Economic Evaluation

Cost Component		T-D01	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	-	Enterprise provided a cost estimate for electrification using EPA Cost Control Manual Section 5.2, which pertains to acid gas scrubbers. As this is not applicable to replacement with EMD, a Total Capital Cost metric of $2,084 (2023$/hp) was calculated using detailed cost information provided by other facilities. The TCI figure assumes no costs associated with substation or distribution line upgrades. This assumption underestimates costs given that Enterprise indicated in its August 2023 update that utility infrastructure upgrades would be needed to support electrification at all three of its facilities.

Unit T-C01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	189.1	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,568,007,662	scf/Year
	8549	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5605	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.3448	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0690	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit T-C01: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	189	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,606,708,050	scf/Year	
Actual Annual fuel consumption (Mactual) =		1,568,007,662	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.976	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8549	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	52.16	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	222.96	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.10		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	749.34	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	20	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	70	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	9	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	3,200	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	111.95	kW

Unit T-C01: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$8,436,472	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$199,269	in 2024 dollars
Indirect Annual Costs (IDAC) =	$1,028,166	in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$1,227,434	in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$42,182	in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$42,228	in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$95,705	in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$19,153	in 2024 dollars
Direct Annual Cost =		$199,269	in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,134	in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,025,031	in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,028,166	in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,227,434	per year in 2024 dollars
NOx Removed =	223	tons/year
Cost Effectiveness =	$5,505	per ton of NOx removed in 2024 dollars

Unit T-C02: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	189.1	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,586,532,493	scf/Year
	8650	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 5605 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.3522	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0704	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024			
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI
Annual Interest Rate (i)	10.5	Percent		
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia		
Electricity ($Cost_{elect}$)	0.1000	$/kWh		
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst		
Operator Labor Rate	60.00	$/hour (including benefits)*		
Operator Hours/Day	4.00	hours/day*		

CEPCI = Chemical Engineering Plant Cost Index

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit T-C02: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	189	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,606,708,050	scf/Year
Actual Annual fuel consumption (Mactual) =		1,586,532,493	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.987	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8650	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	53.28	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	230.44	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	751.19	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	21	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	71	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	10	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	3,300	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	111.95	kW

Unit T-C02: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$8,436,472	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$201,863 in 2024 dollars
Indirect Annual Costs (IDAC) =	$1,028,166 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$1,230,029 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$42,182 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$43,645 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$96,836 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$19,200 in 2024 dollars
Direct Annual Cost =		$201,863 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,134 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,025,031 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,028,166 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,230,029 per year in 2024 dollars
NOx Removed =	230 tons/year
Cost Effectiveness =	$5,338 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Enterprise Field Services - Blanco C&D Compressor Station

Unit T-D01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	311.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	2,571,097,575	scf/Year
	8518	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5605	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.3891	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0778	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024

Unit T-D01: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$11,662,378	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$325,376	in 2024 dollars
Indirect Annual Costs (IDAC) =	$1,420,307	in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$1,745,683	in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$58,312	in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$78,149	in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$156,930	in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$31,985	in 2024 dollars
Direct Annual Cost =		$325,376	in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,328	in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,416,979	in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,420,307	in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,745,683	per year in 2024 dollars
NOx Removed =	413	tons/year
Cost Effectiveness =	$4,231	per ton of NOx removed in 2024 dollars

Re: Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program
Enterprise Field Services, LLC
Blanco C&D Compressor Station and Chaco Gas Plant

Mr. Singleton:

Enterprise Field Services, LLC is submitting an analysis of control measures for the Blanco C&D Compressor Station and the Chaco Gas Plant in San Juan County, New Mexico, as requested by the NMED by letter dated July 18, 2019 and extended by the NMED letter dated October 29, 2019.

In addition, Enterprise has included legal comments, which are integral to Enterprise's position on the appropriateness of the control measures analyzed for all three facilities. For convenience and to avoid duplication, the legal comments are for the South Carlsbad Compressor Station, Blanco C&D Compressor Station and the Chaco Gas Plant.

If you have questions or require additional information, please contact me at (713) 381-6698 or by email at rmhavalda@eprod.com or Bradley Cooley at (713) 381-5828.

Thank you,

Robert Havalda, P.E.

Re: Request for Two-Week Extension for Submittal of the Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program
Enterprise Products Partners, L.P.

Mr. Havalda:

The New Mexico Environment Department Air Quality Bureau (AQB) has received and reviewed your written request to extend the submittal deadline for the Blanco C & D Compressor Station and Chaco Gas Plant four-factor analyses from November 1, 2019 to November 15, 2019.

This letter grants the requested extension. Should you have any additional questions or concerns as these reports are finalized, please do not hesitate to contact Mark Jones at 505.566.9746 (mark.jones@state.nm.us) or me at 505.476.4350 (kerwin.singleton@state.nm.us).

Sincerely,

Kerwin C. Singleton

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across with United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977. EPA has since amended the RHR in certain respects, most recently on January 10, 2017.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, the states, among other things:

(A) "[E]valuate and determine the emission reduction measures that are necessary to make reasonable progress by considering the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment" and "include in [the state's] implementation plan a description of the criteria it used to determine which sources or groups of sources it evaluated and how the four factors were taken into consideration in selecting the measures for inclusion in its long-term strategy." 40 CFR 51. 308(f)(2)(i). This is known as a four-factor analysis.

(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the state must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the state must consider the uniform rate of improvement in visibility. 40 CFR 51. 308(f)(1). The uniform rate of progress or improvement is sometimes referred to as the "URP" or the glidepath and is considered in the process of developing the state's Long Term Strategy (LTS).

The second implementation, or planning, period (2019-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Regional Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations. EPA has issued guidance to states for development of State Implementation Plans (SIPs) for regional haze requirements for the second planning period.[1,2]

[1] U.S. EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, EPA-457/B-19-003 (Aug. 2019); U.S. EPA, Technical Guidance on Tracking Visibility Progress for the Second Implementation Period of the Regional Haze Program, EPA-454/R-18-010 (Dec. 2018).

[2] U.S. EPA, Technical Support Document for EPA's 2028 Regional Haze Modeling (Sept. 2019).

Pursuant to 40 CFR 51.308(f)(2), the states are responsible for identifying sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for Title V sources and screened each facility's potential impact on visibility in Class I areas using a "Q/d" analysis, where "Q" is the magnitude of emissions that could impact ambient visibility and "d" is the distance of a facility to a Class I area. The NMED defined a source with a high potential for visibility impairment as one with a "Q/d" greater than 5.5. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019, the NMED informed Enterprise Field Services, LLC (Enterprise) that its facility, the Blanco C&D Compressor Station (Blanco), was identified as one of the sources potentially contributing to regional haze at the Mesa Verde Class I area.

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. The NMED's July 18, 2019 notification letter to Enterprise specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility that is subject to this analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	Unit No.	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
GE 5221W Turbines	T-CO1	80.0	350.4	Yes	< 1.0	1.1	No
	T-CO2	80.0	350.4	Yes	< 1.0	1.1	No
GE M5322B Turbine	T-DO1	143.3	628.0	Yes	< 1.0	1.4	No

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified. One of the reference sources that the NMED has suggested consulting is the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Rate (LAER) Clearinghouse (RBLC).[3] In order to determine the most relevant and current retrofit controls available, the RBLC was queried for the previous ten years. Summaries of the results of this search are provided and discussed in Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis was then conducted for those controls that are technically feasible at the Blanco site.

Based on the technical and economic factors summarized in this report, Enterprise has provided recommendations for the NMED in its efforts to design, in coordination with WRAP, the SIP under the RHR.

2.1. COMBUSTION TURBINES

Three of Blanco's natural gas-fired turbines (Units T-CO1, T-CO2, and T-DO1) are subject to this four-factor analysis due to their NO_X emission rates. The only pollutant subject to evaluation for these units is NO_X.

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor, where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures of up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[4]

The treatment of the exhaust gases exiting the turbine dictates the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[5] The units at Blanco are regenerative cycle turbines, which are essentially simple cycle gas turbines with an added heat exchanger.

NO_x is formed via three fundamentally different mechanisms. The principal NO_x formation mechanism, thermal NO_x, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_x forms in the highest temperature regions of the combustion chamber. The second NO_x formation mechanism, fuel NO_x, arises from the evolution and reaction of fuel-bound nitrogen compounds with oxygen. The final NO_x formation mechanism, prompt NO_x, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_x is negligible in comparison to thermal and fuel NO_x. Fuel NO_x will also be negligible for Blanco's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_x.

The PTE from each turbine is reported in the facility's New Source Review (0613-M11) and Title V (218-R2) permits and is summarized in Table 1.

2.1.2. Potential NO_X Controls for a Combustion Turbine

There are three general methods of controlling NO_X emissions from gas turbines: (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation, (2) dry controls that use

[4] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

[5] Ibid.

advanced combustor design to suppress NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[6]

The categories of retrofit control equipment identified for combustion turbines during a comprehensive review of the RBLC are reported in Table 2. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control, is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible	NO_X Control Efficiency
Good Combustion Practices and Fuel Selection	Base Case	N/A
Dry Low NO_X	For M5322B Only	46%
Water/Steam Injection	Yes	15%
Selective Catalytic Reduction	No	N/A

2.1.2.1. Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. Applying concepts from engineering knowledge, experience, and the manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for the equipment involved, and using pipeline quality natural gas. If good combustion practices are maintained, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at Blanco. However, these practices are currently in use at Blanco, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.1.2.2. Dry Low NO_X Combustor

The key factors in thermal NO_X formation are the combustion temperature and the residence time of fuel in the combustor. Dry low NO_X burners reduce NO_X emissions by reducing both of these factors. Ultimately, this is accomplished by optimizing the air-to-fuel ratio. According to information received from Baker Hughes, a dry low NO_X burner can reduce NO_X exhaust concentrations to 35 ppmv on the GE M5322B unit (Unit T-DO1), corresponding to a control efficiency of 46%. Currently, per Baker Hughes, there are no dry low NOx burners commercially available for the GE 5221W units (Units T-CO1 and T-CO2).

[6] Ibid.

2.1.2.3. Water/Steam Injection

Water or steam injection is a technology that has been demonstrated to effectively suppress NO_X emissions from gas turbines. The effect of water and stream injection is to increase the thermal mass by dilution and thereby reduce peak temperatures in the flame zone. With water injection, there is an additional benefit of absorbing the latent heat of vaporization from the flame zone. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.

Water or steam injection is capable of reducing NO_x formation in the GE turbines at Blanco. Since the vendor cannot guarantee a control efficiency until the equipment has been installed and tested, Enterprise is estimating the reduction efficiency to be 15% based on AP-42.[7]

Enterprise engineers have stated that water or steam injection is feasible for the GE 5221W and M5322B turbines.

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream at a point downstream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[8] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O \qquad \text{(Equation 1)}$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O \qquad \text{(Equation 2)}$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituents; thermal sintering, or compacting, of active sites due to high temperatures in the reactor; fouling caused by ammonia-sulfur salts and particulate matter in the gas; and erosion due to high gas velocities.[9]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates, which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[10]

In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 °F and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[11]

[8] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.
[9] Ibid.
[10] Ibid.
[11] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

An onsite evaluation was conducted at the Blanco facility during which measurements were taken of any feasible locations for SCR equipment. These measurements took into consideration the amount of buffer space needed to maintain accessibility to equipment and to avoid compromising worker safety. Based on size estimates of SCR units provided by CECO-Peerless, Enterprise determined that it is not possible to install these units at the Blanco Facility.

Enterprise has evaluated the costs of implementing the technically feasible control technologies at Blanco as thoroughly as possible in the time provided to complete this assessment. The cost estimates presented below are calculated according to methods and recommendations described in the EPA Air Pollution Control Cost Manual.[12]

Emission inventory data and stack tests from 2016 were used to assess the baseline emissions for these units.

3.1. GE 5221W TURBINE CONTROLS

Table 3. Cost Analysis Summary of Technically Feasible Controls for GE 5221W Turbines

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
Water Injection	T-CO1	$79,086 per ton	Equipment, engineering, and installation cost. Operating and incremental OEM inspection costs.
	T-CO2	$57,206 per ton	
Steam Injection	T-CO1	$110,101 per ton	Equipment, engineering, and installation cost. Operating and incremental OEM inspection costs.
	T-CO2	$79,640 per ton	

3.1.1. Water Injection

Enterprise received a cost estimate from Baker Hughes to implement water injection control on the GE 5221W turbines at the Blanco Compressor Station (Units T-CO1 and T-CO2). This cost estimate is $6.1 million per unit in equipment cost, plus an additional $1.2 million per unit associated with annual operating cost. The control efficiency for water injection is estimated to be 15%, resulting in an emission rate reduction of 23.79 tpy and 32.89 tpy for Units T-CO1 and T-CO2, respectively. The projected useful life of this control equipment is 15 years. This results in an estimated control cost effectiveness of $79,086 per ton and $57,206 per ton of reduced NO_X emissions for Units T-CO1 and T-CO2, respectively.

3.1.2. Steam Injection

Enterprise received a cost estimate from Baker Hughes to implement steam injection control on the GE 5221W turbines at the Blanco Compressor Station. This cost estimate is $8.1 million per unit in equipment cost, plus an additional $1.7 million per unit associated with annual operating cost. The control efficiency for steam injection is estimated to be 15%, resulting in an emission rate reduction of 23.79 tpy and 32.89 tpy for Units T-CO1 and T-CO2, respectively. The projected useful life of this control equipment is 15 years. This results in an estimated control cost effectiveness of $110,101 per ton and $79,640 per ton of reduced NO_X emissions for Units T-CO1 and T-CO2, respectively.

