are loaded (cyclically or not), operating capacity factor, and size. Nonetheless, given the numerous state and local NOx limits in Table 15 above that reflect operation of NSCR at rich-burn units and LEC or SCR at lean-burn units, these controls for rich-burn and lean-burn units rated at 50 hp or greater should generally be considered as cost effective measures available to make reasonable progress from natural gas-fired RICE units, given that similar sources have assumed similar costs of control to meet Clean Air Act requirements. NSCR has the added visibility benefit of reducing VOCs, as well as NOx.

[224] Prevention of Significant Deterioration Air Construction Permit Application for Mid-Kansas Electric Company, LLC Rubart Station (July 2012), *available at:* http://www.kdheks.gov/bar/midkanec/Mid-Kansas_Rubart_Station_PSD_Air_Permit_App_12_19_12.pdf.

It also must be recognized that it may be as or more cost effective for NOx control, and more beneficial for regional haze, to replace gas-fired RICE units with electric engines rather than install NOx pollution controls. Moreover, electric engines have numerous benefits that should be considered with regard to the energy and non-air impacts factor of a reasonable progress analysis. These additional benefits include reducing on-site emissions of all pollutants, reduced noise levels, more efficient operation and maintenance requirements (including less frequent maintenance required), and decreased methane emissions due to blowdowns because the electric engines do not require as frequent maintenance and do not have as many upsets. In addition, if the power for the electric engines can be derived from renewable energy sources, the greenhouse gas reductions can be very significant. Indeed, with renewable energy becoming an increasingly greater proportion of electricity generation and with coal-fired electricity generation being phased out, these added benefits of replacing gas-fired RICE units with electric engines should be considered in the four-factor analysis of controls. Electrification of engines may be less cost effective than some of the NOx controls evaluated above such as NSCR and LEC, but the potential added benefits with electric motors will likely weigh in favor of electrification as the most effective reasonable progress control for RICE.

III. CONTROL OF VOC EMISSIONS FROM NATURAL GAS-FIRED RICE

VOC emissions from natural gas-fired RICE units result from incomplete combustion. The same is true for CO emissions. The combustion conditions that favor lower NOx emission rates, such as lower temperature combustion, tend to result in less complete combustion and thus higher VOC as well as CO emission rates. In general, the emissions of VOCs from uncontrolled gas-fired RICE are of a lower magnitude compared to NOx emissions. A discussion of the pollution controls to reduce VOC emissions from these engines is provided below.

EPA's AP-42 Emission Factor documentation indicates that the uncontrolled VOC emission factors for natural gas-fired RICE in the range of 0.03 to 0.12 lb/MMBtu,[225] although it must be noted that EPA gives these emission factors a "C" rating. EPA's emission factor ratings indicate the reliability of the emissions factor, and a "C" rating reflects that "[t]ests are based on unproven or new methodology, or are lacking a significant amount of background information."[226] EPA also states that "actual emissions may vary considerably from the published emission factors due to variations in engine operating conditions."[227] That said, EPA's emission factors for uncontrolled VOCs are an order of magnitude lower than uncontrolled NOx emissions from RICE units. For that reason, this report focuses extensively on NOx emission controls for RICE units. However, there are emission controls feasible and implemented for VOCs from RICE units.

VOC Controls for Lean-Burn RICE

For lean-burn natural gas-fired RICE, as well as natural gas-fired combustion turbines, the primary method available for reducing VOC emissions is the use of an oxidation catalyst. For rich-burn RICE, NSCR is the pollution control of choice to address VOCs, as its three-way catalyst generally reduces NOx, CO, and VOCs with proper operation, although an oxidation catalyst can be installed downstream of the NSCR to improve VOC control.

A 2015 report issued by the Manufacturers of Emission Controls Association on emission controls for stationary internal combustion engines states as follows regarding oxidation catalyst for lean-burn engines:[228]

> Oxidation catalysts (or two-way catalytic converters) are widely used on diesel engines and lean-burn gas engines to reduce hydrocarbon and carbon monoxide emissions. Specifically, oxidation catalysts are effective for the control of CO, NMHCs, VOCs, and formaldehyde and other [hazardous air pollutants (HAPs)] from diesel and lean-burn gas engines. Oxidation catalysts consist of a substrate made up of thousands of small channels. Each channel is coated with a highly porous layer containing precious metal catalysts, such as platinum or palladium. As exhaust gas travels down the channel, hydrocarbons and carbon monoxide react with oxygen within the porous catalyst layer to form carbon dioxide and water vapor. The resulting gases then exit the channels and flow through the rest of the exhaust system.
>
> An oxidation catalyst has two simultaneous reactions:
>
> Oxidation of carbon monoxide to carbon dioxide:
> $2CO + O_2 \rightarrow 2CO_2$
>
> Oxidation of hydrocarbons (unburnt and partially burnt fuel) to carbon dioxide and water:
> $C_xH_{2x+2} + [(3x+1)/2]O_2 \rightarrow xCO_2 + (x+1)H_2O$

This 2015 report states that oxidation catalysts can reduce VOC emissions by 60–99%, as well as reduce CO emissions by 70–99%, non-methane HC by 40–90%, and formaldehyde and other hazardous air pollutants by 60–99%.[229] If a lean-burn engine is equipped with SCR for NOx control, an oxidation catalyst can be added to the SCR design.[230]

Cost information of oxidation catalyst was provided to EPA in 2010 to help determine national impacts associated with EPA's RICE NESHAP.[231] The analysis, performed by E^C/R Incorporated, was based on 2009 cost data for oxidation catalyst from industry groups, vendors, and manufacturers of RICE control

[228] *See* Manufacturers of Emission Controls Association, Emission Control Technology for Stationary Internal Combustion Engines, Revised May 2015, at page 8, Section 1.2.1, *available at*: http://www.meca.org/resources/MECA_stationary_IC_engine_report_0515_final.pdf.

[230] *Id.* at 7.
[231] Memo from EC/R Inc. to EPA Re: Control Costs for Existing Stationary SI RICE (June 29, 2010).

technology. E^C/R Incorporated performed a linear regression analysis[232] on the oxidation catalyst cost data set for 2-stroke lean-burn engines and for 4-stroke lean-burn engines to establish an equation for each type of engine to estimate total annual cost and total capital costs as follows:

2SLB Oxidation Catalyst Total Annual Cost = $11.4 x HP + $13,928

2SLB Oxidation Catalyst Total Capital Cost = $47.1 x HP + $41,603

4SLB Oxidation Catalyst Total Annual Cost = $1.81 x HP + $3,442

4SLB Oxidation Catalyst Total Capital Cost = $1.81 x HP + $3,442

Where HP equals the engine size in horsepower.

E^C/R Incorporated developed equations to reflect total annual costs oxidation catalyst assuming a 7% interest rate and a 10-year life for amortizing the capital costs of control and adding in the annual operation and maintenance costs.[233] For the same reasons discussed regarding NSCR in Section II.C. above, it is reasonable to assume a 15-year life of oxidation catalyst controls at lean-burn RICE. Further, a lower interest rate of 5.5% is the appropriate interest rate to currently apply pursuant to the recommendations of EPA's Control Cost Manual for determining annualized capital costs of oxidation catalyst. Table 17 below provides the capital costs for oxidation catalysts at various size gas-fired lean-burn RICE and the total annualized cost of the control, assuming a 5.5% interest rate and a 15-year life.

Table 17. Capital and Annual Costs of Oxidation Catalyst at Lean-Burn RICE.[234]

ENGINE TYPE	HORSEPOWER	TOTAL CAPITAL COSTS	TOTAL ANNUALIZED COSTS
2SLB	50	$43,958	$12,619
	75	$45,136	$12,853
	100	$46,313	$13,088
	250	$53,378	$14,496
	500	$65,153	$16,843
	1000	$88,703	$21,536
	1500	$112,253	$26,229
4SLB	50	$3,533	$3,381
	75	$3,578	$3,425
	100	$3,623	$3,468
	250	$3,895	$3,727
	500	$4,347	$4,160
	1000	$5,252	$5,025
	1500	$6,157	$5,890

[233] *Id.* at 5-6 and Appendix A.

[234] Cost calculations based on E^c/R equations from above, but assuming a 15-year life and a 5.5% interest rate.

A 2019 report by SCAQMD indicates that 500 stationary lean-burn engines have been fitted with oxidation catalyst.[235] In Colorado, sixty lean-burn RICE of sizes greater than 500 hp were required to install oxidation catalyst under the 2004 Denver Early Action Compact rulemaking.[236] As of July 1, 2010, Colorado requires all existing lean-burn RICE greater than 500 hp in the state's ozone action areas to install and operate an oxidation catalyst with an emission performance standard of 0.7 g/hp-hr.[237] Colorado only exempted lean-burn engines in the Denver area from the requirement to install oxidation catalyst if the cost was greater than $5,000/ton.[238] There are also several examples of oxidation catalyst being required as BACT for VOCs for lean-burn RICE. For example, in Missouri, BACT for lean-burn RICE at the Mid-Kansas Electric Company, LLC's Rubart Station was based on good combustion practices and an oxidation catalyst with a VOC BACT limit equivalent to 0.2 g/hp-hr for loads of 50% or higher.[239] In another example, BACT for RICE at the Irving Generating Station in Arizona was based on use of an oxidation catalyst with a VOC BACT limit (less formaldehyde) of 0.7 g/hp-hr.[240] In the BACT analysis for the Irving Generating Station several other recent examples were presented demonstrating consistent VOC BACT limits for natural gas-fired RICE, including limits as low as 0.3 g/hp-hr.[241]

In summary, oxidation catalyst is an available control technology that should be considered as a reasonable progress control option to reduce VOC emissions for lean-burn gas-fired RICE.

VOC Controls for Rich-Burn RICE

As discussed in Section II.C. above, NSCR is a three-way catalyst applicable to rich-burn RICE units, which not only removes NOx emissions, but also reduces CO and VOC emissions. In addition to the NSCR catalyst and housing, NSCR requires installation of an oxygen sensor and an AFRC ensure optimum air-to-fuel ratios to ensure conditions are NSCR is the primary VOC control that is implemented for rich-burn gas-fired RICE. Colorado has indicated that an "oxidation catalyst using additional air can be installed downstream of the NSCR catalyst for additional CO and VOC control."[242] The costs for NSCR have been detailed above in Section II.C. NSCR's cost effectiveness for NOx control and its widespread required use, as shown in the state and local air agency rules detailed in Table 15 above, indicates that NSCR must be considered as a reasonable progress control option to reduce VOC emissions from rich-burn RICE.

IV. CONTROL OF NOx EMISSIONS FROM NATURAL GAS-FIRED COMBUSTION TURBINES

Natural gas-fired combustion turbines are used in the oil and gas development industry generally for two purposes: (1) power generation and (2) compression. Combustion turbines are sometimes used to provide on-site power to gas processing facilities, or combustion turbines are used to drive compressors. There are several points in the oil and gas production process where compression of the natural gas is required to move the gas in the pipeline. When a combustion turbine is used for gas compression, the turbine drives the compressor, which is typically a centrifugal compressor. [243]

Gas turbines have been used for power generation since the late 1930s and are available in sizes as low as 500 kilowatts (kW) to over 300 Megawatts (MW).[244] Gas turbines produce a high-heat exhaust that can be recovered in a combined heat and power to produce steam to power a generator. This process is referred to as combined cycle power generation. However, in the oil and gas production industry, gas turbines are generally operated in simple cycle mode. Gas turbines can be used in remote locations such as oil and gas wellfields to provide distributed generation and portable power generation.[245] In some cases, combustion turbines are used at power plants developed for the purpose of providing power to oil and/or gas development but which are also selling electricity to the grid. If a power generating source is constructed for the purpose of supplying more than one-third of its potential electric output capacity to any utility power distribution system for sale, then it is considered an electric utility.[246] Although this specific analysis of controls will focus on the gas turbines used for gas compression or used for on-site power (i.e., "distributed generation") at oil and/or gas production and processing facilities, the available air pollution controls are the same for simple cycle turbines regardless of whether or not such turbines are part of an electric utility.

When combustion turbines are used to drive a compressor, there is no electrical generator (although there could be some heat recovery which could be used to generate electricity through a steam turbine).[247] Instead, the turbine shaft power is used as mechanical power to drive a compressor. Regardless of the purpose of the gas-fired combustion turbines, the air pollution controls for the associated visibility-impairing pollutants are the same.

The 2012 Ozone Transport Commission Report refers to a report on costs of NOx controls at gas turbines prepared for the U.S. Department of Energy (DOE) in 1999.[248] That DOE Report, "Cost Analysis of NOx Control Alternatives for Stationary Gas Turbines" dated November 5, 1999 (hereinafter "1999 DOE Report")[249] is cited in several EPA and state documents on the cost of NOx controls at gas turbines, including in a Northeast States for Coordinated Air Use Management (NESCAUM) 2000 Status Report on NOx Controls for gas turbines and other sources,[250] which, in turn, serves as EPA's primary reference for the cost of SCR in its recently revised SCR chapter in its Control Cost Manual.[251] The NESCAUM 2000 Status Report on NOx controls also has other cost information for NOx controls for gas turbines. While these reports are twenty years old, the cost analyses have been relied on extensively by EPA and states.[252] In addition, more recent analyses of the costs of NOx controls for gas turbines have been summarized as supporting information for state and local air agency adoption of NOx emission limitations for gas turbines, but those cost analyses are generally not as detailed as the 1999 DOE report. In the discussion below of the NOx pollution control options for gas turbines, we provide information on all of these various cost analyses.

Note that in the following discussion, NOx emission rates are often referred to as parts per million or "ppm." It should be assumed that such concentration rates are in parts per million by volume or "ppmv" measured on a dry basis and corrected to 15% oxygen unless stated otherwise.

A. WATER OR STEAM (DILUENT) INJECTION

Water or steam injection has been used for decades to reduce NOx emissions from gas turbines. EPA describes the control in its "AP-42" emission factor documentation for gas turbines as follows:

> Water or steam injection is a technology that has been demonstrated to effectively suppress NOx emissions from gas turbines. The effect of steam and water injection is to increase the thermal mass by dilution and thereby reduce peak temperatures in the flame zone. With water injection, there is an additional benefit of absorbing the latent heat of vaporization from the flame zone. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.
>
> Depending on the initial NOx levels, such rates of injection may reduce NOx by 60 percent or higher. Water or steam injection is usually accompanied by an efficiency penalty (typically 2 to 3 percent) but an increase in power output (typically 5 to 6 percent). The increased power output results from the increased mass flow required

> to maintain turbine inlet temperature at manufacturer's specifications. Both CO and VOC emissions are increased by water injection, with the level of CO and VOC increases dependent on the amount of water injection.[253]

The 1999 DOE Report on NOx pollution controls for gas turbines indicates that water or steam injection can achieve a NOx rate of 42 ppm.[254] In a more recent document, EPA states that water or steam injection enables a gas turbine to achieve NOx levels of 25 ppm at 15% oxygen.[255] General Electric also indicates that water injection can reduce NOx emissions to 25 ppm for gas-fired turbines.[256] The achievable NOx rate with water or steam injection likely depends on the uncontrolled NOx rate before water or steam injection, which can vary by turbine size and manufacturer.

Water injection has been a commonly applied retrofit NOx control technology for gas turbines for several decades. Water injection is available to most turbines; however, with advances in dry low NOx combustion techniques (discussed in the next section), it is not necessarily the first NOx control of choice given the lower cost and more effective options being available, depending on the turbine type. The turbine modifications necessary to accommodate water or steam injection could range from replacement of fuel nozzles with nozzles capable of supplying both fuel and water or steam, to replacement of the combustors with combustors designed to operate with water or steam injection, depending on the make and model of the combustion turbine.[257] There would also be other required equipment such as appropriate combustion turbine controls, an onsite water plant to demineralize water with storage or a storage tank for delivered demineralized water, a water injection pump, and a water or steam flow metering station.[258]

The 1999 DOE Report listed the capital and annual operating costs for water injection installed at specific makes/models of combustion turbines, which are reiterated in the table below.

Table 18. Capital and Operating Costs of Water or Steam Injection for Select Combustion Turbines[259]

Turbine Make/Model	Size, MW	Size, hp	Capital Costs of Water/Steam Injection 1999$	Annual Costs (Excluding Capital Recovery), 1999$
Solar Centaur 50	4.2 MW	5,632 hp	$405,500	$79,000
Allison 501-KB5	4.0 MW	5,364 hp	$291,000	$100,000
GE LM2500	22.7 MW	30,441 hp	$1,083,175	$294,000
GE MS7001F	161 MW	215,904 hp	$4,834,770	$1,325,000

[257] 2012 OTC Report at 62.
[258] *Id.*
[259] *See* 1999 DOE Report, Appendix A at A-5 (Table A-4).

The 1999 DOE report determined the annualized costs of control assuming only a 15-year life of controls and a 10% interest rate.[260] The DOE report provides no discussion as to why it assumed a 15-year life of controls, other than to state that EPA used the same 15-year life in a 1993 NOx control document.[261] There is no documented justification for assuming a 15-year life of water or steam injection controls for a combustion turbine. Instead, it is reasonable to assume that the design life of a combustion control like water or steam injection at a gas-fired combustion turbine is equal to the design life of the combustion turbine. A literature review indicates that 25 to 30 years is the design life of a gas combustion turbine.[262] Indeed, a review of permitted compressor stations and gas processing facilities in the state of New Mexico shows several combustion turbines operating today that were installed more than 30 years ago.[263] For the purpose of determining the annualized cost of controls, an assumption of a 25-year life of a water or steam injection system is more than reasonable and justified. Thus, to determine annualized costs based on the capital and operational expenses for water/steam injection presented in Table 18 above, a 25-year life of controls was assumed. Further, to be consistent with EPA's Control Cost Manual, which recommends the use of the bank prime interest rate,[264] a lower interest rate of 5.5% was assumed.[265] In its 2019 cost calculation spreadsheet for SCR provided with its Control Cost Manual, EPA used an interest rate of 5.5%.[266] The annualized costs of controls are presented for the four turbine types in Table 19 below.

The 1999 DOE Report calculated cost effectiveness of water or steam injection for the four turbine models listed in Table 18 above based on achieving a NOx rate of 42 ppm.[267] EPA relied on these cost estimates in its 2016 Technical Support Document for the Cross-State Air Pollution Rule regarding non-EGU NOx emissions controls, stating that the "generally accepted threshold" NOx emission rates that can be achieved with water injection was 42 ppmvd.[268] In its 2016 TSD for the CSAPR rule, EPA did not escalate the costs of controls from 1999 dollars.[269] As discussed above, lower NOx rates with water or steam injection of 25 ppm are generally achievable. Thus, in Table 19 below, the cost effectiveness of

---

water/steam injection is calculated both to comply with a 42 ppm limit and a 25 ppm limit, based on a 25-year life and a 5.5% interest rate.

Table 19. Cost Effectiveness to Reduce NOx Emissions by Water or Steam Injection for Select Combustion Turbines Operating at 91% Capacity Factor[270]

Turbine Make/Model	Size, MW	Size, hp	Annualized Costs of Water/Steam Injection 1999$	Cost Effectiveness of Water/Steam Injection to Meet 42 ppm NOx Rate (1999$)	Cost Effectiveness of Water/Steam Injection to Meet 25 ppm NOx Rate (1999$)
Solar Centaur 50	4.2	5,632	$109,230	$1,496/ton	$1,265/ton
Allison 501-KB5	4.0	5,364	$121,694	$1,323/ton	$1,153/ton
GE LM2500	22.7	30,441	$374,750	$846/ton	$752/ton
GE MS7001F	161	215,904	$1,685,429	$409/ton	$373/ton

In sum, the cost effectiveness of water or steam injection at a gas-fired turbine is in the range of $1,150-$1,500/ton for the smaller turbines, $750 to $850/ton for a mid-sized turbine, and $375 to $410 for a large turbine. It must be noted that this cost effectiveness analysis is based on an assumed 8,000 hours of operation per year.[271] A 2012 document of technical information on the oil and gas sector available on the Ozone Transport Commission's website indicates that "on average a compressor unit will tend to experience an annual average capacity factor of approximately 40%."[272] This is presumably an average across all compressor engines used in the oil and gas sector, and there are very likely some compressors that do operate at 90% capacity factors. Indeed, the Ozone Transport Commission document indicates that "[f]or many mainline natural gas compressor stations, industry data indicated that the gas compressor stations have compressors in operation 24 hrs/day and 365 days/year, although not all compressors may be operating or may not be operating at high capacity."[273] Given that a compressor station typically is composed of multiple compressors either in parallel or in series powered either by combustion turbines or by reciprocating engines, it seems very likely that one or more of the compressors at a compressor station would operate at a high capacity factor while others would be operated at lower capacity factors, depending on the volume of gas that is being moved through the pipeline at the time. To provide a complete analysis of the range of costs of water or steam injection at a gas-fired combustion turbine, the cost effectiveness analysis of the 1999 DOE Report was revised to reflect a 40% capacity factor. Specifically, the fuel penalty cost (due to the reduction in turbine efficiency with water injection) and all costs dependent on the gallons of water used per year (i.e., the

[270] *See* 1999 DOE Report, Appendix A at A-5 (Table A-4). Capital costs in 1999 dollars were updated from 1999 to 2018 dollars based on CEPCI and CPI indices. Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a 25-year life of controls and a 5.5% interest rate). Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines and a 91% operating capacity factor was assumed, reflective of the assumed 8,000 hours of operation per year in the November 1999 DOE Cost Analysis report.

[271] *Id.*, Appendix A at A-5.

[272] 2012 OTC Report at 16.

[273] *Id.*

water costs, water treatment costs, associated labor costs, and water disposal costs) in the annual costs of the 1999 DOE Report were reduced by 56% to reflect the reduction in operating hours when the units operate at a 40% capacity factor compared to a 91% operating factor.[274] Also, the tons of NOx reduced per year were revised to reflect operations at a 40% capacity factor.

Table 20. Cost Effectiveness to Reduce NOx Emissions by Water or Steam Injection for Select Combustion Turbines Operating at 40% Annual Capacity Factor[275]

Turbine Make/Model	Size, MW	Size, hp	Annualized Costs of Water/Steam Injection 1999$	Cost Effectiveness of Water/Steam Injection to Meet 42 ppm NOx Rate (1999$)	Cost Effectiveness of Water/Steam Injection to Meet 25 ppm NOx Rate (1999$)
Solar Centaur 50	4.2	5,632	$85,649	$2,675/ton	$2,257/ton
Allison 501-KB5	4.0	5,364	$90,021	$2,232/ton	$1,940/ton
GE LM2500	22.7	30,441	$255,506	$1,316/ton	$1,166/ton
GE MS7001F	161	215,904	$1,060,507	$587/ton	$533/ton

EPA's 2016 TSD for the CSAPR rule provided algorithms for estimating the total capital investment and the total annual costs of water injection based on the hourly heat input of the combustion turbine. These equations were based on a 1993 EPA Control Technique guideline as well as the 1999 DOE Report, and the total annual cost algorithms assumed a 15-year equipment life and a lower interest rate of 7%, but still high compared to today's interest rates.[276] The cost algorithms of EPA's 2016 TSD for the CSAPR Rule are reprinted below.[277]

Water Injection/Gas Turbines:

Total Capital Investment (1999 dollars) = 27665 x (MMBtu/hr)^0.69

Total Annual Costs (1999 dollars) = 3700.2 x (MMBtu/hr)^0.95

Steam Injection/Gas Turbines:

Total Capital Investment (1999 dollars) = 43092 x (MMBtu/hr)^0.82

Total Annual Costs (1999 dollars) = 7282 x (MMBtu/hr)^0.76

[274] It is possible that other items in the annual costs should also be reduced to reflect a 40% capacity factor, but it was not clear how to adjust those other costs.

[275] *See* 1999 DOE Report, Appendix A at A-5 (Table A-4). Capital costs in 1999 dollars were updated from 1999 to 2018 dollars based on CEPCI and CPI indices. Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a 25-year life of controls and a 5.5% interest rate). Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines and a 40% operating capacity factor was assumed. The annual costs due to the fuel penalty, water use, water treatment, associated labor, and water disposal were decreased by 56% to reflect a 40% operating capacity factor as opposed to a 91% capacity factor.

[276] *See* 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls, Appendix A at 3-11 to 12 and Appendix B at B-2.

[277] *Id.,* Appendix A at 3-12.

While the cost estimates and cost algorithms are of a cost basis that is from 1999, it is important to note that beginning in the mid- to late-1990s, EPA and several state and local air agencies have found that the costs of control to achieve NOx emission limits of 42 ppmv or even lower were cost effective to require such a level of control on existing gas turbines. This will be discussed further in Section IV.D. below. It is not possible to accurately escalate these costs in 1999 dollars to 2019 dollars. The CEPCI has been used extensively by EPA for escalating costs, but EPA states that using the indices to escalate costs over a period longer than five years can lead to inaccuracies in price estimation.[278] Further, the prices of an air pollution control do not always rise at the same level as price inflation rates. Moreover, as an air pollution control is required to be implemented more frequently over time, the costs of the air pollution control often decrease due to improvements in the manufacturing of the parts used for the control or different, less expensive materials used, etc. Thus, the costs for water or steam injection are presented on a 1999 dollar cost basis in this report, but in any event, Table 29 in Section IV.D. of this report shows that numerous state and local air agencies found that water or steam injection was cost effective to require as a retrofit NOx pollution control at numerous gas turbines.

The environmental and energy impacts of the use of water or steam injection include the following:

- Requires the use of water, likely including a water treatment system, and disposal of wastewater
- Energy penalty due to decreased combustion turbine efficiency, but also increased power output
- May increase turbine maintenance requirements, depending on turbine type
- Can increase carbon monoxide and HC/VOC emissions[279]

Water use and water availability may be a significant environmental impact for this control technology, especially for locations in the arid West that already have water shortage issues. The 1999 DOE Report included information on expected water usage of water injection at the four turbines evaluated for the cost effectiveness analysis,[280] which can be projected into annual water use for water injection at these turbine types. The projected annual water use is provided in the table below, for both operating at a 91% capacity factor and at a 40% capacity factor. The amount of water needed for water injection is directly related to the operating capacity factor of the unit, with more water being needed for units operating at higher capacity factors.

Table 21. Projected Water Use of Water/Steam Injection at Gas-Fired Combustion Turbines[281]

Turbine Model	Size, MW	Annual Water Use at 91% Capacity Factor	Annual Water Use at 40% Capacity Factor
Solar Centaur 50	4.2	1,401,407	616,003
Allison 501-KB5	4.0	1,889,269	830,448
GE LM2500	22.7	7,093,130	3,117,859
GE MS7001F	161	95,166,555	41,831,453

As shown by the above table, water use with water/steam injection significantly increases with larger turbines and with units operated at higher capacity factors.

In addition to water availability, according to EPA, "[w]ater purity is essential for wet injection systems in order to prevent erosion and/or the formation of deposits in the hot sections of the gas turbine."[282] Water quality may be more of an issue for remote sites, especially if surface water or well water is used for the water supply.[283] The costs for the water use, treatment, and disposal, as well as the energy penalty costs, were taken into account in the annual costs of controls used in the NOx cost effectiveness analyses presented in Tables 19 and 20 above.[284]

Notwithstanding the high water usage, water or steam injection is a well-proven and cost effective control for NOx emissions from gas combustion turbines of all sizes. As is discussed in Section IV.D. below, NOx limits reflective of water or steam injection have been required by EPA and numerous state and local air agencies, and water or steam injection is used to control NOx at combustion turbines extensively throughout the U.S. However, for turbines constructed in the early 1990s or later,[285] dry low NOx combustion controls were much more commonly used at gas-fired combustion turbines than water or steam injection, due to lower costs of control, improved NOx control, and the fact that there would be no need for use and treatment of water.[286] Dry low NOx combustors are also available for retrofit for several turbine makes and models. This technology to control NOx is discussed in the next section of this report.

B. DRY LOW NOx COMBUSTION

In the late 1980s, dry low NOx burners (DLNBs) became available on larger turbines[287] and, currently, such controls are available on all new turbines. As described by EPA, "[l]ean premixed combustion . . . pre-mixes the gaseous fuel and compressed air so that there are no local zones of high temperatures, or 'hot spots,' where high levels of NOx would form. Lean premixed combustion requires specially designed mixing chambers and mixture inlet zones to avoid flashback of the flame."[288] Many DLNBs can achieve reduced NOx rates across the full load range of a gas turbine.[289] DLNBs are also available to retrofit to several types of combustion turbines. General Electric has dry low NOx burner retrofit

options for many of its turbine makes and models, and Solar Turbines has an extensive line of retrofit kits including Solar Turbines' SoLoNOx™ technology.[290] To retrofit such DLNBs, the turbines' combustors must be replaced and there may be changes necessary to associated piping and turbine combustion controls.[291]

Based on the range of NOx emission rates that have been reported as achievable with DLNBs, these combustion controls can achieve in the range of 80% to 95% control of NOx emissions.[292] For the turbines for which DLNBs are available, NOx rates have generally ranged from 9–15 ppm.[293] The 1999 DOE Report assumed only a 25 ppmv NOx rate would be achieved at most of the combustion turbines with DLN combustion which reflects approximately 84% NOx reduction, although the DOE report also calculated costs for a larger turbine to meet a 9 ppmv NOx rate which reflects approximately 95% NOx reduction.[294] The 1999 DOE Report indicates that the operation and maintenance costs increase with the lower NOx rate being achieved.[295] The ability to achieve 9 ppmv NOx rates with dry low NOx combustors is not limited to large turbines, such as the GE Frame 7FA turbine (169.9 MW) for which the 1999 DOE Report calculated costs to achieve a 9 ppm NOx rate. Solar Turbines makes several turbines that are guaranteed to achieve 9 ppmvd NOx with Solar Turbines' SoLoNOx™ burners, including the Solar Centaur 50L which is rated at 6,276 horsepower (< 5 MW).[296] However, the ability to achieve 9 ppm NOx rates through dry low NOx combustor retrofits to existing turbines is likely more limited. Solar Turbines indicates that SoLoNOx™ retrofits are available for the Solar Taurus 70 gas turbine (11,110 horsepower).[297] GE recently announced NOx upgrades completed at 9 GE 9E Gas Turbines (132 145 MW) at a facility in China with its DLN1.0+ with Ultra Low NOx combustors to achieve about 7.5 ppm NOx rates.[298]

In its 2016 CSAPR TSD for Non-EGU NOx Emissions Controls, EPA relied on the cost analyses for DLNBs presented in the November 1999 DOE Report.[299] However, EPA acknowledged that, except for the costs for a 169 MW unit, the costs reported in the 1999 DOE Report are "incremental [costs] relative to the costs of a conventional combustor."[300] Table 22 below reflects the cost effectiveness calculations presented in the 1999 DOE report, but with changes made to the interest rate to reflect a 5.5% interest rate consistent with the EPA's Control Cost Manual and to change and life of the controls to the expected life of a combustion turbine of twenty-five years, as was done for the water/steam injection cost analyses. DLN combustors should be expected to last the life of a natural gas-fired combustion

turbine, which is at least twenty-five years as discussed above. Indeed, there are likely several examples of gas turbines with dry low NOx combustor retrofits that have operated for twenty-five years. The Tennessee Gas Pipeline Company's Compressor Station in Lockport, New York has four Solar Centaur Turbines that were retrofitted with dry low NOx combustion systems in 1995[301] (two of which continue to operate today, twenty-five years later, while the other two were replaced between 2012–2019 with turbines rated at a higher horsepower).[302]

Table 22. Summary of Cost Effectiveness for DLN Combustion (1999$) at 91% Capacity Factor[303]

Turbine Make/Model	Size, MW	Size, hp	Annualized Costs of DLN Combustion 1999$	Cost Effectiveness of Dry Low NOx Combustion to meet 25 ppm NOx Rate	Cost Effectiveness of Dry Low NOx Combustion to Meet 9 ppm NOx Rate
Allison 501-KB7	4.9	6,571	$33,491	$259/ton	
Solar Centaur 50	4.0	5,364	$14,164	$164/ton	
Solar Centaur 60	5.2	6,973	$14,164	$128/ton	
GE LM2500	22.7	30,441	$179,639	$360/ton	
GE Frame 7FA	169.9	227,839	$455,472 (25 ppmv) $474,109 (9 ppmv)	$96/ton	$92/ton

In Table 23 below, the cost effectiveness of dry low NOx combustors is calculated to reflect operation at a 40% capacity factor. Operating at a lower capacity factor should not change the operating or capital costs of the dry low NOx combustion system, given that there is no energy penalty requiring additional fuel use.

[303] *See* 1999 DOE Report, Appendix A at A-3. Capital costs in 1999 dollars were updated from 1999 to 2018 dollars based on CEPCI and CPI indices. Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a twenty-five -year life of controls and a 5.5% interest rate). Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines and a 91% operating capacity factor was assumed.

Table 23. Summary of Cost Effectiveness for DLN Combustion (1999$) at 40% Annual Capacity Factor[304]

Turbine Make/Model	Size, MW	Size, hp	Cost Effectiveness of Dry Low NOx Combustion to meet 25 ppm NOx Rate	Cost Effectiveness of Dry Low NOx Combustion to Meet 9 ppm NOx Rate
Allison 501-KB7	4.9	6,571	$590/ton	
Solar Centaur 50	4.0	5,364	$373/ton	
Solar Centaur 60	5.2	6,973	$292/ton	
GE LM2500	22.7	30,441	$820/ton	
GE Frame 7FA	169.9	227,839	$218/ton	$208/ton

EPA's 2016 TSD for the CSAPR rule provided algorithms for estimating the total capital investment and the total annual costs of DLN combustion based on the hourly heat input of the combustion turbine. These equations were based on a 1993 EPA Control Technique guideline as well as the 1999 DOE Report, and the total annual cost algorithms assumed a 15-year equipment life and a lower interest rate of 7%, which is still high compared to today's interest rates.[305] The cost algorithms of EPA's 2016 TSD for the CSAPR Rule for DLN combustion are reprinted below.[306]

Total Capital Investment (1999 dollars) = 2860.6 x (MMBtu/hr) + 25427

Total Annual Costs (1999 dollars) = 584.5 x (MMBtu/hr)^0.96

In its 2000 Status Report, NESCAUM provided information on the capital and operational expenses for two dry low NOx combustor upgrades to a Solar Centaur turbine (4,700 hp) and a Solar Mars turbine (13,000 hp).[307] Given that it appears the cost data in the 1999 DOE Report may not necessarily reflect retrofit costs (in that, with the exception of the costs for the GE Frame 7FA, the costs were identified in the 1999 DOE Report as "incremental" costs relative to the cost of a conventional combustor), the NESCAUM cost information for retrofit DLNC is also presented here. NESCAUM used a shorter useful life of controls than twenty-five years and a higher interest rate than the 5.5% interest rate used by EPA in its cost spreadsheets provided with its 2018 updates to the Control Cost Manual.[308] NESCAUM also assumed that DLNCs could only reduce NOx to 50 ppm, whereas such combustors should be able to reduce NOx to at least 25 ppm. Thus, in Table 24 below, the cost effectiveness of the DLNC retrofit projects discussed in the NESCAUM report are revised to reflect amortized capital costs assuming a 25-year life and a 5.5% interest rate and to reflect reducing NOx to both 50 ppm and to 25 ppm.

[304] *See* 1999 DOE Report, Appendix A at A-3. Capital costs in 1999 dollars were updated from 1999 to 2018 dollars based on CEPCI and CPI indices. Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a twenty-five -year life of controls and a 5.5% interest rate). Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines and a 40% operating capacity factor was assumed.