[12] U.S. EPA, "Air Pollution Control Cost Manual," available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

3.2. GE M5322B TURBINE CONTROLS

Table 4. Cost Analysis Summary of Technically Feasible Controls for GE M5322B Turbine

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
Dry Low NO_X	T-DO1	$9,934 per ton	Equipment, engineering, and installation cost. Operating and incremental OEM inspection costs.
Water Injection	T-DO1	$63,551 per ton	Equipment, engineering, and installation cost. Operating and incremental OEM inspection costs.
Steam Injection	T-DO1	$88,474 per ton	Equipment, engineering, and installation cost. Operating and incremental OEM inspection costs.

3.2.1. Dry Low NO_X

For the GE M5322B turbine (Unit T-DO1), Enterprise received a capital cost estimate from Baker Hughes for the dry low NO_X control equipment of $8.2 million. Based on information received from Baker Hughes, Enterprise estimates that other annual costs associated with inspections, maintenance, and repairs will be $44,986. The expected useful life of this control equipment is 20 years. Baker Hughes reported a lower target NO_X concentration of 35 ppm. The corresponding control efficiency of the dry low NO_X burner is therefore 46%, or an annual NO_X emission reduction of 91.04 tpy. This results in an amortized cost effectiveness of $9,934 per ton of reduced NO_X emissions.

3.2.2. Water Injection

Enterprise received a cost estimate from Baker Hughes to implement water injection control on the GE M5322B turbine at the Blanco Compressor Station. This cost estimate is $6.1 million in equipment cost, plus an additional $1.2 million associated with annual operating costs. The control efficiency for water injection is estimated to be 15%, resulting in an emission rate reduction of 29.60 tpy. The projected useful life of this control equipment is 15 years. This results in an estimated control cost effectiveness of $63,551 per ton of reduced NO_X emissions.

3.2.3. Steam Injection

Enterprise received a cost estimate from Baker Hughes to implement steam injection control on the GE M5322B turbine at the Blanco Compressor Station. This cost estimate is $8.1 million in equipment cost, plus an additional $1.7 million associated with annual operating cost. The control efficiency for steam injection is estimated to be 15%, resulting in an emission rate reduction of 29.60 tpy. The projected useful life of this control equipment is 15 years. This results in an estimated control cost effectiveness of $88,474 per ton of reduced NO_X emissions.

4. TIME NECESSARY FOR COMPLIANCE

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of Enterprise's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

Enterprise estimates that approximately 3 to 4 years would be needed to budget, design, procure, and construct those categories of control equipment discussed in this report that would be technically feasible to install on the respective units.

5. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS OF COMPLIANCE

This section addresses the potential energy and non-air quality environmental impacts that would result from installation of the technically feasible control options at Blanco. Consideration of energy impacts involves assessing the impact of a control measure on the amount of energy that the source would have to consume. Non-air quality environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air quality environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

5.1. GE 5221W AND M5322B TURBINE CONTROLS

5.1.1. Dry Low NO_X Combustor

There would be no anticipated unique or site-specific energy or non-air quality environmental impacts from installation and operation of dry low NO_X burners on Unit T-DO1.

5.1.2. Water and Steam Injection

Water or steam injection is usually accompanied by an efficiency penalty (typically 2% to 3%) but an increase in power output (typically 5% to 6%).[13] The increase in power output results from the increased mass flow required to maintain the turbine inlet temperature at the manufacturer's specifications. Both CO and VOC emissions are significantly increased by water injection, with the level of CO and VOC emission increases dependent on the amount of water injection.[14] This increase in CO and VOC emissions could potentially warrant the installation of oxidation catalyst, resulting in significant additional costs to implement water injection.

[13] U.S. EPA, AP-42, Section 3.1.4.1, "Stationary Gas Turbines."

[14] Ibid.

6. REMAINING USEFUL LIFE OF SOURCES

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system.[15] Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.

6.1. GE 5221W TURBINE CONTROLS

6.1.1. Water Injection

The estimated useful life of a water injection control system is 15 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.

6.1.2. Steam Injection

The estimated useful life of a steam injection control system is 15 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.

6.2. GE M5322B TURBINE CONTROLS

6.2.1. Dry Low NOx Combustor

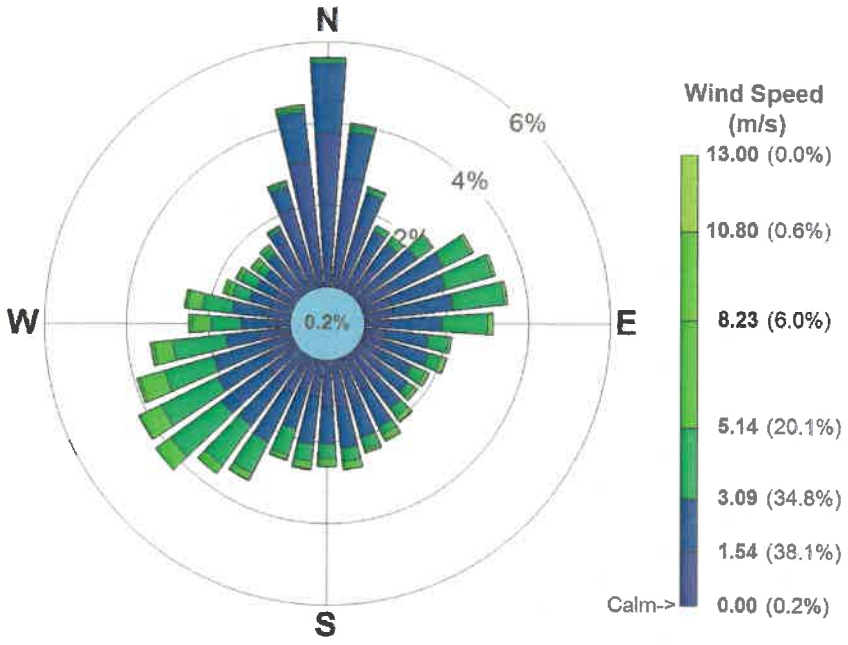
The estimated useful life of a dry low NO_X burner is 20 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.

6.2.2. Water Injection

The estimated useful life of a water injection control system is 15 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.

6.2.3. Steam Injection

The estimated useful life of a steam injection control system is 15 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.



---

[15] 40 CFR 51, Appendix Y, Section IV.D.4.k.

Enterprise does not believe that implementing any of the evaluated controls would meaningfully improve visibility in nearby Class I areas based on climatological data and ambient pollutant data.

The Blanco C&D Compressor Station is located approximately 50 miles from the Mesa Verde Class I area at a wind vector range of approximately 155 degrees to 165 degrees (SSE). According to 2015 meteorological data collected in Bloomfield, NM, which is presented in Figure 1 below, wind blows from this direction range at a frequency of only 2.4%. Moreover, when the wind direction is within this range, the wind speed is typically relatively low; the frequency of wind speeds greater than 3.09 m/s (or ~7 mph) is only 0.3%, or about 25 hours per year. Higher wind speeds would be needed to effectively transport emissions from Blanco to the Mesa Verde Class I area. Moreover, over the 50 miles of transport, pollutants undergo significant dispersion. While full dispersion and photochemical modeling would be needed to more robustly evaluate Blanco's impact, based on this evidence, Blanco's impact on visibility is likely insignificant.

Figure 1. Windrose Reporting 2015 Wind Direction and Speed in Bloomfield, NM

Additionally, according to aerosol composition data reported during visibility-impaired periods at the nearby San Pedro Parks and Mesa Verde IMPROVE Monitors, the main contributing pollutant to anthropogenic regional haze is ammonium sulfate.[16] Therefore, installing NO_X controls on the units at Blanco would not significantly improve visibility.

[16] See, e.g., U.S. EPA, Technical Support Document for EPA's Updated 2028 Regional Haze Modeling (Sept. 2019), App. B at pp. B-55 (Fig. 52), B-79 (Fig. 76); 2007 to 2017 Regional Haze Trends (https://www.env.nm.gov/wp content/uploads/sites/2/2019/02/2000_2017_trends-in-NM.pdf).

Re: NMED Follow-Up Letter Response
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC
Blanco C&D Compressor Station

Mr. Singleton:

Enterprise Field Services, LLC (Enterprise) submits herein to the New Mexico Environment Department (NMED) the enclosed responses to the follow-up questions contained in NMED correspondence dated December 23, 2019 for the Regional Haze Four-Factor Analysis submitted for the Enterprise Blanco C&D Compressor Station located in San Juan County, New Mexico.

Enterprise considers the information included in Appendix C of the enclosed response to be confidential business information (CBI) and request that it be treated as such to the full extent applicable.

Should you have questions or require further information regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828.

Thank you,
Enterprise Field Services, LLC

TABLE OF CONTENTS

1. RESPONSES TO THE NMED 1-3
   1. Selective Catalytic Reduction (SCR) Technology 1-3
   2. Water/Steam Injection 1-3
   3. Cost Effectiveness (*Dry LOW NO_x*) 1-4
   4. Emissions Data 1-4
   5. Other Control Options 1-5

APPENDIX A: AERIAL MAPS WITH SCR DIMENSIONS 1-7

APPENDIX B: UPDATED COST CALCULATIONS 1-9

APPENDIX C: VENDOR DOCUMENTATION 1-10

APPENDIX D: 2016 STACK TEST DATA 1-11

The NMED posed the following questions regarding the emissions control options Enterprise presented for the three (3) GE turbines: 5221W (2); 5322B (1).

1. SELECTIVE CATALYTIC REDUCTION (SCR) TECHNOLOGY

a. *You rejected consideration of SCR technology (CECO-Peerless) on account of space considerations; please provide more details on the specific dimensions and space required for SCR.*

Response: Enterprise received information from CECO-Peerless (Natalie Boone) on October 17, 2019, which stated that an area of approximately 40' by 20' is required for an SCR unit. This correspondence is included in Appendix C. As mentioned in our original report, space at the Blanco C & D Compressor Station is restricted. We have included aerial images in Appendix A of the facility with measurement overlays to demonstrate that the limited space precludes the option of installing an SCR.

b. *Please also provide an estimated NO_X control efficiency.*

Response: Because, as discussed above, space limitations at the Blanco C & D Compressor Station would preclude the installation of an SCR, and the control technology is therefore technically infeasible, the control efficiency was not estimated. However, based on information provided in AP-42 Section 3.1.4.3, an SCR can control NO_X emissions from turbines with a minimum efficiency of approximately 65%.[1]

2. WATER/STEAM INJECTION

a. *Your reported reduction effectiveness of 15% appears to be on the low side; a literature search suggests efficiencies greater than 50% to be more common. The AP-42 3.1.4.1 section you refer to in your analysis, in particular, indicates achievable NO_X reduction on the order of 60%. Table 3.1-1 within the same AP-42 document shows reduction from an uncontrolled 0.32 lb NO_X/MMBtu to 0.13 lb NO_X/MMBtu via Water-Steam Injection. Please clarify your 15% determination.*

Response: According to the Alternative Control Techniques document and the EPA Assessment of Non-EGU NO_X Emission Controls, NO_X can typically be controlled to 42 ppmv.[2, 3] The cost calculations have been updated to reflect this and are included in Appendix B. It should be noted that, as described in Section 2.1.2.3 of the original report, the original equipment manufacturer (General Electric) cannot guarantee a control efficiency for water/steam injection on the three turbines until the equipment has been installed and tested, which is the basis of using the AP-42 reduction efficiency of 15% in the original report. At this time, a third party

[2] Alternative Control Techniques Document – NOx Emissions from Stationary Gas Turbines, EPA-453/R-93-007. https://www3.epa.gov/airquality/ctg_act/199301_nox_epa453_r-93-007_gas_turbines.pdf

[3] Assessment of Non-EGU NOx Emission Controls, Cost of Controls, and Time for Compliance Final TSD. Docket ID No. EPA-HQ-OAR-2015-0500. https://www.env.nm.gov/wp-content/uploads/sites/2/2019/02/final_assessment_of_non-egu_nox_emission_controls_cost_of_controls_and_time_for_compliance_final_tsd-1.pdf

vendor has not been identified and no performance guarantee has been obtained for water/steam injection.

b. *Your mention of increased CO and Unburned Hydrocarbons (UHC) with this technology can, in fact, be mitigated through the water/fuel ratio, with lower ratios favoring smaller increases in undesired CO and UHC. How have you considered this in your analysis?*

Response: This mitigation technique is not discussed in AP-42 or the Alternative Control Techniques document, so this was not directly considered.[4] A literature review indicated, and NMED's question appears to recognize, that increases in VOC and CO emissions may result from use of this technology. Although it may be possible to mitigate the resulting VOC and CO emission increases with changes to the water/fuel ratio, emissions of those pollutants would nevertheless increase with use of that technology, thereby potentially reducing visibility improvement.

3. COST EFFECTIVENESS (*DRY LOW NO_X*)

a. *Please provide a vendor quote from Baker Hughes for the Dry Low NO_X system proposed for the GE 5322B turbine.*

Response: A vendor quote from Baker Hughes for the dry low NO_X burner is attached in Appendix C.

b. *Are there no other vendors who make similar systems that could be fitted to the GE 5221W turbines?*

Response: Baker Hughes is a subsidiary of General Electric. As mentioned in the original four-factor report, Baker Hughes/GE does not offer dry low NO_X technology for this unit. No vendors have been identified that would provide dry low NO_X technology with guaranteed NO_X performance.

4. EMISSIONS DATA

a. *Adjacent to the turbine NO_X emissions lb/hr and tpy data you provide in your analysis of Dry Low NO_X and Water/Steam Injection implementation is the statement, "from 2016 stack test data". Your 2016 Emissions Inventory submittal, however, does not match the data presented in your analysis (Unit T-CO1: 36.92 lb/hr, 158.60 tpy; Unit T-CO2: 51.56 lb/hr, 219.26 tpy; Unit T-DO1: 49.32 lb/hr, 197.37 tpy). Further observation of your 2016 Emissions Inventory supplemental attachment reveals lb/hr values for the turbine units do not match the ones you used in the analysis. Please clarify.*

Response: The stack tests conducted in 2016 at the facility, which reference the emissions, are included with this submission in Appendix D. The stack tests are the most accurate representation of engine emissions during 2016. These emissions, along with the hours of operation of each unit recorded that year, were used to represent the baseline emissions

[4] AP-42 Section 3.1.4.1 Stationary Gas Turbines, Control Technologies, Water Injection.

reported in the four-factor analysis report.

5. OTHER CONTROL OPTIONS

a. Have you considered other options not otherwise listed in your 4-Factor Analysis?

i. Staged Combustion

Response: AP-42 Section 3.1.2 provides a technical background on turbine combustion. The second paragraph of that section describes lean-premixed staged combustion.[5] That paragraph defines lean-premixed staged combustion as a synonym for dry low NO_X. If such a technology were to be implemented, it would not be appropriate to use a third-party vendor. The Baker Hughes (a General Electric subsidiary) dry low NO_X equipment is specifically designed to work effectively with GE turbines and has been robustly demonstrated on the GE M5322B turbine. While it may be possible to install a third-party burner on GE turbines, the performance cannot be guaranteed.

ii. Ultra-Lean Combustion

Response: Ultra-lean combustion is informally defined as dry low NO_X technology that can achieve relatively low NO_X emissions compared to dry low NO_X. However, there is no formal definition of this technology that clearly delineates ultra-low NO_X or ultra-lean combustion from lean combustion. As part of the original four-factor analysis, Enterprise requested information on the most effective dry low NO_X units currently available and used the information it received in preparing that analysis.

iii. Post-Combustion other than SCR (e.g., XONON, SCONO$_X$, NSCR)

Response: XONON is not a post-combustion technology. The XONON combustor is completely contained within the combustion chamber of the turbine. As stated in the US EPA Environmental Technology Verification report, "The design of each Xonon™ combustor is customized to the particular turbine model and operating conditions of the application and would typically be defined through a collaborative effort with the manufacturer of the turbine to integrate the hardware into the design."[6] Moreover, the Air Pollution Training Institute Manual for Controlling NO_X Formation in Gas Turbines states that, "Both GE and Solar Turbines have successfully operated on a 7.5 MW and a 10 MW engine using the XONON combustion system. Both engines demonstrated performance at less-than 2.5 ppmvd at 15% O2, but neither has yet made them commercially available, and it is not likely that they will."[7]

SCONO$_X$ was not identified in an exhaustive query of the RACT/BACT/LAER Clearinghouse (RBLC) and was not considered to be a widely implemented technology. Therefore, this technology was not considered. AP-42 Section 3.1.4.4 also states that the limited emission data available for SCONO$_X$ units cannot be used to robustly verify the manufacturer's claims for these units. Moreover, the technology is referred to as a "niche" technology, catering to a narrow range of turbines, in a DOE technical cost analysis document evaluating the costs of NO_X

[5] AP-42 Section 3.1.2 Stationary Gas Turbines, Process Description.

[6] Environmental Technology Verification Report – NO_X Control Technologies: Catalytica Combustion Systems, Inc. Xonon™ Flameless Combustion System, at 2 (December 2000). https://archive.epa.gov/nrmrl/archive-etv/web/pdf/05_vr_xonon.pdf

controls for turbines.[8] In this cost analysis, the cost per ton of NO_X controlled for the class of turbines installed at the Blanco C & D Compressor Station was greater than $16,000 (Table A-1). As that table in the cost analysis indicates, this technology is only relatively cost effective for turbines of at least 150 MW, or those typically used for power generation.

NSCRs were not identified in either the RBLC or AP-42 as a control option for turbines and were therefore not considered.[9]

Hello Rhett,

Yes, we are doing all good. Hope you all are okay too.

I've responded to the 3 follow-up items below in purple font. Please let us know if you need additional details.

Thanks
Tucker

Subject: [EXTERNAL] RE: Regional Haze 4-Factor Analysis: Carlsbad CS and Blanco C&D CS

[Use caution with links/attachments]
Hello Tucker,

The NMED has been working on other regional haze issues since we last were in regular contact with 4-factor facilities in March.

I want to follow up on Blanco C&D Compressor Station.

1) The errors encountered with South Carlsbad CS conversion from the stack testing results for which the adjusted O2 was not considered, also applies to Blanco C&D. I did not review in detail the ppm values for the Blanco C&D in detail. Please revisit the data to make any appropriate adjustments as you did for South Carlsbad CS. As mentioned in the 3/17/20 email; NOx concentrations used in the Blanco C & D analysis were adjusted for oxygen so no changes are needed.

2) Water/Steam Injection for Blanco C&D: There seems to be an incongruence between the attainable reduction amount shown in South Carlsbad CS vs. Blanco C&D. In the former, you appropriately indicated the 42 ppm attainable from EPA data (even though you also reference the 15% reduction that I have been unable to confirm in AP-42 you referred to – and to which I had also referenced larger percentage reduction within that very publication). The 42 ppm appears to be the value to go with based on the most current EPA literature (while AP-42 is dated). Please adjust Blanco C&D to reflect the 42 ppm limit as was done with South Carlsbad CS. In our follow-up response dated 2/14/20 and subsequent cost effectiveness revision dated 2/26/20, the cost effectiveness for water and steam technologies on the three turbines at Blanco C & D were based on the ability to control NOx to a concentration of 42 ppm. Attached is a copy of the non-CBI portion of the submittals. Maybe I don't understand your question?

3) Please provide a more detailed record of Enterprise's cost calculations for South Carlsbad CS and Blanco C&D CS, that include breakdowns of Annual O&M Costs, as well as Total Capital Investment Costs. For the latter, for example, the Blanco C&D CS T-D01 dry low NOx system capital cost reported in your 4-factor submittal is $8,205,400; whereas, the information provided in your follow-up CBI on page 4 of 4 is notably less (value not mentioned for CBI purposes). NMED needs to confirm that all cost categories you have considered are valid costs to be considered for 4-factor analysis. Below is an example of another industry's itemized breakdown of its cost categories (annual and other categories not shown for brevity). What cost year was used for your analysis?
Costs were assumed at present day values. The cost listed on Page 4 of 4 of the CBI information for Blanco C & D was the Purchased Equipment Cost (PEC) quoted from the DLN equipment vendor and did not include the Direct Installation Cost (DC) or Indirect Installation Cost (IC); hence the difference from the amount listed in "Total Cap Investment" on the cost effectiveness spreadsheet.

The "Total Capital Investment" amount listed for each unit is based on the following:

Total Capital Investment = PEC + DC + IC

- PEC is based on the estimated technology equipment cost
- DC is based on 25% of PEC
- IC is based on the sum of the following:
  - 3rd Party Engineering (3.75% of PEC)
  - Inspection (3.75% of PEC)
  - Enterprise (3.125% of PEC)
  - Contingency (10% of PEC)

The sum of PEC, DC, and IC was rounded up to the nearest $100

The "Total Annual Cost" amount listed for each type of turbine is outlined below:

Water Injection

Total Annual O&M Cost = Annual Inspection/Overhaul Cost (provided by OEM) + (18% of PEC)

Steam Injection

Total Annual O&M Cost = Annual Inspection/Overhaul Cost (provided by OEM) + (20% of PEC)

SoloNOx and DLN

Total Annual O&M Cost = Annual Inspection/Overhaul Cost provided by OEM

CAPITAL COST

Direct Costs

- Purchased equipment costs
  - Reactor housing
  - Ammonia handling and injection
    - Ammonia Injection Grid & dilution skid
    - Anhydrous ammonia tank
    - Air Compressors (plant's existing has spare
    - Vaporizers
    - Ammonia unloading skids
    - Ammonia supply pump skid
    - Miscellaneousequipment/components
    - Mixing Chamber (included)
    - Piping (ammonia supply, etc)
  - Initial catalyst (Ceram)
  - Flue gas handling: ductwork
  - Air heater modifications
  - ASH handling (e.g. conveyors)
  - Electrical equipment
  - Structrual steel
  - ID Fan
  - Misc. equipment
    - Sonic horns
    - LPA screens / rappers
    - NOx/NH3 monitoring
    - Flow modeling
      - Subtotal capital cost (CC)
  - Instruments and controls
  - Taxes
  - Freight
    - Total purchased equipment cost (PEC)

- Direct installation costs
  - Subsurface construction
    - Earthwork, underground utilities, etc.
    - Foundations (including embedments)
  - Superstructures construction
    - Reactor housing, ductwork, etc.
  - Demo and Rebuild
  - Mechanical construction
  - Electrical construction
  - Spare parts, training, TA
    - Total direct installation costs (DIC)

Total direct costs (DC) = (PEC) + (DIC)

Thank you, and I hope all is well you, with Enterprise staff and their families and friends.

Rhett,

This is not a typo. Based on the information we have available, to estimate annual NOx emissions with control, we took the ratio of the controlled guarantee concentration and the base uncontrolled concentration then multiplied the ratio by the base annual uncontrolled emissions. Since we were asked to use the 2016-2018 average reported in Annual Emission Inventories as our base, it resulted in a different controlled emission rate when compared against the original estimate that was based only on 2016 data.

Original (2016): 35 ppm/65ppm x 197.37 tpy = 106.3 tpy

-

Revised (2016-2018): 35 ppm/59 ppm x 215.21 tpy = 127.6 tpy

Hope this helps.

Thanks
Tucker

[Use caution with links/attachments]
Hello Tucker,

There appears to be an inconsistency/typo in the revised vs original 4F control tpy values for Blanco C&D on T-DO1. See highlighted below: the guarantee 35 ppm is the same in both cases; this should yield the same lb/hr and tpy, all else equal.

Revised Cost Analysis:

Blanco C&D Compressor Station

Re: NMED Follow-Up Discussion Response
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC
Blanco C & D Compressor Station

Mr. Singleton:

Enterprise Field Services, LLC ("Enterprise") submits herein to the New Mexico Environment Department (NMED) the responses to the follow-up requests from a virtual meeting held on August 28, 2020 for the Regional Haze Four-Factor Analysis submitted for the Enterprise Blanco C & D Compressor Station located in San Juan County, New Mexico. NMED requested information regarding six additional items identified as (a) through (f) in email correspondence dated September 2, 2020. Enterprise responded to each of the six items and committed to further developing and providing additional information for requests (b) and (c). The NMED follow-up requests and Enterprise responses for requests (b) and (c) are provided below.

Enterprise considers the information included in Attachment A of the enclosed response to be confidential business information (CBI) and requests that it be treated as such to the full extent of applicable law.

NMED Request (b): *We discussed an adjustment to the interest rate Enterprise originally used in its amortization of capital costs. You made an argument to use an interest rate higher than the adjusted rate of 3.25% NMED presented. Please provide in writing the reasoning for your higher interest rate (on top of the explanation provided in an email communication provided to NMED earlier this year), more precisely, the interest rate that would be specific to Enterprise for air pollution control projects. Note that no other New Mexico 4-factor submittal used an interest rate as high as the 8.38% you suggested would be appropriate to Enterprise. Providing official information from a potential lender would support your case when EPA and other entities review NMED's Regional Haze recommendations.*

Enterprise Response: In our original Four-Factor Analysis, Enterprise used an annual interest rate of 8.38% based on its application of a 2018 FERC rulemaking that reflected an average capital structure for Enterprise's industry of 57% equity (with an average 10.55% annual return) and 43%

www.enterpriseproducts.com

debt (to which Enterprise applied the then-applicable prime rate of 5.5%). This approach tracked the basic manner in which Enterprise's industry raises funds, i.e. through a combination of investment equity and taking on debt. The NMED's response stated that Enterprise's proposed rate "is appropriate for pipeline operation and construction, not for air pollution control technologies. The prime rate [3.25%] or a rate specific to Enterprise should be used, and a rate representative of 2020 conditions."

Enterprise respectfully disagrees with the NMED's statement that the FERC methodology is only appropriate for pipeline construction and operation. As noted during our August 28, 2020 virtual meeting, Enterprise's cost of capital is based on the company's overall health and financial condition and generally is not sensitive to the specific purpose for which capital is raised. Put another way, Enterprise would not expect to obtain a lower interest rate on expenses for air pollution control equipment than for other types of expenses such as pipeline construction and operation. Accordingly, we continue to believe that the 8.38% rate derived from the FERC methodology would have been suitable for the Four-Factor Analysis. We also do not believe that the NMED's proposed prime rate of 3.25%, which reflects highly unusual but ultimately temporary conditions in the economy as the result of the COVID-19 pandemic, is a suitable basis for calculating the cost of control measures that would be implemented years in the future when interest rates are likely to return to higher levels more commensurate with their historical patterns.

Nonetheless, at the NMED's request, Enterprise has calculated a company-specific interest rate of 9.62% as of June 30, 2020 and requests that the NMED rely on this interest rate to calculate the cost-effectiveness of potential control measures on our facilities. This interest rate was calculated by Enterprise's Finance department using the Capital Asset Pricing Model. We emphasize that this interest rate reflects our company's overall cost of capital and is applicable to capital raised for a range of purposes, including air pollution control costs, construction of new facilities, or otherwise. The specific calculations behind this interest rate are described in the confidential white paper included as Attachment A. Enterprise consents to disclosure of the 9.62% rate and this explanation in the NMED's public record. However, we request that the NMED treat the white paper itself (i.e. Attachment A) as our confidential business information.

Enterprise has revised the cost-effectiveness calculations for potential retrofit control technologies for the combustion units subject to the Four-Factor Analysis at the Blanco C & D Compressor Station using the calculated company-specific interest rate of 9.62%. The revised cost-effectiveness calculations are enclosed as Attachment B.