[308] *Id.*

Table 24. Summary of Cost Effectiveness for Retrofit DLN Combustion at 40% and 91% Annual Capacity Factors Based on Retrofit Costs Provided in 2000 NESCAUM Report[309]

Turbine Make/Model	Size, hp	Capacity Factor	Cost Effectiveness of Retrofit DLN Combustion to meet 50 ppm NOx Rate	Cost Effectiveness of Retrofit DLN Combustion to Meet 25 ppm NOx Rate
Solar Centaur	4,700	91%	$1,217/ton	$940/ton
Solar Centaur	4,700	40%	$2,769/ton	$2,140/ton
Solar Mars	13,000	91%	$359/ton	$296/ton
Solar Mars	13,000	40%	$816/ton	$673/ton

The NESCAUM 2000 Status Report notes that the capital costs reported for these two turbine types were the "total project costs the owners attributed to the project, which may include project management or other charges associated with the project beyond the equipment and installation."[310] Thus, the costs reflected in Table 24 may be higher than what would typically be reported for DLNC controls in a cost effectiveness analysis consistent with EPA's Control Cost Manual, because EPA does not generally allow such owner's costs to be considered in a cost effectiveness analysis.[311]

In terms of non-air environmental or energy impacts with the use of DLNCs, there are relatively few impacts. There is not an energy penalty associated with the operation of the DLNCs, nor is there any waste product that requires proper disposal. However, there can be increased maintenance required with DLNCs, and those additional maintenance costs are often proprietary.[312] In fact, the increased maintenance costs are not reflected in the cost analyses for the Solar Centaur 50 and Solar Centaur 60 turbines in Tables 22 and 23 above, due to the information being considered proprietary.[313] A non-air quality environmental impact is that DLNBs "tend to create harmonics in the combustor that result in significant vibration and acoustic noise."[314]

EPA has indicated that the length of time to install DLNBs is 6–12 months.[315]

As previously discussed, while the cost estimates and cost algorithms for DLN combustion are of a cost basis that is from 1999-2000, it is important to note that, beginning in the late-1990s, EPA and numerous several state and local air agencies have found that the costs of control to achieve NOx emission limits of 25 ppmv or even lower were cost effective to require such a level of control on existing gas turbines. This will be discussed further in Section IV.D. below.

[309] *Id.* at III-16. Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a 25-year life of controls and a 5.5% interest rate). Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines and both a 91% and a 40% operating capacity factor were assumed.

Given the lower costs compared to water or steam injection, along with lower operational costs and no need to have water nearby, it is clear why DLNC has been preferable to water or steam injection since such dry low NOx combustion systems have been available. However, as stated above, these DLNC systems are not available for retrofit for all gas-fired turbines and thus, for many turbines, water or steam injection would be the available combustion control. As Tables 22 through 24 show, DLNC is more cost effective than water or steam injection and can achieve lower NOx rates. Thus, low NOx combustion is a preferable combustion-related retrofit option for gas turbines, if a low NOx combustion retrofit option is available for the turbine make and model.

C. SELECTIVE CATALYTIC REDUCTION

SCR is a post-combustion NOx reduction control that is commonly applied to gas-fired combustion turbines used for power generation. SCR technology can reduce NOx emissions by 80–90% or more and, when used along with water injection or DLNC, it can achieve NOx emission rates in the range of 1.5 to 5 ppm.[316] The 1999 DOE Report stated that SCR was the "primary post-combustion NOx control method in use" as of 1999.[317]

An SCR system consists of a reagent injection system (typically ammonia or urea) and a catalyst. The ammonia or urea (which converts to ammonia in the flue gas) is injected into the exhaust stream and the flue gas then passes over a catalyst reduced NOx to N_2, H_2O, and CO_2. The catalyst selected depends on the temperature range of the flue gas and the size of the catalyst depends on the level of NOx reduction to be achieved. SCR technology requires a reagent injection system, including a storage tank and reagent injectors and controls to regulate the quantity of reagent, and the SCR catalyst. According to the 1999 DOE Report, the cost of conventional SCR had dropped significantly by 1999 with innovations in catalysts allowing for a significant reduction in catalyst volume with no change in NOx removal performance.[318] Catalysts are also available for SCR to work at a variety of flue gas temperatures, from as low as 300 degrees Fahrenheit to as high as 1,100 degrees Fahrenheit.[319] For simple cycle turbines, which are more commonly used in the oil and gas sector, the reactor chamber with the catalyst is in place directly at the turbine exhaust, which may require the use of high temperature catalyst such as zeolite.[320] Several options for SCR catalyst exist for simple cycle turbines. For example, BASF makes several SCR catalysts that it claims can achieve up to 97% NOx reduction.[321] The NOxCat ETZ catalyst is specifically designed for simple-cycle power generating turbines and other high temperature turbine applications.[322] The NOxCat VNX and ZNX catalysts can achieve up to 99%

NOx reduction and are most effective at a temperature range of 550 to 800 degrees Fahrenheit.[323] A related catalyst called NOxCat VNX-HT is designed for use in aeroderivative simple-cycle turbines that can achieve 99% NOx removal and can reach optimal performance at 800 to 850 degrees Fahrenheit.[324]

Conventional SCR systems can be used with simple cycle turbines if the gas stream is cooled to the optimal temperatures for conventional SCR catalysts, through air dilution or tempering.[325] Further, aeroderivative turbines typically have somewhat lower exhaust gas temperatures which can work better with conventional SCR systems than frame-type turbines.[326] The optimal temperature of the flue gas to both minimize the amount of catalyst needed and ensure the highest NOx removal (> 90%) is 700 to 750 degrees Fahrenheit for conventional SCR catalysts.[327] Conventional catalysts can achieve 80% or greater NOx removal over a wide temperature range of approximately 625 to 900 degrees Fahrenheit.[328] SCR vendors have experience installing SCR to achieve low NOx emission rates on numerous simple cycle turbines of all types and sizes.[329]

In its Control Cost Manual chapter on SCR, which was updated in 2019, EPA cites capital costs of SCR for simple cycle gas turbines that range from $237/kilowatt for a 2 MW gas turbine down to $50/kilowatt for a larger gas turbine, all in 1999 dollars cost basis.[330] For these cost ranges, EPA cites to the NESCAUM 2000 Status Report.[331] That NESCAUM report in turn relies on the 1999 DOE Report, as well as a 1991 report by the Electric Power Research Institute and some personal communications.[332] The NESCAUM 2000 Status report provides a range of cost effectiveness data based on these reports for the application of high temperature SCR to gas turbines of varying operating capacity factors, sizes, and baseline NOx emission rates. Table 25 below presents that data for turbines with year-round high temperature SCR operation.

Table 25. Cost Effectiveness for High Temperature SCR Retrofit on Simple Cycle Gas Turbines.[333]

Turbine Size, MW	Turbine Size, hp	Uncontrolled NOx, ppm	Controlled NOx, ppm	Cost Effectiveness of SCR, $/ton (2000$), at listed capacity factor	Capacity Factor
75	100,590	154	15	$849	45%
75	100,590	154	15	$664	65%
75	100,590	154	15	$566	85%
75	100,590	42	7	$2,980	45%
75	100,590	42	7	$2,247	65%
75	100,590	42	7	$1,859	85%
75	100,590	15	3	$8,441	45%
75	100,590	15	3	$6,303	65%
75	100,590	15	3	$5,171	85%
5	7,000	142	15	$3,395	45%
5	7,000	142	15	$2,523	65%
5	7,000	142	15	$2,061	85%
5	7,000	42	5	$11,335	45%
5	7,000	42	5	$8,341	65%
5	7,000	42	5	$6,756	85%

The different shading in the table reflects different levels of NOx combustion controls of the existing turbine:

- Gray shading reflects the cost effectiveness of SCR applied to gas turbines with no water injection or dry low NOx combustion controls, in which case the SCR was assumed to achieve about 90% NOx reductions.
- Blue shading reflects the cost effectiveness of SCR applied to gas turbines with, presumably, water injection which can achieve 42 ppm or lower NOx emission rates, in which case the SCR was assumed to achieve about 83–88% removal.
- Green shading reflects the cost effectiveness of SCR applied to gas turbines with, presumably, low NOx combustion controls that can achieve 15 ppm NOx, in which case the SCR was assumed to achieve 80% removal.

[333] *Id.* at III-24.

The NESCAUM cost effectiveness numbers in Table 25 above reflect a 15-year equipment life and an interest rate of 7.5%.[334] The NESCAUM cost effectiveness numbers were also primarily based on the 1999 DOE report.[335] However, EPA has indicated that a 25-year life is a more appropriate life of an SCR system at a gas turbine used in an industrial setting like a compressor station.[336] Further, as stated above, EPA currently uses a 5.5% interest rate in its cost effectiveness calculations. Tables 26 and 27 below present the cost effectiveness for conventional and high-temperature SCR added to a gas-fired combustion turbine meeting an uncontrolled rate of 42 ppmv, reflective of water or steam injection, to achieve a controlled NOx rate of 9 ppmv, which reflects a 79% reduction in NOx emissions. These cost effectiveness analyses are based on the costs of the 1999 DOE Report, but with the capital cost amortized to reflect a 25-year equipment life and a 5.5% interest rate.[337] The 1999 DOE cost analyses were based on operating 8,000 hours per year, or a 91% capacity factor. Given information previously cited that, on average, a compressor unit may operate at a 40% annual capacity factor,[338] revisions to the cost data and emissions reduced were made to reflect a 40% capacity factor. Specifically, the electricity costs (due to the parasitic load of the SCR system) and the ammonia costs in the direct annual costs of the 1999 DOE Report were reduced by 56% to reflect the reduction in SCR operating hours when the units operate at a 40% capacity factor compared to a 91% operating factor.[339]

[340] 1999 DOE Report, Appendix A at A-6 (Table A-5). Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a 25-year life of controls and a 5.5% interest rate). To reflect a 40% capacity factor, the annual operating costs due to the fuel penalty and ammonia use were decreased by 56%, to reflect a 40% capacity factor rather than a 91% capacity factor. Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines.

Table 27. Cost Effectiveness to Reduce NOx Emissions by High Temperature SCR for Select Combustion Turbines with Existing Water or Steam Injection, Operating at Either a 91% or 40% Annual Capacity Factor[341]

Turbine Model	Size, MW	Size, hp	Uncontrolled NOx, ppm at 15% O2	Controlled NOx with SCR, ppm at 15% O2	Annualized Costs of SCR, 1999$	Cost Effectiveness of High Temperature SCR at Stated Capacity Factor, 1999$	Capacity Factor
Solar Taurus 60	5.2	6,973	42	9	$179,385	$13,238/ton	40%
Solar Taurus 60	5.2	6,973	42	9	$188,760	$6,123/ton	91%
GE LM2500	22.7	30,441	42	9	$324,122	$6,680/ton	40%
GE LM2500	22.7	30,441	42	9	$364,879	$3,305/ton	91%
GE Frame 7FA	161	215,904	42	9	$1,379,722	$3,695/ton	40%
GE Frame 7FA	161	215,904	42	9	$1,680,250	$1,978/ton	91%

Although the above costs reflect a 1999-2000 dollar cost basis, EPA has indicated that the costs of conventional SCR "have dropped significantly over time – catalyst innovations have been a principal driver, resulting in a 20% in catalyst volume and cost with no change in performance."[342] Moreover, high temperature SCR catalysts are not necessarily required for turbines operated in simple cycle mode, as was assumed in the NESCAUM 2000 report, because air tempering can be used to lower the cost of the exhaust gas stream, as discussed above. Thus, it is likely that costs for SCR at gas-fired turbines are lower than the cost estimates in the 1999 DOE report and the NESCAUM 2000 Status Report. Indeed, in 2015, the SCAQMD in California collected SCR cost information from vendors for 20 non-refinery, non-power plant gas turbines including turbines used in gas compression, and total installed costs ranged

[341] 1999 DOE Report, Appendix A at A-7 (Table A-6). Annualized costs of control were calculated using a capital recovery factor of 0.074549 (assuming a 25-year life of controls and a 5.5% interest rate). The annual costs due to the fuel penalty and ammonia use were decreased by 56% to reflect a 40% capacity factor, rather than the 91% capacity factor. Uncontrolled and controlled NOx emissions were calculated based on procedures outlined in outlined in Appendix A of EPA's 1993 ACT for Stationary Gas Turbines.

[342] *See* EPA, Combined Heat and Power Partnership, Catalog of CHP Technologies, Section 3. Technology Characterization-Combustion Turbines, March 2015, at 3-18.

from $1.5 million to $2.9 million with the annual costs ranging from $63,000 to $727,000.[343] These costs reflected SCR achieving 95% control for those turbines with NOx rates of 40 ppm or higher and achieving 2 ppm for those turbines with NOx rates lower than 40 ppm.[344] The cost basis of these costs is not identified, but presumably the costs are from the 2010-2015 timeframe.[345] In 2019, SCAQMD ultimately determined it was cost effective to require SCR retrofits as BARCT for non-refinery, non-power plant combustion turbines. SCAQMD required gas turbines of capacities 0.3 MW and larger that power compressor stations to install retrofit NOx controls to meet a NOx limit of 3.5 ppmv at 15% oxygen and required other gas turbines, such as those used for power generation, to meet a NOx limit of 2.5 ppmv.[346] These limits are required to be met by 2024.[347] Other California air districts have adopted NOx limits for existing simple cycle gas turbines that reflect installation of SCR with NOx limits ranging from 2.5 to 9 ppm.[348] While several of these air districts limits were based on SCR applied to turbines of 10 MW capacity or greater, the SJVAPCD in California adopted NOx limits in the range of 5 to 9 ppmv for gas turbines in 2007 that were based on the installation of SCR, with the higher limits for turbines with capacities between 0.3 MW and 10 MW.[349]

The use of SCR presents several non-air quality and energy impacts, most of which are accounted for in the annual operating costs. Those impacts include the following:

- Parasitic load of operating an SCR system, which requires additional energy (fuel use and electricity) to maintain the same steam output at the boiler.[350]
- The spent SCR catalyst must be disposed of in an approved landfill if it cannot be recycled or reused, although it is not generally considered hazardous waste.[351] The use of regenerated catalyst can reduce the amount of spent catalyst that needs to be disposed of.[352]

- If anhydrous ammonia is used, there would be an increased need for risk management and implementation and associated costs for receiving and storing the anhydrous ammonia.[353] If urea or aqueous ammonia is used as the reagent, the hazards from use of pressurized anhydrous ammonia do not apply.
- Excess ammonia can pass through the SCR (called "ammonia slip"), which then can react with sulfate or nitrate in the ambient air to form ammonium bisulfate or ammonium nitrate (i.e., fine particulate matter).[354] Typically, permitting authorities limit the amount of ammonia slip that may occur with SCR to limit the formation of ammonium bisulfate or ammonium nitrate.

There are typically not overarching non-air quality or energy concerns with this technology, and SCR technology is widely used at natural gas-fired combustion turbines. Most of the impacts mentioned above are considered as additional costs of using SCR and are taken into account in the SCR cost effectiveness analysis.

In terms of length of time to install SCR at gas-fired combustion turbines, a report prepared for the SCAQMD found that the typical installation time is about twenty-four months after an engineering firm begins the engineering design for the SCR, or a total of about 27–30 months.[355] These costs should all be included in the annual operating costs.

There are numerous examples of natural gas-fired combustion turbines with SCR installed for NOx control. Just in the electric utility industry, there are at least 310 gas-fired combustion turbines operating with SCR.[356] Clearly, SCR has been considered to be a cost effective NOx reduction technology for combustion turbines, including smaller compressor engines and those that power compressor stations, since at least 2007. Further, SCR is often combined with a combustion control like water injection or dry low NOx combustors, which optimizes the NOx emissions reductions and costs of control.

D. NOx EMISSION LIMITS THAT HAVE BEEN REQUIRED FOR EXISTING NATURAL GAS-FIRED COMBUSTION TURBINES

In 2005, EPA proposed a new NSPS for gas turbines, which was eventually promulgated at 40 C.F.R. Part 60, Subpart KKKK in 2006.[357] In promulgating Subpart KKKK, EPA updated the NSPS for gas turbines, which had last been reviewed for EPA's initial promulgation of NSPS for gas turbines in 1979.[358] As a starting point for considering the level of control that EPA considered to be cost effective as a retrofit control for existing gas turbines, it is instructive to review what EPA required in the NSPS Subpart KKKK

[353] Anhydrous ammonia is a gas at standard temperature and pressure, and so it is delivered and stored under pressure. It is also a hazardous material and typically requires special permits and procedures for transportation, handling, and storage. *See* EPA Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, June 2019, at pdf page 15.
[354] *See* 1999 DOE Report at 2-11.
[355] *See* ETS, Inc., NOx RECLAIM BARCT INDEPENDENT EVALUATION OF COST ANALYSIS PERFORMED BY SCAQMD STAFF FOR BARCT IN THE NON-REFINERY SECTOR, FINAL REPORT, NOVEMBER 26, 2014, at 17.
[356] Based on a search on EPA's Air Markets Program Database, *available at*: https://ampd.epa.gov/ampd/.
[357] 70 Fed. Reg. 8,314-8,332 (Feb. 18, 2005), 71 Fed. Reg. 38,482-38,506 (July 6, 2006).
[358] 44 Fed. Reg. 52,798.

for existing gas turbines that were modified on or after February 18, 2005. These standards are summarized in the table below. It is important to note that these standards were adopted for gas turbines that generate electricity or that are used for mechanical drive such as at a gas compressor station.

Table 28. NSPS Subpart KKKK NOx Control Requirements for Modifications to Existing Gas Turbines Occurring on or after February 18, 2005.[359]

Turbine Size/Range	Approximate Turbine size range, hp[360]	Subpart KKKK NOx limits for modified sources after 2/2005, ppmv	Control that NOx limit reflects
≤50 MMBtu/hr	≤6,850 hp	150	Probably none
>50 MMBtu/hr and ≤850 MMBtu/hr	>6,850 hp and ≤116,456 hp	42	Water/Steam Injection
>850 MMBtu/hr	>116,456 hp	15	DLNC

Thus, in 2005, EPA found that the cost of water or steam injection or dry low NOx combustion was cost effective for gas-fired turbines with capacity greater than 50 MMBtu/hr (or 116,500 hp, ~86 MW). In considering reasonable progress controls for gas-fired combustion turbines in the oil and gas industry in 2020, the EPA's NSPS NOx limits for sources modified in 2005 or later should be considered the "floor" of potential NOx controls to consider for an existing gas turbine meaning that, at the very minimum, this level of control should be considered cost effective for NOx reductions at gas turbines. However, installation of SCR, with or without water/steam injection or DLNC, would be the much more effective pollution control that should be evaluated in an analysis of controls to achieve reasonable progress, as it has been found to be a cost effective control for gas-fired combustion turbines.

Numerous states and local air agencies have adopted similar or more stringent NOx limits for existing gas turbines to meet, many of which have been in place for 10–20 years. In Table 29 below, we summarize those state and local air pollution requirements. Some of this information was initially obtained from EPA's 2016 CSAPR TSD,[361] which provided a summary of state NOx regulations for gas turbines and other NOx sources as of September 2014.[362] The current state/local requirements for those CSAPR states were confirmed by a review of the state and local rules. The CSAPR TSD focused on the rules applicable in the CSAPR states. EPA found that 9 CSAPR states did not have regulations limiting NOx emissions from existing gas turbines: Alabama, Arkansas, Indiana, Kentucky, Michigan, Mississippi, Oklahoma, South Carolina, and West Virginia.[363] We also reviewed California Air District rules, because several of those air districts have adopted the most stringent NOx emission limitations for existing gas turbines. Indeed, several air districts in California have adopted rules necessitating installation of SCR at

[359] *See* 40 C.F.R. Part 60m Subpart KKKK, Appendix, Table 1.
[360] Converted MMBtu/hr to hp based on following assumptions/conversion factors: Typical heat rate of simple cycle turbine of 9,788 Btu/kWh (per https://www.eia.gov/todayinenergy/detail.php?id=32572), and 0.7457 kW= 1 hp.
[361] *See* 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls, Appendix B at 11-13.
[362] *Id.*
[363] *Id*. at 13.

virtually all simple cycle turbines. We reviewed some of the remaining states' regulations to determine whether there were NOx limitations for existing gas turbines. Specifically, we reviewed air regulations in New Mexico, Colorado, Utah, Montana, North Dakota, South Dakota, and Washington. It appears there are no NOx emission limits required for existing gas turbines in those states aside from what applies to modified gas turbines under the NSPS Subpart KKKK.

Table 29 is a summary of the NOx emission limits required of existing simple cycle gas-fired combustion turbines in state and local air districts across the United States. It is important to note that these are limits that, unless otherwise noted, currently apply to existing gas turbines. Unlike the NSPS standards of 40 C.F.R. Part 60, Subpart KKKK, gas turbines did not have to be modified to trigger applicability to these emission limits. Instead, these emission limits apply to existing gas turbines and generally require an air pollution control retrofit or an outright replacement of the gas turbine with a new turbine with integrated dry low NOx combustors. These state and local NOx limits were most likely adopted to address nonattainment issues with the ozone NAAQS and possibly also the $PM_{2.5}$ NAAQS. Nonetheless, what becomes clear in this analysis is that numerous states and local governments have adopted NOx regulations that require, at the very least, water or steam injection at existing gas turbines (or DLNC if available) to meet NOx limits of 42 ppmv,[364] and several state/local air agencies have adopted NOx limits in the range of 9–25 ppmv which require dry low NOx combustors or, if unavailable as a retrofit for the turbine type, SCR. Moreover, four California air districts and Georgia have adopted NOx limits for gas turbines that clearly require SCR, probably along with water injection or DLNC, to comply with NOx limits in the range of 2–5 ppmv. The lowest NOx limits are those recently adopted by the SCAQMD which require, by January 1, 2024, gas-fired combustion turbines of 0.3 MW or greater size to meet a 2.5 ppmv limit and compressor gas turbines to meet a 3.5 ppmv limit.

These limits were adopted generally to meet RACT and California BARCT requirements, and costs of controls are considered in making these RACT and BARCT determinations. However, RACT is not necessarily as stringent as BARCT. RACT is generally defined as: "devices, systems, process modifications, or other apparatus or techniques that are reasonably available taking into account: (1) The necessity of imposing such controls in order to attain and maintain a national ambient air quality standard; (2) The social, environmental, and economic impact of such controls."[365] BARCT, on the other hand, is defined as "an emission limitation that is based on the maximum degree of reduction achievable, taking into account environmental, energy, and economic impacts by each class or category of source."[366] BARCT is similar to a BACT determination under the federal PSD program, but it evaluates controls to be retrofit to existing sources, rather than applying to new or modified sources.

[364] Even some of the NOx limits in Table 29 that are higher than 42 ppmv may require water or steam injection to meet the limit.

[372] EFF = gas turbine efficiency, which can never be less than 25%. In other words, this multiplier allows a higher ppm limit than the reference limit if a turbine is more efficient than 25%.

[373] https://www.valleyair.org/rules/currntrules/r4703.pdf.

[374] Note that NOx limits reflective of water/steam injection, DLNC, and/or SCR have been in effect in San Joaquin Valley since 2000. Compliance with the Tier 3 limits was required between 2009-2012.

[375] Tier 2 limits, that were to be complied with in 2005, require turbines greater than 10 MW and greater than 877 hours per year to meet NOx limits in the range of 3-5 ppmv. *See* Table 5-2 of San Joaquin AQMD Rule 4703. Tier 3 limit is 5 ppmv for turbines>10 MW but with operations between 200 hr/yr - 877 hrs/yr. *See* Table 5-3 of San Joaquin AQMD Rule 4703.

which were adopted in 2007, also reflect application of SCR.[402] The state of Georgia has stringent NOx limits for larger turbines in its 45-county ozone nonattainment area that also likely require SCR to comply with the NOx emission limits. These air agencies have thus found that the levels of NOx control listed in Table 29, including NOx limits as low as the 2.5–5 ppmv range of NOx emissions, are cost effective for existing simple cycle natural gas-fired combustion turbines.

NOx Limits Required for New Gas Turbines Used in the Oil and Gas Sector

Recently, there have been some examples of SCR being required in draft or final air construction permits for proposed new installations of compressor stations powered by gas-fired combustion turbines. Specifically, SCR was proposed to meet BACT requirements for the proposed Buckingham Compressor Station to be located in Virginia, with all four combustion turbines ranging from 6,276 to 15,900 hp to be subject to a NOx BACT emission limit of 3.75 ppmv at 15% oxygen.[403] In addition, SCR was proposed to be installed at the Charles Compressor Station to be located in Maryland,[404] the Northampton Compressor Station to be located in North Carolina,[405] and the Marts Compressor Station to be located in West Virginia.[406] These draft and final permits provide additional evidence of states and companies finding SCR to not be a cost prohibitive control for a compressor station.

E. SUMMARY – NOx CONTROLS FOR EXISTING NATURAL GAS-FIRED COMBUSTION TURBINES

The above analyses and state/local rule data demonstrates that numerous state and local air agencies have found water/steam injection, dry low NOx combustors, and SCR as cost effective controls for natural gas-fired combustion turbines, with costs ranging from $128/ton to $13,500/ton (1999$) to

[402] *See* September 2007, SJVAPCD, Amendments to Rule 4703 (Stationary Gas Turbines), Initial Study and Negative Declaration, at 5, *available at*: https://www.valleyair.org/notices/Docs/priorto2008/08-08-07/Negative%20Declaration.pdf. The fact that these limits require SCR to meet is reflected in permits for two compressor stations – the Wheeler Ridge Compressor Station and the Kettleman Compressor Station. *See* March 25, 2015 Title V Permit for Southern California Gas Co. Wheeler Ridge Compressor Station, *available at*: https://www.valleyair.org/notices/Docs/2015/03-25-15_(S-1134792)/S-1134792.pdf; February 5, 2018 Title V Permit for Pacific Gas and Electric Company – Kettleman Compressor Station, *available at*: http://www.valleyair.org/notices/Docs/2018/2-5-18_(C-1161601)/C-1161601.pdf.

It is not clear whether the final air permit has been issued yet for this facility.

[405] *See* Air Permit No. 10466R00, issued February 27, 2018, *available at*: https://edocs.deq.nc.gov/WaterResources/PDF/bf820b89-33eb-4cf9-bf89-2d6fb31b7418/Final%20Permit%20Northampton%20Compressor%20Station.pdf.

[406] *See* Permit No. R13-3271, issued July 21, 2016, *available at*: https://dep.wv.gov/daq/Documents/July%202016%20Permits%20and%20Evals/041-00076_PERM_13-3271.pdf.

meet NOx limits ranging from 42 ppmv down to 2.5 ppmv. Further, it is notable that, in the rules summarized above in Table 29, the primary exemptions or higher allowable NOx limits for low use turbines are those that operate at 10% or lower annual capacity factors (i.e., less than 877 hours/year), although there are several California districts with no exemptions for low capacity factor turbines. In addition, although there are some states that limited applicability of NOx emission limits to larger turbines (e.g., greater than 10 MW (or greater 13,500 hp or 100 MMBtu/hour)), there are several states and local air pollution control agencies that set NOx limits requiring NOx controls for turbines smaller than 10 MW. In fact, several California districts set a NOx limit reflective of water or steam injection (i.e., 42 ppmv) for turbines as small as 0.3 MW.

As states evaluate the level of NOx control to require at gas-fired combustion turbines associated with the oil and gas industry to make reasonable progress towards the national visibility goal, costs of NOx control should not be a significant consideration in the decision of what NOx emission limits to require existing natural gas-fired combustion turbines to meet, as there are ample examples of existing gas-fired combustion turbines being required to incur similar costs of control. Indeed, SCR should be considered the control technology of choice for NOx removal at gas-fired combustion turbines of 0.3 MW size or larger, including those that operate compressor stations and/or that operate at lower capacity factors. Combustion turbines with SCR should be able to meet NOx limits in the range of 2.5 to 9 ppmv NOx. For those turbines for which SCR is not technically or economically feasible, DLNCs should be the next control technology with NOx emission limits achievable in the 7.5 to 25 ppm range. If DLNCs are not available for retrofit to the turbine model, water or steam injection should be considered for NOx control, which should enable the combustion turbine to meet NOx limits in the range of 25 to 42 ppmv. It also must be recognized that, in some cases, it may be more effective for NOx control — and more cost effective — to require replacement of existing gas-fired turbines with new turbines designed with state-of-the-art dry low NOx combustion controls, as such controls can achieve much lower NOx rates than water or steam injection and do not require water usage.

V. CONTROL OF VOC EMISSIONS FROM NATURAL GAS-FIRED COMBUSTION TURBINES

VOC emissions from natural gas-fired combustion turbines result from incomplete combustion. The same is true for CO emissions. The combustion conditions that favor lower NOx emission rates, such as lower temperature combustion, tend to result in less complete combustion and thus higher VOC as well as CO emission rates.

Similar to RICE units, NOx is emitted at much higher rates from uncontrolled natural gas-fired combustion turbines compared to VOC emissions, with uncontrolled VOC emissions about two orders of magnitude lower than NOx emissions according to EPA's AP-42 emission factor documentation.[407] On the basis of pounds of VOC emission per heat input, EPA's AP-42 emission factors indicate that natural

[407] EPA, AP-42, Section 3.1, Tables 3.1-1 and 3.1-2, *available at*: https://www3.epa.gov/ttn/chief/ap42/ch03/final/c03s01.pdf.

gas-fired combustion turbines emit VOCs at a much lower rate that natural gas-fired RICE.[408] However, it must be noted that EPA's uncontrolled VOC emission factor has an emission factor rating of "D," which means tests are based on a generally unaccepted method and/or from a small number of facilities.[409] Regardless, the same control for VOC emissions from lean-burn RICE units – oxidation catalyst – applies to control of VOC emissions from natural gas-fired combustion turbines.

According to EPA, oxidation catalyst is typically used on combustion turbines to control CO emissions as well as HAP emissions – primarily formaldehyde.[410] Removal of VOCs is a co-benefit of oxidation catalyst at natural gas-fired combustion turbines. Data collected by CARB of emission test results at combustion turbines used for power generation that were equipped with oxidation catalysts, among other air pollution controls, showed VOC emission rates generally in the range of 1 to 3 ppmv at 15% oxygen.[411]

It is not clear that oxidation catalyst has been widely implemented at existing natural gas-fired combustion turbines. According to documentation for EPA's 2019 Risk and Technology Review for its Stationary Combustion Turbine NESHAP, a review of air permits for 719 turbines found 50 units using oxidation catalyst.[412] That said, the data collected by CARB in 2004 indicated 31 natural gas-fired combustion turbines using oxidation catalyst.[413]

In addition, oxidation catalyst has been recently proposed and required for new natural gas-fired combustion turbines used in the oil and gas industry. For example, in its permit application for the Weymouth Compressor Station to be located in Massachusetts, oxidation catalyst was proposed to be installed on a combustion turbine-driven compressor unit to reduce VOCs as well as to reduce CO and HAP to meet BACT. Oxidation catalyst has been proposed to be installed along with SCR at the proposed Buckingham Compressor Station to be located in Virginia,[414] the Charles Compressor Station to be located in Maryland,[415] the Northampton Compressor Station to be located in North Carolina,[416] and the

Marts Compressor Station to be located in West Virginia.[417] These draft and final permits provide evidence of states and companies finding oxidation catalyst to be a cost effective control for a combustion turbine-powered compressor stations.

In summary, oxidation catalyst is an available air pollution control to reduce VOC emissions, as well as to reduce CO and HAP emissions, from natural gas-fired combustion turbines used in the oil and gas industry. States should consider oxidation catalyst when evaluating reasonable progress controls for natural gas-fired combustion turbines used in the oil and gas industry.

VI. CONTROL OF EMISSIONS FROM DIESEL-FIRED RICE

Compression-ignited (*i.e.*, diesel-fired) RICE units are used in oil and gas exploration, production, and transmission sectors. These types of engines are generally used in the oil and gas industry for on-site power generation, as well as to power or to drive drill rigs, drive hydraulic fracturing pumps, and to power other pumping and compression applications. According to EPA's Alternative Control Techniques Document for Stationary Diesel Engines (2010), many of the "stationary" diesel RICE (meaning engines that are not mobile) are designated for continuous power use or used in standby power applications.[418] Company data suggests that those engines used as standby or emergency generators are generally less than 300 horsepower (hp), and diesel engines used for onsite power generation are typically greater than 300 hp although this is not a firm cutoff for standby diesel generator capacities.[419] The size of diesel engines for drilling rigs are likely much larger. A 2014 drilling rig emission inventory prepared for the state of Texas found that the mechanical drill rig engine sizes ranged from 430 hp for vertical wells less than 7,000 feet deep to 1,094 hp for vertical wells greater than 7,000 feet deep.[420] The study also found that, in Texas, mechanical rigs (diesel engines) were used for 96% of shallow vertical wells (< 7,000 feet) and 80% of deep vertical wells (> 7,000 feet), whereas 86% of horizontal wells are drilled by electric rigs.[421] According to the Texas drilling rig report, the trend in new drilling rigs is mostly electric rigs especially for larger drilling rigs, meaning that diesel-fired electrical generating sets are used to power the drilling engines (rather than diesel engines driving the drilling engines).[422] The electrical rigs typically have three large identical diesel generators, with one of the three units designated for standby

[417] *See* Permit No. R13-3271, issued July 21, 2016, *available at*: https://dep.wv.gov/daq/Documents/July%202016%20Permits%20and%20Evals/041-00076_PERM_13-3271.pdf.

[418] EPA, Alternative Control Techniques Document: Stationary Diesel Engines, March 5, 2010, at 13, *available at*: https://www.epa.gov/sites/production/files/2014-02/documents/3_2010_diesel_eng_alternativecontrol.pdf [hereinafter referred to as "EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE"]. Note, this ACT document expands upon the 1993 and 2000 ACT documents to address pollutants other than NOx.

[419] *Id.*

[420] Eastern Research Group, Inc., 2014 Statewide Drilling Rig Emissions Inventory with Updated Trends Inventories, Final Report, Prepared for Texas Commission on Environmental Quality, July 31, 2015, at 5-4, *available at:* https://www.tceq.texas.gov/assets/public/implementation/air/am/contracts/reports/ei/5821552832FY1505-20150731-erg-drilling_rig_2014_inventory.pdf.

[421] *Id.* at 4-1.

[422] *Id.* at 3-1.

capacity.[423] The Texas inventory report indicates that the typical size of electric generators to power the electric rigs is 1,338 hp.[424] This report was specific to Texas, and other states may have a different mix of size engines used for different types and depth wells. Diesel engine pumps are also used in hydraulic fracturing ("fracking"). In 2016, fracking accounted for 69 percent of all new oil and gas wells, according to the Energy and Information Administration.[425] Diesel engines used to power hydraulic fracturing pumps are generally in the range of 1,000–1,500 hp, with 8 to 12 pumps necessary per well site (total of 20,000+ hp per well site).[426]

A. CONTROL OPTIONS FOR DIESEL-FIRED RICE

Uncontrolled diesel RICE emit several pollutants that can contribute to regional haze, including NOx, particulate matter (PM), SO2, and VOCs. In some cases, the pollutant controls used for one pollutant can negatively or positively affect control of another pollutant. For example, combustion modifications employed to reduce NOx emissions will tend to increase PM emissions and VOC emissions, and vice versa. Controlling SO2, which is achieved by use of ultra-low sulfur diesel (ULSD) fuel, will reduce PM emissions as well. Thus, it can be important to evaluate pollution controls for diesel RICE holistically.

In its 1993 Alternative Control Techniques Document for Stationary RICE, EPA described NOx controls for diesel RICE, including combustion modifications (injection timing retard) and add-on controls (SCR), as follows:

> Ignition timing retard delays initiation of combustion to later in the power cycle, which increases the volume of the combustion chamber and reduces the residence time of the combustion products. This increased volume and reduced residence time offers the potential for reduced NOx formation. … Achievable NOx reductions using IR is engine-specific but generally ranges from 20 to 30 percent. Based on an average uncontrolled NOx emission level for diesel engines of 12.0 g/hp-hr (875 ppmv), the expected range of controlled NOx emissions is from 8.4 to 9.6 g/hp-hr (610 to 700 ppmv). [427]

> Selective catalytic reduction applies to all CI engines and can be retrofit to existing installations except where physical space constraints may exist. … Based on an average uncontrolled NOx emission level of 12.0 g/hp-hr (875 ppmv) for diesel engines, the expected range of controlled NOx emissions is from 1.2 to 2.4 g/hp-hr (90 to 175 ppmv). … Limited emission test data show NOx reduction efficiencies of approximately 88 to 95 percent for existing installations, with ammonia slip levels ranging from 5 to 30 ppmv.[428]

[427] EPA 1993 Alternative Control Techniques Document for RICE at 2-5 and 2-22.