NMED Request (c): *Replacing turbines with electric compressors has not been excluded from consideration; therefore, a technical feasibility analysis and cost analysis is required. Given the deadline of September 10 for NMED to submit information to WRAP for the 2nd round PAC photochemical grid modeling, a qualitative ballpark estimate will suffice if you cannot put together a comprehensive analysis within the next week. However, a more complete analysis would be appreciated by the end of the month.*

Enterprise Response: To assess the potential conversion of combustion driven compressors to electric driven compressors, numerous significant considerations require evaluation. For the

purposes of this discussion, Enterprise has evaluated existing electrical capacity to determine the additional electrical capacity that likely would be required to provide equivalent station horsepower for the units that are subject to the Four-Factor Analysis. The total added electric load that would be required if the two GE Frame 5 turbines (T-CO1 and T-CO2) and one GE M5322B turbine (T-D01) were converted to electric driven units is approximately 63,000 kilowatts (KW) or 63 megawatts (MW). The electric provider, Farmington Electric Utility System (FEUS), is at peak capacity and therefore would need to invest in a new electricity generating station to provide the additional 63 MW needed. The cost of a new generating station is not included in the analysis but is estimated to cost approximately $2,500/KW, or $157,500,000 for 63 MW. Additionally, the increased electricity demand would require upgrades to the utility transmission infrastructure from the generating station to the Blanco C & D Compressor Station; these costs would be directly borne by Enterprise. The existing 2.5–mile, 69 kilovolt (kV) distribution system, including a substation, would need to be upgraded to 115 kV to provide the additional required load. In addition to replacing the three combustion driven compressor packages with electric compressor packages, Enterprise would need to construct additional utility infrastructure within the Blanco C & D Compressor Station to distribute the energy needed to drive the electric compressors. Cost-effectiveness figures for electrification of each unit (excluding third-party costs to install additional electricity generating capacity), including the cost estimation methodology used to estimate the total capital investment, is included in Attachment C. Please note that the electrification costs are based on best professional judgement and not reflective of an actual quoted facility-specific price. The timeline to implement electrification of the three units at the Blanco C & D Compressor Station would likely be between five and eight years, depending on the new third-party generating station source siting requirements, environmental permitting, and right of way negotiations. No consideration has been given to potential nitrogen oxide (NO_X) emissions as a result of generating the additional electrical capacity that would be necessary for electrification of the combustion units at the Blanco C & D Compressor Station.

Enterprise does not believe that any further evaluation of electrification of the three units at the Blanco C & D Compressor Station is warranted. Electrification is not technically feasible because of the necessary additional power generation and utility infrastructure upgrades needed by the local utility over which Enterprise has no control. Additionally, redefining a source is not a retrofit control technology and is beyond the authority of the Regional Haze Rule.

Should you have any questions regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828.

Sincerely,

Enterprise Field Services, LLC

W. Tucker Jacobson

Attachment A (Confidential Business Information)

Company-Specific Interest Rate Calculation

The Confidential information in this Attachment meets the conditions of NMAC § 20.2.1.115.B(3), as follows. Enterprise considers the information to be confidential, and requests that it be treated as such to the full extent of applicable law. We have taken reasonable measures to protect the confidentiality by keeping the information in secure data systems that are only available to authorized users, who are subject to confidentiality obligations per company policy, and by making this confidentiality claim. Further, neither NMED nor a third party could obtain the information without our consent, as this is information developed by Enterprise.

Economic Evaluation

Cost Component		Unit 12	Unit 13	Unit 14	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	$ -	$ -	-	Enterprise provided a cost estimate for electrification using EPA Cost Control Manual Section 5.2, which pertains to acid gas scrubbers. As this is not applicable to replacement with EMD, a Total Capital Cost metric of $2,084 (2023$/hp) was calculated using detailed cost information provided by other facilities. The TCI figure assumes no costs associated with substation or distribution line upgrades. This assumption underestimates costs given that Enterprise indicated in its August 2023 update that utility infrastructure upgrades would be needed to support electrification at all three of its facilities.

NMED Final Cost Evaluation
Enterprise Field Services - Chaco Gas Plant

Unit 17: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	175.5	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,461,535,403	scf/Year
	8586	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW
Plant Elevation	6020	Feet above sea level

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days	Number of SCR reactor chambers (n_{scr})	1
Number of days the boiler operates (t_{plant})	365	days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR	0.10	lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR	0.02	lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050		Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
			Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours		
Estimated SCR equipment life	20	Years*	Gas temperature at the SCR inlet (T)	650 °F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour		

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

* For industrial boilers, the typical equipment life is between 20 and 25 years.

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 17: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	176	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,491,154,219	scf/Year
Actual Annual fuel consumption (Mactual) =		1,461,535,403	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.980	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8586	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	14.04	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	60.27	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.25	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	638.74	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	19	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	900	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	103.90	kW

Unit 17: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$8,163,254	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$157,765 in 2024 dollars
Indirect Annual Costs (IDAC) =	$994,953 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$1,152,718 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$40,816 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$11,416 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$89,207 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$16,326 in 2024 dollars
Direct Annual Cost =		$157,765 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,118 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$991,835 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$994,953 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,152,718 per year in 2024 dollars
NOx Removed =	60 tons/year
Cost Effectiveness =	$19,125 per ton of NOx removed in 2024 dollars

Unit 18: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	178.5	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,486,518,914	scf/Year
	8632	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW
Plant Elevation	6020	Feet above sea level

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days	Number of SCR reactor chambers (n_{scr})	1
Number of days the boiler operates (t_{plant})	365	days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR	0.11	lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR	0.02	lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050		Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
			Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours		
Estimated SCR equipment life	20	Years*	Gas temperature at the SCR inlet (T)	650 °F
Concentration of reagent as stored (C_{stored})	29	percent*	Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK ft^3/min-MMBtu/hour
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14	days		

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

* For industrial boilers, the typical equipment life is between 20 and 25 years.

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 18: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	179	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,516,644,035	scf/Year
Actual Annual fuel consumption (Mactual) =		1,486,518,914	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.980	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8586	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	15.01	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	64.43	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.25	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	650.85	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	20	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	105.67	kW

Unit 18: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$8,253,687	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$160,838 in 2024 dollars
Indirect Annual Costs (IDAC) =	$1,005,946 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$1,166,785 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$41,268 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$12,203 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$90,732 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$16,636 in 2024 dollars
Direct Annual Cost =		$160,838 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,123 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$1,002,823 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$1,005,946 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$1,166,785 per year in 2024 dollars
NOx Removed =	64 tons/year
Cost Effectiveness =	$18,110 per ton of NOx removed in 2024 dollars

Unit 35: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	115.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	840,139,670	scf/Year
	7480	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	6020	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.23	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.05	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 35: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	116	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	983,906,887	scf/Year
Actual Annual fuel consumption (Mactual) =		840,139,670	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.854	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7480	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	20.98	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	78.45	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.25	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	440.78	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	8	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	28	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	4	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,300	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	68.55	kW

Unit 35: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$6,230,081	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$108,554 in 2024 dollars
Indirect Annual Costs (IDAC) =	$759,957 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$868,511 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$31,150 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$14,859 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$51,279 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$11,266 in 2024 dollars
Direct Annual Cost =		$108,554 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,002 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$756,955 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$759,957 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$868,511 per year in 2024 dollars
NOx Removed =	78 tons/year
Cost Effectiveness =	$11,071 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Enterprise Field Services - Chaco Gas Plant

Unit 36: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	115.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	688,173,230	scf/Year
	6127	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	6020	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.26	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.05	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 36: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	116	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	983,906,887	scf/Year
Actual Annual fuel consumption (Mactual) =		688,173,230	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.699	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6127	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	24.16	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	74.01	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.25	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	446.04	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	9	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	32	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	4	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,500	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	68.55	kW

Unit 36: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$6,230,081	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$98,573 in 2024 dollars
Indirect Annual Costs (IDAC) =	$759,957 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$858,529 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$31,150 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$14,018 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$42,004 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$11,400 in 2024 dollars
Direct Annual Cost =		$98,573 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,002 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$756,955 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$759,957 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$858,529 per year in 2024 dollars
NOx Removed =	74 tons/year
Cost Effectiveness =	$11,600 per ton of NOx removed in 2024 dollars

Unit 37: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	115.8	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	621,905,529	scf/Year
	5537	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	6020	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.26	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.05	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information

Unit 37: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	116	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	983,906,887	scf/Year
Actual Annual fuel consumption (Mactual) =		621,905,529	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.632	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	5537	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	23.74	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	65.74	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.25	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	445.35	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	9	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	32	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	4	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,500	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	68.55	kW

Unit 37: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$6,230,081	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$92,942 in 2024 dollars
Indirect Annual Costs (IDAC) =	$759,957 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$852,899 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$31,150 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$12,450 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$37,959 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$11,383 in 2024 dollars
Direct Annual Cost =		$92,942 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$3,002 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$756,955 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$759,957 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$852,899 per year in 2024 dollars
NOx Removed =	66 tons/year
Cost Effectiveness =	$12,975 per ton of NOx removed in 2024 dollars

Re: Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program
Enterprise Field Services, LLC
Blanco C&D Compressor Station and Chaco Gas Plant

Mr. Singleton:

Enterprise Field Services, LLC is submitting an analysis of control measures for the Blanco C&D Compressor Station and the Chaco Gas Plant in San Juan County, New Mexico, as requested by the NMED by letter dated July 18, 2019 and extended by the NMED letter dated October 29, 2019.

In addition, Enterprise has included legal comments, which are integral to Enterprise's position on the appropriateness of the control measures analyzed for all three facilities. For convenience and to avoid duplication, the legal comments are for the South Carlsbad Compressor Station, Blanco C&D Compressor Station and the Chaco Gas Plant.

If you have questions or require additional information, please contact me at (713) 381-6698 or by email at rmhavalda@eprod.com or Bradley Cooley at (713) 381-5828.

Thank you,

Robert Havalda, P.E.

Re: Request for Two-Week Extension for Submittal of the Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program
Enterprise Products Partners, L.P.

Mr. Havalda:

The New Mexico Environment Department Air Quality Bureau (AQB) has received and reviewed your written request to extend the submittal deadline for the Blanco C & D Compressor Station and Chaco Gas Plant four-factor analyses from November 1, 2019 to November 15, 2019.

This letter grants the requested extension. Should you have any additional questions or concerns as these reports are finalized, please do not hesitate to contact Mark Jones at 505.566.9746 (mark.jones@state.nm.us) or me at 505.476.4350 (kerwin.singleton@state.nm.us).

Sincerely,

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across with United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977. EPA has since amended the RHR in certain respects, most recently on January 10, 2017.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, the states, among other things:

(A) *"[E]valuate and determine the emission reduction measures that are necessary to make reasonable progress by considering the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment" and "include in [the state's] implementation plan a description of the criteria it used to determine which sources or groups of sources it evaluated and how the four factors were taken into consideration in selecting the measures for inclusion in its long-term strategy."* 40 CFR 51. 308(f)(2)(i). This is known as a four-factor analysis.

(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the state must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the state must consider the uniform rate of improvement in visibility. 40 CFR 51. 308(f)(1). The uniform rate of progress or improvement is sometimes referred to as the "URP" or the glidepath and is considered in the process of developing the state's Long Term Strategy (LTS).

The second implementation, or planning, period (2019-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Regional Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations. EPA has issued guidance to states for development of State Implementation Plans (SIPs) for regional haze requirements for the second planning period.[1,2]

[1] U.S. EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, EPA-457/B-19-003 (Aug. 2019); U.S. EPA, Technical Guidance on Tracking Visibility Progress for the Second Implementation Period of the Regional Haze Program, EPA-454/R-18-010 (Dec. 2018).

[2] U.S. EPA, Technical Support Document for EPA's 2028 Regional Haze Modeling (Sept. 2019).

Pursuant to 40 CFR 51.308(f)(2), the states are responsible for identifying sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for Title V sources and screened each facility's potential impact on visibility in Class I areas using a "Q/d" analysis, where "Q" is the magnitude of emissions that could impact ambient visibility and "d" is the distance of a facility to a Class I area. The NMED defined a source with a high potential for visibility impairment as one with a "Q/d" greater than 5.5. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019, the NMED informed Enterprise Field Services, LLC (Enterprise) that its facility, the Chaco Gas Plant, was identified as one of the sources potentially contributing to regional haze at the Mesa Verde Class I area.

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. The NMED's July 18, 2019 notification letter to Enterprise specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility that is subject to this analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	Unit No.	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
General Electric (GE) Frame 5 Turbines	17	78.5	344.0	Yes	2.1	9.1	No
	18	78.5	344.0	Yes	2.1	9.1	No
Solar Mars T-15000 Turbines	35	76.2	333.6	Yes	1.4	6.3	No
	36	76.2	333.6	Yes	1.4	6.3	No
	37	76.2	333.6	Yes	1.4	6.3	No
Clark TLA-10 2SLB SI-RICE Engines	12	49.7	218.0	Yes	< 1.0	1.9	No
	13	49.7	218.0	Yes	< 1.0	1.9	No
	14	49.7	218.0	Yes	< 1.0	1.9	No

*All emission rates reported in this table are on a per unit basis.

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified. One of the reference sources that the NMED has suggested consulting is the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Rate (LAER) Clearinghouse (RBLC).[3] In order to determine the most relevant and current retrofit controls available, the RBLC was queried for the previous ten years. Summaries of the results of this search are provided and discussed in Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The

[3] See NMED 2021 Regional Haze Planning Website ("Links to other information"). https://www.env.nm.gov/air-quality/reg-haze/

four-factor analysis was then conducted for those controls that are technically feasible at the Chaco Gas Plant site.

Based on the technical and economic factors summarized in this report, Enterprise has provided recommendations for the NMED in its efforts to design, in coordination with WRAP, the SIP under the RHR.

2.1. COMBUSTION TURBINES

Five of Chaco's natural gas-fired turbines (Units 17, 18, 35, 36, and 37) are subject to this four-factor analysis due to their NO_X emission rates. The only pollutant subject to evaluation for these units is NO_X.

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor, where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures of up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[4]

The treatment of the exhaust gases exiting the turbine dictates the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[5] The units at Chaco are regenerative cycle turbines, which are essentially simple cycle gas turbines with an added heat exchanger.

NO_x is formed via three fundamentally different mechanisms. The principal NO_x formation mechanism, thermal NO_x, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_x forms in the highest temperature regions of the combustion chamber. The second NO_x formation mechanism, fuel NO_x, arises from the evolution and reaction of fuel-bound nitrogen compounds with oxygen. The final NO_x formation mechanism, prompt NO_x, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_x is negligible in comparison to thermal and fuel NO_x. Fuel NO_x will also be negligible for Chaco's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_x.

The PTE from each turbine is reported in the facility's New Source Review (1555-M7) and Title V (116-R2-M1) permits and is summarized in Table 1.

2.1.2. Potential NO_X Controls for a Combustion Turbine

There are three general methods of controlling NO_X emissions from gas turbines: (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation, (2) dry controls that use

[4] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

[5] Ibid.

advanced combustor design to suppress NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[6]

The categories of retrofit control equipment identified for combustion turbines during a comprehensive review of the RBLC are reported in Table 2. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control, is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible	NO_X Control Efficiency
Good Combustion Practices and Fuel Selection	**Base Case**	**N/A**
SoloNOx	**Mars T-15000 Only**	**91%**
Dry Low NOx	**No**	**N/A**
Water/Steam Injection	**GE Only**	**15%**
Selective Catalytic Reduction	**No**	**N/A**

2.1.2.1. Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. Applying concepts from engineering knowledge, experience, and the manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for the equipment involved, and using pipeline quality natural gas. If good combustion practices are maintained, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at Chaco. However, these practices are currently in use at Chaco, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.1.2.2. Dry Low NO_X Combustor or SoloNOx

The key factors in thermal NO_X formation are the combustion temperature and the residence time of fuel in the combustor. Dry low NO_X burners (or SoloNOx for Solar Turbines) reduce NO_X emissions by reducing both of these factors. Ultimately, this is accomplished by optimizing the air-to-fuel ratio. According to information received from Solar, SoloNOx can reduce NO_X exhaust concentrations to 15 ppmv on the Mars T-15000 units. This corresponds to a control efficiency of approximately 90%.

[6] Ibid.

Enterprise requested quotes for dry low NO_x burners for the GE Frame 5 Turbines from Baker Hughes. The vendor stated that no burners were currently commercially available. Therefore, this option is not considered technically feasible for the GE Frame 5 units.

2.1.2.3. Water/Steam Injection

Water or steam injection is a technology that has been demonstrated to effectively suppress NO_X emissions from gas turbines. The effect of water and steam injection is to increase the thermal mass by dilution and thereby reduce peak temperatures in the flame zone. With water injection, there is an additional benefit of absorbing the latent heat of vaporization from the flame zone. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.

Water or steam injection is capable of reducing NO_x formation in the GE Frame 5 turbines with a control efficiency of 15%.[7]

Enterprise received information from Solar stating that the Mars T-15000 units cannot support steam injection and that Solar does not offer water injection equipment. Solar also stated that, while a third-party vendor may be able to develop water injection controls for the Mars Turbines, such controls might create a risk of damaging this equipment and any damage caused by water injection would not be covered under the equipment's warranty. Based on the statements from Solar regarding the installation of water and steam injection equipment, Enterprise does not consider this control technically feasible at these units.

However, Enterprise engineers believe that water or steam injection is feasible for the GE Frame 5 Turbines.

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream at a point downstream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[8] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O \quad \text{(Equation 1)}$$

$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O \quad \text{(Equation 2)}$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituents; thermal sintering, or compacting, of active sites due to high temperatures in the reactor; fouling caused by ammonia-sulfur salts and particulate matter in the gas; and erosion due to high gas velocities.[9]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form

---

[7] Ibid.
[8] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.
[9] Ibid.

ammonium sulfates, which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[10]

In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 °F and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[11]

An onsite evaluation was conducted at the Chaco facility during which measurements were taken of any feasible locations for SCR equipment. These measurements took into consideration the amount of buffer space needed to maintain accessibility to equipment and to avoid compromising worker safety. Based on size estimates of SCR units provided by CECO-Peerless, Enterprise determined that it is not possible to install these units at the Chaco facility.

2.2. TWO-STROKE LEAN-BURN ENGINES

The Chaco Gas Plant has three natural gas-fired two-stroke lean-burn engines, Units 12 through 14, that are subject to this four-factor analysis. The only pollutant subject to evaluation for these units is NO_X. Please note that in regards to these vintage Clark TLA-10 engines, there is no OEM support for these units.

2.2.1. Two-Stroke Lean-Burn Engines Background

A reciprocating internal combustion engine (RICE) is a device that uses the combustion of fuel and air in an internal chamber to generate a reciprocating motion and convert heat energy into mechanical work. The units use a piston to draw air and fuel into the combustion chamber and compress them. The compressed air/fuel mixture is then ignited, generating combustion in the chamber. The energy of combustion pushes out the piston, turning a crankshaft and producing mechanical work. In the same cycle, the products of combustion remaining in the chamber are released and exhausted from the unit.

Natural gas-fired RICE are categorized according to multiple design classes, including two-stroke lean-burn (2SLB), four-stroke lean-burn (4SLB), and four-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1), with exhaust oxygen levels less than 4%, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12% or more. The units at the Chaco Gas Plant evaluated here are 2SLB engines.

NO_X is formed in reciprocating engines via three mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

These engines use natural gas fuel, which contains a negligible amount of nitrogen compounds. Therefore, the formation of fuel and prompt NO_X will be insignificant. This analysis thus focuses on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion

[10] Ibid.
[11] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[12]

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:

(1) Parametric control methods, such as adjusting the timing or operating parameters.
(2) Combustion control techniques, for example, reducing the peak flame temperature or introducing inerts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X to elemental nitrogen (N_2).

The potential to emit (PTE) from each engine is reported in the facility's NSR (1555-M7) and Title V (116-R2-M1) permits, as well as above in Table 1. NO_X emissions from the RICE are calculated using stack test data collected on 4/18/1995. The maximum emission rate was used to represent emissions with a 5% safety factor to account for any variability in engine emissions. The maximum hourly emission rate corresponds to a NO_X exhaust concentration of 1032 ppmv.

2.2.2. Potential NO_X Controls for 2SLB Engines

The categories of retrofit control equipment that were identified for 2SLB reciprocating engines during a comprehensive review of the RBLC and available technical literature are reported in Table 3. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control, is provided below.

Table 3. Potential Control Options for 2SLB RICE

Control Equipment	Technically Feasible	NO_X Control Efficiency
Good Combustion Practices and Fuel Selection	**Base Case**	**N/A**
Selective Catalytic Reduction	**No**	**N/A**
Clean Burn Technology	**Base Case**	**N/A**

2.2.2.1. Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. Applying concepts from engineering knowledge, experience, and the manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for the equipment involved, and using pipeline quality natural gas. If good combustion practices are maintained, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is

[12] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines."

feasible for the units at Chaco. However, these practices are currently in use at Chaco, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.2.2.2. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream at a point downstream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O). The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O \quad \text{(Equation 1)}$$

$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O \quad \text{(Equation 2)}$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic controls to accurately meter the quantity of reagent injected as a function of engine load, speed, temperature, and NOx emissions reductions to be achieved. The lifespan of the catalyst is primarily determined by the erosion caused by the flue gas, deactivation caused by ammonium bisulfate (NH_4HSO_4) poisoning, and the build-up of and fouling by the catalyst.

For the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 °F and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted reagent in the exhaust can form ammonium sulfates, which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[13]

In engines that typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, either causing periods of ammonia slip or resulting in amounts of ammonia that are insufficient to obtain the emission reductions needed.[14]

An onsite evaluation was conducted at the Chaco facility during which measurements were taken of any feasible locations for SCR equipment. These measurements took into consideration the amount of buffer space needed to maintain accessibility to equipment and to avoid compromising worker safety. While installing an SCR on a two-stroke lean burn engine is not typical and may or may not be an effective means of NO_X reduction for such an engine, Enterprise determined that, based on the space limitations at Chaco, it would not be possible in any event to install SCR controls on the engines.

---

[13] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

[14] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines."

2.2.2.3. Clean Burn Technology

Clean Burn Technology (CBT) is a term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding or enhancing an air-to-fuel-ratio controller, making the unit capable of operating at these more desirable ratios.

Rich-burn engines are normally designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio of 16:1, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1). A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. 2SLB engines are typically, by design, configured to operate at the high air-to-fuel ratios employed in CBT; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease NO_X emissions.[15]

In order to avoid de-rating the engine, combustion air must be increased at constant fuel flow. To achieve this, the engine will need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel-ratio controller.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.

The Clark TLA-10 engines at Chaco are currently operating with CBT.

---

[15] State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines, State of New Jersey Department of Environmental Protection, 2003.

Enterprise has evaluated the costs of implementing the technically feasible control technologies at Chaco as thoroughly as possible in the time provided to complete this assessment. The cost estimates presented below are calculated according to methods and recommendations described in the EPA Air Pollution Control Cost Manual.[16]

Emission inventory data and stack test data from 2016 were used to assess the baseline emissions for these units.

3.1. GE FRAME 5 TURBINE CONTROLS

Table 4. Cost Analysis Summary of Technically Feasible Controls for GE Frame 5 Turbines

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
Water Injection	17	$106,606 per ton	Equipment, engineering, and installation costs. Operating and incremental OEM inspection costs.
	18	$106,784 per ton	
Steam Injection	17	$148,512 per ton	Equipment, engineering, and installation costs. Operating and incremental OEM inspection costs.
	18	$148,760 per ton	

3.1.1. Water Injection

Enterprise received a cost estimate from Baker Hughes to implement water injection control on the GE Frame 5 turbines at the Chaco Gas Plant (Units 17 and 18). This cost estimate is $6.6 million per unit in equipment cost, plus an additional $1.2 million per unit associated with annual operating cost. The control efficiency for water injection is estimated to be 15%, resulting in an emission rate reduction of 19.02 tpy and 18.99 tpy for Units 17 and 18, respectively. The projected useful life of this control equipment is 15 years. This results in an estimated control cost effectiveness of $106,606 per ton and $106,784 per ton of reduced NO_X emissions for Units 17 and 18, respectively.

3.1.2. Steam Injection

Enterprise received a cost estimate from Baker Hughes to implement steam injection control on the GE Frame 5 turbines at the Chaco Gas Plant. This cost estimate is $8.7 million per unit in equipment cost, plus an additional $1.8 million per unit associated with annual operating cost. The control efficiency for steam injection is estimated to be 15%, resulting in an emission rate reduction of 19.02 tpy and 18.99 tpy for Units 17 and 18, respectively. The projected useful life of this control equipment is 15 years. This results in an estimated control cost effectiveness of $148,512 per ton and $148,760 per ton of reduced NO_X emissions for Units 17 and 18, respectively.

[16] U.S. EPA, "Air Pollution Control Cost Manual," available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

3.2. SOLAR MARS T-15000 TURBINE CONTROLS

Table 5. Cost Analysis Summary of Technically Feasible Controls for Mars T-15000 Turbines

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
SoloNOx	35	$6,800 per ton	Equipment costs, annual overhaul and labor costs
	36	$6,668 per ton	
	37	$9,435 per ton	

3.2.1. SoloNOx

For the Solar Mars T-15000 turbines (Units 35, 36, and 37), Enterprise received capital cost estimates from Solar for the SoloNOx control equipment of $5.6 million, $5.4 million, and $5.4 million for Units 35, 36, and 37, respectively. Based on equipment overhaul cost information provided by Solar, other associated annual costs are estimated to be $124,567 per unit. The expected useful life of this control equipment is 20 years. Based on the target NOx exhaust concentration of 15 ppmv provided by Solar, the expected control efficiencies associated with SoloNOx are 88%, 88%, and 85% for Units 35, 36, and 37, respectively. This results in an amortized cost effectiveness of $6,800, $6,668, and $9,435 per ton for Units 35, 36, and 37, respectively.

4. TIME NECESSARY FOR COMPLIANCE

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of Enterprise's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

Enterprise estimates that approximately 3 to 4 years would be needed to budget for, design, procure, and construct those categories of control equipment discussed in this report that would be technically feasible to install on the respective units.

5. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS OF COMPLIANCE

This section addresses the potential energy and non-air quality environmental impacts that would result from installation of technically feasible control options at Chaco. Consideration of energy impacts involves assessing the impact of a control measure on the amount of energy that the source would have to consume. Non-air quality environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air quality environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

5.1. GE FRAME 5 TURBINE AND SOLAR MARS T-15000 TURBINE CONTROLS

5.1.1. Water and Steam Injection

Water or steam injection is usually accompanied by an efficiency penalty (typically 2% to 3%) but an increase in power output (typically 5% to 6%).[17] The increase in power output results from the increased mass flow required to maintain the turbine inlet temperature at the manufacturer's specifications. Both CO and VOC emissions are significantly increased by water injection, with the level of CO and VOC emission increases dependent on the amount of water injection.[18] This increase in CO and VOC emissions could potentially warrant the installation of oxidation catalyst, resulting in significant additional costs to implement water injection.

5.1.2. SoloNO$_X$

There would be no anticipated unique or site-specific energy or non-air quality environmental impacts from installation and operation of SoloNO$_X$ on the Mars T-15000 turbines at Chaco.

[17] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

[18] Ibid.

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system.[19] Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.