[428] *Id.*

Compression-ignition diesel-fueled engines operate lean, meaning there is excess air during combustion. And while the application of similar control techniques can differ for spark-ignition (gas-fired) and compression-ignition (diesel-fired) engines, according to EPA's 1993 Alternative Control Techniques Document for RICE, the: (1) process; (2) application considerations; (3) performance factors; and (4) potential NOx emissions reductions for SCR applications with diesel engines are similar to those for natural gas applications.[429]

In its 2010 Alternative Control Techniques Document for Stationary Diesel RICE, EPA discusses combining SCR with a particulate filter to reduce both NOx and PM emissions.[430] EPA describes diesel particulate filters (DPF) and catalyzed diesel particulate filters (CDPF) as follows:

> [DPF and CDPF] emission control technologies are designed to remove PM from the diesel engine exhaust stream using a wall flow filter material in which the exhaust gas must pass through a ceramic wall. In addition to PM, the catalyst in the CDPF also reduces emissions of [Total Hydrocarbons (THC)] and CO. … CARB reports PM emission reductions of 85 to 97 percent for various types of verified DPF or CDPFs. The EPA has verified DPF and CDPF systems that achieve up to 90 percent reduction. In addition to the PM reductions, the CDPF filter also reduces emissions of CO and THC by 90 percent but requires sufficient exhaust temperatures to facilitate regeneration by the catalyst. These reductions have been verified by both the CARB and EPA diesel control technology verification programs.[431]

CDPFs are thus a control device for PM and also for VOCs (THC) and CO.

Stationary diesel engine exhaust emissions include SO_2 due to sulfur in fuel, although a smaller percentage of the sulfur in fuel is converted to sulfates (particulate matter). At high temperatures, SO_2 can oxidize to form sulfates, contributing to further increases in PM emissions from engine exhaust. The use of ULSD fuel is essential in conjunction with exhaust treatment control technologies for reducing NOx and PM and is also, by itself, an effective and commonly applied way to reduce SO_2 emissions. Manufacturers require diesel engines equipped with CDPF to use ULSD fuel. EPA, in its 2010 Alternative Control Techniques Document for Stationary Diesel RICE, describes the use of ULSD as follows:

> EPA [] finalized NSPS for stationary CI engines that require all new stationary diesel engines to use ULSD in 2010. This ULSD fuel enables the use of aftertreatment technologies for new and existing diesel engines and can also by itself reduce emissions of criteria pollutants. The use of ULSD reduces the formation of sulfur oxides and particulate sulfates from the diesel engine exhaust. The reductions in PM are expected to be approximately 5 to 30 percent depending on the sulfur content of the fuel that is replaced. … It should be noted that ULSD is prevalent in the fuel pool today, including in some nonroad fuels that may not be labeled as such, and therefore may already be used in many stationary diesel engines.[432]

[429] EPA 1993 Alternative Control Techniques Document for RICE at 5-73.
[430] EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 35.
[431] *Id.* at 32 and 34.
[432] *Id.* at 47 and 48.

In summary, while any one of these pollution controls can be used at a diesel RICE to control one pollutant, the co-benefits of using all of these controls together (ULSD, CDPF, and SCR) ensure the most effective control of NOx, PM, SO2, as well as CO and hazardous air pollutants.

B. EXISTING FEDERAL AIR REGULATIONS FOR DIESEL-FIRED RICE

The diesel engines that power and/or drive drill rigs and wellsite pumping operations may be considered to be nonroad engines (as opposed to stationary engines), if they meet the regulatory criteria to be considered a nonroad engine. According to EPA, a diesel engine is considered a nonroad engine if it is self-propelled or propelled while performing its function or portable or transportable (if it has wheels, skids, carrying handles, a dolly, trailer, or platform), although a nonroad engine becomes a stationary engine if it stays in one location for more than 12 months (or for a full annual operating period of a seasonal source).[433] EPA distinguishes between nonroad diesel engines and stationary diesel engines because the Clean Air Act directs EPA to set emission standards for new nonroad engines and generally does not allow states to set emission standards for nonroad engines except through a specific process outlined in Section 209 of the Clean Air Act.[434]

EPA has established emission limitations to decrease air emissions from nonroad diesel engines using a tiered approach, with the most stringent Tier 4 standards currently in effect for engine manufacturers. See 40 C.F.R. §§89.112, 1039.101, 1039.102. These are emission standards that the manufacturers must meet in their production and sale of diesel engines and for which they demonstrate compliance on a fleetwide basis. There have been four tiers of emission standards applicable to diesel RICE, with Tier 1 standards applying to engines constructed beginning in 1996-1998, Tier 2 standards applying in 2000-2004, Tier 3 standards applying in 2006-2008, and Tier 4 standards applying in approximately 2014 and beyond.[435] The emission standards do not specify any one pollution control technology that needs to be installed to meet the emission limitations. Instead, the standards set limitations on emissions. Generally, the Tier 1, 2, and 3 emission standards were met with advanced engine design, while the Tier 4 emission standards reflect application of CDPF and SCR.[436] These controls reduce PM and NOx emissions by over 90% from diesel RICE. In addition, the Tier 4 standards mandate that ULSD be used in Tier 4 engines.[437] This requirement also ensures reduced SO_2 emissions from diesel engines.

EPA has also established NSPS for stationary diesel engines (i.e., those diesel RICE not considered to be nonroad engines) in 40 C.F.R. Part 60, Subpart IIII. Those emission standards generally require engine manufacturers to meet the same emission standards applicable to nonroad diesel engines for the size and model year, beginning in model year 2007, for non-emergency engines of displacement below 10

[436] *See*, e. g., EPA's Frequently Asked Questions from Owners and Operators of Nonroad Engines, Vehicles, and Equipment Certified to EPA Standards, available at https://nepis.epa.gov/Exe/ZyPDF.cgi?Dockey=P100U8YP.pdf.
[437] 40 C.F.R. §1037.501(d)(2)

liters per cylinder.[438] Non-emergency engines of displacement higher than 10 liters per cylinder must generally meet the applicable emission standards for marine engines in 40 C.F.R. §94.8 which vary based on year of manufacturer and cylinder displacement.[439] Emergency engines that operate in emergency situations (like standby generators) do not have to meet the Tier 4 standards and instead must meet less stringent standards.[440]

The NSPS have separate requirements for owners or operators of stationary diesel engines that are generally not as stringent either in date of applicability or emission limits as the limits applicable to engine manufacturers. As summarized by an industry website, owners or operators of engines of pre-2007 model year must meet Tier 1 nonroad engine standards for engines less than 10 liters per cylinder and must meet Tier 1 marine standards for engines greater than or equal to 10 but less than 30 liters per cylinder.[441] For engines of 2007 model year or later, owners or operators of engines less than 30 liters per cylinder must buy engines that are certified to meet the NSPS standards applicable to manufacturers.[442] Owners or operators of 2007 model or later year engines greater than or equal to 30 liters per cylinder displacement must meet emission standards that vary depending on the year the engine was installed, with installations after January 1, 2016 having to meet emission limits reflective of application of DPF and SCR.[443]

Significantly, the NSPS do not apply to owners or operators of stationary diesel RICE that have been modified or reconstructed, nor do they apply to engines that were removed from one location and reinstalled at a new location.[444] Further, while the NSPS required by October 1, 2010 the use of ULSD fuel for those engines subject to the NSPS that are below 30 liters per cylinder displacement, engines with greater than or equal to 30 liters displacement that are subject to the NSPS are allowed to use 1,000 ppm sulfur content fuel.[445]

EPA has also adopted a National Emission Standard for Hazardous Air Pollutants for Stationary RICE (RICE NESHAP) that requires emission limits on CO that effectively also limit hazardous air pollutants and VOCs.[446]

C. POLLUTION CONTROL UPGRADES OR RETROFITS FOR DIESEL-FIRED RICE

1. REPLACEMENT OF EXISTING DIESEL-FIRED RICE WITH TIER 4 ENGINES

Given that manufacturers are currently producing diesel RICE with integrated SCR and DPF to meet EPA's Tier 4 emission standards, it is likely the more cost effective option to consider the replacement of existing engines with new Tier 4 engines rather than requiring retrofitting of pollution controls. The emission reduction benefits from replacing existing diesel RICE with Tier 4 diesel RICE can be quite significant. It is difficult to directly compare the regulatory emission standards for Tiers 1–3 to the Tier 4 emission standards because the Tier 2 and 3 emission standards for NOx were based on the total of non-methane hydrocarbons (NMHC) plus NOx. EPA's 2010 Alternative Control Techniques Document for Stationary Diesel Engines summarized the NOx and PM emission rates for various size ranges and for the Tiers 1, 2, and 3, based on EPA's Exhaust and Crankcase Emission Factors for Nonroad Engine Modeling – Compression Ignition (EPA 420-P-04-009), April 2004.[447] In the table below, we compare "Tier 0" (pre-1998) and EPA's Tier 1, 2, and 3 emission factors to the emission standards of the Tier 4 standards promulgated by EPA for specific size engines that fall within the various size ranges of applicability for EPA's nonroad emission standards.[448] The table below shows the NOx and PM emission rates expected for each of the four Tiers of diesel RICE rules, as well as NOx and PM emissions from diesel RICE manufactured before the EPA emission standards applied (i.e., pre-1998 or "Tier 0").

[447] *See* EPA's Alternative Control Techniques Guideline Stationary Diesel Engines, March 5, 2010 at 58 and 61 (Tables 5-2 and 5-3).
[448] *See* May 2004, EPA Regulatory Announcement, Clean Air Nonroad Diesel Rule, Table 1, *available at:* https://nepis.epa.gov/Exe/ZyPDF.cgi/P10001RN.PDF?Dockey=P10001RN.PDF.

Table 30. Comparison of NOx and PM Emission Rates for Various Engine Sizes and Tier Engines.[449]

ENGINE SIZE, HP	TIER ENGINE	NOX EMISSIONS, G/HP-HR	PM EMISSIONS, G/HP-HR
75	0	6.89	0.72
	1	5.58	0.47
	2	4.72	0.24
	3	3.00	0.30
	4	3.50[450]	0.02
174	0	8.39	0.40
	1	5.58	0.25
	2	4.00	0.13
	3	2.50	0.15
	4	0.30	0.01
600	0	8.39	0.40
	1	5.58	0.22
	2	4.10	0.13
	3	2.50	0.15
	4	0.30	0.01
750	0	8.39	0.40
	1	5.58	0.22
	2	4.10	0.13
	3	2.60	0.15
	4	2.60	0.075
1500 GEN SET[451]	0	8.9	0.40
	1	5.58	0.22
	2	4.10	0.13
	3	2.50	0.15
	4	0.5	0.02

As shown in the above table, the Tier 4 NOx limits reflect significant NOx reductions from each prior Tier engine for some engine sizes, except the smallest engines and the non-electrical generating set engines that are greater than 750 hp in size for which there is no different between Tier 3 and Tier 4 NOx emissions. The PM emissions, on the other hand, get increasingly more stringent with each Tier engine.

To determine the cost effectiveness of replacing an existing engine with a Tier 4 engine, one needs to know the costs of a Tier 4 engine. A 2010 analysis done by CARB collected cost data from equipment manufacturers for Tier 4 compliant Generator-Set Engines (or "Gen Sets") and determined the average cost per horsepower for a Tier 4 engine equipped with DPF and SCR.[452] Although this CARB analysis was

[449] Data from EPA's Alternative Control Techniques Guideline Stationary Diesel Engines, March 5, 2010 at 58 and 61 (Tables 5-2 and 5-3), and from May 2004, EPA Regulatory Announcement, Clean Air Nonroad Diesel Rule, Table 1.
[450] This limit applies to NMHC plus NOx. *See* https://nepis.epa.gov/Exe/ZyPDF.cgi/P10001RN.PDF?Dockey=P10001RN.PDF.
[451] Generator-set engines or "Gen Sets." These engines are used to operate an electrical generator or an alternator to produce electric power for other applications.
[452] CARB, Analysis of the Technical Feasibility and Costs of After-Treatment Controls on New Emergency Standby Engines at B-11, *available at:* https://ww3.arb.ca.gov/regact/2010/atcm2010/atcmappb.pdf.

for emergency standby engines, the cost data can provide a reasonable estimate of the capital costs to purchase diesel RICE meeting Tier 4 standards. This data was collected in 2010, and thus presumably reflects a 2010 $ cost basis.[453] CARB provided an average cost per horsepower of Tier 4 engines installed with DPF and SCR as follows:

Table 31. Average Cost Per Horsepower for Diesel RICE Meeting Tier 4 Final Requirements[454]

HP RANGE	$/HP FOR NEW ENGINES MEETING TIER 4 FINAL STANDARDS (2010 $)
50-174	$250
175-749	$184
750-1,206	$160
1,207-2,000	$155
>2,000	$125

With this average cost per horsepower data, the average cost effectiveness of replacing an older engine with a Tier 4-compliance diesel engine can be estimated. For the purpose of this cost effectiveness analysis, a 10-year useful life was assumed. The useful life for the emissions warranty guarantee period required in EPA's nonroad diesel engine rules is only 10 years.[455] While we contend that it is likely a RICE unit including such an engine with SCR installed, can have a useful life of 20 years or more, it is not as clear that the diesel particulate filter would have a life of more than 10 years.[456] Thus, for the purpose of this cost effectiveness analysis, a 10 year life of the new Tier 4 engines was assumed. A 5.5% interest rate was also assumed to be consistent with EPA's Control Cost Manual which recommends use of the bank prime interest rate.[457] The bank prime rate fluctuates over time, and the highest it has been in the past 5 years is 5.5%.[458] Reductions in NOx and PM emissions with the replacement of existing diesel RICE with Tier 4 engines were based on the emission factors reflected in Table 30 above. Given that the Tier 4 engines have significantly lower emissions of both NOx and PM, the total of NOx plus PM emissions reduced were considered in calculating cost effectiveness. The table below provides the cost effectiveness of replacing either a pre-1998 or a Tier 1, 2, or 3 engine with a Tier 4 engine. Calculations were done assuming that the engines operate at two different levels: 1,000 hours per year and 4,000 hours per year. EPA assumed 1,000 hours per year in cost analyses done for stationary diesel engines in its 2010 Control Techniques Document for Stationary Diesel Engines.[459] However, EPA also presented information from other sources indicating the average operating hours of diesel RICE are as high as 3,790 hours per year.[460] Thus, a 4,000 hour operating level was assumed to capture the upper end capacity factor of diesel RICE.

Table 32. COST EFFECTIVENESS OF REPLACING EXISTING DIESEL RICE WITH TIER 4-COMPLIANT DIESEL RICE (2010$).

ENGINE SIZE, HP	ANNUALIZED COST OF NEW ENGINE[461]	ENGINE REPLACED WITH TIER 4	COST EFFECTIVENESS OF REPLACEMENT, 1,000 OPERATING HOURS/YR, $/TON of NOx+PM REMOVED (2010$)	COST EFFECTIVENESS OF REPLACEMENT, 4,000 OPERATING HOURS/YR, $/TON of NOx+PM REMOVED (2010$)
75	$2,488	Tier 0	$6,544/TON	$1,636/TON
		Tier 1	$9,921/TON	$2,480/TON
		Tier 2	$15,517/TON	$3,879/TON
		Tier 3	$107,526/TON	$26,882/TON
174	$4,247	Tier 0	$2,610/TON	$653/TON
		Tier 1	$4,011/TON	$1,003/TON
		Tier 2	$5,794/TON	$1,448/TON
		Tier 3	$9,466/TON	$2,367/TON
600	$14,647	Tier 0	$2,610/TON	$653/TON
		Tier 1	$4,034/TON	$1,009/TON
		Tier 2	$5,646/TON	$1,412/TON
		Tier 3	$9,466/TON	$2,367/TON
750	$15,920	Tier 0	$3,147/TON	$787/TON
		Tier 1	$6,164/TON	$1,541/TON
		Tier 2	$12,368/TON	$3,092/TON
		Tier 3	$256,280/TON	$64,070/TON
1500 GEN SETS[462]	$30,845	Tier 0	$2,255/TON	$564/TON
		Tier 1	$3,534/TON	$883/TON
		Tier 2	$5,026/TON	$1,256/TON
		Tier 3	$8,760/TON	$2,190/TON

Because the NOx emission rates of the various Tier 1–4 standards did not always decrease to the same extent for the smallest and the mid-size to large (non-Gen Set) engines, the cost effectiveness of replacing an existing engine with a Tier 4 engine of 75 hp and of 750 hp increases significantly between installing a Tier 4 engine to replace a Tier 0, 1, or 2 engine as compared to a Tier 3 engine. Also, as would be expected, it is generally more cost effective to replace an engine that operates 4,000 hours per year compared to one that operates 1,000 hours per year. In any event, as Table 32 demonstrates, it should at least be considered cost effective to replace a Tier 0 or Tier 1 engine with a Tier 4 engine of any size or operating hours. For engines in the range of 174 hp to less than 750 hp that operate 4,000 hours or more per year, it is also clearly cost effective to replace any tier engine with a Tier 4 engine, as it also is cost effective for large generator set engines.

[461] Based on the costs per horsepower given in Table 31 above and a capital recovery factor based on a 10-year life and a 5.5% interest rate of 0.132668.

[462] Generator sets > 1,200 hp have more stringent Tier 4 emission standards than other engines that are greater than 750 hp. *See* May 2004, EPA Regulatory Announcement, Clean Air Nonroad Diesel Rule, Table 1.

Although the above review focused on the cost effectiveness for the combined reductions of NOx plus PM, it is important to note that the EPA nonroad engine requirements also set emission limits on THC. Specifically, the Tier 4 standards set a THC emission limit that reflects an 87% reduction in THC compared to pre-1998 (Tier 0 levels). Further, only ULSD is to be used on Tier 4 engines. That is not only a legal requirement but, as discussed above, it is technically required by the manufacturer to ensure that the CDPF works effectively. The use of ULSD which is 15 ppm sulfur, compared to diesel fuel which may be 500 ppm sulfur, reflects a 97% reduction in SO2 emissions from diesel RICE. The increased costs for using ULSD are estimated to be $0.07 more per gallon, but the costs would be reduced to $0.04 per gallon due to anticipated savings because of decreased RICE maintenance with the use of low sulfur fuel.[463] Some states may already mandate the use of ULSD or it could be that ULSD is the only fuel available in some areas, so installation of a Tier 4 engine may not necessarily reduce SO2 emissions for all sources.

In terms of the non-air quality environmental and energy impacts associated with the replacement of an older engine with a Tier 4 engine, the impacts associated with the pollution controls could include increased fuel consumption due to reduced efficiency/parasitic load of SCR and CDPF and/or result in reduced power output. However, improvements in combustion efficiency that have been required and engineered into these newer engines also mean fuel savings that will make up for any parasitic loads, particularly for Tier 0 or Tier 1 engines replaced with Tier 4 engines. Other environmental impacts include solid waste disposal issues from spent catalysts. Further, the Tier 4 engines will require operator training and may result in increased maintenance, although the switch from higher sulfur diesel to ULSD which is mandated for use in Tier 4 engines will result in decreased maintenance. One likely benefit regarding maintenance associated with these controls when purchasing an engine with the NOx and PM controls built into the design as one package (as comparted to retrofitting an existing engine) is that the manufacturers will have a standard set of operating and maintenance procedures for each engine, whereas for a retrofit of SCR and/or CDPF to an existing diesel RICE, the operating and maintenance procedures will presumably need to be tailored to the specific make, model, and condition of the existing engine.

There are also other environmental benefits of replacing existing diesel engines with Tier 4 engines, particularly due to effects that increased engine efficiency and the use of a CDPF will have on reducing black carbon emissions from diesel RICE. Black carbon is very effective at absorbing solar energy. The black carbon particles in the atmosphere absorb solar energy and thus can warm the planet, although black carbon is considered a short-lived climate change pollutant.[464] And when the black carbon particles precipitate to surfaces of snow and ice, it reduces the reflecting power of the snow or ice which results in increased melting of snow and ice. The increased melting of the snow and ice results in a feedback loop with more land exposed to absorb, rather than reflect, solar energy, melting more snow and ice as well as permafrost that releases carbon trapped in the soils which further adds to climate change pollution.[465] Thus, the reduction in black carbon emissions by switching older diesel RICE with Tier 4 engines could have climate change benefits as well as visibility benefits.

---

[464] *See* https://oehha.ca.gov/epic/climate-change-drivers/atmospheric-black-carbon-concentrations; *see also* Cho, Renee, The Damaging Effects of Black Carbon, March 22, 2016, Earth Institute, Columbia University, *available at*: https://blogs.ei.columbia.edu/2016/03/22/the-damaging-effects-of-black-carbon/.

[465] *Id. See also* https://scied.ucar.edu/shortcontent/melting-ice-and-climate-change.

Given that manufactures were required to exclusively produce Tier 4 nonroad diesel engines by January 1, 2015, the Tier 4 engines should be readily available for purchase and installation, or be available in fairly short order. Thus, the replacement of an existing diesel RICE with a Tier 4 diesel RICE should presumably be able to be completed within six months to one year.

When EPA adopted the nonroad diesel engine emission standards, EPA envisioned that the nonroad diesel engine fleet would be comprised entirely of Tier 4 engines by 2030.[466] It is not clear whether the diesel RICE used in the oil and gas industry are on track to be operating on Tier 4 engines by 2030. As part of the process of evaluating controls to achieve reasonable progress towards the national visibility goal, States should evaluate the age and EPA emission compliance status (i.e., Tier) of existing diesel RICE operating within the oil and gas industry in the state. If states do not already collect such information, states should gather this information through required source inventory and/or source registration or licensure requirements.

It is clear that requiring replacement of existing diesel RICE with Tier 4 RICE engines is a cost effective control to reduce NOx and PM along with VOCs and SO_2 for many size engines in a range of operating hours. Requiring the replacement of existing diesel RICE with new Tier 4 engines along with requiring the use of ULSD fuel is the most readily implementable approach to reducing visibility-impairing emissions from diesel RICE.

It would be most effective to require use of Tier 4-compliant generator sets in conjunction with electric motors for all drilling operations, because large Gen Sets (which would be necessary to power electric drill rigs) are subject to much more stringent NOx limits than large diesel RICE (i.e., 0.5 g/hp-hr is the NOx limit for Tier 4 engines, compared to the 2.60 g/hp-hr NOx limit for large diesel RICE, as shown in Table 30 above). Indeed, the Superintendent of Carlsbad National Park has requested this approach as a mitigation measure for the Chevron U.S.A. Hayhurst Master Development Plan for which the western boundary of the project area was to be located only 17 kilometers from Carlsbad National Park in New Mexico. Specifically, the National Park Service stated that "[i]f this option were implemented, engines would meet the 0.5 g NOx/hp-hr [limit] and would reduce drilling and completion emissions by 90%."[467]

In summary, for stationary diesel RICE units, states should require the replacement of older existing engines with Tier 4 engines. For those diesel RICE that are considered nonroad engines, states should consider adopting emission requirements for diesel nonroad engines if California has adopted emission standards that have been approved by EPA under Section 209(e)(2) of the Clean Air Act, where the state adopts the same standards. Alternatively, a state can incentivize the replacement of existing nonroad engines with Tier 4 engines. Further, the state should otherwise encourage use of electric engines for drill rigs and the use of Tier 4 Gen Sets to power those electric engines, as that will result in the greatest reduction in NOx due to the lower emission limits that apply to Tier 4 Generator Set engines. States should evaluate all available options to, at the minimum, encourage replacement of older existing nonroad engines with Tier 4 engines.

---

2. REPLACEMENT OF EXISTING DIESEL-FIRED RICE WITH NATURAL GAS-FIRED RICE

A second option for reducing emissions from diesel RICE is to replace the engines with natural gas-fired or dual-fuel RICE. This was another mitigation measure recommended by the National Park Service to the Bureau of Land Management for the Chevron U.S.A. Hayhurst Master Development Plan. Specifically, the National Park Service stated: "[b]oth natural gas-fired and dual-fuel engines have proven to be feasible, cost effective options for drilling operations in various basins throughout the United States and Canada [fn omitted]."[468] The National Park Service gave numerous examples of companies employing natural gas-fired or dual-fuel drill rig engines, including "EQT, Apache Corporation, Chesapeake Energy, Statoil, Encana Corporation, Cabot Oil and Gas, Antero Resources, CONSOL Energy and Seneca Resources."[469] The National Park Service specifically highlighted Chesapeake Energy's move to "transition all of its hydraulic fracturing equipment to [liquefied natural gas]."[470]

The Four Corners Air Quality Task Force (4CAQTF) also evaluated this option of using natural gas-fired engines on the drill rigs in the Four Corners region.[471] The 4CAQTF found that this switch from diesel RICE to lean burn RICE engines would result in approximately a 91% reduction in NOx from use of Tier 0 diesel engines and approximately an 85% reduction in NOx from use of Tier 1 diesel engines, but this was based on an assumed NOx emission rate from lean burn natural gas-fired RICE of 2 to 3 g/hp-hr.[472] As discussed in Section II.D. and E. of this report, use of LEC or SCR at lean burn engines is cost effective for lean-burn RICE and could achieve NOx emission rates of no higher than 2 g/hp-hr and more likely 1 g/hp-hr or even lower. Use of natural gas-fired RICE instead of diesel RICE would also significantly reduce SO_2 and PM emissions. The 4CAQTF report found that use of natural gas-fired RICE may be less expensive than diesel RICE if natural gas is located within close proximity and able to be piped to the natural gas-fired RICE.[473] Diesel fuel generally needs to be hauled to the drill rig, thus replacement of diesel RICE with natural gas-fired RICE would also reduce mobile source tailpipe and fugitive emissions associated with transporting the diesel fuel. The 4CAQTF report gave one example of a natural gas-fired drill rig being utilized in the Jonah Field in Wyoming to indicate that the use of natural gas-fired drill rigs is a technically feasible option,[474] which is clearly the case given the number of companies cited by the National Park Service that are employing natural gas-fired or dual-fuel drill rig engines.[475] The 4CAQTF indicated a capital cost of up to $1.2 million dollars per rig for the retrofit.[476] Some of the negative impacts included that the use of natural gas-fired RICE would increase carbon monoxide emissions by

[476] *Id.*

approximately 175%, and also that there could be increased land disturbance regarding the installation of natural gas pipelines for delivery of fuel.[477]

In summary, replacement of diesel RICE with natural gas-fired RICE is a viable control option for addressing the visibility-impairing emissions from diesel RICE that states should consider in evaluating reasonable progress measures for diesel RICE units.

3. RETROFIT OF DIESEL-FIRED RICE WITH AIR POLLUTION CONTROLS

Another option to control emissions from stationary diesel RICE is to require retrofits of specific pollution controls. Provided below are cost effectiveness analyses for SCR retrofits and for DPF retrofits to diesel RICE.

a) RETROFITTING SCR TO EXISTING DIESEL-FIRED RICE TO REDUCE NOx

EPA's 2010 Alternative Control Techniques Document for Stationary Diesel RICE presented control costs for SCR and for CDPF retrofits at diesel RICE units. For SCR, EPA estimated capital costs at $98 per hp, based on industry data, and this included costs for the catalyst, reactor housing and ductwork, ammonia injection system, controls, and engineering and installation of the equipment.[478] EPA estimated annualized costs for SCR at $40 per hp, based on annualized capital costs and costs for operating/supervisory labor, maintenance, ammonia, steam diluent, and fuel penalty calculated using the EPA Control Cost Manual and based on 1,000 hours of operation per year.[479]

EPA's cost data for the 2010 Alternative Control Techniques document for Stationary Diesel RICE assume 90 percent reduction of NOx emissions from SCR, which should be readily achievable.[480] EPA estimates uncontrolled NOx emissions based on emission factors from modeling for the different tiers of EPA's exhaust emission standards for nonroad engines: (1) Tier 0 Standards (pre-1998); (2) Tier 1 Standards (1998-2003); (3) Tier 2 Standards (2004-2007); and Tier 3 Standards (2006-2010). As discussed above, the Tier 4 standards reflect the NOx control levels achievable with SCR, and thus it would not make sense for EPA to evaluate SCR retrofits for a Tier 4 engine.

The following table shows the cost effectiveness, based on EPA's cost data, of retrofitting SCR to an uncontrolled stationary diesel RICE and to a Tier 1, 2, or 3 diesel RICE operating 1,000 hours per year and 4,000 hours per year using EPA uncontrolled NO_x emissions estimates. EPA assumed 1,000 hours per year in cost analyses done for stationary diesel engines in its 2010 Control Techniques Document for Stationary Diesel Engines.[481] However, EPA also presented information from other sources indicating the average operating hours of diesel RICE as high as 3,790 hours per year.[482] Thus, a 4,000 hour operating level was assumed to capture the upper end capacity factor of diesel RICE. To estimate operating costs for operating at 4,000 hours per year, EPA's annual cost estimates for an engine

operating 1,000 hours per year were multiplied by a factor of four to estimate potential annual costs reflective of engines operating closer to 4,000 hours per year. For the cost effectiveness analysis presented herein, the SCR system was assumed to have a life of 20 years. EPA states that SCRs at boilers, refineries, industrial boilers, etc. have a useful life of 20-30 years.[483] To be consistent with EPA's statements on SCR and also considering the useful life of diesel RICE, this analysis will assume a 20-year life of the SCR. A 5.5% interest rate was used to be consistent with EPA's Control Cost Manual which recommends use of the bank prime interest rate.[484]

Table 33. Cost Effectiveness to Reduce NOx Emissions by 90% from Stationary Diesel RICE with SCR Operating 1,000 Hours per Year and 4,000 Hours per Year[485]

ENGINE SIZE, hp	ANNUALIZED COSTS OF SCR, 2005$	EMISSIONS STANDARD	COST EFFECTIVENESS OF SCR, 1,000 HOURS PER YEAR, 2005$	COST EFFECTIVENESS OF SCR, 4,000 HOURS PER YEAR, 2005$
75	$2,808	TIER 0	$5,474/ton	$4,575/ton
		TIER 1	$6,739/ton	$5,632/ton
		TIER 2	$8,021/ton	$6,703/ton
		TIER 3	$12,581/ton	$10,514/ton
238	$8,911	TIER 0	$4,500/ton	$3,761/ton
		TIER 1	$6,781/ton	$5,667/ton
		TIER 2	$9,430/ton	$7,881/ton
		TIER 3	$15,093/ton	$12,614/ton
675	$25,272	TIER 0	$4,500/ton	$3,761/ton
		TIER 1	$6,485/ton	$5,420/ton
		TIER 2	$9,207/ton	$7,694/ton
		TIER 3	$15,097/ton	$12,617/ton
1,000	$37,441	TIER 0	$4,497/ton	$3,759/ton
		TIER 1	$6,500/ton	$5,432/ton
		TIER 2	$9,204/ton	$7,692/ton
		TIER 3	$15,073/ton	$12,597/ton

[483] *See* EPA's Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, June 2019, at pdf page 80.
[484] U.S. EPA, Control Cost Manual, Section 1, Chapter 2 (November 2016) at 16.
[485] *See* EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 58, Table 5-2. Annualized costs of control were based on a 20-year life and a 5.5% interest rate. NOx emission reductions are based on 90% NOx removal efficiency, with uncontrolled emissions based on EPA estimates (EPA-420/P-04-09, 2004).

Lower cost data were reported by EPA in its 2000 Updated Information on NOx Emissions and Control Techniques for what it referred to then as 'modern SCR': "The vendor carried out a similar analysis for a 1,000 bhp diesel engine. For an engine operating 200 hours per year, the cost effectiveness was calculated at almost $4,000 per ton. For an engine operating 2,000 hours per year, the cost effectiveness dropped to less than $900 per ton."[486]

In its 1993 Alternative Control Techniques Document for RICE, EPA included a cost effectiveness analysis for diesel-fueled RICE with SCR operating 8,000 hours per year with costs as low as $690/ton for the largest engine sizes (4,000-8,000 hp). EPA noted costs of $1,000/ton or less for engines larger than 3,200 hp and costs of $3,000/ton or less for engines larger than 750 hp.[487]

It is clearly cost effective to retrofit SCR to diesel RICE units that emit NOx at levels similar to the older tier nonroad engines (*e.g.*, Tiers 0 or 1) even at low levels of operating hours per year. And, diesel RICE used in the oil and gas industry have been retrofitted with SCR to reduce NOx. For example, the state of Wyoming and the Bureau of Land Management coordinated with companies drilling in the Pinedale Anticline in western Wyoming to reduce NOx emissions from all drill rigs and, as a result, Shell Exploration and Production Company retrofitted 21 drill rigs with SCRs that have achieved 91-99% reduction in NOx emissions with low levels of ammonia slip (averaging 2-3 ppm).[488] There are several examples of successful SCR retrofits to diesel RICE, including for stationary diesel electrical generating sets and backup generators.[489]

[489] *See* Manufacturers of Emission Controls Association, Case Studies of Reciprocating Diesel Engine Retrofit Projects, November 2009, at 14, 5-7 and 12.

The environmental and energy impacts of SCR systems for diesel RICE include the following:

- 0.5 percent increase in fuel consumption for SCR and associated air emissions increases[490]
- 1 to 2 percent reduction in power output for SCR[491]
- Increased solid waste disposal from spent catalysts[492]
- If ammonia is used instead of urea (which is assumed to be the reagent used in the SCR cost analyses presented above), there would be an increased need for risk management and implementation and associated costs.[493] If urea or aqueous ammonia is used as the reagent, the hazards from the use of pressurized anhydrous ammonia do not apply. It is likely that urea is the most common reagent used in SCR for diesel RICE

SCR technology is widely used at many industrial sources. There are typically not overarching non-air quality or energy concerns with this technology, and many of the concerns are addressed in the cost analysis.

In terms of length of time to install SCR, EPA has estimated that it takes 28-58 weeks to install SCR at a diesel-fired (lean-burn) RICE unit.[494]

b) RETROFITTING CDPF TO DIESEL-FIRED RICE TO REDUCE PM AND VOCS

For CDPF, EPA estimated capital and annual costs in its 2010 Alternative Control Techniques Document for Stationary Diesel RICE based on cost equations developed for the RICE NESHAP. EPA's analysis was based on 2008 cost data from stationary diesel RICE retrofits. The following linear equation for annual cost includes annual operating and maintenance costs plus annualized capital costs based on a 7% interest rate and 10-year life of controls:

CDPF Annual Cost = 11.6 x ENGINE HP + 1,414 (2008$)

The capital cost equation for retrofitting a CDPF on a diesel engine was determined by EPA to be:

CDPF Capital Cost = 63.4 x ENGINE HP + 5,699 (2008$)

These relationships are derived from a data set that includes engines ranging from 40–1,400 hp.[495] EPA's cost estimates are based on 1,000 hours of operation per year.[496]

[493] Anhydrous ammonia is a gas at standard temperature and pressure, and so it is delivered and stored under pressure. It is also a hazardous material and typically requires special permits and procedures for transportation, handling, and storage. *See* EPA Control Cost Manual, Section 4, Chapter 2 Selective Catalytic Reduction, June 2019, at pdf page 15.

[494] 2016 EPA CSAPR TSD for Non-EGU NOx Emissions Controls at 15.

[495] EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 59.

[496] EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 61.

EPA's cost data for the 2010 Alternative Control Techniques document for Stationary Diesel RICE assume 90 percent reduction of PM emissions from CDPF.[497] EPA estimates uncontrolled PM emissions based on emission factors from nonroad engine modeling for the different tiers of EPA's exhaust emission standards for nonroad engines: (1) Tier 0 Standards (pre-1998); (2) Tier 1 Standards (1998-2003); (3) Tier 2 Standards (2004-2007); and Tier 3 Standards (2006-2010). In 2004, EPA adopted Tier 4 Standards, which were to be phased-in from 2008 to 2015. The Tier 4 Standards require 90 percent reduction of PM and NOx emissions. According to EPA, "[t]hese emission reductions can be achieved through the use of control technologies, including advanced exhaust gas aftertreatment, similar to those required by the 2007-2010 standards for highway engines."[498]

The following table shows the results of a cost analysis, based on EPA's cost data, of retrofitting CDPF to an uncontrolled stationary diesel RICE operating 1,000 hours per year and 4,000 hours per year using EPA uncontrolled PM emissions estimates. For this cost analysis of CDPF, a 10-year life and 5.5% interest rate. As discussed above, while we contend that it is likely a RICE unit can have a useful life of 20 years, it is not as clear that the diesel particulate filter would have a life of more than 10 years.[499] Therefore, a useful life of a CDPF retrofit was assumed to be 10 years in determining annualized costs of CDPF. A 5.5% interest rate was also assumed to be consistent with EPA's Control Cost Manual which recommends use of the bank prime interest rate.[500] To estimate annual operating costs for operation of CPDF at 4,000 hours per year, EPA's annual cost estimates which were based on 1,000 operating hours per year were multiplied by a factor of four.