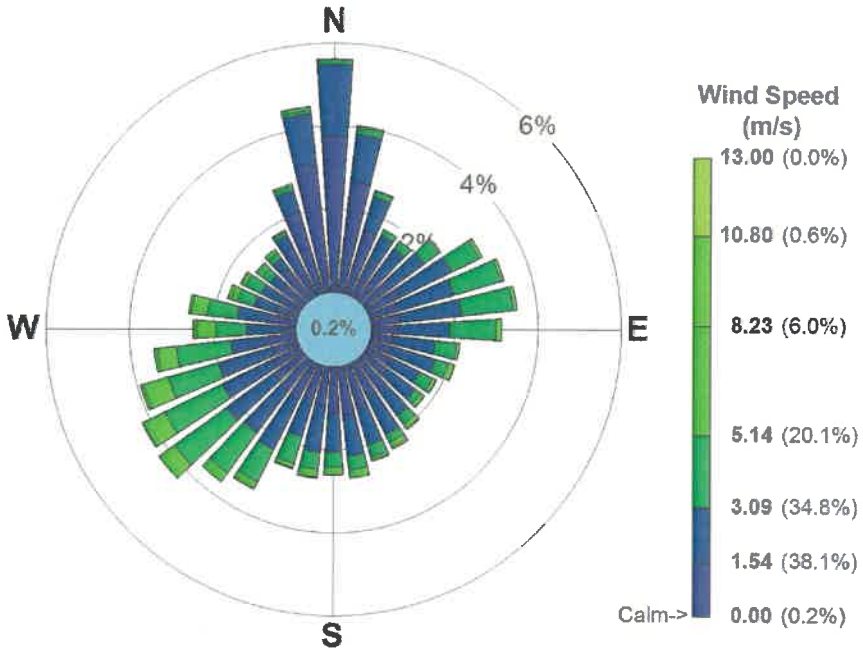
6.1. GE FRAME 5 TURBINE CONTROLS

6.1.1. Water and Steam Injection

The estimated useful life of a water or steam injection control system is 15 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.

6.2. SOLAR MARS T-15000 TURBINE CONTROLS

6.2.1. SoloNO$_X$



The estimated useful life of a SoloNO$_X$ control is 20 years. This estimate has been incorporated in the cost analysis section in calculating the total annualized cost of the control.

[19] 40 CFR 51, Appendix Y, Section IV.D.4.k.

Enterprise does not believe that implementing any of the evaluated controls would meaningfully improve visibility in nearby Class I areas based on climatological data and ambient pollutant data.

The Chaco Gas Plant is located approximately 50 miles from the Mesa Verde Class I area at a wind vector range of approximately 155 degrees to 165 degrees (SSE). According to 2015 meteorological data collected in Bloomfield, NM, which is presented in Figure 1 below, wind blows from this direction at a frequency of only 2.4%. Moreover, when the wind direction is within this range, the wind speed is typically relatively low; the frequency of wind speeds greater than 3.09 m/s (or ~7 mph) is only 0.3%, or about 25 hours per year. Higher wind speeds would be needed to effectively transport emissions from Chaco to the Mesa Verde Class I area. Moreover, over the 50 miles of transport, pollutants undergo significant dispersion. While full dispersion and photochemical modeling would be needed to more robustly evaluate Chaco's impact, based on this evidence, Chaco's impact on visibility is likely insignificant.

Figure 1. Windrose Reporting 2015 Wind Direction and Speed in Bloomfield, NM

Additionally, according to aerosol composition data reported during visibility-impaired periods at the nearby San Pedro Parks and Mesa Verde IMPROVE Monitors, the main contributing pollutant to anthropogenic regional haze is ammonium sulfate.[20] Therefore, installing NO_X controls on the units at Chaco would not significantly improve visibility.

[20] See, e.g., U.S. EPA, Technical Support Document for EPA's Updated 2028 Regional Haze Modeling (Sept. 2019), App. B at pp. B-55 (Fig. 52), B-79 (Fig. 76); 2007 to 2017 Regional Haze Trends (https://www.env.nm.gov/wp content/uploads/sites/2/2019/02/2000_2017_trends-in-NM.pdf).

Re: NMED Follow-Up Letter Response
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC
Chaco Gas Plant

Mr. Singleton:

Enterprise Field Services, LLC (Enterprise) submits herein to the New Mexico Environment Department (NMED) the enclosed responses to the follow-up questions contained in NMED correspondence dated December 23, 2019 for the Regional Haze Four-Factor Analysis submitted for the Enterprise Chaco Gas Plant located in San Juan County, New Mexico.

Enterprise considers the information included in Appendix B of the enclosed response to be confidential business information (CBI) and requests that it be treated as such to the full extent applicable.

Should you have questions or require further information regarding this submittal, please contact Tucker Jacobson at 713-381-4313 (wtjacobson@eprod.com) or Bradley Cooley at 713-381-5828.

Thank you,
Enterprise Field Services, LLC

TABLE OF CONTENTS

1. RESPONSES TO THE NMED 1-3
1. Engines 1-3
2. Flaring 1-5
3. Turbines 1-6

APPENDIX A: AERIAL MAP WITH SCR DIMENSIONS 1-9

APPENDIX B: VENDOR DOCUMENTATION 1-10

1. ENGINES

The NMED requested the following information regarding the three Clark 2SLB engines (Units 12, 13, and 14) installed at the Chaco Gas Plant.

a. *Please provide a more thorough Selective Catalytic Control (SCR) evaluation. Include documentation of the spacing evaluation on SCR equipment and verify how that makes it impossible to install at the site. Are there other possible installation designs and what would the potential emissions reductions be? If there are other restrictions or problems with potential SCR installation, please provide documentation.*

Response: Enterprise received information from CECO-Peerless (Natalie Boone) on October 17, 2019, which stated that an area of approximately 40' by 20' is required for an SCR unit. This correspondence is included in Appendix B. The size estimate was not specific to a specific configuration of an SCR, but rather was a generic conservative estimate for any SCR unit. As mentioned in our original report, space at the Chaco Gas Plant is restricted. We have included an aerial image of the facility in Appendix A with measurement overlays to demonstrate that the limited space precludes the option of installing SCR.

b. *Please verify and provide documentation that control systems have not yet been developed for SCR controls that can handle variable load engines. This appears to be one main reason that SCR has not been implemented on 2SLB internal combustion engines in oil and gas midstream operations.*

Response: Per our initial submission, AP-42 Section 3.2 is referenced to support this claim. Section 3.2.4.2 states the following: "SCR is most suitable for lean-burn engines operated at constant loads, and can achieve efficiencies as high as 90 percent. For engines which typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed."[1]

c. *Consider Good Combustion Practices (GCP) and the routine maintenance as controls and provide the details how both would be achieved including a maintenance schedule and procedures.*

Response: As stated in our original submittal, Good Combustion Practices (GCP) are currently implemented at the Chaco Gas Plant. The following routine maintenance and monitoring are conducted on the Clark engines: Engine oil is sampled monthly, internal inspections are conducted annually, emissions testing is conducted annually, and the engines' turbochargers are replaced every 5 years. The following maintenance kits are replaced in a cycle; one kit is replaced every 2,000 hours of operation:

Kit A – The following parts are replaced: Ignition wiring, spark plugs and wires, primary and secondary coils, and inlet filters.

[1] AP-42 Section 3.2.4.2 Natural Gas-fired Reciprocating Engines, Control Technologies, Control Techniques for Lean-burn Reciprocating Engines, Selective Catalytic Reduction.

Kit B – Air filters are replaced.

Kit C – Engine speed sensors, wiring, and cables are replaced. Yard valve, waste gate, and jacket water valve positionings are checked and corrected.

Kit D – Air filters, thermocouples, and thermocouple wiring are replaced.

For each of the kits, the transmitter calibration is checked; Thermocouple, pressure level. and vibration function are tested; yard valve positioning, waste gate positioning, and jacket water valve positioning are checked.

d. *Consider and include a discussion on the feasibility and cost of technology that limits engine capacity to reduce NO_X emissions. Also evaluate limitations on engine operating hours or shutting down engines that are no longer needed to reduce emissions.*

Response: Enterprise cannot commit to decreasing engine capacity as the facility must meet contractual demands. Additionally, it is important to retain the flexibility to operate at maximum capacity to facilitate the transfer of gas from upstream facilities and to maintain a stable infrastructure to handle that demand..

e. *Please consider and include a discussion on the feasibility of replacing natural gas-fueled engines/turbines with commercial electric powered compressors.*

Response: 40 CFR 51 Appendix Y, states the following: "We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis."[2] Replacing the existing combustion engines with electric powered engines may be feasible; however, numerous engineering evaluations would be required, and it is anticipated that there would be substantial obstacles in converting these units to electric.

f. *Provide information on the Clean Burn Technology (CBT) used in the base case. Consider and include a discussion of variations of CBT used to reduce NO_X emissions that may be more effective than the existing package if available. Please include cost and efficiencies in analysis.*

Response: Altronic Ignition Control Systems and engine balancing are currently being implemented on these units. At this time, Enterprise has not identified any other variations of CBT for the Clark TLA-10 model; if any other variations are identified to be available and feasible they will be considered.

g. *Provide vendor specifications that include the cost information, recommendations, and equipment specifications for the engine cost control estimates.*

Response: As stated above, the engines utilize Altronic Ignition Control Systems and engine balancing to control NO_X emissions. At this time, Enterprise has not identified any other

[2] 40 CFR 51 Appendix Y: Guidelines for BART Determinations Under the Regional Haze Rule, Section IV.D.1.5.

variations of CBT for the Clark TLA-10 model; if any other variations are identified to be available and feasible they will be considered.

h. *Provide any electronic spreadsheets used for control technology calculations.*

Response: At this time, Enterprise has not identified any other variations of CBT for the Clark TLA-10 model; if any other variations are identified to be available and feasible they will be considered.

2. FLARING

The NMED requested the following information regarding the flares installed at the Chaco Gas Plant.

a. *Provide a description of each flare, the design and type, and its purpose.*

Response: Units 42 and 43 are a staged flare system. Unit 42 is a Zeeco UFA-6-24 candlestick flare and Unit 43 is a Zeeco four-staged ground level flare. Although they are identified separately, the units consist of one ground flare. The flare functions as a process flare and an emergency/upset flare. Under normal operation, the flare has a continuous methane pilot and purge gas estimated at 200 scf/hr. The flare controls emissions from compressor station vents, drain valves, and relief valves from the inlet of the plant. In addition, NGL and methanol bullet tanks, storage tank relief valves, pressure regulator valves, drain valves, and vents associated with the inlet compression are tied to the flare for safety.

Unit 44 is a flare used as a process flare, a startup, shutdown, and maintenance (SSM) flare, and an emergency/upset control device for the cryogenic liquids plant. Under normal conditions, the flare operates on pilot and purge gas with a flow of approximately 200 scf/hr (per manufacturer's data), and condenser off-gas from the glycol dehydration unit with a flow of approximately 300 scf/hr is routed to the flare for destruction. This flare will also serve to control emissions from the methyldiethanolamine (MDEA) sweetening unit when the thermal oxidizer is down.

b. *Complete a review and include an analysis about how the entire facility and/or source specific operations can be improved to reduce the frequency of Startup, Shutdown and Maintenance (SSM) flaring events. If it is not possible to make any improvements to the facility or its processes to reduce SSM flaring events, then please explain why.*

Response: Enterprise does not believe that any control practices or techniques could be implemented to reduce flaring emissions at this facility. The units have hourly emission rates of less than 10 pounds per hour and/or 5 tons per year for SO_2. As a result, none of these flares are required to undergo a Four-Factor Analysis for SO_2. In regard to NO_X, only Flare 44 is over the 10 lb/hr and 5 tons per year threshold; however, its emissions are quite small in regard to impacting the regional haze at Mesa Verde.

3. TURBINES

The NMED requested the following information for NO_X from Turbine Unit Numbers 35, 36, 37, 17, and 18.

a. *Please provide a more thorough SCR evaluation. Include documentation of the spacing evaluation on SCR equipment and verify how that makes it impossible to install at the site. Are there other possibilities of installation designs and what would the potential emissions reductions be? If there are other restrictions or problems with potential SCR installation, please provide documentation.*

Response: Enterprise received information from CECO-Peerless (Natalie Boone) on October 17, 2019, which stated that an area of approximately 40' by 20' is required for an SCR unit. This correspondence is included in Appendix B. The size estimate was not specific to a specific configuration of an SCR, but rather was a generic conservative estimate for any SCR unit. As mentioned in our original report, space at the Chaco Gas Plant is restricted. We have included an aerial image of the facility in Appendix A with measurement overlays to demonstrate that the limited space precludes the option of installing SCR.

At this time, Enterprise has not fully evaluated engineering concerns associated with the installation of SCR controls as SCR was determined to be technically infeasible during the preparation of the initial four-factor report. Since a full engineering study was not conducted to determine specific design and operating parameters, Enterprise projects that a minimum NO_X control efficiency of 65% could be achieved with the SCR, according to AP-42. [3]

b. *Provide vendor specifications for the SoLoNO$_X$ Dry Low NO$_X$ (DLN) combustion technology to include the guaranteed NO$_X$ emission rates used in cost analysis, the cost information, recommendations, and equipment specifications for the turbine control estimates.*

Response: A vendor quote from Solar for the SoLoNO$_X$ conversion is attached (sent September 19, 2019). There are two components to the total cost considered: (1) the capital cost of the SoLoNO$_X$ unit (which includes equipment cost from Solar, installation, engineering, and inspection) and (2) the incremental annual overhaul costs. The incremental annual overhaul costs are based on hourly overhaul rates for the gas producer and power turbine, which differ for units that are operating with or without SoLoNO$_X$. This information was provided by Solar on October 22, 2019. The capital and overhaul costs are amortized with the specified interest rate to calculate an annualized total capital investment. This information is submitted with this response in Appendix B.

c. *How will upgrading the turbine combustors with SoLoNO$_X$ affect the turbine capacities and the emission rates of NO$_X$ and CO?*

Response: According to documentation received from Solar on September 19, 2019, the SoLoNO$_X$ unit would reduce the NO_X exhaust concentration from 125 ppm to 15 ppm. According, to AP-42, CO emissions would be increased from the implementation of this control,[4] but Solar has not provided any guidance on the magnitude of the emission increase.

---

[3] AP-42 Section 3.1.4.3 Stationary Gas Turbines, Control Technologies, Catalytic Reduction System.

[4] AP-42 Section 3.1.4.2 Stationary Gas Turbines, Control Technologies, Dry Controls.

d. *Provide the statement by the turbine vendor stating why water injection is not technically feasible for Solar Turbines.*

Response: As discussed in Enterprise's original submission in November 2019, Solar stated on October 21, 2019 (*see* Appendix B to this report) that they do not offer water injection on the Mars 15000 turbine. As mentioned in Enterprise's November 2019 submission, it may be possible to install a third-party water-steam injection system on Solar turbines, but such a modification could void the turbines' warranty should damage to the unit be caused by the third-party equipment.

e. *Provide more detail of the GCP that have been implemented on the turbines, including routine inspections, maintenance and training schedules. It is unclear if these practices are fully optimized or conform to permit conditions alone.*

Response: As stated in Enterprise's original submission, Good Combustion Practices (GCP) are currently implemented at the Chaco Gas Plant. Regular maintenance activities for the Solar Mars 15000 turbines (Units 35, 36, and 37) include the following: Oil is sampled monthly and emission testing occurs annually. The following maintenance activities also occur annually: Air filters and oil filters are replaced, boroscope inspections and a water wash occur, and Solar representatives perform original equipment manufacturer (OEM) checks and emission testing. Additionally, all transmitters, levels, pressures, and vibration sensors are tested, and DC rundown tests occur.

f. *Please consider and include a discussion on the feasibility of replacing the natural gas-fueled turbines with commercial electric powered turbines.*

Response: 40 CFR 51 Appendix Y, states the following: "We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis."[5] Replacing the existing turbines with electric powered motors may be feasible; however, numerous engineering evaluations would be required, and it is anticipated that there would be substantial obstacles in converting these units to electric.

g. *Provide the electronic spreadsheets used for control technology calculations.*

Response: The electronic spreadsheet used to quantify cost effectiveness has been submitted via email to NMED.

h. *Please include a discussion of the following control options to reduce NO_X emissions: catalytic combustion such as a XONON™ developed by Catalytic Combustion Systems, Incorporated (CESI), lean and staged combustion technology from turbine manufacturers other than Solar, and complete a four-factor analysis on technically feasible options. That Solar does not manufacturer a particular control method or turbine combustor is not grounds for eliminating an option for technical reasons.*

[5] 40 CFR 51 Appendix Y: Guidelines for BART Determinations Under the Regional Haze Rule, Section IV.D.1.5.

i. XONON™

Response: XONON is not a post combustion technology. The XONON combustor is completely contained within the combustion chamber of the turbine. As stated in the US EPA Environmental Technology Verification report, "The design of each Xonon™ combustor is customized to the particular turbine model and operating conditions of the application and would typically be defined through a collaborative effort with the manufacturer of the turbine to integrate the hardware into the design."[6] Moreover, the Air Pollution Training Institute Manual for Controlling NO_X Formation in Gas Turbines states that, "Both GE and Solar Turbines have successfully operated on a 7.5 MW and a 10 MW engine using the XONON combustion system. Both engines demonstrated performance at less-than 2.5 ppmvd at 15% O_2, but neither has yet made them commercially available, and it is not likely that they will."[7]

ii. Staged and Lean Combustion

Response: AP-42 Section 3.1.2 provides a technical background on turbine combustion. The second paragraph of that section describes lean-premixed staged combustion.[8] That paragraph defines lean-premixed staged combustion as a synonym for dry low NO_X. SoLoNO$_X$ is Solar's proprietary dry low NO_X combustor, which would be synonymous with this option. If such a technology were to be implemented, it would not be appropriate to use a third-party vendor for Solar turbines. The SoLoNO$_X$ burners are specifically designed to work effectively with Solar turbines and have been widely implemented on Solar's units. While it may be possible to install a third-party burner on Solar turbines, the performance cannot be guaranteed and, as stated by Solar in correspondence dated October 21, 2019 (Attachment B), such a modification could void the turbines' warranty should damage be caused to the unit by third-party equipment.

Re: NMED Follow-Up Discussion Response
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC
Chaco Gas Plant

Mr. Singleton:

Enterprise Field Services, LLC ("Enterprise") submits herein to the New Mexico Environment Department (NMED) its responses to the follow-up requests from a virtual meeting held on August 28, 2020 for the Regional Haze Four-Factor Analysis submitted for the Enterprise Chaco Gas Plant located in San Juan County, New Mexico. The NMED requested information regarding six additional items identified as (a) through (f) in email correspondence dated September 2, 2020. Enterprise responded to each of the six items and committed to further developing and providing additional information for requests (b) and (c). The NMED follow-up requests and Enterprise responses for requests (b) and (c) are provided below.

Enterprise considers the information included in Attachment A of the enclosed response to be confidential business information (CBI) and requests that it be treated as such to the full extent of applicable law.

NMED Request (b): *We discussed an adjustment to the interest rate Enterprise originally used in its amortization of capital costs. You made an argument to use an interest rate higher than the adjusted rate of 3.25% NMED presented. Please provide in writing the reasoning for your higher interest rate (on top of the explanation provided in an email communication provided to NMED earlier this year), more precisely, the interest rate that would be specific to Enterprise for air pollution control projects. Note that no other New Mexico 4-factor submittal used an interest rate as high as the 8.38% you suggested would be appropriate to Enterprise. Providing official information from a potential lender would support your case when EPA and other entities review NMED's Regional Haze recommendations.*

HOUSTON, TEXAS 77002-5227
www.enterpriseproducts.com

Enterprise Response: In our original Four-Factor Analysis, Enterprise used an annual interest rate of 8.38% based on its application of a 2018 FERC rulemaking that reflected an average capital structure for Enterprise's industry of 57% equity (with an average 10.55% annual return) and 43% debt (to which Enterprise applied the then-applicable prime rate of 5.5%). This approach tracked the basic manner in which Enterprise's industry raises funds, i.e. through a combination of investment equity and taking on debt. The NMED's response stated that Enterprise's proposed rate "is appropriate for pipeline operation and construction, not for air pollution control technologies. The prime rate [3.25%] or a rate specific to Enterprise should be used, and a rate representative of 2020 conditions."

Enterprise respectfully disagrees with the NMED's statement that the FERC methodology is only appropriate for pipeline construction and operation. As noted during our August 28, 2020 virtual meeting, Enterprise's cost of capital is based on the company's overall health and financial condition and generally is not sensitive to the specific purpose for which capital is raised. Put another way, Enterprise would not expect to obtain a lower interest rate on expenses for air pollution control equipment than for other types of expenses such as pipeline construction and operation. Accordingly, we continue to believe that the 8.38% rate derived from the FERC methodology would have been suitable for the Four-Factor Analysis. We also do not believe that the NMED's proposed prime rate of 3.25%, which reflects highly unusual but ultimately temporary conditions in the economy as the result of the COVID-19 pandemic, is a suitable basis for calculating the cost of control measures that would be implemented years in the future when interest rates are likely to return to higher levels more commensurate with their historical patterns.

Nonetheless, at the NMED's request, Enterprise has calculated a company-specific interest rate of 9.62% as of June 30, 2020 and requests that the NMED rely on this interest rate to calculate the cost-effectiveness of potential control measures on our facilities. This interest rate was calculated by Enterprise's Finance department using the Capital Asset Pricing Model. We emphasize that this interest rate reflects our company's overall cost of capital and is applicable to capital raised for a range of purposes, including air pollution control costs, construction of new facilities, or otherwise. The specific calculations behind this interest rate are described in the confidential white paper included as Attachment A. Enterprise consents to disclosure of the 9.62% rate and this explanation in the NMED's public record. However, we request that the NMED treat the white paper itself (i.e. Attachment A) as our confidential business information.

Enterprise has revised the cost-effectiveness calculations for potential retrofit control technologies for the combustion units subject to the Four-Factor Analysis at the Chaco Gas Plant using the calculated company-specific interest rate of 9.62%. The revised cost-effectiveness calculations are enclosed as Attachment B.

NMED Request (c): *Replacing turbines with electric compressors has not been excluded from consideration; therefore, a technical feasibility analysis and cost analysis is required. Given the deadline of September 10 for NMED to submit information to WRAP for the 2nd round PAC photochemical grid modeling, a qualitative ballpark estimate will suffice if you cannot put together*

a comprehensive analysis within the next week. However, a more complete analysis would be appreciated by the end of the month.

Enterprise Response: To assess the potential conversion of combustion driven compressors to electric driven compressors, numerous significant considerations require evaluation. For the purposes of this discussion, Enterprise has evaluated existing electrical capacity to determine the additional electrical capacity that likely would be required to provide equivalent station horsepower for the units that are subject to the Four-Factor Analysis. The total added electric load that would be required if the three Clark TLA-10 engines (Units 12, 13, and 14), two GE Frame 5 turbines (Units 17 and 18), and three Solar Mars T-15000 turbines (Units 35, 36, and 37) were converted to electric driven units is approximately 93,000 kilowatts (KW) or 93 megawatts (MW). The electric provider, Farmington Electric Utility System (FEUS), is at peak capacity and therefore would need to invest in a new electricity generating station to provide the additional 93 MW needed. The cost of a new generating station is not included in the analysis but is estimated to cost approximately $2,500/KW, or $232,500,000 for 93 MW. Additionally, the increased electricity demand would require upgrades to the utility transmission infrastructure from the generating station to the Chaco Gas Plant; these costs would be directly borne by Enterprise. The existing 46.7–mile, 69 kilovolt (kV) distribution system, including three substations, would need to be upgraded to 115 kV to provide the additional required load. In addition to replacing the eight combustion driven compressor packages with electric compressor packages, Enterprise would need to construct additional utility infrastructure within the Chaco Gas Plant to distribute the energy needed to drive the electric compressors. Cost-effectiveness figures for electrification of each unit (excluding third-party costs to install additional electricity generating capacity), including the cost estimation methodology used to estimate the total capital investment, is included in Attachment C. Please note that the electrification costs are based on best professional judgement and not reflective of an actual quoted facility-specific price. The timeline to implement electrification of the eight units at the Chaco Gas Plant would likely be between five and eight years, depending on the new third-party generating station source siting requirements, environmental permitting, and right of way negotiations. No consideration has been given to potential nitrogen oxide (NO_X) emissions as a result of generating the additional electrical capacity that would be necessary for electrification of the combustion units at the Chaco Gas Plant.

Enterprise does not believe that any further evaluation of electrification of the eight units at the Chaco Gas Plant is warranted. Electrification is not technically feasible because of the necessary additional power generation and utility infrastructure upgrades needed by the local utility over which Enterprise has no control. Additionally, redefining a source is not a retrofit control technology and is beyond the authority of the Regional Haze Rule.

Should you have any questions regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828.

Sincerely,

Enterprise Field Services, LLC

W. Tucker Jacobson

Attachment A (Confidential Business Information)

Company-Specific Interest Rate Calculation

The Confidential information in this Attachment meets the conditions of NMAC § 20.2.1.115.B(3), as follows. Enterprise considers the information to be confidential, and requests that it be treated as such to the full extent of applicable law. We have taken reasonable measures to protect the confidentiality by keeping the information in secure data systems that are only available to authorized users, who are subject to confidentiality obligations per company policy, and by making this confidentiality claim. Further, neither NMED nor a third party could obtain the information without our consent, as this is information developed by Enterprise.

Economic Evaluation

Cost Component		Unit 1	Unit 2	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	$ -	-	A retrofit factor of 1.1 was used in the EPA SCR Tool to account for the additional capital costs anticipated to create physical space for the SCR system. This factor was selected based on Enterprise's recurring assertion that the current layout of the existing building can not accommodate the physical space needed for SCR. Aerial photos provided by Enterprise suggest there is space for SCR if building modifications are made.
Other Direct Capital Costs 1 ($)	ODC1	$ -	$ -	-

Economic Evaluation

Cost Component		Unit 1	Unit 2	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	$ -	-	Enterprise provided a cost estimate for electrification using EPA Cost Control Manual Section 5.2, which pertains to acid gas scrubbers. As this is not applicable to replacement with EMD, a Total Capital Cost metric of $2,084 (2023$/hp) was calculated using detailed cost information provided by other facilities. The TCI figure assumes no costs associated with substation or distribution line upgrades. This assumption underestimates costs given that Enterprise indicated in its August 2023 update that utility infrastructure upgrades would be needed to support electrification at all three of its facilities.

NMED Final Cost Evaluation
Enterprise Field Services - South Carlsbad Compressor Station

Unit 1: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	41.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	340,629,292	scf/Year
	8524	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 3070 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.44	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.09	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 1: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	41	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	350,060,136	scf/Year
Actual Annual fuel consumption (Mactual) =		340,629,292	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.973	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8524	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	14.48	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	61.71	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.12	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3007	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	168.40	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	19	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	900	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	24.39	kW

Unit 1: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,851,414	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$51,041 in 2024 dollars
Indirect Annual Costs (IDAC) =	$349,246 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$400,287 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$14,257 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$11,689 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$20,791 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$4,304 in 2024 dollars
Direct Annual Cost =		$51,041 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,799 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$346,447 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$349,246 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$400,287 per year in 2024 dollars
NOx Removed =	62 tons/year
Cost Effectiveness =	$6,486 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Enterprise Field Services - South Carlsbad Compressor Station

Unit 2: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1.1

* NOTE: You must document why a retrofit factor of 1.1 is appropriate for the proposed project.