[497] *Id.*

[498] EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 22.

[499] *See*, e.g., EPA Technical Bulletin, Diesel Particulate Filter General Information, *available at:* https://www.epa.gov/sites/production/files/2016-03/documents/420f10029.pdf.

[500] U.S. EPA, Control Cost Manual, Section 1, Chapter 2 (November 2016) at 16.

Table 34. Cost Effectiveness to Reduce PM Emissions by 90% from Stationary Diesel RICE with CDPF Operating 1,000 Hours per Year and 4,000 Hours per Year[501]

ENGINE SIZE, hp	ANNUALIZED COSTS OF CDPF, 2008$	EMISSIONS STANDARD	COST EFFECTIVENESS OF CDPF, 1,000 HOURS PER YEAR, 2008$	COST EFFECTIVENESS OF CDPF, 4,000 HOURS PER YEAR, 2008$
75	$1,670	TIER 0	$31,088/ton	$10,155/ton
		TIER 1	$47,467/ton	$15,505/ton
		TIER 2	$93,735/ton	$30,619/ton
		TIER 3	$74,837/ton	$24,445/ton
238	$2,955	TIER 0	$31,265/ton	$10,510/ton
		TIER 1	$49,665/ton	$16,696/ton
		TIER 2	$95,155/ton	$31,988/ton
		TIER 3	$83,321/ton	$28,010/ton
675	$6,397	TIER 0	$23,774/ton	$8,150/ton
		TIER 1	$43,343/ton	$14,860/ton
		TIER 2	$72,608/ton	$24,892/ton
		TIER 3	$63,467/ton	$21,759/ton
1,000	$8,958	TIER 0	$22,468/ton	$7,740/ton
		TIER 1	$40,960/ton	$14,110/ton
		TIER 2	$68,644/ton	$23,646/ton
		TIER 3	$59,960/ton	$20,654/ton

It must be noted that the higher cost effectiveness values for CDPF in comparison to SCR cost effectiveness values are due to the magnitude of PM emissions from diesel RICE being much lower than the NOx emissions from diesel RICE. The capital costs of CDPF range from $10,000 to $70,000, which is somewhat lower than the range of capital costs for SCR (which range from $7,300 to $100,000), and the annual operating costs of CDPF are significantly lower than the operating costs of SCR ($800-$3,200 per

[501] *See* EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 58, Table 5-2. Annualized costs of control were calculated assuming a 10-year life of controls and a 5.5% interest rate. NOx emission reductions are based on EPA's assumed 90% removal efficiency. Uncontrolled NOx emissions are based on EPA estimates (EPA-420/P-04-09, 2004).

year for CDPF compared to $2,200 to $29,000 per year for SCR).[502] Although CDPF can achieve greater than 90% reduction of PM, overall the tons of PM reduced with CDPF is an order of magnitude lower than the NOx emissions reduced with SCR, and thus the cost effectiveness of CDPF is much higher than the cost effectiveness of SCR.

To truly understand whether this control is considered cost effective, one has to evaluate whether similar sources have been required to install the control at similar costs. Indeed, there are several examples of diesel particulate filter systems being retrofitted to diesel RICE.[503]

As previously stated, the use of a CDPF requires the use of ULSD fuel. It should be noted that ULSD is prevalent in the fuel pool today, including in some nonroad fuels that may not be labeled as such, and therefore may already be used in many stationary diesel engines.[504] The use of ULSD which is 15 ppm sulfur, compared to higher sulfur diesel fuel which may be of 500 ppm sulfur content, reflects a 97% reduction in SO_2 emissions from diesel RICE. The increased costs for using ULSD are estimated to be $0.07 more per gallon, but the costs would be reduced to $0.04 per gallon due to anticipated savings because of decreased RICE maintenance with the use of low sulfur fuel.[505] EPA's 2010 Alternative Control Techniques Document for Stationary Diesel RICE estimated that using ULSD fuel would increase fuel costs by only $0.03 to $0.05 per gallon.[506]

The environmental and energy impacts of controls for stationary diesel RICE include the following:

- 1 to 2 percent fuel penalty for CDPF[507]
- Increased solid waste disposal from spent catalysts[508]

The CDPF will have an added benefit of reducing VOCs and associated air toxics. EPA has found that CDPF can reduce THC by 90 percent.[509] Thus, CDPF can be considered a top control technology for both PM and VOCs.

CDPF can be installed fairly quickly. EPA has indicated that diesel particulate filters can be installed in less than a day,[510] although this claim likely pertains to onroad diesel engines (i.e., trucks). Nonetheless, it is the same technology whether applied to a mobile source or a larger generating diesel RICE. It can be assumed that even taking into account time for engineering, design, ordering of parts, etc., the time to install a CDPF is likely under a year.

---

[502] These costs reflect the range of capital and operating costs for the engine sizes evaluated in Tables 33 and 34, using EPA's SCR and CDPF cost calculations from its 2010 Alternative Control Techniques Document for Stationary Diesel RICE.

D. EXAMPLES OF STATE AND LOCAL AIR AGENCY RULES FOR EXISTING DIESEL-FIRED RICE

States and local air agencies have adopted NOx limits for diesel RICE, some of which have been in place for over 20 years. In Table 35 below, we summarize some of the stronger state and local air pollution requirements. Note that this is not a comprehensive list of state and local air regulations for diesel RICE.

California has adopted fleet-wide emission requirements for existing diesel "off-road" (i.e., non-road) diesel-fueled engines of 25 hp or greater (*see* Title 13 California Code of Regulations Sections 2449 through 2449.2), and EPA has authorized those rules under Section 209(e) of the Clean Air Act.[511] The goal of this program is to turnover nonroad diesel RICE to Tier 4 engines. The rule established in-use statewide emission performance standards that apply to any person owning and operating a nonroad diesel engine in California of 25 hp or greater. The fleet requirements phase in over time and require that fleets either meet fleet average emission targets or meet best available control technology (BACT). States may be able to adopt requirements like this for nonroad diesel RICE, pursuant to Section 209(e)(2) of the Clean Air Act.

Table 35 is a summary of the stronger NOx emission limits required of diesel RICE in states and local air districts across the United States. It is important to note that these are limits that generally do not apply to portable or nonroad engines, unless clearly stated otherwise. The most broadly applicable NOx limit required is approximately 1.10 g/hp-hr which applies in several air districts in California, although SCAQMD has adopted a more stringent NOx limit of 0.15 g/hp-hr. Those limits all likely reflect application of SCR to diesel RICE. These limits were adopted generally to meet RACT and BARCT (in California) and, as previously discussed, costs are taken into account in making these RACT and BARCT determinations. Thus, the fact that state and local air agencies have adopted emission limits reflective of SCR indicate that these agencies have found SCR to be a cost effective control to retrofit to existing stationary diesel RICE.

Table 35. State/Local Air Agency Diesel RICE Rules for NOx Emissions[512]

State/Local	Regulation	Applicability	NOx Limit and units[513] (equivalent g/hp-hr)
CA-Bay Area AQMD[514]	Reg. 9, Rule 8 Effective 1/1/2012:	51 to 275 bhp	180 ppmvd (2.47 g/hp-hr)
	>50 bhp &/or not Low Usage (<100 hrs/yr) &/or not registered as portable:	>175 bhp	110 ppmvd (1.51.g/hp-hr)

[511] 78 Fed. Reg. 58090-58121 (Sept. 20, 2013).
[512] This table attempts to summarize the requirements and emission limits of State and Local Air Agency rules, but the authors recommend that readers check each specific rule for the details of how the rule applies to different units, and in case of any errors in this table.
[513] Emission limits that are in ppmvd are at @ 15% oxygen.
[514] http://www.baaqmd.gov/~/media/dotgov/files/rules/reg-9-rule-8-nitrogen-oxides-and-carbon-monoxide-from-stationary-internal-combustion-engines/documents/rg0908.pdf?la=en.

State/Local	Regulation	Applicability	NOx Limit and units[513] (equivalent g/hp-hr)
CA-Mojave Desert APCD[515]	Rule 1160 (Amended 1/22/18)	>50 bhp &/or >100 hours/4 quarters, not portable, not subject to Airborne Toxic Control Measure, and only if located in the Federal Ozone Nonattainment area	80 ppmv (1.09 g/hp-hr)
CA-Sacramento AQMD[516]	Rule 412	>50 bhp with exemptions if portable, or if operated less than certain # of hours which vary based on rating of engine	80 ppmv (1.10 g/hp-hr) Alt Limit: 90% NOx reduction
CA-San Joaquin Valley APCD[517]	Rule 4702 Exemptions for <50 bhp, portable, or low use engines Non-EPA certified Compression Ignition Engines installed on or before 6/1/06. ---------- Applicable to EPA-certified CI Engines	>50 & ≤ 500 bhp	EPA Tier 3 or Tier 4 by 1/1/2010
		>500 & ≤750 bhp and < 1000 hrs/yr	EPA Tier 3 by 1/1/2010
		>750 bhp & < 1000 hrs/yr	EPA Tier 4 by 7/1/2011
		>500 bhp & ≥1000 hrs/yr	80 ppmv (1.10 g/hp-hr)
		EPA Tier 1 or 2 engine	EPA Tier 4 by 1/1/2015 or 12 years after install date, but no later than 6/1/2018.
		EPA Tier 3 or Tier 4 engine	Meet certified CI engine standard at time of installation

E. SUMMARY – CONTROL OPTIONS FOR DIESEL-FIRED RICE UNITS

Based on all of the analysis provided above, there are several options for reducing visibility-impairing emissions from diesel-fired RICE units. These options are as follows, in order of most beneficial for reducing visibility-impairing pollutants from this source category:

1) Replace existing older diesel-fired engines with Tier 4 engines.

   Replacement of existing older diesel-fired RICE with Tier 4 engines is cost effective as shown in Table 32 above, and has the benefit of reducing NOx by 49% to 96% and PM by 81% to 97.5% (with the percentage reduction based on the emission rates the existing engines is complying with). Replacement of older diesel RICE with Tier 4 engines will also result in a reduction in VOC emissions, due to the VOC emission limits required of Tier 4 engines, and it will also reduce SO_2 emissions because ULSD fuel is required for Tier 4 engines.

   The cost effectiveness of replacing existing diesel-fired RICE varies based on the size of the engine being replaced (smaller engines and larger engines that are not electrical generating sets have less stringent Tier 4 emission limits, which impacts cost effectiveness for those engines, and also the annual operating hours impact cost effectiveness). In general, as demonstrated in Table 32 above, it is cost effective to replace a Tier 0 or Tier 1 engine with a Tier 4 engine for any size engine including for those engines operating on the lower end of annual operating hours.

   For drill rigs, it is most preferable from an air emissions perspective to replace existing older diesel-fired drill rigs with electric-motor drill rigs that are powered by a Tier 4 Electrical Generating Set. Tier 4 Electrical Generating Set engines greater than 1,500 hp are required to meet the lowest NOx and PM emission rates, significantly lower than large non-electrical generating engines (as shown in Table 30 above). Thus, installing electric drill rigs that are powered by Tier 4 electrical generating diesel RICE will result in the greatest reduction in visibility-impairing emissions if the only option is to continue to power the engines with diesel fuel.

2) Replace existing diesel-fired RICE with natural gas-fired RICE equipped with LEC or SCR. Replacing existing older diesel-fired RICE with natural gas-fired RICE, particularly those equipped with LEC or SCR, is also a very effective method for reducing NOx emissions by 85% to 95% and also significantly reducing if not eliminating SO_2 and PM emissions. While we did not calculate

the cost effectiveness of this control option, it is significant to note that the National Park Service has highlighted several companies that employ natural gas-fired or dual fuel drill rig engines, [527] and such engines are also being used in the Jonah Field in Wyoming.[528]

3) As a third option, existing diesel RICE can be retrofit with SCR and/or with CDPF. As demonstrated in Table 33, it is most cost effective to retrofit SCR to an existing Tier 0 or Tier 1 engine, and SCR can result in NOx emission reductions of 90% or more. And, as shown in Table 35, several California air districts have adopted NOx emission limitations that would require retrofitting of SCR to diesel RICE.
   In addition, CDPF can be retrofit to existing diesel RICE and achieve greater than 90% reduction of PM as well as reductions in VOC emissions. It must be noted that, overall, the tons of PM reduced with CDPF is an order of magnitude lower than the NOx emissions reduced with SCR, and thus the cost effectiveness of CDPF is much higher than the cost effectiveness of SCR- but that does not mean it is has not been considered a cost effective control. There are several examples of diesel particulate filter systems being retrofitted to diesel RICE.[529]

   Existing diesel-fired RICE should also be required to use ULSD fuel. EPA estimated that use of ULSD fuel would increase fuel costs by only $0.03 to $0.05 per gallon.[530] ULSD fuel is prevalent in the available fuels today and may already be required to be used in some areas/states. It is also required by the CDPF manufacturer to use ULSD fuel.

Thus, there are several options to cost effectively reduce emissions from diesel-fired engines used in the oil and gas industry. States must evaluate all available options for addressing this significant source of NOx, SO_2, PM and VOC emissions as part of their reasonable progress analysis. The most preferable options are those that address all of the visibility-impairing pollutants from this source category, with replacement of older diesel-fired engines with Tier 4 engines or replacing diesel-fired engines with natural gas-fired RICE equipped with LEC or SCR as the most effective emission limiting options.

VII. CONTROL OF NOx EMISSIONS FROM NATURAL GAS-FIRED HEATERS AND BOILERS

Natural gas-fired heaters and boilers are used in a variety of applications, including power generation and the production of process heat and steam. Boilers, reboilers, and heaters can be found throughout the production and processing segments of the oil and gas industry.

[527] *See* August 29, 2016 Memorandum from Doug Neighbor, Superintendent, Carlsbad Caverns National Park, to Paul Murphy, Project Lead, Bureau of Land Management, Carlsbad Field Office, at 7.
[528] See Four Corners Air Quality Task Force, Report of Mitigation Options, November 1, 2007, at 62.
[529] *See* Manufacturers of Emission Controls Association, Case Study of Reciprocating Diesel Engine Retrofit Projects, November 2009, at 6-14.
[530] EPA 2010 Alternative Control Techniques Document for Stationary Diesel RICE at 71.

In oil and gas production and processing, heaters can be used to aid in separation (e.g., heater-treaters, gas production units (GPUs), heated flash separator units),[531] to maintain temperatures within pipes / connectors (e.g., line heaters),[532] to maintain storage tank temperatures (e.g., tank heaters), and as regenerators / reboilers (e.g., glycol dehydrators, desiccant dehydrators).[533,534] These smaller integrated units are generally rated at less than about 2.5 million Btu per hour (MMBtu/hr) heat input.[535] Larger units can be found at gas processing plants, including steam boilers, hot oil heaters, fractionation column heaters, and other process heaters that range in size from a few MMBtu/hr to 100 MMBtu/hr heat input, or more.[536]

There are two basic ways of supplying combustion air to these types of external combustion units (i.e., two draft types): (1) natural draft (i.e., atmospheric units); and (2) mechanical or forced draft. In atmospheric units, the pressure difference between the hot stack gases and the cooler ambient air creates a draft, drawing supply air into the burners. These units are open to the atmosphere (i.e., non-sealed units). Mechanical draft units use a fan to introduce combustion air into the burners. Draft type can affect the level of excess air in the combustion chamber, and the resulting emissions from the unit (e.g., NOx emissions are generally lower in mechanical draft units by operating with lower excess air and improved flame characteristics).

---

[531] Heater-treaters consist of a heater, free-water knockout, and oil/condensate and gas separator. GPUs consist of a heater and a separator to remove liquid from gas prior to further processing. Heated flash separators are equipped with small boilers to facilitate condensate removal through flashing.

[532] In-line heaters are used to maintain temperatures as pressure decreases, in order to prevent formation of hydrates. Note, in-line heaters can also be used to heat gas transmission lines further downstream in the oil and gas industry.

[533] Glycol dehydrators use glycol to remove water from the gas stream in order to prevent corrosion and freezing; small reboilers are used to regenerate the glycol. Dehydrators can be located at well pads, as well as at centrally-located gathering stations and processing facilities. Solid-desiccant dehydrators are generally used for large volumes of gas, e.g., downstream of a compressor station and use a heater to regenerate the desiccant.

[534] Dehydrator use varies depending on the moisture content of the gas; dry gas requires little dehydration. For example, according to the *Four Corners Air Quality Task Force Report of Mitigations* (Oil and Gas Section), "[i]n the [coal bed methane] areas of Colorado the gas is predominantly methane and the gas is relatively dry gas and requires little dehydration . . . Conventional production in New Mexico also has very little moisture in the gas and little dehydration is required." *See* p. 90.

[536] Hot oil heaters, or thermal fluid heaters, are used in the oil and gas industry in combination with a heat exchanger to warm up a secondary fluid (gas or liquid). This can be useful in situations with certain temperature limitations (e.g., amine used to remove H_2S can degrade at high temperatures) or to prevent corrosive fluids from degrading heating coils. Fractionation column heaters are used at natural gas processing plants to separate out natural gas liquids for further use and can be larger than 10 MMBtu/hr.

Natural gas-fired external combustion units are sources of NOx, CO, VOC, and particulate matter emissions, with NOx the primary pollutant and the focus of this section. SO_2 emissions may also occur if the field-gas used to fire the heaters contains H_2S, which converts to SO_2 during combustion. While emissions from natural gas-fired heaters (e.g., heater-treaters, line heaters, tank heaters, and reboilers) may be relatively small on a unit level, compared to other combustion sources at oil and gas production and processing sites, these units may operate continuously throughout the year. And cumulative emissions from all of the heaters in use at an oil and gas production site or processing facility can be significant.

In its initial regional haze plan, Colorado completed a Reasonable Progress Evaluation for the Heater-Treater Source Category, including a NOx emission 4-Factor analysis for reasonable progress toward the national visibility goal.[537] In its evaluation, Colorado reported that, "the multitude of gas wells in Colorado (~26,000 by 2018) result in cumulative heater-treater NOx emissions that are projected to be the largest single area source category in Colorado by 2018."[538] Colorado projected NOx emissions in 2018 would reach close to 23,000 tons per year.[539]

Federal standards, in the form of NSPS and NESHAP, exist for industrial boilers and process heaters. The NSPS for industrial-commercial-institutional steam generating units are outlined in 40 C.F.R. Part 60, Subparts Db and Dc, and apply to boilers that are capable of combusting over 10 MMBtu/hr of fuel (burning coal, oil, natural gas, or wood). Subpart Db covers industrial-commercial-institutional steam generating units with heat inputs greater than 100 MMBtu/hr and that commenced construction after September 18, 1978. Subpart Dc covers smaller industrial-commercial-institutional steam generating units that commenced constructed after June 9, 1989. These NSPS include emission standards for sulfur oxides (SOx) and PM from burning fuels other than natural gas. In addition, there are no performance testing standards for boilers burning only natural gas. EPA also regulates VOC emissions from boilers and process heaters that are used as combustion control devices under Subpart OOOO and OOOOa through VOC emission reduction requirements, operating requirements, performance testing and monitoring requirements.[540] The NESHAP for industrial boilers, commercial and institutional boilers, and process heaters is outlined in 40 C.F.R. Part 63 Subpart DDDDD and controls mercury, hydrogen chloride, particulate matter (as a surrogate for non-mercury metals), and CO (as a surrogate for organic hazardous emissions) from coal-fired, biomass-fired, and liquid-fired major source boilers based on the maximum achievable control technology. However, these requirements will not address NOx emissions. In addition, all major source boilers and process heaters are subject to a work practice standard to periodically conduct tune-ups of the boiler or process heater.

When EPA adopts or revises Federal standards for a source category, EPA is establishing an emission standard applicable to all of the source types and variable fuels, operating conditions, etc. that exist for that source category. Thus, the NSPS are generally-applicable emission standards and not a source-specific evaluation of controls. It is necessary to evaluate if more broadly applicable and more stringent requirements and pollution controls are available to achieve reasonable progress towards the national

[537] *See* CDPHE RP for Heater-Treaters.
[538] *Id.* at 1.
[539] *Id.*
[540] *See, e.g.,* 40 C.F.R. Part 60 Subpart OOOOa §§ 60.5412, 60.5412a, 60.5413a, 60.5417a.

visibility goal, especially because the NSPS and NESHAP standards have not been re-evaluated in at least 8 years. Review of state regulations, particularly to address the NAAQS which require reductions in emissions from *existing* sources, is also necessary to fully evaluate controls for emission sources associated with oil and gas development to achieve reasonable progress towards the national visibility goal.

The information provided in this section for heaters and boilers reflects a review of the available pollution controls and techniques and associated emissions levels applicable to these source categories, along with data on cost of controls where available, non-air quality environmental and energy impacts, and the useful life of the emission source being evaluated.

Uncontrolled Emission Factors from Natural Gas-Fired External Combustion Units

NOx emissions from natural gas-fired heaters and boilers are generally expressed as emission rates in pounds per million Btu heat input (lb/MMBtu) or pounds per million standard cubic feet of gas (lb/MMscf) or as a concentration in parts per million by dry volume (ppmv or ppmvd). All concentrations expressed in ppmv are on a dry basis and corrected to 3% oxygen. The following emission factors are used in this section:

EPA Emission Factor
AP-42 Natural Gas Combustion (Section 1.4, last revised 1998)
Small Boilers <100 MMBtu/hr (Uncontrolled)…….100 lb/MMscf (0.098 lb/MMBtu)
Converted to lb/MMBtu based on fuel heating value of 1,020 Btu/scf

SCAQMD Emission Factor
Units ≤2 MMBtu/hr ……110 ppmv (0.136 lb/MMBtu)
SCAQMD derived an average emission rate to calculate baseline emissions for this size category in its implementation studies for Rule 1146.2 Emissions of Oxides of Nitrogen from Large Water Heaters and Small Boilers and Process Heaters. This factor accounts for units that are considerably older and also for ones that have not had continual maintenance and upkeep.[541]

[541] *See* SJVAPCD Final Draft Staff Report with Appendices For Proposed Amendments to Rule 4308 (November 5, 2009), B-4, *available at:* http://www.valleyair.org/board_meetings/GB/agenda_minutes/Agenda/2009/November/Agenda_Item_26_Nov_5_2009.pdf [hereinafter referred to as "SJVAPCD 2009 Final Draft Staff Report for Rule 4308"].

A. COMBUSTION MODIFICATIONS

Combustion modification—such as flue gas recirculation (FGR), low-NOx burners (LNB), and ultra-low NOx burners (ULNB)—reduce NOx formation by controlling the combustion process. The following is EPA's description of these combustion control techniques:

> Staging techniques are usually used by LNB and ULNB to supply excess air to cool the combustion process or to reduce available oxygen in the flame zone. Staged-air LNB's create a fuel-rich reducing primary combustion zone and a fuel-lean secondary combustion zone. Staged-fuel LNB's create a lean primary combustion zone that is relatively cool due to the presence of excess air, which acts as a heat sink to lower combustion temperatures. The secondary combustion zone is fuel-rich. Ultra-low-NOx burners use staging techniques similar to staged-fuel LNB in addition to internal flue gas recirculation. Flue gas recirculation returns a portion of the flue gas to the combustion zone through ducting external to the firebox that reduces flame temperature and dilutes the combustion air supply with relatively inert flue gas.[542]

Retrofitting natural gas-fired heaters and boilers with LNB was identified by EPA in 1998 as one of the two most prevalent control techniques in its AP-42 Emission Factor documentation, along with FGR.[543] EPA states that, "NOx emission reductions of 40 to 85 percent (relative to uncontrolled emission levels) have been observed with low NOx burners."[544] And EPA further states that, "[w]hen low NOx burners and FGR are used in combination, these techniques are capable of reducing NOx emissions by 60 to 90 percent."

CARB, in its 1991 RACT and BARCT determinations for Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters, also identified LNB as one of four control methods (along with FGR, SCR, and selective noncatalytic reduction (SNCR)).[545] CARB concluded that, for units ≥5 MMBtu/hr (and ≥90,000 therms annual heat input) a BARCT NOx limit of 30 ppmv (0.036 lbs/MMBtu) could be achieved by installing new burners with FGR, noting that some units would "need to install selective noncatalytic reduction or other emission control technology instead of flue gas recirculation due to particular unit design problems."[546] However, these determinations were from 1991, and the NOx removal capabilities of low NOx burners and similar combustion controls for NOx has greatly improved over time.

[544] *Id.*

[545] CARB Determination of Reasonably Available Control Technology and Best Available Retrofit Control Technology for Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters, July 18, 1991, p. 7 *available at:* https://ww3.arb.ca.gov/ractbarc/boilers.pdf [hereinafter referred to as "CARB 1991 Guidance"].

[546] CARB 1991 Guidance at 6.

For example, in 2018, California's SCAQMD concluded the following with regard to ULNB technology and its ability to meet very low NOx emission limits across a wide range of unit sizes:

> It was noted in the 2008 Rule 1146 and 1146.1 staff reports that there was clear evidence that these types of [ultra-low NOx] burners had been successfully retrofitted on boilers and heaters in the San Joaquin Valley Unified Air Pollution Control District (SJVUAPCD) in their Rule 4306. Source tests that were conducted in conjunction with Rule 4306 showed a 98% compliance rate with a 9 ppm NOx limits using ultra-low NOx burners. In 2010, staff published a technology assessment report discussing the implementation assessment of ultra-low NOx burners subject to Rules 1146 and 1146.1. **The report concluded that the 9 ppm NOx limit can be achieved by ultra-low NOx burner systems for boilers and process heaters greater than 2 MMBtu/hour.** There were ultra-low NOx burners from 16 different manufacturers that could achieve the 9 ppm NOx compliance limit.[547]

In 2010, California's Sacramento Metropolitan AQMD (SMAQMD) determined, based on SCAQMD's rules for similar size sources and models being sold that meet SCAQMD limits, that ULNB technology was available to meet emissions limits for very small units, less than 1 MMBtu/hr.[548] Specifically, SMAQMD found that very small units less than 1 MMBtu/hr could meet a NOx limit equivalent to 20 ppmv:

> The proposed standards are technically feasible. The low NOx technology is commercially available and widely used. Additionally, these standards have already been adopted by the South Coast AQMD and the Bay Area AQMD, and except for the limits proposed for 2013 (which take effect for the SCAQMD in 2012), are already in effect in SCAQMD. As documented in the SCAQMD staff report for Rule 1146.2, as of 2006, 18% of the certification tests for units between 75,000–400,000 Btu/hr and 44% of the certification tests for units between 400,000 and 2,000,000 Btu/hr were already meeting the 14 ng/J (20 ppmv) standard. SCAQMD currently keeps a list of well over 100 certified models that are complaint with the standards in Rules 1146.2 and 1121.[549]

SMAQMD concluded that, "[t]he proposed emission limits are readily achievable through the use of low NOx burners."[550]

---

[547] SCAQMD Draft Staff Report Rules 1146, 1146.1, 1146.2, and 1100, p. 2-2 [emphasis added], *available at:* http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/rule-1146-1146.1-and-1146.2/dsr-1146-final.pdf?sfvrsn=6 [hereinafter referred to as "SCAQMD 2018 Draft Staff Report"].

[548] SMAQMD Staff Report Rule 414 Water Heaters, Boilers and Process Heaters Rated Less Than 1,000,000 Btu Per Hour, January 15, 2010, p. 5, *available at:* http://www.airquality.org/ProgramCoordination/Documents/Rule414%20StaffReport%20011510.pdf [hereinafter referred to as "SMAQMD 2010 Rule 414 Staff Report"].

[549] *Id.* at 16.

[550] *Id.* at 13.

In 2015, a Ventura County Air Pollution Control District (VCAPCD) analysis for amendments to its rules for boilers, steam generators, and process heaters ≥2 and <5 MMBtu/hr found:

> Ultra-low NOx burner systems can achieve less than 9 ppm NOx for boilers, steam generators, or process heaters without the use of Flue Gas Recirculation (FGR) systems. Source tests performed by the San Joaquin Unified Air Pollution Control District showed a 95 percent compliance rate with 9 ppm limits using ultra-low NOx burners. The average NOx concentration measured was 7 ppm.[551]

And as recently as April 2019, Santa Barbara County APCD concluded the following about the ability of ULNB technology to achieve lower NOx limits of between 9 and 12 ppm for units between 2–5 MMBtu/hr:

> The focus of this rule amendment is to lower the emission limits for new and modified natural gas and field gas units from 30 ppm to the 9-12 ppm NOx emission limits, beginning on January 1, 2020. To meet these lower standards, most boilers will have to be equipped with ultra-low NOx burners. Ultra-low NOx burners are designed to achieve low emissions while maintaining good flame stability and heat transfer characteristics. Furthermore, these burners may increase thermal efficiencies by reducing the amount of excess air needed for combustion. This has the added benefit of reducing fuel usage, which results in energy savings.
>
> For most systems, a blower will be required to mix the fuel and air prior to combustion. Even atmospheric boilers, where the burners are not totally enclosed, may still need a blower to premix the fuel and air. Due to the design criteria of these atmospheric boilers, it is only feasible to have them reach the 12 ppm NOx limit, as opposed to the 9 ppm limit for non-atmospheric boilers. It is possible to reach both the 9 and 12 ppm NOx limits without the use of Flue Gas Recirculation (FGR), yet some operators may still choose to use this technology.[552]

Thus, in rulemakings enacted in California air districts from 2015 to 2019, it was essentially deemed reasonable to impose a NOx emission limit of 9 ppm for natural gas-fired heaters and boilers with heat input capacities greater than or equal to 2 ppm. However, as will be discussed in Sections B. and F., even lower NOx limits have been required for heaters and boilers in some California Air Districts.

[552] Santa Barbara County APCD Draft Staff Report for Amended Rule 361. Boilers, Steam Generators, and Process Heaters (Between 2–5 MMBtu/hr); Amended Rule 342. Boilers, Steam Generators, and Process Heaters (5 MMBtu/hr and greater), April 22, 2019, p. 5, *available at*: https://www.ourair.org/wp-content/uploads/2019-05cac-r361-r342-att1.pdf [hereinafter referred to as "Santa Barbara County APCD 2019 Draft Staff Report"].

There are several emerging combustion technologies that demonstrate the potential for even lower levels of NOx without the use of post-combustion controls, such as SCR:

- SOLEX™ Burner is an emerging technology designed to achieve 5 ppm NOx.[553] This burner technology is available as a burner-only alternative to SCR for units "with heat releases between 1 MMBtu/hr and +20 MMBtu/hr."[554] It can be retrofit to existing units and fits traditional ULNB footprints.

- ClearSign Ultra Low NO_x Technology is designed to achieve sub 5 ppm NOx.[555] This technology is reportedly less costly than traditional ultra-low NOx controls with no FGR, lower fuel use, and can be retrofit to existing units. This technology has been installed on several units in SJVAPCD with more testing / demonstration needed:
    - Installation at two refinery heaters (burning natural gas, not refinery gas):
        - 15 MMBtu/hr heater
        - 8 MMBtu/hr heater
    - Installation at two natural gas-fired 62.5 MMBtu/hr oil field steam generators
    - Installation at six enclosed flares (thermal oxidizers)

- Altex Technology Corporation Near Zero NOx Burner has been applied to an 8 MMBtu/hr unit and is capable of achieving 5 ppm under some operating conditions.[556] This technology is being developed as an alternative to SCR for meeting NOx limits as low as 5 ppm for smaller units (e.g., in response to SCAQMD's consideration of a 5 ppm NOx limit for units ≥2 MMBtu/hr).[557]

1. COST EFFECTIVENESS EVALUATIONS FOR COMBUSTION MODIFICATION RETROFITS, REPLACEMENTS, AND UPGRADES

California Air Districts have long been regulating NOx emissions from boilers and process heaters, with CARB issuing RACT / BARCT guidance to Air Districts in 1991.[558] In its 1991 guidance CARB determined the cost effectiveness of LNB (in 1986$) for units as small as 3.5 MMBtu/hr and as large as 150 MMBtu/hr, as follows: (1) $500–$6,400/ton for units operating at a 50% capacity factor; and (2) $300–$4,000/ton for units operating at a 90% capacity factor.[559]

More recent and more detailed cost data are available from California Air Districts that have adopted, and continue to update, regulations for these sources. Based on a review of the various California Air

[558] CARB 1991 Guidance.
[559] CARB 1991 Guidance Table 4. Note, CARB does not identify the underlying assumptions for annualized costs, life of controls, etc.

District rules and in researching vendor information, the source category of boilers and heaters should be subcategorized into three categories for assessing cost effectiveness and achievable NOx emission rates with combustion modifications: (1) Units > 20 MMBtu/hr (achieving NOx levels as low as 6 ppm); (2) Units >5 MMBtu/hr and ≤20 MMBtu/hr (achieving NOx levels as low as 6 ppm); and (3) Units ≤5 MMBtu/hr (achieving NOx levels of 9–20 ppm). Below, we evaluate cost effectiveness of combustion controls for each of these categories of boilers and heaters, based on cost analyses that local air agencies have relied on for regulating these units.

a) Units >20 MMBtu/hr

SJVAPCD is in the process of reviewing its rules for boilers and process heaters >5 MMBtu/hr and is proposing updates as part of its 2018 $PM_{2.5}$ Attainment Plan commitments to reduce NOx emissions.[560] SJVAPCD is considering lowering NOx limits for units >5 MMBtu/hr to levels ranging from 2–3.5 ppm.[561] As part of its control measure analysis, SJVAPCD analyzed the cost effectiveness of retrofitting units of varying sizes with ULNB to achieve a NOx level of 6 ppm, based on vendor cost data. We assume these data are in 2018$.

The SJVAPCD cost data for retrofitting existing units with ULNB includes detailed direct and indirect capital and operating costs for two unit size categories: (1) units >5 and ≤20 MMBtu/hr; and (2) units >20 MMBtu/hr.[562] For the larger size units (>20 MMBtu/hr), SJVAPCD notes that the retrofit may involve "upgrades to various systems such as fuel train to comply with up to date codes, and may involve upgrades to air intake fans, as these units require more air for the burner to operate at its optimum level."[563]

Table 36 below summarizes the total costs for retrofitting existing units >20 MMBtu/hr with ULNB, based on SJVAPCD vendor data, along with calculated annualized costs of the control, assuming a 5.5% interest rate and a 25-year life. Low NOx technologies should last the life of the emission unit. SCAQMD is currently assuming a 25-year life for refinery heaters and boilers.[564] And a review of the emission units in New Mexico permitted oil and gas sources such as gas processing plants show average ages of boilers and heaters of 30-35 years. Thus, we used a 25-year life as a minimum life for a heater or boiler controls in the cost effectiveness analysis, which seems more than justified. Table 36 presents the cost effectiveness of applying these low NOx technologies to existing units to reduce NOx emissions from uncontrolled levels to 6 ppm. Uncontrolled emissions are based on the EPA AP-42 uncontrolled

[562] SJVAPCD 2018 $PM_{2.5}$ Attainment Plan pp. C-80–C-82. Note, the cost estimates assume that the existing foundation and supports will not be replaced and that direct and indirect annual costs are presumed to be the same as the existing burner.

[563] SJVAPCD 2018 $PM_{2.5}$ Attainment Plan at C-81.

[564] *See, e.g.,* SCAQMD Presentation for Rule 1109.1 – NO_x Emission Reduction for Refinery Equipment, Working Group Meeting #9, December 12, 2019, slides 41 and 57, *available at:* http://www.aqmd.gov/docs/default-source/rule-book/Proposed-Rules/1109.1/pr1109-1-wgm_9_final.pdf?sfvrsn=12.

emission rate for small boilers <100 MMBtu/hr of 100 lb/MMscf (0.098 lb/MMBtu). Meeting an emission limit of 6 ppm from this uncontrolled level reflects a control efficiency using state-of-the-art ultra-low NOx burner technology of 93%. Cost effectiveness is presented for operation at a 50% and 90% capacity factor.

Table 36. Cost Effectiveness of Retrofitting Existing Units with ULNB to Achieve a NOx Level of 6 ppm at Boilers and Heaters >20 MMBtu/hr Operating at a 50% and 90% Capacity Factor.[565]

UNIT SIZE (MMBtu/hr)	TOTAL CAPITAL COSTS (2018$)	TOTAL ANNUALIZED COSTS (2018$)	COST EFFECTIVENESS ($/TON) 50% CAPACITY FACTOR	COST EFFECTIVENESS ($/TON) 90% CAPACITY FACTOR
30	$261,813	$19,518	$3,270	$1,817
40			$2,452	$1,362
50			$1,962	$1,090
60			$1,635	$908
70			$1,401	$779
80			$1,226	$681
90			$1,090	$606
100			$981	$545

Based on this analysis of SJVAPCD cost data, it can be cost effective to apply ULNB to existing units >20 MMBtu/hr to reduce NOx emissions to a level of 6 ppm.

SJVAPCD provides separate cost data for oilfield steam generators, noting that most of these units would be 62.5 MMBtu/hr.[566] The SJVAPCD analysis notes that, "[a]s many steam generators are one off built units, they may have different firebox configurations that may not accept the new burner without varying degrees of modification."[567] However, SJVAPCD analyzed retrofitting these units with new burner technology to achieve a NOx level as low as 5 ppm, based on vendor data. Using this same vendor cost data, the cost effectiveness of retrofitting a 62.5 MMBtu/hr unit to reduce NOx levels to 5 ppm ranges from $1,664/ton to $6,656/ton, depending on the extent of the modifications or upgrades that are needed.[568]

[565] Cost data provided by vendors to SJVAPCD, annualized costs calculated assuming a 25-year life and a 5.5% interest rate.

[566] SJVAPCD 2018 $PM_{2.5}$ Attainment Plan at C-83.

[567] *Id.*

[568] This range of cost effectiveness is based on retrofit cost data of $450,000–$1,800,000 and assumes an 80% capacity factor from SJVAPCD's analysis. Annualized costs are calculated assuming a 25-year life and a 5.5% interest rate.

b) Units >5 and ≤20 MMBtu/hr

We also completed a cost effectiveness analysis of retrofitting existing units >5 and ≤20 MMBtu/hr with ULNB based on SJVAPCD vendor cost data for units of this size.[569] Table 37 presents the cost effectiveness of retrofitting existing units >5 and ≤20 MMBtu/hr with ULNB to reduce NOx emissions to 6 ppm from uncontrolled levels based on the EPA AP-42 uncontrolled emission rate for small boilers <100 MMBtu/hr of 100 lb/MMscf (0.098 lb/MMBtu). Meeting an emission limit of 6 ppm from this uncontrolled level reflects a control efficiency using state-of-the-art ultra-low NOx burner technology of 93%. Cost effectiveness is presented for operation at a 50% and 90% capacity factor.

Table 37. Cost Effectiveness of Retrofitting Existing Units with ULNB to Achieve a NOx Level of 6 ppm at Boilers and Heaters >5 and ≤20 MMBtu/hr Operating at a 50% and 90% Capacity Factor.[570]

UNIT SIZE (MMBtu/hr)	TOTAL CAPITAL COSTS (2018$)	TOTAL ANNUALIZED COSTS (2018$)	COST EFFECTIVENESS ($/TON) 50% CAPACITY FACTOR	COST EFFECTIVENESS ($/TON) 90% CAPACITY FACTOR
5	$69,816	$5,205	$5,232	$2,906
10			$2,616	$1,453
15			$1,744	$969
20			$1,308	$727

Based on this analysis using SJVAPCD cost data, it can be cost effective to apply ULNB to existing units >5 and ≤20 MMBtu/hr to reduce NOx emissions to a level of 6 ppm.

c) Units ≤5 MMBtu/hr

SMAQMD, in a cost effectiveness analysis for its most recent revision of its rules (in 2005) for boilers and heaters ≥1 MMBtu/hr, noted that, for units ≥1 MMBtu/hr and <5 MMBtu/hr, "[s]ome of these units may not be retrofitted because of equipment age and design and will have to be replaced with new units."[571]

---

[569] SJVAPCD 2018 $PM_{2.5}$ Attainment Plan pp. C-81–C-82. Note, the cost estimates assume that the existing foundation and supports will not be replaced and that direct and indirect annual costs are presumed to be the same as the existing burner.

[570] Cost data provided by vendors to SJVAPCD, annualized costs calculated assuming a 25-year life and a 5.5% interest rate.

[571] Sacramento Metropolitan AQMD Staff Report Rules 411 and 301, October 27, 2005, p. 10, *available at:* http://www.airquality.org/ProgramCoordination/Documents/Rules411and301%20StaffReport%20102705%20Item11.pdf [hereinafter referred to as "SMAQMD 2005 Rule 411 Staff Report"].

The SMAQMD cost data included the costs for replacing existing units with new units equipped with "low NOx technologies" in order to meet the District's emission limits, including costs for equipment, installation, permitting, and source testing for unit sizes ranging from 1–100 MMBtu/hr.[572] Operating and maintenance costs of a new low-NOx unit are assumed to be the same as older units. Thus, it is assumed that it is more cost effective to replace units that are of a size less than or equal to 5 MMBtu/hr with new units equipped with state-of-the-art combustion controls for NOx.

Table 38 below summarizes cost data for replacing units ≤5 MMBtu/hr with new units with "low NOx technologies." The costs include costs for equipment, installation, permitting, and source testing, along with calculated annualized costs of the control, and assume a 5.5% interest rate and a 30-year life of the new unit.[573] These low NOx technologies should last the life of the emission unit, and Colorado assumed a 30–40 year life for heater-treater units of this size based on manufacturer data.[574] We used a 30-year life as a minimum useful life for replacement heater or boiler controls in the cost effectiveness analysis, which is justified.

Table 38. Total and Annualized Costs of Replacement of Boilers and Heaters ≤5 MMBtu/hr with New Units with Low NOx Technologies.[575]

UNIT SIZE (MMBtu/hr)	TOTAL CAPITAL COSTS (2005$)	TOTAL ANNUALIZED COSTS (2005$)
1	$36,284	$2,551
2	$52,284	$3,652
3	$72,284	$5,028
4	$80,284	$5,579
5	$135,567	$9,328

For the units of 5 MMBtu/hr and lower, SMAQMD's Rule 411 establishes a NOx limit of 30 ppm, but there have been improvements in low NOx technologies demonstrating that units in this size range can meet NOx limits of 20 ppm and even as low as 9 ppm for some applications, based on a review of vendor information.[576] Several California Air Districts require units >2 and <5 to meet a limit of 7–12 MMBtu/hr and units ≤2 MMBtu/hr to meet a limit of 20 ppm. For example, SCAQMD Rule 1146.1 requires units >2 and <5 MMBtu/hr meet limits between 7–12 ppm, depending on the type of unit. And SJVAPCD Rule 4307 requires units >2 and ≤5 MMBtu/hr meet limits of 9 ppm (non-atmospheric units) and 12 ppm

[572] SMAQMD 2005 Rule 411 Staff Report Attachment D-1.
[573] SMAQMD 2005 Rule 411 Staff Report Attachment D-2.
[574] CDPHE RP for Heater-Treaters at 5.
[575] Cost data provided by boiler manufacturers to SMAQMD, annualized costs calculated assuming a 30-year life and a 5.5% interest rate.
[576] *See, e.g.,* Parker Industrial Boiler, offering units <5 MMBtu/hr with Low NOx Power Burners for NOx levels to 9 ppm. *Available at*: https://www.parkerboiler.com/products/.

(atmospheric units). SCAQMD Rule 1146.2 requires units ≤2 MMBtu/hr be manufactured to meet a NOx limit of 20 ppm and SCAQMD provides a list of numerous units that are pre-certified to meet this limit.[577] SJVAPCD also requires point-of-sale NOx limits for units ≤2 MMBtu/hr of 20 ppm.[578] And VCAPCD's Rule 74.15.1 currently requires new and replacement units ≥1 and ≤2 MMBtu/hr to also meet a 20 ppm NOx limit.[579] See Table 42 for a complete and more detailed list of state and local rules, including many with limits for units in this size range of 9–20 ppm.

While the costs of NOx combustion control technologies to meet NOx limits as low as 9 ppm may be higher than what SMAQMD assumed in its 2005 cost analysis, it is also likely that the costs of low NOx combustion controls have not changed much since then. This is because as air pollution controls are required to be implemented more frequently over time, the cost of the air pollution control often decreases due to improvements in the manufacturing of the parts used for the control or different, less expensive materials used, etc. For example, SCAQMD concluded from its 2008 cost analysis that, "[t]he capital cost for retrofitting a unit has decreased by about 70%...."[580]

Therefore, we calculated the cost effectiveness of retrofitting these size units with low NOx technologies using these cost data based on two emission control scenarios: (1) meeting the SMAQMD limit of 30 ppm; and (2) meeting limits achievable today with low NOx combustion technology.

Table 39 below summarizes the cost effectiveness of replacing existing units ≤5 MMBtu/hr with new units with low NOx technologies, based on SMAQMD cost data shown above in Table 38. Table 39 below presents the cost effectiveness of replacement units with low NOx technologies to reduce NOx emissions from the uncontrolled emission rate based on EPA for units >2 MMBtu/hr and the SCAQMD-derived average unit emission rate of 110 ppmv (0.136 lb/MMBtu/hr) for units ≤2 MMBtu/hr. The SCAQMD-average unit emission rate was, "derived by the SCAQMD to calculate the baseline emissions for this [size] category."[581] This rate, "accounts for units that are considerably older and also for ones that have not had continual maintenance and upkeep."[582] Operating and maintenance costs of a new low-NOx unit are assumed to be the same as older units. For the second scenario, the analysis assumes units >2 and ≤5 MMBtu/hr meet a NOx limit of 9 ppm and units ≤2 MMBtu/hr meet a NOx limit of 20 ppm. Meeting emission limits of 9 ppm and 20 ppm from the estimated uncontrolled levels reflect a control efficiency of 89% and 82%, respectively. Cost effectiveness is presented for operation at a 50% and 90% capacity factor.

[580] SCAQMD 2018 Draft Staff Report at 4-3. Note, while SCAQMD's analysis specifically applies to retrofitting units ≥20 and <75 MMBtu/hr with ULNB it's also possible that these changes in cost would apply to units of other sizes, as well.
[581] SJVAPCD 2009 Final Draft Staff Report for Rule 4308.
[582] *Id.*

Table 39. Cost Effectiveness of Replacing Existing Boilers and Heaters ≤5 MMBtu/hr with New Units with Low NOx Technologies Operating at a 50% and 90% Capacity Factor.[583]

UNIT SIZE (MMBtu/hr)	COST EFFECTIVENESS ($/TON) 50% CAPACITY FACTOR NOx RATE: 30 ppm	COST EFFECTIVENESS ($/TON) 90% CAPACITY FACTOR NOx RATE: 30 ppm	COST EFFECTIVENESS ($/TON) 50% CAPACITY FACTOR NOx RATES: 20 ppm (≤2 MMBtu/hr) 9 ppm (>2 MMBtu/hr)	COST EFFECTIVENESS ($/TON) 90% CAPACITY FACTOR NOx RATES: 20 ppm (≤2 MMBtu/hr) 9 ppm (>2 MMBtu/hr)
1	$12,160	$6,756	$10,809	$6,005
2	$8,703	$4,835	$7,736	$4,298
3	$12,322	$6,846	$8,771	$4,873
4	$10,254	$5,696	$7,298	$4,055
5	$13,715	$7,619	$9,762	$5,423

For the smallest units, San Joaquin Valley APCD (SJVAPCD) analyzed the cost of reducing NOx emissions for its point-of-sale rule for boilers and process heaters sized 0.075 to less than 2 MMBtu/hr. Table 40 below shows the differential capital costs (i.e., the difference in cost between a compliant and non-compliant unit), the annualized costs re-calculated using on a 5.5% interest rate (in place of the 10% interest rate assumed by SJVAPCD), and the cost of NOx reduction based on a current unit average emission rate of 110 ppmv meeting a limit of 20 ppmv. For units ≤2 MMBtu/hr uncontrolled emissions are estimated based on the SCAQMD-derived average unit emission rate of 110 ppmv (0.136 lb/MMBtu/hr). Operating and maintenance costs of a new low-NOx unit are assumed to be the same as older units. Cost data were provided to SJVAPCD by stakeholders, retailers, and manufacturers. And again, we used a 30-year life as a minimum life for replacing unit controls with low NOx technologies in the cost effectiveness analysis, as previously discussed. SJVAPCD used a 22% capacity factor in its analysis based on survey data collected by SCAQMD and Bay Area AQMD for "typical usages for these units," which presumably reflect a wide range of application and do not necessarily reflect how these size units are used in oil and gas applications, where heaters can operate continuously.

[583] Cost data provided by boiler manufacturers to SMAQMD (2005$), annualized costs calculated assuming a 30-year life and a 5.5% interest rate.

Table 40. Cost Effectiveness Based on Differential Costs to Reduce NOx Emissions from Replacing Units with Units with Low-NOx Burner Technology to Meet a NOx Limit of 20 ppm, Operating at 22% Capacity[584]

UNIT SIZE (MMBtu/hr)	DIFFERENTIAL CAPITAL COST (2009$)	ANNUALIZED COST (2009$)	COST EFFECTIVENESS (2009$)
0.75	$100	$8	$883/ton
0.4	$750	$63	$1,242/ton
2.0	$3,000	$251	$994/ton

For units operating at a higher capacity factor, as would likely be the case for many of the units used in the oil and gas production and processing segments, the cost per ton of NOx removal of choosing to replace a unit with a new unit with low NOx technologies over a higher-emitting unit would be even less than what is shown in Table 40. For these type of smaller units, SCAQMD Rule 1146.2 requires units with rated capacities between 400,000 and 2,000,000 Btu/hr (i.e., 0.04 and 2 MMBtu/hr) and more than 15 years old, depending on the original manufacturer date, to meet the same emission standards as new units.[585] Meeting these standards, according to SCAQMD, requires the retrofit, or more likely, replacement of the older units.[586]

In its initial regional haze plan, Colorado completed a Reasonable Progress Evaluation for the heater-treater source category, including a NOx emission 4-Factor analysis for reasonable progress toward the national visibility goal.[587] In its evaluation, Colorado reported that:

> The Four Corners Air Quality Task Force considered low NOx burners as a mitigation option for the Four Corners area and had the following finding: "Application not appropriate for the San Juan Basin, because most burners commonly used in the Four Corners Area are smaller than the technology is capable of providing emission reduction." It appears likely that this technology would also be technically infeasible for the Denver-Julesburg (DJ) Basin considering that low-NO_X burners are not commercially available for very small combustion sources such as heater-treaters.[588]

[584] *See* SJVAPCD 2009 Final Draft Staff Report for Rule 4308. Annualized costs of control were calculated using a capital recovery factor of 0.068805 (assuming a 30-year life of controls and a 5.5% interest rate). NOx emission reductions are based on SJAPCD's assumed unit average emission rate of 110 ppmv meeting an emission limit of 20 ppmv.

[585] SCAQMD Rule 1146.2, *available at:* http://www.aqmd.gov/docs/default-source/rule-book/reg-xi/rule-1146-2.pdf?sfvrsn=17.

[586] *See* SMAQMD 2010 Rule 414 Staff Report at 13 (describing SCAQMD rules).

[587] CDPHE RP for Heater-Treaters.

[588] *Id.* at 3.

The Four Corners Air Quality Task Force report was from 2007 and there have been great improvements since then in low NOx technologies. As shown throughout this section on combustion modifications, however, units around 2 MMBtu/hr, and even smaller, are available with low NOx technologies that can meet very low NOx emission limits and can even, in some cases, be retrofitted with these technologies to achieve emissions reductions from existing units. Note, Colorado's RP for Heater-Treaters indicates that a typical heater-treater design rate is about half of the 5 MMBtu/hr threshold for exemptions from Colorado's permitting requirements.[589] And beyond these very small units, low NOx technologies are widely available and generally cost effective for units ≥5 MMBtu/hr.

2. LOWERING COMBUSTION TEMPERATURES TO REDUCE NOx EMISSIONS

Colorado also considered lowering heater-treater temperatures to reduce NOx emissions and described this combustion modification approach, as follows:

> This technology (lowering the heater-treater temperature) was identified by EPA Natural GasSTAR in PRO Fact Sheet No. 906. The fact sheet was written with reduction of methane in mind, although this technology would also reduce combustion emissions because it would reduce fuel use. The following is from the fact sheet: "...heater-treater temperatures at remote sites may be higher than necessary, resulting in increased methane emissions. Commonly, the reason for this is that operators need to reduce the chance of having a high water content in the produced oil and manpower limitations do not allow for constant monitoring at remote sites. Field personnel, consequently, are inclined to operate the equipment at levels that cause the least problems, but also result in higher than necessary emissions."[590]

Estimates for NOx emission reductions from lowering heater-treater temperatures were not provided in EPA's Gas STAR analysis and were not assessed by Colorado. Capital costs were estimated at $1,000–$10,000 and annual operating and maintenance costs were estimated to range from $100–$1,000.[591] Colorado anticipated that there would be no additional time needed for achieving compliance with this technology, that the lowered heater-treater temperature would reduce fuel use, and that there would be no non-air quality impacts. Further, Colorado concluded that this control technology would not affect the service life of the heater-treater, noting that the typical life of a heater-treater is 30 to 40 years.[592]

There are few energy and non-air environmental impacts of combustion modifications for heaters and boilers. Generally, the combustion practices used to reduce NOx emissions also increase thermal efficiencies by reducing the amount of excess air needed for combustion, which has the added benefit

---

[590] *Id.* at 2.
[591] *See* EPA Partner Reported Opportunities (PRO) Fact Sheet No. 906 (last updated September 2004), *available at:* https://www.globalmethane.org/documents/m2mtool/docs/lowerheatertreatertemp.pdf and CDPHE RP for Heater-Treaters at 3.
[592] CDPHE RP for Heater-Treaters at 4.

of reducing fuel usage and increasing energy savings. According to EPA, "[r]eductions in NOx formation achieved by reducing flame temperature and oxygen levels can increase CO and HC emissions if NOx reductions by combustion controls are taken to extremes."[593] And systems where blowers or fans are used, e.g., for LNB plus FGR, will require additional electric energy.

According to EPA, the length of time to install ULNB is 6–8 months (excluding permitting, reporting preparation, and programmatic and administrative considerations).[594]

While the cost estimates in this section on combustion modification are of a cost basis that spans a timeframe from 1986–2018, it is important to note that, beginning in 2006, several state and local air agencies adopted rules to lower NOx emission limits of 30 ppmv to as low as 5–12 ppm for larger units and found it was cost effective to require such a level of control on existing boilers and heating units. This will be discussed further in Section F. below. It is not possible to accurately escalate the older costs to more current dollars. EPA cautions against escalating costs over a period longer than five years because it can lead to inaccuracies in price estimation.[595] Further, the prices of an air pollution control do not always rise at the same level as price inflation rates. In some cases, the cost of the air pollution control decreases over time due to improvements in the manufacturing of the parts used for the control or different, less expensive materials used, etc.[596] In any event, the fact that air agencies have found low NOx combustion technologies to be cost effective to meet NOx emission limits in the range of 5 to 30 ppm indicates that similar sources have had to incur the costs reflected in Tables 36-40 to meet reduced NOx emission limits, and thus the costs of low NOx combustion technology should be considered reasonable for most heaters and boilers.

B. POST-COMBUSTION CONTROLS: SCR AND SNCR

Post-combustion controls, such as SCR and SNCR, reduce NOx formation in the flue gas. The following is EPA's description of these add-on control techniques:

> These techniques control NOx by using a reactant that reduces NOx to nitrogen (N2) and water. The reactant, ammonia (NH3) or urea for SNCR, and NH3 for SCR, is injected into the flue gas stream. Temperature and residence time are the primary factors that influence the reduction reaction. Selective catalytic reduction uses a catalyst to facilitate the reaction.[597]

[594] 2016 EPA CSAPR TSD for Non-EGU Emissions Controls at 15.
[595] EPA Control Cost Manual, Section 1, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017.
[596] For example, SCAQMD concluded from its 2008 cost analysis that, "[t]he capital cost for retrofitting a unit has decreased by about 70%...." (SCAQMD 2018 Draft Staff Report at 4-3).
[597] EPA 1993 ACT for Process Heaters at 2-6.

SCR systems on natural gas-fired boilers and heaters should be able to achieve NOx removal efficiencies in the range of 80 to 90+%.[598] SNCR systems on natural gas-fired industrial boilers and heaters can achieve NOx reductions in the range of 30-75%.[599]

As early as 1991, CARB, in its 1991 RACT / BARCT determination for Industrial, Institutional, and Commercial Boilers, Steam Generators, and Process Heaters, identified SCR and SNCR as two of four control methods (along with FGR and LNB).[600] CARB concluded that, for units ≥5 MMBtu/hr (and ≥90,000 therms annual heat input), a BARCT NOx limit of 30 ppmv (0.036 lbs/MMBtu) could be achieved by installing new burners with FGR, noting that some units would "need to install selective noncatalytic reduction or other emission control technology instead of flue gas recirculation due to particular unit design problems."[601]

EPA provided cost effectiveness data for SNCR at model heaters in its 1993 Alternative Control Techniques document. Specifically, cost effectiveness of SNCR for heaters, at the time, ranged from: (1) $3,200–$6,700/ton for a 77 MMBtu/hr heater; (2) $2,700–$5,700/ton for a 121 MMBtu/hr heater; and (3) $2,300–$4,900/ton for 186 MMBtu/hr heater.[602]

California Air Districts have long been regulating NOx emissions from boilers and process heaters, with CARB issuing RACT / BARCT guidance to Air Districts in 1991.[603] In its 1991 guidance, CARB determined the cost effectiveness of SNCR (in 1986$) for units as small as 50 MMBtu/hr and as large as 375 MMBtu/hr, as follows: (1) $1,500–$6,000/ton for units operating at a 50% capacity factor; and (2) $1,300–$3,800/ton for units operating at a 90% capacity factor.[604]

More recent and more detailed cost data are available from California Air Districts that have adopted, and continue to update, regulations for these sources. A recent analysis by California's SCAQMD for revisions to its series of rules for boilers and process heaters (i.e., Rules 1146, 1146.1, and 1146.2) concluded that, "[u]pon reviewing the type of pollution control technologies available to control NOx emissions applicable to the boilers, steam generators and process heaters subject to Rule 1146 and 1146.1, SCR and ultra-low NOx burners are still the main technologies that can achieve the NOx concentration limits specified in these rules."[605] SCAQMD further determined that, "[b]ased on the 2008 staff reports for Rule 1146 and 1146.1, SCR as applied to Rule 1146 boilers can achieve NOx

concentrations from 5 to 6 ppm for units greater than or equal to 75 MMBtu/hr."[606] SCAQMD's revisions to Rule 1146 for Boilers, steam generators, and process heaters ≥5 MMBtu/hr allow facilities until January 1, 2022 to retrofit all existing units and until January 1, 2023 to replace any existing units to meet a NOx emission limit of 5 ppm for units ≥75 MMBtu/hr burning natural gas.[607] SCAQMD determined that the 1146 rule series are cost effective, including for units ≥75 MMBtu/hr retrofitted with SCR to meet an emission limit of 5 ppm.[608]

In the SJVAPCD, the District described the following approach to achieving lower NOx limits, acknowledging certain technical and cost feasibility considerations with SCR for certain units:

> The amendment of Rule 4306 in October 2008 was initially proposed to lower the NOx emission limit from 9 ppmv to 6 ppmv for units greater than 20 MMBtu/hr. It was determined that the proposed NOx limits could be accomplished by using selective catalytic reduction (SCR) or a combination of SCR and ultra-low NOx burners (ULNBs), thus making the lower limits technologically feasible. However, through the public workshop process and additional research it was also determined that most of the units subject to Rule 4306 have undergone several generations of NOx controls, and consequently, certain applications of SCR may not be cost effective and/or technological infeasible because of physical limitations. Therefore, the lower NOx limits were included in new Rule 4320 and an option was provided in the rule that allows for the payment of an annual emissions fee based on total actual emissions, rather than installation of additional NOx controls. These fees are used by the District to achieve cost effective NOx reductions through District incentive programs, the District's Technology Advancement Program, and other routes.[609]

SJVAPCD is in the process of reviewing its rules for boilers and process heaters >5 MMBtu/hr and is proposing updates as part of its 2018 $PM_{2.5}$ Attainment Plan commitments to reduce NOx emissions.[610] SJVAPCD is considering lowering NOx limits for units >5 MMBtu/hr to levels ranging from 2–3.5 ppm.[611] As part of its control measure analysis, SJVAPCD analyzed the cost effectiveness of retrofitting units of varying sizes with SCR to achieve these NOx levels, based on information from SCR vendors. We assume these data are in 2018$.

The SJVAPCD cost data for retrofitting existing units with SCR includes detailed direct and indirect capital, installation, and operating and maintenance costs for two unit size categories: (1) units >5 and ≤20 MMBtu/hr; and (2) units >20 MMBtu/hr.[612]

[612] SJVAPCD 2018 $PM_{2.5}$ Attainment Plan pp. C-80–C-82. Note, the cost estimates assume that the existing foundation and supports will not be replaced and that direct and indirect annual costs are presumed to be the same as the existing burner.

Table 41 below summarizes the total costs for retrofitting existing units ≥5 MMBtu/hr with SCR, based on SJCAPCD-obtained vendor data, along with calculated annualized costs of the control, assuming a 5.5% interest rate and a 25-year life for SCR. SCAQMD is currently assuming a 25-year life for refinery heaters and boilers.[613] Table 41 also presents the cost effectiveness of applying SCR existing units to reduce NOx emissions from uncontrolled levels to levels of: (1) 2.5 ppm for units >20 MMBtu/hr; and (2) 3.5 ppm for units >5 and ≤20 MMBtu/hr.[614] Uncontrolled emissions are based on the EPA AP-42 uncontrolled emission rate for small boilers <100 MMBtu/hr of 100 lb/MMscf (0.098 lb/MMBtu). Meeting emission limits of 2.5 ppm and 3.5 ppm from this uncontrolled level reflects a control efficiency using state-of-the-art SCR technology of 96% and 97%, respectively. Cost effectiveness is presented for operation at a 50% and 90% capacity factor.

Table 41. Cost Effectiveness of Retrofitting Existing Units with SCR to Achieve NOx Levels of 2.5 ppm for Units >20 MMBtu/hr and 3.5 ppm for Units >5 and ≤20 MMBtu/hr Operating at a 50% and 90% Capacity Factor.[615]

UNIT SIZE (MMBtu/hr)	TOTAL CAPITAL COSTS (2018$)	TOTAL ANNUALIZED COSTS (2018$)	COST EFFECTIVENESS ($/TON) 50% CAPACITY FACTOR	COST EFFECTIVENESS ($/TON) 90% CAPACITY FACTOR
5	$261,728	$26,055	$25,354	$14,086
10			$12,677	$7,043

[614] *See* SJVAPCD 2018 $PM_{2.5}$ Attainment Plan at C-85 and C-87, stating: "Source test results of various units with SCR systems indicate that an SCR can potentially achieve 3.5 ppmv NOx @ 3% O2 for units rated between 5 to 20 MMBtu/hr." and "Source test results of various units with SCR system indicate that an SCR can reliably achieve 2.5 ppmv NOx @ 3% O2 (or less) emissions for units greater than 20 MMBtu/hr."

[615] Cost data provided by vendors to SJVAPCD, annualized costs calculated assuming a 25-year life and a 5.5% interest rate.

SJVAPCD based its cost analysis on vendor data for the SCR systems and largely on EPA's Air Pollution Control Cost Manual (6th Edition) for installation, operating and maintenance costs, etc., for these systems.

This analysis indicates that it is cost effective to retrofit units, especially those >20 MMBtu/hr, with SCR to achieve NOx levels as low as 2.5–3.5 ppm.

The energy and non-air environmental impacts of post-combustion control techniques include:

- Parasitic load of operating an SCR system, which requires additional energy (fuel use and electricity) in order to maintain output across the catalyst;
- Solid waste disposal of spent SCR catalyst;
- Ammonia, CO, and nitrous oxide emissions with the use of SNCR;
- Ammonia and sulfite emissions with the use of SCR; and
- Ammonia handling and storage with SNCR and SCR.[616]

According to EPA, the length of time to install SCR is 28–58 weeks (excluding permitting, reporting preparation, and programmatic and administrative considerations).[617] The Institute of Clean Air Companies has stated that SCRs for smaller units (less than 20,000 standard cubic feet per minute gas throughput) are often available in ready-to-install SCR skid packages, and thus SCR for smaller units would take closer to 28 weeks to install.[618] An SNCR would take much less time to install. The Institute of Clean Air Companies states that it takes about 10-13 months to install SNCR, which covers the time from bid evaluations to startup of the SNCR.[619]

C. NOx CONTROLS FOR SEPARATORS

Colorado's Reasonable Progress Evaluation for the heater-treater source category evaluated the installation of insulation on the separator to reduce fuel usage, and resulting combustion emissions (including NOx).[620] Installation of insulation on separators was also included in the Four Corners Air Quality Task Force Report of Mitigation Options for the oil and gas industry and determined to be a technically feasible technique for reducing NOx emissions.[621] Estimates for NOx emission reductions from insulating separators were not provided in the Four Corners Air Quality Task Force report and were not assessed by Colorado. The cost effectiveness of this control will depend on the remaining life of the

equipment to which it is applied. Colorado anticipated that there would be no additional time needed for achieving compliance with this technology and that there would be no non-air quality impacts.

D. NOx CONTROLS FOR DEHYDRATORS

Use of a zero emission dehydrator can significantly reduce fuel requirements for a reboiler and therefore reduce combustion emissions (including NOx). The Four Corners Air Quality Task Force report identified this type of dehydrator as a mitigation option and described this type of unit and its emissions, as follows:

> The zero emissions dehydrator combines several technologies that lower emissions. These technologies eliminate emissions from glycol circulation pumps, gas strippers and the majority of the still column effluent. . . . Benefits of this technology include: . . . Reduces emissions of particulate matter, sulfur dioxide, NOx or CO emissions . . . Significantly reduces fuel requirements for glycol reboiler. Natural gas that was used for this purpose can now be sent to market.[622]

The Four Corners Air Quality Task Force report describes how existing dehydrators can be retrofitted to zero emissions dehydrators, "by modifying the gas stream piping and using a 5 kW engine-generator for electricity needs."[623] The Four Corners Air Quality Task Force reports that operating and maintenance costs are lower than for conventional glycol dehydrators and further reports that EPA estimates the payback for installing a zero emission dehydrator in place of a conventional glycol dehydrator to occur in less than a year.[624]

E. CENTRAL GATHERING FACILITIES TO REDUCE NOx EMISSIONS FROM WELLHEAD SEPARATION SOURCES

Centralization of gas well gathering facilities can be employed to reduce and consolidate wellsite sources, including heaters and separators. Colorado's Reasonable Progress Evaluation for the heater-treater source category evaluated central gathering facilities to remove wellhead separation.[625] With centralization, emissions from heater-treaters would be reduced because fewer heater-treaters would be needed. Colorado described the effectiveness of this restructuring, as follows:

> Removing individual heater-treaters and replacing them with a central gathering facility would eliminate emissions from the heater-treaters. The central gathering facility would be a new source of emissions; however, overall emissions will be reduced. Not only would combustion emissions from the multiple heater-treaters be eliminated, VOC emissions from condensate

[622] *Id.* at 92.
[623] *Id.* at 93. The report further notes that the electricity needs require a "fuel or power source, for which associated emissions need to be quantified."
[624] *Id.* at 93.
[625] CDPHE RP for Heater-Treaters.

> tanks (which would also be removed from wellheads if this technology was implemented) would be eliminated. If a vapor recovery unit (VRU) were used at the central gathering facility, VOCs could be compressed back into the gas stream.[626]

Colorado acknowledges that it would be most cost effective to implement a centralized gathering facility on a new field but indicates that retrofitting a field already set up with infrastructure for wellhead separation would be site-specific and depends on several considerations, including the number of heater-treaters being removed, topography, gas composition, mineral rights, etc. Additional benefits of a centralized gathering facility include reduced truck traffic to wellheads (which can be significant sources of fugitive PM emissions) and a reduction in condensate and water tanks (and their associated fugitive emissions). States should consider requiring or otherwise advocating for centralized gathering facilities for new oil and gas development as a measure to prevent future visibility impairment.

Estimates for NOx emission reductions from the centralization of gas well gathering facilities were not assessed by Colorado other than saying that overall emissions will be reduced. Colorado anticipated that additional time needed for achieving centralization would be site-specific, e.g., depending on gas well density and topographical barriers. Finally, Colorado notes that central gathering facilities would be more efficient to operate, reducing overall energy impacts.

F. NOx EMISSION LIMITS THAT HAVE BEEN REQUIRED FOR HEATERS AND BOILERS

States and local air agencies have adopted NOx limits for existing boilers and heaters, many of which have been in place for more than 20 years and many of which have been strengthened over the years. In Table 42 below, we summarize some of those state and local air pollution requirements. Primarily, a review of California Air District rules was done for this report, because several of those air districts have adopted the most stringent NOx emission limitations.

Table 42 is a summary of the NOx emission limits required of existing boilers and heaters in states and local air districts across the United States. It is important to note that these are limits that, unless otherwise noted, currently apply to existing units and generally required an air pollution control retrofit. These NOx limits were most likely adopted to address nonattainment issues with the ozone and $PM_{2.5}$ NAAQS. Regardless of the reason for adopting the NOx emission limits, what becomes clear in this analysis is that governments have adopted NOx limitations that require low NOx technologies at boilers and heaters as small as 0.4 MMBtu/hr and SCR for units ≥75 MMBtu/hr. The lowest, most broadly applicable NOx limits are those recently adopted by SCAQMD and SJVAPCD. SJVAPCD has a more stringent limit than SCAQMD rules for units between 20 and 75 MMBtu/hr (7 ppm in SJVUAPCD Rule 4320 vs. 9 ppm in SCAQMD Rule 1146), however, it is important to note that for SJVUAPCD's Rules 4306 and 4320, the owner or operator has the option of paying into an annual emissions fee in lieu of

[626] *Id.* at 3.

complying with these limits. For units ≥ 75 MMBtu/hr, the emission limit in SCAQMD Rule 1146 of 5 ppm is more stringent than SJVAPCD's limit of 7 ppm.

Table 42. State/Local Air Agency Natural Gas-Fired Boiler and Heater Rules[627]

State/Local	Regulation	Applicability	NOx Limit and units (equivalent lb/MMBtu)
CA–SCAQMD	Rule 1146.[628] Adopted 9/9/98 Last revised 12/7/18	≥5 MMBtu/hr Effective 9/5/08	30 ppm (0.036 lb/MMBtu)
		≥5 MMBtu/hr Effective 1/1/14 Atmospheric units	12 ppm (0.015 lb/MMBtu)
		≥75 MMBtu/hr Effective 1/1/13 Excluding thermal fluid heaters	5 ppm (0.0062 lb/MMBtu)
		≥20 and <75 MMBtu/hr Effective 12/7/18 Excluding thermal fluid heaters, certain fire-tube boilers, and units with a previous NOx limit ≤12 and >5 ppm prior to 12/7/18	5 ppm (0.0062 lb/MMBtu)
		≥5 and <20 MMBtu/hr Effective 1/1/15 (or later for units with a previous NOx limit ≤12 ppm prior to 9/5/08) Excluding atmospheric units and thermal fluid heaters	9 ppm (0.011 lb/MMBtu)
		≥5 and <20 MMBtu/hr Effective 12/7/18 (or later for units with a previous NOx limit ≤9 ppm prior to 12/7/18) Fire-tube boilers excluding units with a previous NOx limit ≤12 and >9 ppm prior to 12/7/18	7 ppm (0.0085 lb/MMBtu)
		≥5 MMBtu/hr Effective 12/7/18 (or later for certain units at non-RECLAIM facilities) Thermal fluid heaters	12 ppm (0.015 lb/MMBtu)

[627] This table attempts to summarize the requirements and emission limits of State and Local Air Agency rules applicable to the types of units found in the oil and gas industry, but the authors recommend that readers check each specific rule for the details of how the rule applies to different units, and in case of any errors in this table.

Most stringent NOx Limits of State/Local Rules:

5 ppm (0.0062 lb/MMBtu)……Units ≥75 MMBtu/hr
5–12 ppm (0.0062–0.015 lb/MMBtu) …… Units >2 and <75 MMBtu/hr
20 ppm (0.024 lb/MMBtu)…… Units ≤2 MMBtu/hr

As Table 42 shows, several state and local air pollution control agencies have adopted NOx emission limits for boilers and heaters that reflect the application of low NOx burner technologies, and reflect SCR for units ≥75 MMBtu/hr. These air agencies have thus found that the levels of NOx control listed in Table 42, including NOx limits as low as 5 ppm for larger units, in the range of 5–12 ppm for smaller units, and as low as 20 ppm for very small units, providing relevant examples for states to consider in their second round haze plans to help make reasonable progress towards remedying existing visibility impairment. The fact that these limits could apply to modified units >2 MMBtu/hr means that the states consider retrofit controls to meet the emission limits in Table 42 above to be cost effective, and should also consider the cost effectiveness of retrofitting units >5 MMBtu/hr to meet NOx limits as low as 2–3.5 ppm based on the work being done in the SJVAPCD.

G. SUMMARY – NO_x CONTROLS FOR NATURAL GAS-FIRED HEATERS AND BOILERS

The above analyses and rule data demonstrate that numerous state and local air agencies have found that low NOx burner technology is a cost effective retrofit NOx control for boilers and heaters >5 MMBtu/hr with costs ranging from $545/ton to $5,232/ton. Smaller units ≤5 MMBtu/hr can be replaced with new units with low NOx burner technology at costs ranging from $4,055/ton to $10,809/ton. Low NOx burner technologies can generally meet limits down to 5–6 ppm, with the potential for emerging technologies to meet NOx levels lower than 5 ppm. For most units, including atmospheric units, a blower may be required to mix the fuel and air prior to combustion. It is possible to reach NOx levels of 9 ppm for non-atmospheric units and 12 ppm for atmospheric units without the use of FGR.[662]

Further, SJVAPCD has found that SCR is cost effective for larger units with costs ranging from $1,025/ton to $6,149/ton to meet NOx levels as low as 2.5 ppm. For the lowest NOx limit of 5–6 ppm currently applicable to units under rules adopted by SCAQMD and SJVAPCD, SCR is presumably necessary to meet these limits.

As states evaluate regulation of NOx emissions from boilers and heaters, there are several factors to consider, such as draft type (i.e., atmospheric vs. non-atmospheric), operating capacity factor, and size. Nonetheless, given the numerous local NOx limits in Table 42 above that reflect operation of low NOx burner technology, and SCR for larger units, these controls for units of all sizes should generally be considered as cost effective measures available to make reasonable progress from boilers, reboilers, and

[662] *See, e.g.,* Santa Barbara County APCD 2019 Draft Staff Report.

heaters, given that similar sources have assumed similar costs of control to meet Clean Air Act requirements.

VIII. ADDRESSING VISIBILITY-IMPAIRING EMISSIONS FROM FLARING AND THERMAL INCINERATION OF EXCESS GAS AND WASTE GAS

Gas flaring is a process to combust excess or waste gases from oil wells, gas processing plants, or oil refineries. Flaring is intended as a means of disposal of excess gas as a safety measure and is also done to relieve pressure in gas pipelines. Combustion of excess or waste gas can also be accomplished with thermal incinerators rather than flaring.[663] Combustion of excess gas whether done through flaring or thermal incineration is also a VOC control device, as the combustion of the gas destroys most of the VOCs. However, the extent to which VOC emissions are effectively destroyed depends on the design and operation of the combustion device.

There are several processes associated with oil and gas development in which excess gas is flared or combusted, including the following: during testing of a new oil or gas well, when natural gas co-occurs with a new oil well, at gas pipeline headers and at gas processing plants when needed to relieve pressure, at gas compressor stations to combust vapors captured by a dehydrator unit, at gas processing plants and at oil refineries when an upset occurs or to allow maintenance of equipment, and at gas sweetening plants.[664]

A flare system is a thermal oxidation process using an open flame. It consists of an elevated flare stack through which the waste or excess gas stream flows, where it is combusted at the tip of the stack producing a flame. This is sometimes referred to as a "candlestick" flare. A thermal incinerator, which is also called a direct flame incinerator, thermal oxidizer, or an afterburner, is a thermal oxidation process that occurs in an enclosed combustion chamber. The temperature of the waste gas is raised in the combustion chamber in the presence of oxygen above its autoignition point by passing the gas through a flame which is maintained by the waste gas and auxiliary fuel, and combustion of the waste gas occurs. More specific descriptions of these control devices are provided below. The purpose of both a flare and a thermal incinerator is to combust the excess or waste gas and reduce VOC emissions.

A. FLARING SYSTEM

EPA describes a flare system as follows:

> Flaring is a high-temperature oxidation process used to burn waste gases containing combustible components such as volatile organic compounds (VOCs), natural gas (or

[663] *See* Alberta Energy Regulator, EnerFAQS, Flaring and Incineration, *available at:* https://www.aer.ca/providing-information/news-and-resources/enerfaqs-and-fact-sheets/enerfaqs-flaring.

> methane), carbon monoxide (CO), and hydrogen (H_2). The waste gases are piped to a remote, usually elevated location, and burned in an open flame in ambient air using a specially designed burner tip, auxiliary fuel, and, in some cases, assist gases like steam or air to promote mixing for nearly complete (e.g., ≥ 98%) destruction of the combustible components in the waste gas. Note that destruction efficiency is the percentage of a specific pollutant in the flare vent gas that is converted to a different compound (such as carbon dioxide [CO_2], carbon monoxide, or another hydrocarbon intermediate), while combustion efficiency is the percentage of hydrocarbon in the flare vent gas that is completely converted to CO_2 and water vapor. . . .
>
> Combustion requires three ingredients: fuel, an oxidizing agent (typically oxygen in the air), and heat (or ignition source). Flares typically operate with pilot flames to provide the ignition sources, and they use ambient air as the oxidizing agent. The waste gases to be flared typically provide the fuel necessary for combustion. Combustible gases generally have an upper and lower flammability limit. The upper flammability limit (UFL) is the highest concentration of a gas in air that is capable of burning. Above this flammability limit, the fuel is too rich to burn. The lower flammability limit (LFL) is the lowest concentration of the gas in air that is capable of burning. Below the LFL, the fuel is too lean to burn. Between the UFL and the UFL, combustion can occur. Completeness of combustion in a flare is governed by flame temperature, residence time and flammability of the gas in the combustion zone, turbulent mixing of the components to complete the oxidation reaction, and available oxygen for free radical formation. Combustion is complete if all hydrocarbons and CO are converted to CO_2 and water. Incomplete combustion results in some hydrocarbons or CO discharged to the flare being unaltered or converted to other organic compounds such as aldehydes or acids.[665]

Flares, if operated in a manner to provide for complete combustion, are intended to destroy hydrocarbons and VOCs. Flaring also converts methane to CO_2. Both are greenhouse gases, but methane is a more powerful greenhouse gas.[666] EPA indicates that properly operated flares should achieve 98% destruction efficiency of VOCs.[667] However, according to EPA studies, flares "can operate at a wide range of Destruction and Removal Efficiency (DRE)." As a result, although flares are a VOC control device, flares are also a source of VOC emissions especially when not designed or operated in a manner to achieve high levels of DRE. Further, "[s]mall amounts of uncombusted vent gas will escape the flare combustion zone along with products of incomplete combustion,"[668] which can add to VOC emissions as well as methane emitted from the flare. Flaring of natural gas also results in emissions of NOx, as well as particulate matter emissions of carbon particles (soot) and unburned hydrocarbons.

[668] Shah, Tejas, Ramboll Environ (EPA Contractor), Greg Yarwood (Ramboll Environ), Alison Eyth (EPA), and Madeleine Strum (EPA), Composition of Organic Gas Emissions from Flaring Natural Gas, August 18, 2017, at 6, *available at:* https://www.epa.gov/sites/production/files/2017-11/documents/organic_gas.pdf.

Flaring is also a significant cause of SO_2 emissions when sour gas or acid gas is flared. Although the sulfur content for gas to be considered sour gas can vary by state, gas with a hydrogen sulfide (H_2S) content of 5.7 milligrams per cubic meter of gas (about 4 ppm) is generally considered to be sour gas.[669] Among other places in the United States, sour gas exists in areas of New Mexico, Texas, Wyoming, and North Dakota.

In terms of air pollution control measures to apply directly to flare design and operation, controls and techniques to ensure or improve DRE are the primary pollution control for natural gas flares. These are discussed further below in Section E.

B. THERMAL INCINERATION

Thermal incineration of gases is generally able to result in more complete combustion due to the greatly improved ability to control fuel and air flow, temperature, turbulence, and residence time.[670] Thus, incineration of excess gases may result in greater destruction of hydrocarbons and lower VOC emissions than if the same amount of gas was flared. As with flaring, while thermal incineration is a VOC control technology, the incineration of waste gas does result in emissions of NOx and some particulate matter as a result of incomplete combustion, along with CO_2. Further, when sour gas or acid gas is combusted in a thermal incinerator, SO_2 will be emitted. In the absence of SO_2 pollution controls, incineration of waste or excess gases may not be the best choice compared to flaring for gas with sulfur compounds, because the elevated height of the flare can allow for greater dispersion of the SO_2 emissions.[671] On the other hand, use of a thermal incinerator to combust excess or waste gas allows for the addition of an acid gas scrubber to remove SO_2 and also could allow for use of the thermal heat produced by the waste gas combustion, whereas those opportunities for SO_2 control and for getting some energy benefit from the combustion of waste gases do not exist with a flare. Further, low NOx combustion controls exist for thermal incinerators. The pollution controls to apply directly to thermal incinerators are discussed further below in Section F.

The best method to reduce/eliminate air emissions from flaring or incineration of excess or waste gas is to avoid the need for combustion of the gases altogether. The options for doing so are discussed further below in Section D.

C. SO_2 EMISSIONS FROM THE DESTRUCTION OF SOUR GAS WASTE STREAMS

For sour gas, the sulfur compounds must be removed to produce pipeline quality natural gas. H_2S is the sulfur compound of most concern in sour gas because the majority of sulfur compounds in sour gas are in the form of H_2S and because it is it is very poisonous, explosive and corrosive. According to the Occupational Safety and Health Administration (OSHA), exposure to H_2S can cause significant eye and respiratory irritation and exposure to high concentrations of H_2S "can cause shock, convulsions, inability

[669] http://naturalgas.org/naturalgas/processing-ng/.
[670] *See*, e.g., EPA, Air Pollution Control Technology Fact Sheet, Thermal Incinerator, EPA-452/F-03-022, *available at:* https://www3.epa.gov/ttnchie1/mkb/documents/fthermal.pdf.
[671] *See* https://www.aer.ca/providing-information/news-and-resources/enerfaqs-and-fact-sheets/enerfaqs-flaring#what.

to breathe, extremely rapid unconsciousness, coma and death."[672] It is also very corrosive to gas pipelines and can be explosive. Thus, H_2S has to be removed from sour gas streams before the gas can be sent into gas pipelines to consumers. H_2S is removed from the gas in gas sweetening plants, usually via an amine process which separates the H_2S and also CO_2 from the natural gas.[673] Since 1985, the EPA's NSPS have required gas sweetening plants with a capacity of more than 2 long tons per day of H_2S in the acid gas to either 1) completely reinject the acid gas stream into oil- or gas-bearing geologic strata or 2) to use a sulfur reduction and removal technology to reduce SO_2 emissions from the acid gas before it is flared or combusted.[674] Sweetening plants that aren't subject to such requirements may be allowed to flare the acid gas stream or incinerate the gas stream, either of which could release very significant quantities of SO_2 emissions, although it is not clear that any such plants continue to operate. However, even for gas sweetening plants required to control the H_2S by reinjecting into the geologic strata or by using a sulfur recovery unit or other control method, SO_2 emissions from flaring or from thermal incineration is of significant concern. For those plants, flaring episodes occur due to malfunctions or due to maintenance or possibly for other reasons.[675] When flared or combusted, the H_2S in the acid gas stream converts to SO_2, which is a significant visibility-impairing pollutant. EPA states that "100 tons or more of SO_2 can be released in [a flaring episode] within a 24-hour period."[676] In the case of flaring of acid gas streams, the only methods to reduce SO_2 emissions directly from flaring acid gas streams at gas sweetening plants are to reduce or eliminate flaring episodes. Methods to reduce such flaring episodes are discussed in the next section.

D. CONTROL MEASURES, TECHNIQUES, AND OPERATING PRACTICES TO PREVENT FLARING OR INCINERATION OF EXCESS OR WASTE GAS

Prevention of flaring/incineration of excess or waste gases is the best method to reduce the air emissions from this source category. It will also prevent NOx, particulate matter, air toxic emissions including formaldehyde, and CO_2 emissions, as well as any VOCs and methane that are not destroyed in the combustion process. Available methods and techniques to reduce flaring or thermal combustion of excess or waste gas are discussed below.

1. REDUCING FLARING AT THE WELL SITE

In 2016, the U.S. Bureau of Land Management (BLM) issued a rule intended "to reduce the waste of natural gas from venting, flaring, and leaks during oil and gas production on onshore Federal and Indian (other than Osage Tribe) leases."[677] This rule is often referred to as the "BLM Waste Prevention Rule."

[676] *Id.*
[677] 81 Fed. Reg. 83,008 (Nov. 18, 2016).

The fact sheet issued by EPA at the time of the rulemaking stated that the rule would phase in, over several years, a flaring limit per development oil well that ratcheted down over time.[678] There were several options for complying with the flaring limits, including: "expanding gas-capture infrastructure (e.g., installing compressors to increase pipeline capacity, or connecting wells to existing infrastructure through gathering lines); adopting alternative on-site capture technologies (e.g., compressing the natural gas or stripping out natural gas liquids and trucking the product to a gas processing plant); or temporarily slowing production at a well to minimize losses until capture infrastructure is installed."[679] The rule also required operators to evaluate opportunities for gas capture before drilling a development oil well, which were to be submitted with an Application for a Permit to Drill and which were to be shared with midstream gas capture companies "to facilitate timely pipeline development. . . ."[680] In 2018, the BLM rescinded the gas capture requirements of the 2016 rule "in favor of an approach that relies on State and tribal regulations and reinstates the NTL-4A standard for flaring in the absence of State or tribal regulations."[681] The 2018 BLM rulemaking describes the NTL-4A standard as the BLM's existing policy from before the 2016 BLM Waste Prevention Rule, which was published in the Federal Register in 1979 (44 Fed. Reg. 76600, Dec. 27, 1979)[682] and "governed venting and flaring from BLM-administered leases for more than 35 years."[683] The BLM has clearly indicated that states could regulate flaring. Indeed, development of the BLM Waste Prevention Rule considered "analogous state requirements related to waste of oil and gas resources," and the BLM "reviewed requirements from Alaska, California, Colorado, Montana, North Dakota, Ohio, Pennsylvania, Utah, and Wyoming."[684] Further, EPA has been requiring the capture and collection of excess gas from the drilling of natural gas wells under the NSPS since 2012.[685]

Thus, there are example state and federal rules[686] and methods that states should adopt, if not already in place, to reduce flaring of gas associated with oil wells, that would not only reduce visibility-impairing pollution from flaring, but that would also reduce air toxics and greenhouse gases emissions as well as ensure that the natural gas produced along with oil at oil wells is utilized as an energy source rather than just flared or combusted to destroy the VOCs.

2. REDUCING FLARING AT COMPRESSOR STATIONS, GAS PROCESSING PLANTS, AND GAS SWEETENING PLANTS

As discussed above, flaring at compressor stations and gas processing plants including gas sweetening plants, is often due primarily to plant upsets and maintenance. Flaring of sour gas or acid gas streams at gas sweetening plants can be a significant source of visibility-impairing SO_2, and thus reducing flaring emissions at gas sweetening plants could be an effective reasonable progress measure to address regional haze. Reducing flaring will also reduce the NOx, PM, VOCs, and CO_2 emitted from the flares.

EPA listed the following measure to prevent excess flaring at refineries, and this same approach can be used to identify methods and techniques to reduce flaring at natural gas compressor stations and at gas processing facilities:

> Conduct a root-cause analysis of each flaring incident to identify if any equipment and/or operational changes are necessary to eliminate or minimize that cause so as to reduce or avoid future flaring events. As appropriate, corrective measures should be taken and implemented. If the analysis shows that the same cause has happened before, the incident should not be considered a malfunction and corrective measures should be taken to prevent future occurrences….[687]

In addition, it is imperative to ensure that there is adequate gas handling capacity at the various processing points in a compressor station, gas processing or gas sweetening plant. EPA states that "[r]edundant units can prevent flaring by allowing one unit to operate if the other needs to be shut down for maintenance or an upset. . . ."[688] Thus, adding excess capacity and/or backup units could be very important in reducing the amount of flaring due to upsets.

As part of their evaluation of measures to provide for reasonable progress towards the national visibility goal, states should evaluate the flaring episodes at the compressor station and at gas processing plants, including the collection of data on the length of time of each flaring episode, frequency, and causes. For plants that have more frequent flaring episodes, and especially for those plants flaring sour gas or acid gas streams from a gas sweetening plant, states should evaluate the root causes of upsets that cause flaring episodes to determine if measures, such as improved maintenance or duplicative parts or processing units, can be employed to reduce flaring episodes.

E. POLLUTION CONTROL TECHNIQUES FOR FLARES

EPA has described the control techniques for flares, based on the federal requirements in EPA's New Source Performance Standards (NSPS) (at 40 C.F.R. §60.8) and EPA's National Emission Standards for Hazardous Air Pollutants (NESHAPs) (at 40 C.F.R. §63.11) as follows:

---

[687] *See* EPA, Enforcement Alert, Frequent, Routine Flaring May Cause Excessive, Uncontrolled Sulfur Dioxide Releases, October 2000, at 3 *available at:* https://www.epa.gov/sites/production/files/documents/flaring.pdf.
[687] 81 Fed. Reg. 83,008 (Nov. 18, 2016).
[688] *Id.*

> At a minimum, these [NSPS and NESHAP] rules require flares to be:
>
> - Designed and operated with no visible emissions using EPA [test] Method 22 (except for periods not to exceed 5 minutes in 2 hours);
> - Operated with a flame present at all times, confirmed by the use of a thermocouple or equivalent device;
> - Used only when the net heating value of the gas to be combusted is 300 BTU per standard cubic foot (BTU/scf) or greater (if the flare is steam- or air-assisted), or 200 BTU/scf or greater (if the flare is nonassisted); and
> - Designed for and operated with an exit velocity less than 60 feet per second (f/sec). An exit velocity of greater than 60 ft/sec but less than 400 ft/sec may be used if the net heating value of the gas being combusted is sufficiently high.[689]

Other requirements that must be met include that the flare must be operated at all times in a manner consistent with good air pollution control practices for minimizing emissions, and that flaring operations must be monitored to ensure they are operated and maintained according to their design.[690] EPA has listed several other more detailed guidelines to ensure flares are properly operated.[691] Proper training of employees is also an important part of ensuring the flares are properly operated. States must require documentation of each flaring episode to ensure that the flaring regulations of the NSPS and NESHAPs have been complied with, as well as to ensure that adequate records of the amount of gas flared and causes of flaring are maintained and reported.

The above operating standards are required for all flaring. Alternatives to flaring include 1) gas capture to decrease or eliminate flaring as discussed above, or 2) combusting the gas in a thermal incinerator which can provide for greater destruction of VOC emissions. Also, additional air pollution controls can be used at an incinerator, as is discussed below.

F. POLLUTION CONTROL TECHNIQUES FOR THERMAL INCINERATION OF EXCESS OR WASTE GAS

As discussed above, waste gases or excess gas can be disposed of via thermal incineration rather than a flare. EPA describes a thermal incinerator, or a thermal oxidizer, as follows:

> Incineration, or thermal oxidation is the process of oxidizing combustible materials by raising the temperature of the material above its auto-ignition point in the presence of oxygen, and maintaining it at high temperature for sufficient time to complete combustion to carbon dioxide and water. Time, temperature, turbulence (for mixing), and the availability of oxygen all affect the rate and efficiency of the combustion process. These factors provide the basic design parameters for VOC oxidation systems (ICAC, 1999).

---

[689] *See* EPA, Enforcement Alert, EPA Enforcement Targets Flaring Efficiency Violations, August 2012, at 1, *available at:* https://www.epa.gov/sites/production/files/documents/flaringviolations.pdf.
[690] *Id.* at 2; see also 40 C.F.R. §63.172(e) and 60.482-10.
[691] *See*, e.g., EPA, Enforcement Alert, EPA Enforcement Targets Flaring Efficiency Violations, August 2012, at 3.

> A straight thermal incinerator is comprised of a combustion chamber and does not include any heat recovery of exhaust air by a heat exchanger (this type of incinerator is referred to as a recuperative incinerator).
>
> The heart of the thermal incinerator is a nozzle-stabilized flame maintained by a combination of auxiliary fuel, waste gas compounds, and supplemental air added when necessary. Upon passing through the flame, the waste gas is heated from its preheated inlet temperature to its ignition temperature. . . . The required level of VOC control of the waste gas that must be achieved within the time that it spends in the thermal combustion chamber dictates the reactor temperature. The shorter the residence time, the higher the reactor temperature must be. The nominal residence time of the reacting waste gas in the combustion chamber is defined as the combustion chamber volume divided by the volumetric flow rate of the gas. . . . .[692]

EPA indicates that thermal incinerators can achieve 98% to 99.9999% destruction of VOCs.[693] However, thermal incinerators typically require auxiliary fuel to preheat the waste gas and sustain the heat necessary for destruction of VOCs.[694] The high temperature reaction necessary in an incinerator to destroy the VOC and air toxic emissions can result in increased NOx emissions. To limit NOx emissions, low NOx burners or other low NOx processes are available control measures to integrate into the thermal incinerator to limit NOx emissions.[695] Thus, for any thermal incinerators or thermal oxidizers, low NOx burners or other low NOx emission systems should be installed to minimize NOx emissions from the thermal incinerator.

It is important to note that thermal incinerators can be used at gas sweetening plants along with acid gas scrubbers to remove the SO_2 that is formed from combusting the H_2S in the acid gas. Such a system could potentially be used as an SO_2 control,[696] or it could be used as a backup system for a sulfur recovery unit when it is down due to malfunction, maintenance, or during startup or shutdown.[697] This method of control could greatly reduce if not eliminate the SO_2 emissions that occur at gas sweetening

facilities when the gas injection well or sulfur recovery unit is not in operation due to malfunctions or maintenance.

In many respects, combusting of waste gases and/or excess gas in a thermal incinerator seems more preferable from an air pollutant perspective than flaring, because thermal incineration will likely result in a greater destruction efficiency of VOCs and because control options exist for limiting emissions of NOx and of SO_2 (to the extent that sour gas or an acid gas stream is what was being flared). Further, there could be an option of gathering and routing excess gas emission from multiple points to a centralized thermal incinerator. Moreover, continuous emission monitoring systems (CEMS) could be installed in the thermal oxidizer stack to provide valuable actual emissions data due to the combustion of waste or excess gases, including information to ensure that optimal VOC destruction efficiency is achieved.

However, the need for auxiliary fuel in thermal combustion means more CO_2 will be emitted than if the gas stream was flared. Yet, there are options for thermal incinerators that recover the waste heat, which are called recuperative oxidizers or regenerative oxidizers.[698] The recovered waste heat can be used to preheat the incoming air which would reduce the amount of supplemental fuel required.[699]

To sum up, use of a recuperative or regenerative thermal incinerator (thermal oxidizer) with low NOx combustion controls, CEMs, and an acid gas scrubber if necessary, seems to be a preferable alternative to flaring of waste gas streams. Such a system would provide better control of VOCs, reduce NOx emissions from combustion of the waste gas via the use of low NOx combustion controls, and provide the ability to add an acid gas scrubber to remove SO_2 (which is a control option that does not exist for flares).

G. SUMMARY – BEST OPTIONS FOR CONTROLLING EMISSIONS DUE TO FLARING OR INCINERATION OF EXCESS OR WASTE GAS

Based on the above analysis, it seems evident that prevention of flaring through the collection of excess gas is the most beneficial option for reducing emissions from flaring. Capturing and using the natural gas that is produced at oil wells would ensure that the energy value of the gas is not wasted by being combusted in a flare or in an incinerator, and it is very likely that the end user of the gas would at least be using some level of NOx and VOC control.

Thermal incineration should be considered in lieu of flaring for waste gases due to the pollution controls for NOx and SO_2 that are available and because of the improved operation and VOC destruction. Moreover, use of a thermal incinerator provides the opportunity to monitor and accurately track emissions from the combustion of waste or excess gases with the use of CEMS.

At gas processing facilities including gas sweetening plants, it is important that the causes of flaring episodes be documented and assessed to determine any changes in operations, training, and/or in equipment that may be needed to reduce plant upsets and maintenance during which flaring occurs due

[698] EPA, Air Pollution Control Technology Fact Sheet, Thermal Incinerator, EPA-452/F-03-022, at 5.
[699] *Id.*

to the unavailability of plant equipment to process the gas stream. As stated above, adding excess capacity and/or backup units could be very effective in reducing the amount of flaring due to upsets. Proper maintenance of equipment is also key, as is appropriate training of staff to minimize flaring episodes due to maintenance and upsets.

In general, states should ensure that their rules require companies to document all flaring episodes, including the cause, duration of the flaring, flue gas flow, actions taken to stop the flaring, and emission estimates, and to submit such documentation to the state or local air agency in a timely manner. This data will best enable states to develop appropriate rules and procedures to limit the various causes of flaring emissions within its state.

Overall, the goal of state programs to address flaring emissions should be to minimize flaring to the maximum extent possible. However, for those situations when flaring does occur, it is imperative that the flares be operated in accordance with NSPS and NESHAP requirements, and that the flares are operated and maintained in accordance with their design. Moreover, to ensure these requirements are being met and to ensure that flaring is minimized to the maximum extent possible, the state or local air agencies must conduct thorough oversight into the causes of flaring episodes, to ensure that the facility is being maintained and operated in a manner to minimize all flaring episodes to the extent possible.

Appendix F: Federal Land Manager Formal Consultation Supporting Documentation

F.1 New Mexico Environment Department Communications to Federal Land Managers during 60-day formal review period

Supporting documentation for New Mexico Environment Department (NMED) communication to FLMs during formal FLM review period is provided below. The following documents are included in this section (in reading order):

---

Dear representatives from the U.S. Fish and Wildlife Service, U.S. Forest Service, and the U.S. National Park Service,

The NMED Regional Haze planning team has completed a draft Regional Haze SIP revision for the second planning period (2019-2028). We are providing it to you today, May 20, 2024, to initiate the 60-day Federal Land Manager (FLM) consultation period. A copy of the draft SIP revision and the appendix containing the four-factor analysis technical support document (TSD) are attached to this email. Our team plans to send a follow-up email with a link to a shared folder which will include the attached drafts as well as additional technical documentation.

We would like to set up a time to meet with you via Teams in May or early June (or whatever time is most useful and convenient to you) to provide an overview and summary of our draft plan. Our team is open to additional meetings and/or periodic check-ins during the 60-day review period to discuss any topics of interest. You're also welcome to reach out with questions at any time. For this 60-day formal consultation period, we request that you provide any comments on the draft SIP revision by July 21, 2024.

I'd also like to take this opportunity to introduce Eric Peters, the new manager of the NMED Air Quality Bureau—Control Strategies Section. Please include him in communications related to Regional Haze planning moving forward.

Thank you,

Mark

F.2 Formal Federal Land Manager Comments

Supporting documentation for New Mexico Environment Department (NMED) formal consultation with Federal Land Managers is provided below. The following documents are included in this section (in reading order):

- U.S. Forest Service Formal Comments (7/24/24)
- U.S. National Park Service Formal Comments (7/26/24)

United States Department of Agriculture **Forest Service** **Southwestern Region Regional Office**

333 Broadway SE
Albuquerque, NM 87102
505-842-3292
Fax: 505-842-3800

File Code: 2580
Date: July 19, 2024

Dana Bahar
Deputy Director, Environmental Protection Division
New Mexico Environment Department
1190 St. Francis Drive
PO Box 5469
Santa Fe, NM 87505

Dear Ms. Bahar:

On May 20th, 2024, the Air Quality Bureau of the New Mexico Environment Department (NMED) submitted a draft Regional Haze State Implementation Plan describing your proposal to continue improving air quality by reducing regional haze impacts at mandatory Class I airsheds across the region. We appreciate the opportunity to work closely with the NMED through the initial evaluation, development, and subsequent review of this plan. Cooperative efforts such as these ensure that, together, we will continue to make progress toward the Clean Air Act's goal of natural visibility conditions for Class I areas.

This letter acknowledges that the U.S. Department of Agriculture, U.S. Forest Service, has received and conducted a substantive review of your proposed draft Regional Haze State Implementation Plan. This review satisfies your requirements under the federal regulations 40 C.F.R. § 51.308(i)(2). Please note, however, that only the U.S. Environmental Protection Agency (EPA) can make a final determination about the document's completeness, and therefore, only the EPA has the authority to approve the document.

We are satisfied with the document as provided and offer no suggestions for change beyond the informal suggestions to clarify language that were shared via email on July 19th, 2024. For further information, please contact Anita Rose (anita.rose@usda.gov).

We appreciate the opportunity to work closely with the New Mexico Environment Department. The Forest Service compliments you on your hard work and dedication to significant improvement in our nation's air quality values and visibility.

Sincerely,

MICHIKO J. MARTIN
Regional Forester

1 Introduction

The NPS appreciates this opportunity to provide Federal Land Manager (FLM) consultation comments on New Mexico's proposed Regional Haze State Implementation Plan (SIP) for the Second Planning Period. The New Mexico Environment Department, Air Quality Bureau (NMED) held a consultation meeting with the NPS on July 11, 2024. These written technical comments support and document the preliminary feedback provided by the NPS during the July 11 consultation meeting. Overall, the NPS finds that NMED has developed a clear, concise, and well-organized draft SIP that proposes to implement significant emission reductions at 13 facilities. As described below, the NPS supports many of the control determinations presented in the draft SIP and agrees that ongoing emission reductions are necessary to advance progress toward the national regional haze visibility goal. NPS conclusions and recommendations, including facility-specific feedback, are provided to further strengthen the SIP (see Sections 2 and 3).

New Mexico is home to two NPS-managed Class I areas: Bandelier National Monument and Carlsbad Caverns National Park. The NPS values clean air and clear views and recognizes they are essential to park visitor experience and the very purpose of federal Class I areas. Visitors from around the world come to these special places to explore the wonders of the desert southwest and gaze into distant galaxies visible through the parks' dark night skies. The NMED's consideration and implementation of air pollution emission controls shows the state's commitment to improving regional haze.

The emission reductions proposed in the SIP are necessary to improve visibility in New Mexico's Class I areas. A recent review of visibility impairment rankings by the NPS shows that the shared visibility monitor of Carlsbad Caverns and Guadalupe Mountains National Park in Texas is the fourth most impaired NPS Class I area site in the country. Further, monitoring data over the past ten years show that visibility on the most impaired days in New Mexico parks is not improving. In fact, both Bandelier National Monument and Carlsbad Caverns National Park would have been above the uniform rate of progress (URP) glidepath had the URP not been adjusted for international and prescribed fire emissions.

The NPS appreciates the steps NMED is proposing to reduce haze-causing pollution and address regional haze in national parks in this planning period. The NPS looks forward to ongoing consultation with NMED and welcomes opportunities for further dialogue as New Mexico progresses towards a final SIP.

2 Overarching Feedback

2.1 FLM Consultation

To date, the NPS finds that NMED's process for FLM engagement has been exceptional. The NMED initiated early and ongoing dialog with the FLM agencies, including the NPS, and NMED requested FLM feedback on key SIP components as they were under development rather than after they were completed (e.g., source selection). The NMED incorporated NPS suggestions into the draft SIP throughout the planning process.

The NPS appreciates these early and ongoing opportunities to share agency expertise. These steps ensure that the FLMs can "*meaningfully inform"* the long-term strategies incorporated into the SIP as required in 40 C.F.R (i)(2). The NPS finds that the current NMED approach meets the spirit, intent, and letter of the law with respect to FLM consultation and coordination requirements. The NPS encourages NMED to continue this approach by substantively addressing the NPS conclusions and recommendations provided in this document. As a reminder, the CAA requires that the state *shall include a summary of the conclusions and recommendations of the Federal land managers in the notice to the public* (Section 169A, codified at 42 U.S.C. §7491 (d)).

2.2 Source Selection

Selecting the pollutants and sources for evaluation are foundational components of the regional haze planning process. A robust and thorough source selection approach is necessary to develop an adequate long-term strategy and reasonable progress determinations. The NPS finds that the NMED approach to source selection in the second implementation period was sufficiently robust and supports NMED's final list of 23 facilities evaluated in the SIP.

The NMED source selection approach relied on surrogate visibility impairment metrics to identify sources potentially contributing to visibility impairment in New Mexico and nearby Class I areas. This is consistent with EPA recommendations provided in the 2019 regional haze implementation guidance document and the 2016 draft regional haze implementation guidance document, which both note that surrogate metrics are an appropriate method to identifying sources for analysis. The NMED initially used an emissions over distance approach (Q/d) to select stationary point sources for analysis. This approach sums the quantity of precursor pollutants emitted by a facility (Q in tons per year of sulfur dioxide (SO_2) plus nitrogen oxides (NO_x)) and divides it by the distance from the facility to the nearest Class I Area (distance(d) in kilometers (km)).

The NMED substantiated their Q/d results using the Weighted Emissions Potential (WEP) and Area of Influence (AOI) products developed by the Western Regional Air Partnership (WRAP). The WRAP WEP-AOI results were made available for use in regional haze planning in September 2020. The WRAP WEP-AOI analysis was performed for the most impaired days (MID) during each year of the five-year period from 2014 through 2018 at 76 Interagency Monitoring of Protected Visual Environments (IMPROVE) monitoring sites representing 116 Class I Areas in the contiguous WRAP region as well as neighboring states.

The NPS concludes that NMED identified a reasonable number of sources by capturing 80% of the stationary source SO_2 plus NO_x emissions contributing to visibility impairment in Class I areas affected by New Mexico emissions. The 80% threshold is consistent with recommendations in the 2016 EPA draft regional haze guidance and NPS recommendations for source selection. The NMED and City of Albuquerque Environmental Health Department (EHD) jointly selected 24 facilities statewide for reasonable progress analysis (one in Albuquerque and 23 in the rest of New Mexico) and evaluated both SO_2 and NO_x emission reduction opportunities at these facilities. The final list included all NPS-recommended facilities. The NPS appreciates that NMED included San Juan Basin Gas Plant and Blanco Compressor Stations A, C, and D. These compressor stations are considered a single facility for the purposes of New Source Review (NSR) and their emissions impact Mesa Verde National Park in Colorado.

Finally, the NPS notes that oil and gas non-point sources in New Mexico were estimated to have emitted over 50,000 tons per year in 2014 - 2018(see Table 5-11 in the SIP). In addition, emission inventories developed in support of New Mexico's Oil and Gas Sector Ozone Precursor Pollutants Rule demonstrate that oil and gas non-point sources emissions have further increased since 2018. The NPS recommends that NMED not only evaluate oil and gas non-point sources but also additional source category-wide rules as explained in Section 3.11.

2.3 Visibility Benefit and the URP

The NMED appropriately declined to consider visibility benefit of potential control measures in the individual facility reasonable progress determinations. From the SIP:

> *NMED did not directly consider the visibility benefits of potential control measures when making its control determinations. EPA has consistently stated that the CAA and Regional Haze Rule allow, but do not require, states to consider visibility alongside the four statutory factors when making control determinations.161 NMED's approach is based on the assumption that substantial reductions in emissions of NO_X and SO_2 will translate into visibility benefits.*

The Clean Air Act (CAA) specifies that reasonable progress comes from emission reduction measures incorporated into a state's long-term strategy and that, after the first planning period, control determinations are to be based on the *four statutory factors*, which are provided Section 169A of the CAA:

> *(1)* ***in determining reasonable progress*** *there shall be taken into consideration the costs of compliance, the time necessary for compliance, and the energy and nonair quality environmental impacts of compliance, and the remaining useful life of any existing source subject to such requirements. [§7491 (g)(1)]*

According to the CAA, the regulations drafted by EPA to govern SIP development shall:

> *[R]equire each applicable implementation plan for a State . . . to contain such emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress toward meeting the national goal specified in subsection (a) of this section. [§7491 (b)(2)]*

Congress omitted visibility benefit from the definition for determining reasonable progress in subsequent rounds of haze planning because later planning periods were meant to be different from the first planning round Best Available Retrofit Technology (BART) provisions. Therefore, the NPS supports NMED's decision that visibility benefit should not be used as a fifth-factor to dismiss controls that would otherwise be reasonable based on the four statutory factors.

2.4 Criteria Used in Reasonable Progress Determinations

The NPS finds that the New Mexico four factor analysis reviews generally follow EPA guidance and are well organized, consistent, and thorough. The NMED clearly described the criteria used to (1) identify the sources evaluated and (2) take the four factors into consideration in selecting the measures for inclusion in the long-term strategy. Notably, NMED heavily weighted the costs of control in the final facility-specific reasonable progress determinations and used a cost-effectiveness threshold (CETV) of $10,000/ton of pollutant reduced. This approach is consistent with EPA recommendations that suggest cost is frequently the determining factor in control technology reviews[1]. Further, NMED thoroughly documented the rationale for selecting this CETV in the SIP, which was based on a statistical analysis of control cost information and determinations:

> *NMED chose to apply a cost effectiveness threshold value (CETV) to remove control measures deemed not cost-effective from further consideration. To determine its CETV, which represents the cost effectiveness value above which further incremental reductions in NO_x emissions are insufficient to justify more expensive controls, NMED catalogued the available controls, identified the most effective controls available at potential CETVs ranging from $1,000/ton to $20,000/ton, and then determined the estimated total and incremental NO_x reductions provided by the most effective controls at each potential CETV. NMED then binned the incremental NO_x reductions and performed a segmented linear regression on a plot of the estimated total NO_x reductions with breakpoints at the bin edges. The results are shown in Figure 7-1. The binning and associated regression analysis showed that incremental NO_x reductions were significant up to $10,000/ton and then decreased by approximately 50%, with an even larger decrease at $14,000/ton. This led NMED to identify $10,000/ton as its CETV.*

[1] Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, EPA-457/B-19-003, August 20, 2019

The NPS supports NMED's approach. The NPS also notes that after the initial analysis, NMED categorically excluded electrification from further consideration (SIP Section 7.4.2). The NMED subsequently updated its CETV analysis using revised cost estimates that exclude electrification and found that the breakpoints in cost-effectiveness changed. From the draft SIP:

> *Notably, the breakpoint at $10,000/ton observed in the initial analysis is missing in the updated analysis due to incremental NO_x reductions being fairly consistent up to $14,000/ton, at which point they decrease significantly, as they did in the initial analysis.*

Given this, the NPS recommends that NMED consider additional controls that are estimated to be right at or just above the New Mexico $10,000/ton CETV (as described in NPS facility-specific feedback provided in Section 3). This recommendation is consistent with the NMED finding that incremental NO_x reductions are consistent (and may be cost-effective) up to $14,000/ton. It is also consistent with EPA guidance which recommends that control costs are typically estimated at an accuracy level of plus or minus 30%.[2]

2.5 Overarching SCR Review Concerns

The NMED evaluated the costs and/or feasibility of using selective catalytic reduction (SCR) to control NO_x emissions for several of the facilities considered in the SIP. The NMED made several general assumptions in the SCR cost analyses, which include:

1) a "margin of safety" for SCR applications, applied as a cushion that was calculated outside of the control cost estimate,
2) dismissal of SCR due to space constraints at several facilities without detailed analyses and justification, and
3) additional operator costs above what is already included in the EPA Control Cost Manual (CCM) workbooks for SCR.

The NPS is not aware of these types of general assumptions being used for the other technically feasible NO_x control technologies evaluated. As described below, the NPS recommends that NMED remove these blanket assumptions. If NMED does not choose to remove such assumptions then, where appropriate, the NPS recommends that NMED provide additional site-specific documentation and justification as to why these assumptions are applicable to the affected facilities.

With respect to "margin of safety," NMED established this threshold to address concerns regarding *building and/or exhaust system modifications which can easily cost as much if not more than the SCR equipment itself* (SIP Section 7.4.2). In this case, NMED is setting the "margin of safety" value based on the total capital investment (TCI) at $10,000/ton versus the calculated TCI for the unit. *If the TCI margin of safety exceeded 100%, then TCI could increase*

[2] EPA Control Cost Manual 7th Edition, Section 1 Introduction, Chapter 2 Cost Estimation: Concepts and Methodology, November 2017, p. 6.

twofold and the cost effectiveness would still be at or below $10,000/ton (staff-to-staff communications with NMED, July 16, 2024). The NPS has several concerns with this approach:

1) Building costs and exhaust system modifications (e.g., balance of plant costs) are already built into the CCM TCI estimates. The CCM default retrofit factor value of 1.0 includes a 25% increase over a "greenfield" application to account for necessary plant modifications and applies to most retrofits of "average difficulty." Adequate and thorough documentation should be provided to justify retrofit factors greater than 1.0 (up to 1.5 is the maximum recommended in the CCM workbook).[3]
2) The NMED "margin of safety" effectively implies a retrofit factor of more than two. This represents an exceedingly difficult and highly unusual retrofit situation that would require extensive justification and documentation to be an acceptable claim (staff-to-staff communications with NPS and EPA OAQPS, July 18, 2024).
3) The NMED "margin of safety" is applied outside of the CCM cost calculations as opposed to integrating the cost of building and exhaust system modifications into the overall TCI and cost-effectiveness estimate. Again, significant justification is required for retrofit assumptions that exceed average difficulty.
4) The NMED's "margin of safety" was developed based on the assumed TCI associated with the CETV of $10,000/ton, not site-specific information identifying constraints that would suggest SCR installation may be particularly challenging in the given application.

Given this, the NPS finds that NMED's application of a general "margin of safety" is likely overstating the retrofit costs for SCR at individual sites and is not appropriate without the adequate site-specific justification. In many cases, determining if a retrofit factor is appropriate and identifying what that factor should be is not a simple process. The NPS recommends basing retrofit factors on site-specific considerations or constraints and applying them to the retrofit factor within the CCM cost calculation workbook. Higher-than-average retrofit cost assumptions (e.g., greater than 1.0) should include a thorough and well-documented analysis of the project-specific factors affecting retrofit difficulty. The procedure outlined by William Vatavuk on pages 59-62 in his book, *Estimating Costs of Air Pollution Control,* may be useful in these determinations. The Vatavuk process involves estimating and assigning a retrofit factor to each major element of a project and from that deriving an overall retrofit factor. In the absence of such a proper analysis, the NPS assumed a retrofit factor of 1.0 in all SCR analyses.

The NMED also dismissed SCR from consideration at several facilities due to space constraints. For example, at Enterprise Field Service's Blanco C and D Compressor Station, NMED did not include a cost assessment for SCR based on an aerial photograph. Materials in Appendix D note:

[3] From the CCM chapter for SCR: *The capital costs estimated by the equation represent average retrofit costs; costs for new construction are typically 20 to 30 percent less than for average retrofits for units of the same size and design. The TCI equations include a retrofit factor (RF). A retrofit factor of 0.8 should be used for new construction and a retrofit factor of 1 should be used for average retrofits. The equations may overestimate costs for some simple retrofits of existing plants. For retrofits that are more complicated than average, a retrofit factor of greater than 1 can be used to estimate capital costs provided the reasons for using a higher retrofit factor are appropriate and fully documented.*

> *An aerial map of the facility was provided in the 2020 follow up which suggests that new buildings (or substantial extensions of the existing building) would be required to house an SCR. The associated costs of building construction coupled with corresponding exhaust system modifications would be costly. Considering the calculated cost effectiveness of SCR for other CTs in New Mexico, it is reasonable to conclude that SCR is cost prohibitive for the Blanco C/D units.*

The NPS recommends providing a detailed, site-specific analysis, justification, and cost estimate to document and support the decision to exclude SCR from consideration. In the case of Blanco C and D Compressor Station, NMED and Enterprise did not address why the SCR would need to be housed *within* the building or the costs associated with building construction. The aerial photograph provided illustrates that the facility is located on a large gravel pad with ample additional space. As noted above, many of the retrofit costs, including exhaust system modifications, are incorporated into the CCM TCI calculations for retrofits. If excessive building costs are necessary, this should be documented and included in the cost estimates. Therefore, the NPS estimated the costs of SCR in several cases where it was excluded from the analysis due to space constraints (see Section 3).

Finally, with respect to operator costs, NMED included an additional cost of $87,600/year (4hours*365 days*$60/hour). It appears NMED used the workbook included with the CCM to estimate SCR retrofit costs, but included an additional annual operator cost to the workbook. The NMED based this cost on the CCM, which notes that EPA's Integrated Planning Model (which is the source of many of the costing equations) estimates operating labor time as 4 hours per day, which is the default value included in the workbook. (The CCM also notes operation of an SCR system requires only minimal operating or supervisory labor.) These costs are already included in the CCM SCR cost spreadsheet and are used with other data to estimate the administrative charges (see Data Inputs Tab, cells C58 and C59, which are used in the administrative charges calculation in cell D93 on the Cost Estimate Tab). The NPS recommends that NMED verify these assumptions and correct any errors in the annual operator cost assumptions. The NPS did not include this additional operator cost in its SCR cost estimates.

3 Facility-Specific Recommendations

3.1 Bloomfield Group Sources

Blanco Compressor Station A, San Juan Basin Gas Plant, & Blanco C&D Compressor Station

The Bloomfield group consists of three facilities, two natural gas compression stations and one natural gas processing plant located near Bloomfield, New Mexico, approximately 40 miles southeast of Mesa Verde National Park. The Bloomfield group includes Blanco Compressor Station A, owned and operated by El Paso Natural Gas (EPNG); the San Juan Basin Gas Plant, owned and operated by Hilcorp; and, Blanco C & D Compressor Station, owned by Enterprise and operated by Enterprise Products Operating, LLC. For the purposes of NSR, the Bloomfield group facilities are permitted as a single source.[4] Common control of the three facilities was established in 1984 through the issuance of a common NSR permit.[5] However, the plants continue to be permitted as three separate facilities for Title V purposes, under Title V Operating Permit numbers P048-R4, P124-R4 and P218-R3, respectively. Combined, these three facilities have the potential to emit over 3,700 tons/year of NO_x and are extremely important to address for haze impacts at Mesa Verde National Park, both cumulatively and individually.

The NPS appreciates that NMED included each of the three Bloomfield group facilities in the SIP four-factor analyses as requested by the NPS during New Mexico's source selection process. The NMED performed four-factor analyses for 24 individual units at the three facilities and is proposing some level of NO_x reduction for four of these units. The NPS appreciates and supports the need for additional NO_x reductions. However, the NPS recommends that greater NO_x reductions may be cost-effective and reasonable at the Bloomfield group units. The NPS recommends that NMED revise their cost analyses and reasonable progress determinations as described in Sections 3.1.1, 3.1.2, and 3.1.3 below. Addressing NO_x emissions at the three Bloomfield group facilities is important for the following reasons:

1) Along with ammonium sulfate, ammonium nitrate is one of the most important species contributing to visibility impairment at Mesa Verde National Park. Over the period of 2018–2022, ammonium nitrate was responsible for nearly 13% of impairment at Mesa Verde National Park on the 20% most impaired days.[6] In the winter months, ammonium

[4] San Juan Basin Gas Plant is owned and operated by ConocoPhillips Company and belongs to the Standard Industrial Classification (SIC) Major Group 13 (Oil & Gas Extraction)). Blanco A Compressor Station is owned and operated by El Paso Natural Gas Company and belongs to SIC Major Group 49. The Blanco C & D Compressor Station is owned by Enterprise Field Services, LLC and operated by Enterprise Products Operating, LLC and belongs to SIC Major Group 49.

[5] From the New Mexico statement of basis for a 2014 significant revision to the NSR permit: The NSR permit was issued jointly because Conoco (San Juan Gas Plant) had relied on reductions in boiler emissions from EPNG-Blanco to net out of the PSD Program. For Conoco to take credit for the emissions reduction at the EPNG-Blanco, common control of both plants had to be established. "Any separation of "THIS PLANT" into independent NSR permits would require an examination of PSD implications [EPA R6].

[6] See composition data, MEVE1 (2018-2022) available at: https://views.cira.colostate.edu/fed/Reports/Aqrv/BextComposition.aspx

nitrate is often the greatest contributor to haze at Mesa Verde National Park, comprising up to 40% of total impairment on individual most impaired days.[7]

2) Based on the WRAP WEP-AOI results, the Bloomfield group facilities are significant contributors to nitrate impairment at Mesa Verde National Park. The NPS sorted and ranked WRAP WEP-AOI data to evaluate the importance of individual facilities for Mesa Verde National Park[8] and found that:
    a) When considered individually, the Bloomfield group facilities are ranked among the top ten facilities contributing to nitrate impairment at Mesa Verde National Park. Individually, Blanco Compressor Station A is ranked number six, Blanco C & D Compressor Station is ranked number four, and San Juan Basin Gas Plant is ranked number five.[9]
    b) When considered cumulatively as a single facility (consistent with the NSR permit), the Bloomfield group is ranked the number two facility contributing to nitrate impairment at Mesa Verde National Park.[10]

For these reasons, the NPS requests that NMED reconsider the reasonable progress determinations for the Bloomfield group facilities in consideration of the NPS analyses provided below.

3.1.1 Blanco Compressor Station A

Blanco Compressor Station A (BCSA) is a natural gas compressor station located near Bloomfield, New Mexico, approximately 39.8 miles southeast of Mesa Verde National Park. The primary NO_x emission units at BCSA include 14 identical two-stroke lean-burn (2SLB) reciprocating internal combustion engines (RICE), each rated at 943 HP (units A01-A14). All 14 engines were manufactured by Cooper Bessemer and were installed in August of 1953.

The NMED evaluated the cost of installing Low Emission Combustion (LEC) controls at various levels as well as the cost of replacing each engine with a newer, low emission unit. The NMED identified cost-effective controls for units A11 and A13 and determined that engine replacement is necessary to make reasonable progress for these units.

The NPS appreciates NMED's well-documented analysis and agrees that engine replacement is likely the most stringent and cost-effective option for these aging emission units, which were installed over 70 years ago. However, the NPS recommends that NMED consider replacement costs based on facility-wide utilization rates rather than a unit-specific basis. This approach

[7] See the most impaired days, by sample day for MEVE1 (2022), available at: https://www.nps.gov/subjects/air/park-conditions-trends.htm?tabName=composition&parkCode=MEVE&paramCode=Visibility&startYr=2013&endYr=2022&monitoringSite=MEVE1%20(IMPROVE)&timePeriod=10-year

[8] See spreadsheet MEVE_POINT_RANK_NOX_NPS_WEPAOI.xlsx in NPS Attachment 2.

[9] This ranking removes the San Juan Generating Station (SJGS) from the overall rankings because it ceased operations in 2022 and is no longer a concern for Mesa Verde National Park. SJGS was previously ranked the number 2 impacting facility for this park.

[10] This ranking removes the San Juan Generating Station (SJGS)—see footnote 5.

indicates that replacing all 14 engines would be cost-effective. This approach is recommended the following reasons:

- There is significant annual variation in utilization rates for the individual engines (e.g., unit A01 ran nearly 7,000 hours in 2016 but zero hours in 2021), making it difficult to develop utilization and emission assumptions on a per-engine basis.
- NPS analysis demonstrates that the average facility-wide utilization is relatively consistent at approximately 25% annual utilization facility-wide (2016–2021 average). The recent maximum occurred in 2019 at 29% utilization. See Table 1.
- Likewise, estimated annual NO_x emissions for individual engines vary widely from year-to-year, but facility-wide emissions are relatively consistent, averaging approximately 200 tons/year.[11]

*Average Facility-wide Utilization 2016–2021 = 25% (See NPS workbook[13] in Attachment 2)

[11] NMED's assumed future actual emissions were developed using "representative" baseline utilization rates (2016-2021) for each engine. NMED notes that the SIP analysis conservatively adjusted reported emission factors to 100 percent load to represent worst-case emissions. The NPS assessment used NMED's adjusted emission factors but calculated representative emissions using the reported annual utilization rates for each unit (rather than representative emissions), summed emissions for each unit for each year to get the facility-wide annual emissions and then took the average of facility-wide emissions from 2016 to 2021. See NPS workbook "Blanco.Compressor.Station.A-NPS_CFs-emission _assumptions.xlsx" in Attachment A.

[12] Data Source: Appendix C: Four-Factor Analyses and Control Measures Determinations Technical Support Document, Section C.4.5.

[13] Blanco.Compressor.Station.A-NPS_CFs-emission _assumptions.xlsx

NPS Conclusions and Recommendations for Blanco Compressor Station A:

Given that the purpose of the facility is to provide natural gas compression, and that annual facility-wide utilization rates (i.e., compression needs) appear to be relatively consistent, the NPS recommends calculating replacement costs according to facility-wide utilization rather than on an individual engine basis. The NPS re-analyzed replacement costs for BCSA using:

1) NMED reported utilization rates,
2) NMED's cost metric of $3,227/hp (2020$) and
3) NMED reported emission factors.

This analysis found that replacing facility-wide compression needs is likely cost-effective. The results are summarized below (detailed calculations are provided in the NPS workbook[14] provided in Attachment 2):

- $7,320/ton (2023$) using the 2016–2021 average facility-wide utilization rate of 25% and average 2016–2021 emissions.
- $7,273/ton (2023$) using an assumed maximum facility-wide utilization rate of 30%. A capacity factor of 30% was selected to represent the maximum utilization year, 2019 at 29%, increased to 30% (or approximately 4,000 HP capacity). The facility-wide 2019 estimated emissions were used as the baseline emission rate in this scenario.
- NMED noted that their $3,227/hp metric is likely accurate to within ±30 percent.[15] The NPS facility-wide cost-effectiveness estimates are still below the NMED cost-effectiveness threshold of $10,000/ton when increased by 30%, at $9,516/ton (25% utilization) and $9,456/ton (30% utilization).

Finally, the NPS notes that the NMED online facility emissions report for Blanco Compressor station A, available through the air emission tool,[16] reports facility-wide 2019 NO_x emissions of 389 tons/year, which is higher than the estimates derived from the NMED emission factors and utilization rates reported for each of the 14 RICE in Appendix C to the SIP (i.e., 239 tons/year). It is not clear whether the emergency flare at the facility accounted for the additional 150 tons/year NO_x; however, the NO_x emission factors reported for several of the units seem inconsistent with the remaining units. This seems unusual given that the 14 units are identical size, vintage, make and model. For example, the NO_x emission factor reported for unit A04 is only 2.9 lb/hr, the NO_x emission factor reported for unit A03 is 8.4 lb/hr, and the NO_x emission factor reported for unit A02 is 9.1, whereas the emission factors reported for the remaining units

[14] Blanco.Compressor.Station.A-NPS_revisions_Replacement_Cost_Evaluation.xlsx
[15] From Appendix C: "EPNG provided a Total Capital Investment (TCI) cost metric of $3,227/hp (2020$) for the installation of new, replacement RICE at BCSA. The cost metric was developed by Kinder Morgan's Cost Estimating Group based on its extensive industry experience. NMED reviewed several publicly available resources along with information provided by other companies with similar units that could be used to estimate the TCI of a replacement RICE, and determined that the Kinder Morgan metric was reasonable. NMED understands that the use of this metric is likely accurate to within ±30 percent, but also recognizes that various preliminary vendor quotes are often caveated with a similar degree of accuracy."
[16] Available at: https://eatool.air.net.env.nm.gov/aqbeatool/facility-report?year=2019&sourceData=NMED&facilityId=1147

are 11.6 lb/hr (8 units), 12.1 lb/hr (1 unit) and 18.1 lb/hr (2 units) respectively. The NPS requests that NMED verify the reported emission factors, particularly for unit A04, and address the discrepancy between facility-wide emission estimates derived from the four-factor analysis assumptions and the NMED emission inventory.

3.1.2 San Juan Basin Gas Plant

The San Juan Basin Gas Plant (SJBGP) is a natural gas processing facility located near Bloomfield, New Mexico, approximately 39.6 miles southeast of Mesa Verde National Park. The facility consists of 7 NG-fired combustion turbines listed in Table 2.

Table 2: Description of SJBGP Units Selected for Four-Factor Analysis

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	Turbine	Rolls Royce Avon 1535	1985/1986 (1)	15,000 hp
2	Turbine	Rolls Royce Avon 1535	1985/1986 (1)	15,000 hp
3	Turbine	Rolls Royce Avon 1535	1985/1986 (1)	15,000 hp
4	Turbine	Solar Centaur T4501	1986	3,735 hp
5	Turbine	Solar Centaur T4501	1986	3,735 hp
6	Turbine	Solar Centaur T4501	1986	3,735 hp
7	Turbine	Solar Centaur T4501	1986	3,735 hp

The NMED determined that dry low-NO_x (DLN) represents reasonable progress for units 4, 5, 6, and 7. The NMED rejected SCR due to an "inadequate margin of safety" for all seven units, even though SCR costs were at or below NMED's CETV of $10,000/ton for each of the turbines.

NPS Conclusions and Recommendations for SJBGP

The NPS estimates that applying SCR to all seven turbines could reduce 437 tons/year of NO_x emissions versus the 159 tons/year reduction achieved under NMED's proposal to install DLN on turbines 4–7. The NPS recommends that NMED reconsider their control determinations and require SCR for the seven combustion turbines at SJBGP, which is cost-effective relative to NMED's CETV of $10,000/ton.

As discussed in Section 2.6, NMED's "margin of safety" effectively assumes a retrofit factor of two, which represents an difficult and unusual retrofit situation that would require extensive justification and documentation. As such, the NPS finds that NMED's "margin of safety" is likely overstating the retrofit costs for SCR at individual sites.

The NMED summarized its cost-effectiveness estimates for SCR in Appendix C to the SIP but deleted them from the SCR spreadsheet calculations for SJBGP. Because of this, the NPS re-ran the SCR cost analyses to verify NMED's estimates for SJBGP. The NPS generally used NMED's analysis assumptions, including representative operating hours and emissions, cost year, and interest with the following exceptions:

- The NPS used a higher ammonia reagent cost that is reflective of 2023 commodity values ($0.529/gal).

- The NPS used a higher catalyst replacement cost ($9,000/m^3) that is reflective of more recent commodity values based on a 2022 Sargent and Lundy update to the SCR cost calculations prepared in support of EPA's Good Neighbor proposal.
- The NPS used the Chemical Engineering Plant Cost Index (CEPCI) (797.9) to escalate to 2023$ which is slightly higher than the Consumer Price Index (CPI) method used by NMED.
- The NPS assumed a 25-year equipment life. The CCM notes that the equipment lifetime of an SCR system is typically assumed to be 20 to 25 years for industrial boilers. The NPS uses the higher end of this range for combustion turbines firing natural gas, as it is anticipated the equipment life would be longer than for industrial boilers firing coal or oil.

Despite these differences, NPS estimates are similar to NMED's cost estimates for SCR and are below NMED's $10,000/ton CETV for turbines 1–7:

Table 3: Summary of NPS SCR Cost-effectiveness Values for SJBGP vs. NMED SCR and DLN Cost-effectiveness Values

SJBGP Unit No.	Baseline Actual NO_x Emissions (ton/yr)	NMED Proposed Reduction (ton/yr)	NPS Estimated Reductions SCR (ton/yr)	NPS Estimated Cost Effectiveness SCR 2023$ ($/ton)	NMED Estimated Cost Effectiveness SCR 2023$ ($/ton)	NMED Estimated Cost Effectiveness DLN 2023$ ($/ton)
1	83	0	75	$9,691	$10,000	$365,000
2	90	0	81	$9,117	$9,000	$247,000
3	83	0	75	$9,488	$10,000	-$5,195,000 (1)
4	56	38	50	$5,791	$7,000	$10,000
5	55	38	50	$5,839	$7,000	$10,000
6	61	43	55	$5,309	$6,000	$8,000
7	57	40	51	$5,680	$7,000	$9,000
Total	485	159	437			

In addition, both the NPS and NMED SCR cost-effectiveness values are lower than NMED's DLN estimates. The NPS encourages NMED to reconsider the reasonable progress determination for SJBGP and require SCR for turbines 1 through 7.

3.1.3 Blanco C&D Compressor Station

Blanco Compressor Station C & D (BCSCD) is a natural gas compressor station located near Bloomfield, New Mexico, approximately 40 miles southeast of Mesa Verde National Park. The facility includes three natural gas-fired combustion turbines selected for analysis (Table 4).

Table 4: Description of BCSCD Units Selected for Four-Factor Analysis

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
T-C01	Turbine	General Electric 5221W	<June 1989	22,280 hp
T-C02	Turbine	General Electric 5221W	<June 1989	22,280 hp
T-D01	Turbine	General Electric M5322B	<October 1987	32,550 hp

The NMED's four-factor analysis did not identify any cost-effective controls for BCDCS Units T-C01, T-C02, and T-D01and determined that reasonable progress does not require new controls on any of these units. The NMED completely dismissed SCR from consideration at BCSCD due to concerns over "space constraints."

NPS Conclusions and Recommendations for BCSCD

The NPS recommends that NMED reconsider their control determinations and require SCR for units T-C01 and T-C02 and consider SCR for unit T-D01 at BCSCE, as described below. In their review of the four-factor analysis submittal, NMED accepted Enterprise Field Service's demonstration that there is insufficient space to accommodate an SCR. Enterprise Field Service's demonstration consists of an aerial photograph of the site, with rough overlays of "SCR dimensions" and identified the assumed "area available for SCR" (see Figure 1). The materials provided in Appendix D to the SIP (NMED workbook *2024-05-20_NMED's Draft Cost Evaluation for Blanco C&D Compressor Station [External Review Copy].xlsx*, *SCR* tab) note:

> *Enterprise indicated in its initial 2019 FFA submittal, 2020 follow-up and 2023 update that there is insufficient space to accommodate SCR. In support of its assertion, it indicated (2020 follow up) that CECO-Peerless stated that "an area of approximately 40' x 20' is required for an SCR unit" and a copy of the correspondence was provided. An aerial map of the facility was provided in the 2020 follow up which suggests that new buildings (or substantial extensions of the existing building) would be required to house an SCR. The associated costs of building construction coupled with corresponding exhaust system modifications would be costly. Considering the calculated cost effectiveness of SCR for other CTs in New Mexico, it is reasonable to conclude that SCR is cost prohibitive for the Blanco C/D units.*

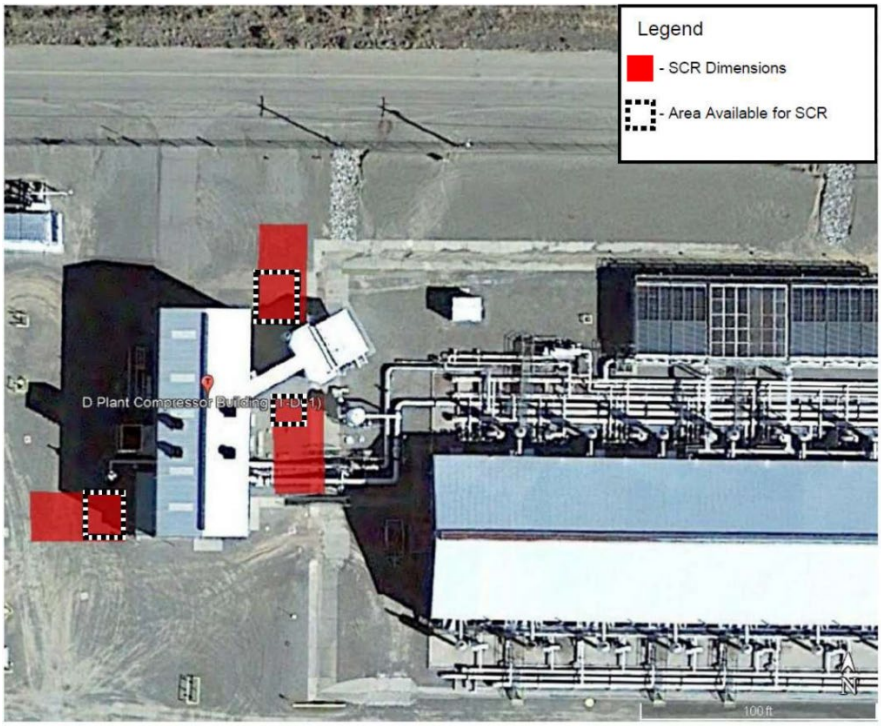

Figure 1: Aerial View of Blanco Compressor Station C & D

As discussed in Section 2.6, NMED and Enterprise did not address why the SCR would need to be housed within the building or the costs associated with building construction. The aerial photograph provided illustrates that the facility is located on a large gravel pad with ample additional space. As noted in Section 2.5, many of the retrofit costs, including exhaust system modifications, are incorporated into the CCM TCI calculations for retrofits. If excessive building costs are necessary, this should be well documented and included in the overall cost estimates. Given the lack of documentation regarding specific space constraints and building costs, the NPS estimated the costs of SCR for the three turbines located at BCSCD.

Based on NPS estimates, installation of SCR on all three turbines could reduce 420 tons/year of NO_x emissions. The NPS recommends that NMED reconsider their control determinations and require SCR for units T-C01 and T-C02 and consider SCR for unit T-D01 at BCSCE. The NPS estimates demonstrate that SCR controls for turbines T-C01 and T-C02 are very cost-effective relative to NMED's CETV of $10,000/ton at $7,458/ton and $5,411/ton, respectively. Costs for unit T-D01 were slightly above NMED's CETV of $10,000/ton, but still below the $14,000/ton breakpoint identified in NMED's revised CETV analysis. As discussed in Section 2.5, the NPS recommends that NMED consider additional controls that are estimated to be right at or just above the New Mexico $10,000/ton CETV. This recommendation is consistent with the NMED finding that incremental NO_x reductions are consistent (and may be cost-effective) up to $14,000/ton. It is also consistent with EPA guidance which recommends that control costs are typically estimated at an accuracy level of plus or minus 30%.

Table 5: Summary of NPS SCR Cost-effectiveness Values for BCSCD

Blanco C & D Unit No.	Baseline Actual NO_x Emissions (ton/yr)	NMED Proposed Reduction (ton/yr)	NPS Estimated Reductions SCR (ton/yr)	NPS Estimated Cost Effectiveness SCR 2023$ ($/ton)
T-C01	140	0	126	$7,458
T-C02	195	0	176	$5,411
T-D01	132	0	118	$11,398
Total	466	0	420	

3.2 Linam Ranch Gas Plant

Linam Ranch Gas Plant is a natural gas processing facility located 7 miles west of Hobbs in Lea County, New Mexico. The shortest distance to the boundary of the nearest Class I Area, Carlsbad Caverns National Park, is approximately 72.7 miles. The facility has a total potential to emit of 973.5 tons per year of NO_x and 87.1 tons per year of SO_2. The SIP reports baseline emissions of 272 tons NO_x/year.

The Linam Ranch plant includes six two-stroke lean-burn (2SLB) RICE engines, two of which are no longer operational (Units 8 and 9), and four turbines.

Table 6. Linam Ranch emissions units.

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
6	2SLB RICE	Clark TLA-6	1974 or before	2,000 hp
7	2SLB RICE	Clark TLA-6	1974 or before	2,000 hp
8	2SLB RICE	Clark HBA-6	1951	1,267 hp
9	2SLB RICE	Clark HBA-6	1951	1,267 hp
10	2SLB RICE	Clark HBA-6	1951	1,267 hp
11	2SLB RICE	Clark HBA-6	1951	1,267 hp
29	Turbine	Solar Taurus T-70	1995	10,702 hp
30	Turbine	Solar Taurus T-70	1995	9,900 hp
31	Turbine	Solar Centaur T-4700	1995	4,700 hp
32B	Turbine	Solar Centaur T-4000	1979	3,961 hp

The four-factor analysis in the SIP evaluated potential options for reducing NO_x emissions from the engines. The NMED concluded that SCR, SNCR, and NSCR are not technically feasible options for the two-stroke engines at Linam Ranch, but LEC retrofit and unit replacement are feasible options. The resulting cost-effectiveness estimates were all above the $10,000/ton cost threshold, and NMED determined that new controls are not required on these engines to meet reasonable progress goals.

The SIP four-factor analysis also evaluated NO_x reduction options for the four turbines at Linam Ranch. The NMED considered retrofitting the turbines with dry low-NO_x (DLN) technology and adding SCR as a post-combustion control. The facility operator has already upgraded Units 29,

30, and 31 with DLN to comply with the state's ozone precursor rule. The NMED's cost effectiveness estimates for DLN and SCR on turbine 32B were below its cost threshold of $10,000/ton, at $9,217/ton NO_x removed for DLN and $7,774/ton for SCR. Despite the lower cost effectiveness estimate, SCR was rejected due to an inadequate "margin of safety." As discussed in detail in Section 2.6, the NPS disagrees with applying a default "margin of safety" to SCR cost-effectiveness estimates. The NMED determined that DLN is cost-effective for Unit 32B and necessary to make reasonable progress.

The NPS used the CCM SCR calculation workbook to complete its cost-effectiveness estimate for SCR, documented in a workbook[17] included in Attachment 2. The NPS workbook includes some differences from NMED's approach. As discussed in Section 2.6, NMED added an extra operator cost that is not included in the NPS estimate. In addition, NPS used an expected lifetime of 25 years rather than 20 years as NMED used in its analysis. The SCR workbook notes that for industrial boilers, the typical equipment life is between 20 and 25 years. The longer lifetime is appropriate for a gas-fired turbine. Finally, the NPS used the CEPCI index to adjust costs to 2023$ rather than the CPI. This resulted in a cost-effectiveness estimate for SCR on turbine 32B of $7,098/ton NO_x removed. While the difference in NO_x emissions removed between SCR and DLN is not large, the cost analysis suggests that SCR may be more cost-effective to reduce NO_x emissions from this turbine.

3.3 Kutz Canyon Processing Plant

Kutz Canyon is a natural gas processing facility located approximately 43.2 miles from the nearest Class I area, Mesa Verde National Park. The SIP evaluated eight Solar Centaur turbines at the facility for potential NO_x emissions reductions; three four-stroke rich-burn RICE engines originally identified for four-factor analysis have shut down. Baseline NO_x emissions for the turbines are shown in the following table.

Table 7. Kutz Canyon turbine baseline emissions.

Unit No.	Adjusted Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual Emissions (ton/yr)
1	16.7	6940	58.0
2	17.7	5375	47.5
3	12.6	5175	32.5
4	14.1	6257 (1)	46.1
5	11.9	6924	41.2
6	11.8	8224	48.4
19	15.6	4812	37.6
20	15.6	3884	30.3

(1) Unit 4 has not operated since 2018, skewing its 2016-21 average operating hours. Therefore, the average 2016-21 average operating hours of identical Units 1, 2, 3, 5, and 6 were used as a surrogate for Unit 4.

[17] Linam_Ranch_A02_32B.xlsm

The four-factor analysis evaluated both DLN and SCR to reduce NO_x emissions from the eight turbines. The NMED's cost-effectiveness estimates for DLN were below the threshold of $10,000/ton for units 1–6 and 19. The SCR retrofit cost estimates were also below NMED's threshold for Units 1, 2, 4, 5, 6, and 19. The NMED rejected SCR for units 1, 2, 6, and 19 due to insufficient "margin of safety" and determined that DLN is required for Units 1–5 and 19. As discussed in detail in Section 2.6, the NPS disagrees with applying a default "margin of safety" to SCR cost-effectiveness estimates. The four-factor analysis estimates that application of DLN to these six engines will reduce the facility's NO_x emissions by 172.8 tons/year.

The NPS used the CCM SCR calculation workbook to estimate costs for retrofitting the turbines with SCR, documented in workbooks[18] included in Attachment 2. The NPS workbooks include some differences from NMED's approach. As discussed in Section 2.6, NMED added an extra operator cost that is not included in the NPS estimates. In addition, NPS used an expected lifetime of 25 years rather than 20 years as NMED used in its analysis. The SCR workbook notes that for industrial boilers, the typical equipment life is between 20 and 25 years. The longer lifetime is appropriate for a gas-fired turbine. Finally, the NPS used the CEPCI index to adjust costs to 2023$ rather than the CPI. The resulting NPS estimates are shown in the following table.

Table 8. NPS SCR cost-effectiveness estimates.

Unit	NO_x tons removed	Cost effectiveness ($/ton)
1	52	$5,243
2	43	$6,284
3	29	$9,179
4	42	$6,481
5	37	$7,370
6	44	$6,275
19	34	$6,782
20	27	$8,329

The NPS cost-effectiveness estimates suggest that SCR is cost-effective for all eight turbines, which could reduce NO_x emissions by 280.2 tons/year. The NPS recommends that NMED consider requiring SCR for all eight turbines, as this would reduce NO_x by an additional 108 tons/year compared to the application of DLN to six of the eight turbines.

3.4 Chaco Gas Plant

The Chaco plant is a natural gas processing facility approximately 49.8 miles from the boundary of the nearest Class I area, Mesa Verde National Park. The NMED selected eight emissions units

[18] *Kutz_A01_SCR.xlsm* through *Kutz_A20_SCR.xlsm*

for evaluation, including three two-stroke RICE engines and five turbines. Baseline emissions for these units are shown in Table 9.

Table 9. Chaco Gas Plant baseline emissions.

Unit	Description	Make & Model	Permitted Capacity	Baseline NO_x Emissions (ton/yr)
12	2SLB RICE	Clark TLA-10	3,400 hp	88.7
13	2SLB RICE	Clark TLA-10	3,400 hp	41.8
14	2SLB RICE	Clark TLA-10	3,400 hp	131.2
17	Turbine	General Electric Frame 5	19,500 hp	75.3
18	Turbine	General Electric Frame 5	19,500 hp	80.9
35	Turbine	Solar Mars T-15000	15,000 hp	98.0
36	Turbine	Solar Mars T-15000	15,000 hp	92.5
37	Turbine	Solar Mars T-15000	15,000 hp	82.2

The four-factor analysis states that the three RICE engines are already equipped with LEC, but that it is feasible to upgrade these engines to meet a 0.5 g/hp-hr NO_x emissions rate. The NMED concluded that only Unit 14 is cost-effective to upgrade and is requiring it only for this unit.

The NMED did not consider SCR to be a technically feasible option to reduce NO_x emissions from the turbines due to a lack of space. This conclusion was based upon an aerial image with measurement overlays. As discussed in more detail in Section 2.6, the analysis should include a detailed, site-specific analysis, justification, and cost estimate to support the decision to exclude SCR from consideration. In the absence of this justification, the NPS recommends NMED analyze the cost-effectiveness of retrofitting the turbines with SCR.

3.5 South Carlsbad Compressor Station

The South Carlsbad Compressor Station is located 2.8 miles northwest of Loving in Eddy County, New Mexico and approximately 16.2 miles from the nearest Class I area, Carlsbad Caverns National Park. The NMED evaluated potential NO_x controls for two gas-powered Solar Centaur T-4702 4,328 hp turbine engines. Emissions for these units are shown in Table 10.

Table 10. South Carlsbad baseline emissions.

Unit No.	Adjusted NO_x Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_x Emissions (ton/yr)
1	18.1	8524	77.2
2	18.2	8467	76.9

The NMED evaluated DLN for NO_x control and found it to be cost-effective at $4,000/ton. The NMED determined DLN is necessary for both turbines to make reasonable progress. Anticipated NO_x reductions are shown in the following table.

Table 11. Expected NO_x emissions reductions at South Carlsbad.

Unit No.	Control Measure	Estimated NO_X Reductions (ton/yr)
1	DLN	61.9
2	DLN	61.5

The NMED also determined that SCR is technically feasible for these turbines but dismissed it from consideration due to a lack of space. The NPS suggests SCR could achieve a NO_x reduction efficiency of 90%, vs an expected 80% reduction for DLN. The operator asserted there is insufficient space to accommodate SCR and provided an aerial image with measurement overlays of buildings to house the units. As discussed in more detail in Section 2.6, the analysis should include a detailed, site-specific analysis, justification, and cost estimate to support the decision to exclude SCR from consideration. In the absence of this justification, the NPS recommends NMED analyze the cost-effectiveness of retrofitting the turbines with SCR and select the cost-effective control that achieves the greatest reduction in emissions.

3.6 Washington Ranch Storage Facility

The Washington Ranch Storage Facility is a natural gas storage facility located 9.1 miles southwest of Whites City in Eddy County, New Mexico. The nearest Class I area is Carlsbad Caverns National Park, which is approximately 3.4 miles away. The facility's total potential to emit is 243.6 tons per year of NO_x and 4.8 tons per year of SO_2.

The four-factor analysis evaluated NO_x control options for two two-stroke RICE engines. Average operating hours and baseline emissions for these units are shown in the following table.

Table 12. Washington Ranch baseline emissions.

Unit No.	Adjusted NO_X Emissions (lb/hr @ 100% load)	Representative Annual Operating Hours (hr/yr)	Baseline Actual NO_X Emissions (ton/yr)
1	7.3	2675	9.7
2	4.2	2607	5.5

Both units already have LEC installed, resulting in controlled NO_x emission rates of 0.5 and 0.8 g/hp-hr, respectively. The NMED determined that engine replacement is technically feasible and would achieve a NO_x emissions rate of 0.3 g/hp-hr but concluded that this option is not cost-effective. Given the relatively low baseline emissions and potential for emissions reduction, the NPS agrees that replacement costs would likely exceed the $10,000/ton threshold. The NPS supports NMED's determination that continued use of the existing controls on these units is necessary for reasonable progress.

3.7 Indian Basin Gas Plant

The Indian Basin Gas Plant (IBGP) is a natural gas processing facility located near the city of Carlsbad in Eddy County, New Mexico, approximately 21.2 miles north of Carlsbad Caverns National Park. The facility is owned and operated by Oxy and currently operates under Title V

Operating Permit No. P103-R3. The facility units selected for four-factor analysis include three NG-fired combustion turbines:

Table 13: Description of IBGP Units Selected for Four-Factor Analysis

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
ES-06/07	Turbine	Solar Centaur 40	1980	4,000 hp
ES-08/09	Turbine	Solar Centaur 40	1980	4,000 hp
ES-10/11	Turbine	Solar Centaur 40	1980	4,700 hp

The NMED evaluated DLN, SCR, and replacement for the three turbines located at IBGP. The NMED determined that DLN represents reasonable progress for each of the three units. The NMED did not select SCR due to estimated cost effectiveness that was over the identified CETV.

NPS Conclusions and Recommendations for IBGP

The NPS supports NMED's decision to implement controls at IBGP. The NPS cost estimates for SCR were much lower than NMED's estimates and were below NMED's $10,000/ton CETV for all three turbines at IBGP. The NPS cost-effectiveness estimates for SCR were also below NMED's estimates for DLN. However, there is minimal difference in the potential NO_x emission reductions between NMED's proposal to require DLN versus the NPS estimated reductions with SCR. Given this, the NPS supports implementation of either DLN or SCR for these units. However, if utilization were to increase in the future, SCR may be a better option to maintain NO_x emission reductions.

A summary of NPS analysis results is provided in Table 14. The NPS generally used NMED's analysis assumptions, including representative operating hours and emissions, cost year, and interest rates with the following exceptions:

- The NPS used a higher ammonia reagent cost that is reflective of 2023 commodity values ($0.529/gal).
- The NPS assumed a 25-year equipment life. The CCM notes that the equipment lifetime of an SCR system is typically assumed to be 20 to 25 years for industrial boilers. The NPS uses the higher end of this range for combustion turbines firing natural gas, as it is anticipated the equipment life would be longer than for industrial boilers firing coal or oil.
- The NPS used the CEPCI cost index to escalate to 2023$ which is slightly higher than the CPI used by NMED.

Table 14. Summary of NPS SCR Cost-effectiveness Values for IBGP vs. NMED SCR and DLN Cost-effectiveness Values

IBGP Unit No.	Baseline Actual NO_x Emissions (ton/yr)	NMED Proposed Reduction (ton/yr)	NPS Estimated Reductions SCR (ton/yr)	NMED Proposed NO_x Reductions DLN (ton/yr)	NPS Estimated Cost Effectiveness SCR 2023$ ($/ton)	NMED Estimated Cost Effectiveness DLN 2023$ ($/ton)	NMED Estimated Cost Effectiveness SCR 2023$ ($/ton)
ES-06/07	49	0	44	37	$6,714	$8,000	$12,000
ES-08/09	47	0	43	35	$7,486	$8,000	$12,000
ES-10/11	43	0	39	29	$8,845	$9,000	$14,000
Total	140	0	126	101			

Not only is the average cost-effectiveness of adding SCR to each of the combustion turbines reasonable, the incremental cost-effectiveness of SCR relative to DLN is also very reasonable, shown in Table 15.

Table 15. Summary of NPS SCR Incremental Cost-effectiveness Values for IBGP vs. NMED SCR and DLN Cost-effectiveness Values

IBGP Unit No.	NPS TAC for SCR	NMED TAC for DLN	Incremental Costs	Removed SCR	Removed DLN	Incremental Removal	Incremental Cost-Effectiveness ($/ton)
	($/yr)			(tons/yr)			
ES-06/07	$295,416	$296,000	($584)	44	37	7	$ (83)
ES-08/09	$321,898	$280,000	$41,898	43	35	8	$ 5,237
ES-10/11	$344,955	$261,000	$83,955	39	29	10	$ 8,396

The NPS recommends considering addition of SCR to each of these three combustion turbines to reduce NO_X emissions by about 126 tons/year.

3.8 Artesia Gas Plant

Artesia Gas Plant (AGP) is a natural gas processing facility located near Artesia in Eddy County, New Mexico, approximately 39.8 miles from Carlsbad Caverns National Park. The NMED evaluated the amine treatment system (ATS) at AGP for potential SO_2 control measures but did not evaluate NO_x emissions for the facility. Based on the permit documents and national emission inventory information, it appears this facility has 17 RICE, (five 4SLB and twelve 4SRB) [19] and two natural gas-fired boilers.[20] Facility-wide potential to emit is 476 tons/year of

[19] These include units 10-17, units 25-27, units 30-34 and unit 39.
[20] These include units 20 & 28.

NO_x and reported actual emissions for 2019 were 181 tons/year NO_x.[21] The NMED did not address NO_x emissions associated with this facility in the four-factor analysis and did not include justification in SIP document materials. The NPS has two clarifying questions with respect to this facility:

1. Why did NMED screen NO_x emissions from four-factor analysis? Were the individual RICE and boiler unit emissions below NMED's screening criteria for individual units (i.e., PTE less than 10 tons/year)? The NPS notes that, based on the permit information, it appears the potential to emit falls below NMED's screening criteria. Please clarify this in the SIP.
2. Are the larger engines subject to NMED's Oil and Gas Sector – Ozone Precursor Pollutants Rule (NMAC 20.2.50.1)? If so, the NPS recommends summarizing any anticipated NO_x reductions in the SIP.

3.9 Cunningham Station Power Plant

Cunningham Station Power Plant (CSPP) is a 487 MW electric power plant owned and operated by Southwestern Public Service Company, a subsidiary of Xcel Energy. The CSPP is located 69.4 miles northeast of Carlsbad Caverns National Park.

Table 16. CSPP Emission Units

Unit No.	Description	Make & Model	Date of Manufacture	Permitted Capacity
1	Boiler	Combustion Engineering 9752	< 1957	82 MW
2	Boiler	Combustion Engineering 19813	< 1957	234 MW
3	Turbine	Westinghouse 501D5	< 1957	115 MW
4	Turbine	Westinghouse 501D5	< 1957	115 MW

3.9.1 NMED Determinations

- NMED determined that:
  - SCR is cost-effective for units 1 & 2.
  - No additional controls are cost-effective for units 3 & 4.
- Unit 1 appears to be shut down already based on EPA Clean Air Markets Program data. Xcel is seeking approval to extend the service life of Unit 2 to 2027 and retire it in 2027, which would preclude the installation of new controls.

3.9.2 NPS Conclusions and Recommendations

The NPS agrees with NMED's control determinations. In addition, the NPS recommends that CSPP be required to install and operate SCR on units 1 and/or 2 no later than January 1, 2031, if either unit operates beyond the December 31, 2027 end of the second planning period.

[21] See NMEDs facility emission report, available at: https://eatool.air.net.env.nm.gov/aqbeatool/facility-report?year=2019&sourceData=NMED&facilityId=199

3.10 NPS Support for NMED Reasonable Progress Determinations

The NPS generally supports the following NMED reasonable progress determinations and encourages the agency to move forward with these decisions in the final regional haze SIP:

- PECOS RIVER COMPRESSOR STATION (PRCS): Located approximately 22.1 miles from Carlsbad Caverns National Park, PRCS has a potential to emit of 697.7 tons/year of NO_x and 5.6 tons per year of SO_2. The NMED performed a four-factor analysis for three turbines located at the facility (units A-01, A-02 and A-03). The NMED determined that SCR is cost-effective and necessary to make reasonable progress on units A-02 and A-03. The cost of SCR was above NMED's CETV for unit A-01 at $12,000/ton.
    - NPS SCR estimates are lower (likely for the reasons discussed in Section 2.5) and find that SCR would also be cost-effective and reasonable for unit A-01 at PRCS.[22]
- MOUNTAINAIR COMPRESSOR STATION (MACS) NO. 7: Located approximately 50 miles from Bosque del Apache Wilderness Area (WA), MACS has a potential to emit of 2,264 tons/year of NO_x. The NMED performed a four-factor analysis for three 4SLB RICE and two 4SRB RICE at MCS. The NMED determined that engine replacement is cost-effective and necessary to make reasonable progress for all five engines evaluated. The NPS is supportive of these determinations that will reduce 1,285 tons/year of NO_x emissions and agrees these measures are necessary to make reasonable progress.
- ROSWELL COMPRESSOR STATION (RCS) NO. 9: Located approximately 5.6 miles from Salt Creek WA, RCS has a potential to emit of 1,123 tons per year of NO_x and 0.8 tons per year of SO_2. The NMED performed a four-factor analysis for two 4SLB RICE at RCS. The NMED determined that replacement of both engines is cost-effective and necessary to make reasonable progress. The NPS is supportive of these determinations that will reduce 645 tons/year of NO_x emissions and agrees these measures are necessary to make reasonable progress.
- EUNICE GAS PROCESSING PLANT (EGPP): Located approximately 73.5 miles from Carlsbad Caverns National Park, EGPP has a potential to emit of 2,606 tons per year of NO_x and 482 tons per year of SO_2. The NMED performed a four-factor analysis for all technically feasible control options for two industrial boilers and seven 2SLB RICE at EGPP. The NMED determined that installation of Low NO_x Burners (LNB) on both boilers (B01 & B02) and replacement of all seven engines (C-01 through C-07) is cost-effective and necessary to make reasonable progress. The NPS is supportive of these determinations that will reduce 1,288 tons/year of NO_x emissions and agrees these measures are necessary to make reasonable progress.
- MONUMENT GAS PLANT (MGP): Located approximately 68.2 miles from Carlsbad Caverns National Park, MGP has a potential to emit of 1,013 tons/year of NO_x and 373 tons/year of SO2. The NMED performed a four-factor analysis for seven 2SLB RICE at MGP. The NMED determined that replacement of five engines is cost-effective and necessary to make reasonable progress (units C-01, C-02, C-05, C-06 & C-24). The NMED did not identify cost-effective controls for units C-04 and C-28. The NPS is

[22] See Spreadsheet in Attachment 2 *Pecos_river_SCR_CCM_spreadsheet_test_A03.xlsm*

supportive of these determinations that will reduce 409 tons/year of NO_x emissions and agrees these measures are necessary to make reasonable progress.

- The NPS notes that the utilization rates on units C-04 and C-28 are relatively inconsistent from year to year. Like the NPS recommendations for Blanco Compressor Station A, NMED may consider also looking at replacement costs on a facility-wide basis.

The NPS appreciates the thorough NMED review of sources and the proposed reductions that could be achieved at these sources. The NPS encourages NMED to move forward with additional recommended measures to reduce haze causing emissions. As NMED observes in the SIP *substantial reductions in emissions of NO_X and SO_2 will translate into visibility benefits*. These types of reduction measures (from many smaller sources) are particularly necessary in states like New Mexico, where numerous "small" oil and gas sources comprise a significant fraction of the statewide emissions inventory. Large emission sources are generally more cost-effective to control and often result in measurable improvement from individual facility reductions. Once these large emission sources are well-controlled, ongoing progress will require reductions from numerous smaller sources, where improvement may only be measurable in the aggregate. The NPS appreciates that NMED recognizes this fact in its CETV and overall approach to regional haze planning.

3.11 Oil and Gas Non-point Sources

In August 2022, NMED finalized the Ozone Precursor Pollutants Rule to address emissions from oil and gas sources located in areas that are with 95% of the ozone National Ambient Air Quality Standard (NAAQS).[23] The NPS applauds NMED's efforts to address the substantial emissions from the oil and gas source sector in New Mexico. This source sector contributes to both increased ozone levels and visibility impairment in New Mexico Class I areas. According to Table 5-11 in the SIP, oil and gas point sources emitted 31,244 tons/year of NO_x and oil and gas non-point sources emitted 50,064 tons/year of NO_x during the 2014–2018 timeframe. The NO_x reductions that will be achieved under NMED's Ozone Precursor Pollutant Rule are essential to addressing the significant air quality concerns in and near large oil and gas development basins in New Mexico and will help further reasonable progress in Class I areas.

The NPS has been supportive of these type of state rulemaking efforts. Consistent with NPS input provided during the NMED rulemaking hearing in September 2021 (EIB No. 21-27 (R))[24], the NPS continues to recommend that New Mexico implement additional rule requirements and further reduce NO_x emissions by (1) addressing smaller engine size classes and (2) requiring lower NO_x limits for various engine size classes/configurations.

[23] The final rule is codified in 20.2.50 NMAC Oil and Gas Sector – Ozone Precursor Pollutants, available at: https://www.env.nm.gov/air-quality/wp-content/uploads/sites/2/2022/07/Oil-and-Gas-Sector-Ozone-Precursor-Polutants-Final-rule-20.2.50-NMAC-06Jul22.pdf

[24] See Appendix 2: *NPS comments oil and gas rule Exhibit B.pdf*

The earlier NPS recommendations were based on rules implemented in other states, including Texas, Pennsylvania, and California. Since the NMED rulemaking, the Colorado Department of Public Health and Environment (CDPHE) issued final oil and gas rules to reduce NO_x emissions from engines statewide. The CDPHE rules address stationary engines 500 HP or larger, as well as pre-production drilling and completion activities located in the Colorado front range nonattainment area.[25] The NPS is including the final Colorado rules adopted by the state's Air Quality Control Commission in December 2023 for reference in Attachment 2 (note: these rule versions are the redline strike out versions issued by Colorado to highlight the final adopted rule changes). The NPS now recommends NMED also consider the CDPHE model for reducing ozone emissions from oil and gas area sources.

[25] See Colorado REGULATION NUMBER 26 Control of Emissions from Engines and Major Stationary Sources 5 CCR 1001-30 and REGULATION NUMBER 7 Control of Emissions from Oil and Gas Emissions Operations 5 CCR 1001-9.

Appendix G: Proposed Rule 20.2.68 NMAC - Regional Haze Requirements

TITLE 20 ENVIRONMENTAL PROTECTION
CHAPTER 2 AIR QUALITY (STATEWIDE)
PART 68 REGIONAL HAZE REQUIREMENTS

20.2.68.1 ISSUING AGENCY: Environmental improvement board.
[20.2.68.1 NMAC – N, 07/01/2025]

20.2.68.2 SCOPE: All geographic areas within the jurisdiction of the environmental improvement board.
[20.2.68.2 NMAC – N, 07/01/2025]

20.2.68.3 STATUTORY AUTHORITY: Environmental Improvement Act, Sections 74-1-1 to 74-1-18 NMSA 1978, including specifically Paragraph (4) of Subsection A of Section 74-1-8 NMSA 1978, and Air Quality Control Act, Sections 74-2-1 to 74-2-17 NMSA 1978, including specifically Paragraph (1) of Subsection D of Section 74-2-5 NMSA 1978.
[20.2.68.3 NMAC – N, 07/01/2025]

20.2.68.4 DURATION: Permanent.
[20.2.68.4 NMAC – N, 07/01/2025]

20.2.68.5 EFFECTIVE DATE: July 1, 2025, except where a later date is cited at the end of a section.
[20.2.68.5 NMAC – N, 07/01/2025]

20.2.68.6 OBJECTIVE: The objective of this Part is to establish enforceable emission limitations, compliance schedules, and other measures that are necessary to make reasonable progress during the second regional haze implementation period, and provisions to make these measures practicably enforceable, including averaging times, monitoring requirements, and recordkeeping and reporting requirements.
[20.2.68.6 NMAC – N, 07/01/2025]

20.2.68.7 DEFINITIONS: In addition to the terms defined in 20.2.2 NMAC – Definitions, as used in this Part, the following definitions apply:

A. "Agency interest number" or "AI #" means the unique identification number assigned to every facility that is regulated by the department.

B. "Calendar year" means a year beginning January 1 and ending December 31.

C. "CFR" means the Code of Federal Regulations.

D. "Continuous emission monitoring system" or "CEMS" means all of the equipment required to sample, condition (if applicable), analyze, and provide a record of emissions on a continuous basis.

E. "Environmental protection agency" or "EPA" means the United States environmental protection agency.

F. "g/bhp-hr" means grams per brake horsepower-hour.

G. "lb/hr" means pounds per hour.

H. "Operator" means the person or persons responsible for the overall operation of a stationary source.

I. "Owner" means the person or persons who own a stationary source or part of a stationary source.

J. "ppmvd" means parts per million by volume, dry.

K. "Reasonable progress unit" or "RP unit" means an emissions unit selected for an analysis of emission control measures during the second regional haze implementation period for which the department has determined an emission limitation or other measures are necessary to make reasonable progress.

L. "Rolling average" means the weighted average of all data, meeting this Part's quality assurance and quality control requirements, collected during the applicable averaging period. For reasonable progress units equipped with CEMS, a 30-operating-day rolling average is calculated by adding the hourly mass emissions over the previous 30 operating days and dividing that sum by the total operating hours during the same period.

M. "Rolling sum" means the sum of all data, meeting this Part's quality assurance and quality control requirements, collected during the applicable summation period. For reasonable progress units not equipped with CEMS and subject to a multi-unit emission limitation, a 12-month rolling sum is calculated by multiplying each individual unit's hourly mass emission rate by its total operating hours over the previous 12 months and summing the results for all units subject to the multi-unit limit.

[20.2.68.7 NMAC – N, 07/01/2025]

20.2.68.8 SEVERABILITY: If any provision of this Part, or the application of this provision to any person or circumstance is held invalid, the remainder of this Part, or the application of this provision to any person or circumstance other than those as to which it is held invalid, shall not be affected thereby.
[20.2.68.8 NMAC – N, 07/01/2025]

20.2.68.9 CONSTRUCTION: This Part shall be liberally construed to carry out its purpose.
[20.2.68.9 NMAC – N, 07/01/2025]

20.2.68.10 SAVINGS CLAUSE: Repeal or supersession of prior versions of this Part shall not affect administrative or judicial action initiated under those prior versions.
[20.2.68.10 NMAC – N, 07/01/2025]

20.2.68.11 COMPLIANCE WITH OTHER REGULATIONS: Compliance with this Part does not relieve a person from the responsibility to comply with other applicable federal, state, or local laws, rules or regulations, including more stringent controls.
[20.2.68.11 NMAC – N, 07/01/2025]

20.2.68.12 DOCUMENTS: Documents incorporated and cited in this Part may be viewed at the New Mexico environment department, air quality bureau.
[20.2.68.12 NMAC – N, 07/01/2025]
[As of September 2024, the air quality bureau is located at 525 Camino de los Marquez, Suite 1, Santa Fe, New Mexico 87505]

20.2.68.13-20.2.68.100 [RESERVED]

20.2.68.101 APPLICABILITY: This Part applies to reasonable progress units as defined in 20.2.68.7 NMAC.
[20.2.68.101 NMAC – N, 07/01/2025]

20.2.68.102 EMISSION LIMITATIONS AND COMPLIANCE DEADLINES:

A. The reasonable progress units listed in Table 1 of Subsection A of 20.2.68.102 NMAC shall not emit or cause to be emitted oxides of nitrogen (NO_x) in excess of the emission limitations shown. The emission limitations must be met as expeditiously as practicable, but in no event later than their respective compliance deadlines.

Table 1 – EMISSIONS LIMITATIONS AND COMPLIANCE DEADLINES

Facility	AI #	RP Unit	Emission Limitation	Compliance Deadline
Bitter Lake Compressor Station	14	C-891	3 g/bhp-hr	0 years
		C-893	3 g/bhp-hr	0 years
Blanco Compressor Station A	1147	A11	0.5 g/bhp-hr	3 years
		A13	0.5 g/bhp-hr	3 years
Blanco C&D Compressor Station	3552	T-C01	13.04 lb/hr	3 years
		T-C02	13.32 lb/hr	3 years
		T-D01	24.22 lb/hr	3 years
Chaco Gas Plant	1148	14	0.5 g/bhp-hr	2 years
Cunningham Station Power Plant	604	1	12.07 lb/hr	3 years
		2	30.05 lb/hr	3 years
Eunice Gas Processing Plant	609	B-01	9 ppmvd @ 3% O_2	2 years
		B-02	9 ppmvd @ 3% O_2	2 years
		C-01	0.5 g/bhp-hr	3 years
		C-02	0.5 g/bhp-hr	3 years
		C-03	0.5 g/bhp-hr	3 years

		C-04	0.5 g/bhp-hr	3 years
		C-05	0.5 g/bhp-hr	3 years
		C-06	0.5 g/bhp-hr	3 years
		C-07	0.5 g/bhp-hr	3 years
Indian Basin Gas Plant	197	ES 06/07	25 ppmvd @ 15% O_2	2 years
		ES 08/09	25 ppmvd @ 15% O_2	2 years
		ES 10/11	25 ppmvd @ 15% O_2	2 years
Kutz Canyon Processing Plant	1158	1	3.34 lb/hr	3 years
		2	3.54 lb/hr	3 years
		4	2.82 lb/hr	3 years
		5	2.38 lb/ hr	3 years
		6	2.36 lb/hr	3 years
		19	3.12 lb/hr	3 years
		20	3.12 lb/hr	3 years
Linam Ranch Gas Plant	589	29	15 ppmvd @ 15% O_2	0 years
		30	25 ppmvd @ 15% O_2	0 years
		31	25 ppmvd @ 15% O_2	0 years
		32B	25 ppmvd @ 15% O_2	1 year
Monument Gas Plant	610	C-01	0.5 g/bhp-hr	3 years
		C-02	0.5 g/bhp-hr	3 years
		C-05	0.5 g/bhp-hr	3 years
		C-06	0.5 g/bhp-hr	3 years
		C-24	0.5 g/bhp-hr	3 years
Mountainair Compressor Station No. 7	1569	701	44.74 ton/yr	3 years
		702		
		703		
		721	9 ppmvd @ 15% O_2	3 years
		722	9 ppmvd @ 15% O_2	3 years
Pecos River Compressor Station	194	A-02	7.28 lb/hr	3 years
		A-03	8.1 lb/hr	3 years
Roswell Compressor Station No. 9	10	903	29 ton/yr	3 years
		904		
San Juan Basin Gas Plant	1177	1	3.96 lb/hr	3 years
		2	4.24 lb/hr	3 years
		3	3.88 lb/hr	3 years
		4	2.78 lb/hr	3 years
		5	2.74 lb/hr	3 years
		6	3.04 lb/hr	3 years
		7	2.88 lb/hr	3 years
South Carlsbad Compressor Station	218	1	15 ppmvd @ 15% O_2	2 years
		2	15 ppmvd @ 15% O_2	2 years
Washington Ranch Storage Facility	220	1	3 g/bhp-hr	0 years
		2	3 g/bhp-hr	0 years

B. The compliance deadlines in Table 1 of Subsection A of 20.2.68.102 NMAC are expressed in years after approval of New Mexico's state implementation plan revision for the second regional haze implementation period by the environmental protection agency.

C. The emission limitation in Table 1 of Subsection A of 20.2.68.102 NMAC for reasonable progress units 701, 702, and 703 at Mountainair Compressor Station No. 7 is a multi-unit limit applicable to all three units combined. Similarly, the emission limitation in Table 1 of Subsection A of 20.2.68.102 NMAC for reasonable progress units 903 and 904 at Roswell Compressor Station No. 9 is a multi-unit limit applicable to both units combined. In the event compliance with either of these multi-unit limits is achieved by replacing the subject units, and the replacement ratio is not 1:1, the limit will apply to all of the replacement units combined, regardless of their number.

D. The owner or operator of a reasonable progress unit that complies with the emission limitations in Table 1 of Subsection A of 20.2.68.102 NMAC using an emission control technology that uses ammonia or urea as a reagent shall ensure that the exhaust ammonia slip is limited to 10 ppmvd or less, corrected to 15 percent oxygen. [20.2.68.102 NMAC – N, 07/01/2025]

20.2.68.103 OTHER MEASURES: The reasonable progress units listed in Table 2 of 20.2.68.103 NMAC have been retired and removed from their facilities' respective construction permits (or were located at a facility that has permanently ceased operations and closed its construction permit) and shall not be reauthorized as a regulated emission source in any future construction permit modification issued by the department without a new analysis of the emission control measures necessary to make reasonable progress and an EPA-approved regional haze state implementation plan revision.

Table 2 – RETIRED UNITS PROHIBITED FROM REAUTHORIZATION

Facility	AI #	RP Unit	Date Removed from Permit or Permit Closed
Denton Gas Plant	568	005	February 4, 2022
		007	February 4, 2022
Eunice Gas Plant	595	17A	November 5, 2021
		18B	November 5, 2021
		19A	November 5, 2021
		25A	November 5, 2021
		26A	November 5, 2021
		Amine-01	November 5, 2021
		31	November 5, 2021
		111	November 5, 2021
		113	November 5, 2021

		I-01	May 31, 2024

[20.2.68.103 NMAC – N, 07/01/2025]

20.2.68.104 MONITORING REQUIREMENTS: Compliance with the emission limitations in Table 1 of Subsection A of 20.2.68.102 NMAC shall be demonstrated as follows.

A. For reasonable progress units one and two at Cunningham Station Power Plant, compliance shall be determined on a 30-operating-day rolling average basis within seven days of the end of each 30-operating-day period, and shall be demonstrated using data from a NO_x continuous emission monitoring system complying with the performance requirements in 40 CFR 75.

B. For reasonable progress units 701, 702, and 703 at Mountainair Compressor Station No. 7 and reasonable progress units 903 and 904 at Roswell Compressor Station No. 9, compliance shall be determined on a 12-month rolling sum basis within seven days of the end of each month, and shall be demonstrated by monitoring operating hours and conducting annual emissions tests using a portable analyzer or EPA reference methods in accordance with the requirements of Subsection D of 20.2.68.104 NMAC. The results of the most recent annual emissions test shall be used to calculate the 12-month rolling sum used to determine compliance.

C. For all other reasonable progress units, compliance shall be demonstrated by conducting annual emissions tests using a portable analyzer or EPA reference methods in accordance with the requirements of Subsection D of 20.2.68.104 NMAC. The arithmetic mean of the results from three separate test runs shall be used to determine compliance pursuant to Paragraph (5) of Subsection D of 20.2.68.104 NMAC.

D. The following requirements apply to annual emissions testing used to demonstrate compliance with the emission limitations in Table 1 of Subsection A of 20.2.68.102 NMAC:

(1) For units with g/bhp-hr emission limits, load shall be calculated using the following equation:

$$\text{Load (hp)} = \frac{\text{Fuel consumption (scf/hr) x Measured lower heating value of fuel (btu/scf)}}{\text{Manufacturer's rated brake-specific fuel consumption (btu/bhp-hr) at 100\% load or best efficiency}}$$

If the manufacturer's rated brake-specific fuel consumption is not available, an alternative load calculation methodology based on available data may be used.

(2) Emissions testing shall be conducted within 10 percent of 100 percent peak (or the highest achievable) load. The load and the parameters used to calculate it shall be recorded to document operating conditions at the time of testing and shall be included with the test report.

(3) Emissions testing utilizing a portable analyzer shall be conducted in accordance with the requirements of the current version of ASTM D6522. If a portable analyzer has met a previously approved department criterion, the analyzer may be operated in accordance with that criterion until it is replaced.

(4) The default time period for a test run shall be at least 20 minutes.

(5) An emissions test shall consist of three separate runs, with the arithmetic mean of the results from the three runs used to determine compliance with the applicable emission limitation.

(6) During emissions tests, pollutant and diluent concentration shall be monitored and recorded. Fuel flow rate shall be monitored and recorded if stack gas flow rate is determined utilizing EPA reference method 19. This information shall be included with the test report.

(7) Stack gas flow rate shall be calculated in accordance with EPA reference method 19 utilizing fuel flow rate (scf) determined by a dedicated fuel flow meter and fuel heating value (btu/scf). The owner or operator shall provide a contemporaneous fuel gas analysis (preferably on the day of the test, but no earlier than three months before the test date) and a recent fuel flow meter calibration certificate (within the most recent quarter) with the final test report. Alternatively, stack gas flow rate may be determined by using EPA reference methods one through four or through the use of manufacturer provided fuel consumption rates.

(8) Emissions testing shall be conducted at least once per calendar year. Emissions testing required by Subparts GG, IIII, JJJJ, or KKKK of 40 CFR 60, or Subparts ZZZZ or DDDDD of 40 CFR 63, may be used to satisfy the emissions testing requirements of this Part if it meets the requirements of 20.2.68.104 NMAC and is conducted at least once per calendar year.

[20.2.68.104 NMAC – N, 07/01/2025]

20.2.68.105 RECORDKEEPING REQUIREMENTS:

A. For reasonable progress units one and two at Cunningham Station Power Plant, the owner or operator shall maintain records of all NO_x CEMS data. The owner or operator shall also maintain records of periods that the CEMS are inoperative and of all CEMS performance test measurements, performance evaluations, calibration checks, adjustments, and maintenance.

B. For all other reasonable progress units, the owner or operator shall maintain records of all annual emissions tests and operating data used to determine compliance with the emission limitations in Table 1 of Subsection A of 20.2.68.102 NMAC. The records shall include:

(1) make, model, and serial number for the tested engine, turbine, or boiler;

(2) the date and time stamp(s), including GPS of the location, of any monitoring event, including sampling or measurements;

(3) date analyses were performed;

(4) name of the person(s) and the qualified entity that performed the analyses;

(5) analytical or test methods used;

(6) results of analyses or tests;

(7) calculated emissions of NO_x in lb/hr, g/bhp-hr, or ppmvd as appropriate; and

(8) operating conditions at the time of sampling or measurement, including load and the parameters used to calculate it.

C. All records required to be maintained pursuant to Subsections A and B of 20.2.68.105 NMAC shall be kept for a period of at least five years.

[20.2.68.105 NMAC – N, 07/01/2025]

20.2.68.106 REPORTING REQUIREMENTS:

A. Test reports for annual emissions tests required by Subsections B and C of 20.2.68.104 NMAC shall be submitted to the department no later than 30 days after completion of the test.

B. If a 30-operating-day rolling average for reasonable progress units one and two at Cunningham Station Power Plant, a 12-month rolling sum for reasonable progress units 701, 702, and 703 at Mountainair Compressor Station No. 7 or reasonable progress units 903 and 904 at Roswell Compressor Station No. 9, or the results of an annual emissions test for any other reasonable progress unit reveals NO_x emissions in excess of the emission limitations in Table 1 of Subsection A of 20.2.68.102 NMAC, the owner or operator shall submit reports of excess emissions in accordance with Subsection A of 20.2.7.110 NMAC. Reports of excess emissions shall be submitted by the means and in the format specified by the department.

C. The owner or operator of a reasonable progress unit shall respond within three business days to a request for information by the department under this Part. The response shall provide the requested information for each reasonable progress unit subject to the request by the means and in the format specified by the department in its request. If the department requests information pertaining to reasonable progress units at multiple facilities with the same owner or operator, additional time will be given as appropriate.