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	41.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	338,351,503	scf/Year
	8467	hr/yr
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3070	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.44	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.09	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	10.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 2: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	41	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	350,060,136	scf/Year
Actual Annual fuel consumption (Mactual) =		338,351,503	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.967	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8467	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	14.56	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	61.64	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.12	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.2	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.10

Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	20	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	900	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.1215

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	24.39	kW

Unit 2: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,851,414	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$50,891 in 2024 dollars
Indirect Annual Costs (IDAC) =	$349,246 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$400,137 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$14,257 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$11,675 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$20,652 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$4,308 in 2024 dollars
Direct Annual Cost =		$50,891 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,799 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$346,447 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$349,246 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$400,137 per year in 2024 dollars
NOx Removed =	62 tons/year
Cost Effectiveness =	$6,492 per ton of NOx removed in 2024 dollars

RE: Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program
Enterprise Field Services, LLC
South Carlsbad Compressor Station

Mr. Singleton:

Please find enclosed Enterprise Field Services, LLC ("Enterprise") analysis of control measures for the South Carlsbad Compressor Station in Eddy County, New Mexico, as requested by the NMED by letter dated July 18, 2019.

Enterprise's submittal of a similar control measure analysis for the Chaco Gas Plant and Blanco C&D Compressor Station will follow by November 15, 2019, per the NMED's October 29 letter granting additional time for Enterprise to submit the analysis for those facilities.

In addition, Enterprise may supplement its submittal of the control measure analyses with legal comments, which would be integral to Enterprise's position on the appropriateness of the control measures analyzed for all three facilities. For convenience and to avoid duplication, we would include the legal comments with our November 15 submittal.

If you have questions or require additional information, please contact me at (713) 381-6698 or by email at rmhavalda@eprod.com or Bradley Cooley at (713) 381-5828.

Thank you,

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across with United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977. EPA has since amended the RHR in certain respects, most recently on January 10, 2017.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, the states, among other things:

(A) *"[E]valuate and determine the emission reduction measures that are necessary to make reasonable progress by considering the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected anthropogenic source of visibility impairment" and "include in [the state's] implementation plan a description of the criteria it used to determine which sources or groups of sources it evaluated and how the four factors were taken into consideration in selecting the measures for inclusion in its long-term strategy."* 40 CFR 51. 308(f)(2)(i). This is known as a four-factor analysis.

(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(f)(1). The uniform rate of progress or improvement is sometimes referred to as the "URP" or the glidepath and is considered in the process of developing the state's Long Term Strategy (LTS).

The second implementation, or planning, period (2019-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Regional Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations. EPA has issued guidance to states for development of State Implementation Plans (SIPs) for regional haze requirements for the second planning period.[1,2]

[1] U.S. EPA, Guidance on Regional Haze State Implementation Plans for the Second Implementation Period, EPA-457/B-19-003 (Aug. 2019); U.S. EPA, Technical Guidance on Tracking Visibility Progress for the Second Implementation Period of the Regional Haze Program, EPA-454/R-18-010 (Dec. 2018).

[2] U.S. EPA, Technical Support Document for EPA's 2028 Regional Haze Modeling (Sept. 2019).

Pursuant to 40 CFR 51.308(f)(2), the states are responsible for identifying sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for Title V sources and screened each facility's potential impact on visibility in Class I areas using a "Q/d" analysis, where "Q" is the magnitude of emissions that could impact ambient visibility and "d" is the distance of a facility to a Class I area. The NMED defined a source with a high potential for visibility impairment as one with a "Q/d" greater than 5.5. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019, the NMED informed Enterprise Field Services, LLC (Enterprise) that its facility, the South Carlsbad Compressor Station, was identified as one of the sources potentially contributing to regional haze at the Carlsbad Caverns Class I area.

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. The NMED's July 18, 2019 notification letter to Enterprise specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility that is subject to this analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Solar Centaur T4702 Turbines (Units 1 and 2)	27.0	90.8	Yes	<1.0	2.2	No

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified. One of the reference sources that the NMED has suggested consulting is the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC). In order to determine the most relevant and current retrofit controls available, the RBLC was queried for the previous ten years. Summaries of the result of this search are provided and discussed in Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis was then conducted for those controls that are technically feasible at the South Carlsbad Compressor Station site.[3]

Based on the technical and economic factors summarized in this report, Enterprise has provided recommendations for the NMED in its efforts to design, in coordination with WRAP, the SIP under the Regional Haze Rule.

2.1. COMBUSTION TURBINES

Two of South Carlsbad's natural gas-fired turbines (Units 1 and 2) are subject to this four-factor analysis due to their NO_X emission rates.

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor, where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures of up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[4]

The treatment of the exhaust gases exiting the turbine dictates the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[5] The units at South Carlsbad are regenerative cycle turbines, which are essentially simple cycle gas turbines with an added heat exchanger.

NO_X is formed via three fundamentally different mechanisms. The principal NO_X formation mechanism, thermal NO_X, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_X forms in the highest temperature regions of the combustion chamber. The second NO_X formation mechanism, fuel NO_X, arises from the evolution and reaction of fuel-bound nitrogen compounds with oxygen. The final NO_X formation mechanism, prompt NO_X, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_X is negligible in comparison to thermal and fuel NO_X. Fuel NO_X will also be negligible for South Carlsbad's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_X.

The PTE from each turbine is reported in the facility's New Source Review (0220-M10R1) and Title V (P130-R3) permits and is summarized in Table 1.

2.1.2. Potential NO_X Controls for a Combustion Turbine

There are three general methods of controlling NO_X emissions from gas turbines; (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation, (2) dry controls that use

[4] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

[5] Ibid.

advanced combustor design to suppress NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[6]

The categories of retrofit control equipment identified for combustion turbines during a comprehensive review of the RBLC are reported in Table 2. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control, is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible	NO_X Control Efficiency
Good Combustion Practices	**Base Case**	**N/A**
SoloNO$_X$	**Yes**	**64%**
Water/Steam Injection	**No**	**N/A**
Selective Catalytic Reduction	**No**	**N/A**

2.1.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. Applying concepts from engineering knowledge, experience, and the manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for the equipment involved, and using pipeline quality natural gas. If good combustion practices are maintained, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at South Carlsbad. However, these practices are currently in use at South Carlsbad, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.1.2.2. SoloNOx

The key factors in thermal NO_X formation are the combustion temperature and the residence time of fuel in the combustor. SoloNO$_X$ reduces NO_X emissions by reducing both of these factors. Ultimately, this is accomplished by optimizing the air-to-fuel ratio. According to information received from Solar, SoloNOx can reduce NO_X exhaust concentrations to 25 ppmv on the Centaur T4702 units.

2.1.2.3. Water/Steam Injection

Water or steam injection is a technology that has been demonstrated to effectively suppress NO_X emissions from gas turbines. The effect of steam and water injection is to increase the thermal mass by dilution and thereby reduce peak temperatures in the flame zone. With water injection, there is an additional benefit of absorbing the

[6] Ibid.

latent heat of vaporization from the flame zone. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.

Enterprise received information from Solar stating that the Centaur T4702 units cannot support steam injection and that they do not offer water injection equipment. They also stated that, while a third-party vendor may be able to develop water injection controls for the turbines, that this control may impose a risk of damaging this equipment and that any damage caused by water injection would not be covered under the equipment's warranty. Based on the statements from Solar regarding the installation of water and steam injection, Enterprise does not consider this control technically feasible.

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream at a point downstream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[7] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O \quad \text{(Equation 1)}$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O \quad \text{(Equation 2)}$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituents, thermal sintering, or compacting, of active sites due to high temperatures in the reactor; fouling caused by ammonia-sulfur salts and particulate matter in the gas; and erosion due to high gas velocities.[8]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates, which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.[9]

In order for the SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 °F and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[10]

The South Carlsbad facility was designed and constructed without considerations for the installation of SCRs in mind. An onsite evaluation was conducted at the South Carlsbad facility during which measurements were taken of any feasible locations for SCR equipment. These measurements took into consideration the amount of buffer space needed to maintain accessibility to equipment and to not compromise worker safety. Based on size estimates of SCR units provided by CECO-Peerless, Enterprise determined that it is not possible to install these units.

[8] Ibid.
[9] Ibid.
[10] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines."

Enterprise has evaluated the costs of implementing the technically feasible control technologies at South Carlsbad as thoroughly as possible in the time provided to complete this assessment. The cost estimates presented below are calculated according to methods and recommendations described in the EPA Air Pollution Control Cost Manual.[11]

Emission inventory data and stack test data from 2016 were used to assess the baseline emissions for these units.

3.1. TURBINE CONTROLS

Table 3. Cost Analysis Summary of Technically Feasible Controls for Turbines

Control Equipment	Unit No.	Cost Effectiveness	Cost Factors
SoloNOx	1	$8,583.57 per ton	Equipment costs, routine overhaul and labor costs
	2	$6,629.15 per ton	

3.1.1. SoloNOx

For the Solar Centaur T4702 turbines (Units 1 and 2), Enterprise received a capital cost estimate from Solar for the SoloNOx control equipment. Total installed cost is estimated to be $1,342,700 per unit. Based on additional information from Solar regarding overhaul costs for these units, Enterprise estimates other associated annual operating costs to be approximately $37,756 per unit. The expected useful life of this control equipment is 20 years. Based on the target NOx exhaust concentration of 25 ppm provided by Solar, the expected control efficiencies associated with SoloNOx are 64% and 66% for Units 1 and 2, respectively. The control would reduce the annual NO_X emissions of unit 1 and 2 by 20.8 tons and 26.9 tons, respectively. This results in an amortized cost effectiveness of $8,583.57 and $6,629.15 per ton of NO_X reduction for Units 1 and 2, respectively.

[11] U.S. EPA, "Air Pollution Control Cost Manual," available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

4. TIME NECESSARY FOR COMPLIANCE

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of Enterprise's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

Enterprise estimates that up to 3 to 4 years will be needed to budget, design, procure, and construct any of the control measures discussed in this report.

5. ENERGY AND NON-AIR QUALITY ENVIRONMENTAL IMPACTS OF COMPLIANCE

5.1. TURBINE CONTROLS

5.1.1. SoloNO$_X$

This section addresses the potential energy and non-air environmental impacts that installation of the technically feasible control options impose on a source. The consideration of energy impacts involves assessing the impact of a control measure on the energy that is consumed by the source. Non-air environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

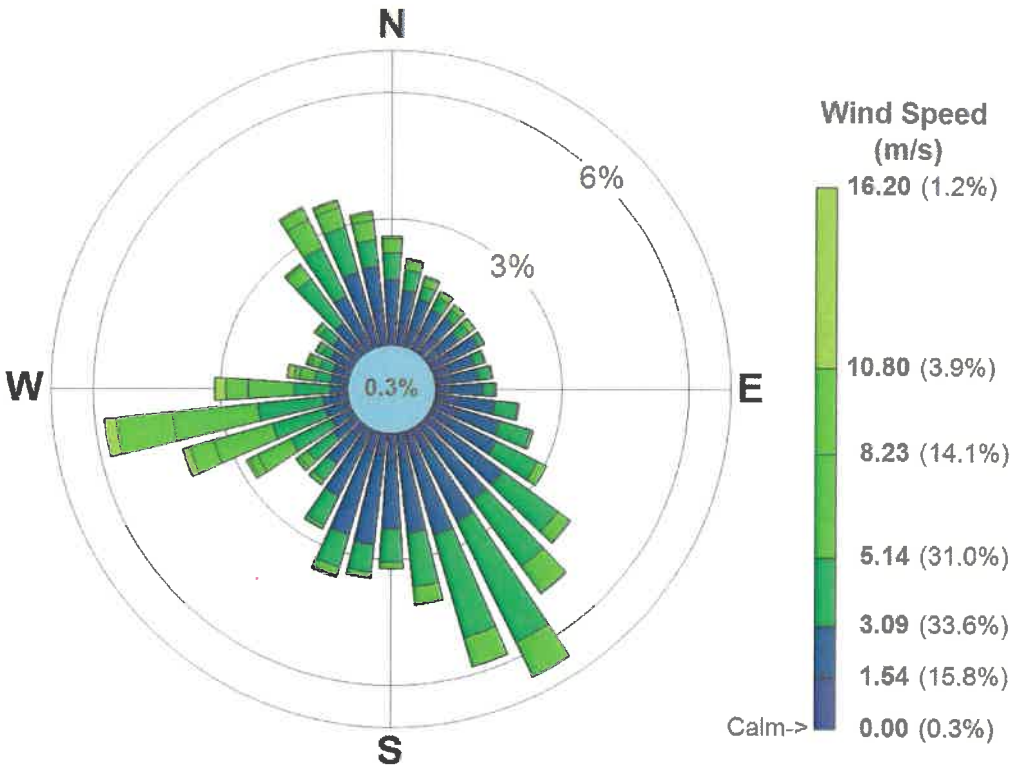
There are no anticipated unique or site-specific energy or non-air quality environmental impacts from installation and operation of SoloNO$_X$ on the South Carlsbad turbines.

6.1. TURBINE CONTROLS

6.1.1. SoloNOx

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system. Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.[12]



The estimated useful life of a SoloNO$_X$ control is 20 years. This estimate has been incorporated in the cost analysis section to calculate the total annualized cost of the control.

[12] 40 CFR 51, Appendix Y, Section II.B.4.f

Enterprise does not believe implementing any of the evaluated controls would improve visibility in nearby Class I areas based on climatological data and ambient pollutant data.

The South Carlsbad Compressor Station is located approximately 16.2 miles from the Carlsbad Caverns Class I area at a wind vector range of approximately 60 degrees to 70 degrees (NE). According to 2017 meteorological data collected in Carlsbad presented in Figure 1, wind only blows from this direction at a frequency of 1.4% or approximately 120 hours per year. Moreover, over the 16 miles of transport, pollutants would undergo significant dispersion. While full dispersion and photochemical modeling would need to be conducted to more accurately evaluate South Carlsbad's impact, based on this evidence, the facility's impact on visibility is likely insignificant.

Figure 1. A Windrose Reporting 2017 Wind Direction and Speed in Carlsbad, NM

Additionally, according to aerosol composition data reported on visibility impaired periods at the Carlsbad Caverns National Park IMPROVE Monitor, the main contributing pollutant to regional haze is ammonium sulfate.[13] Therefore, installing NO_X controls on the units at South Carlsbad would not significantly improve visibility.

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input on the available control technologies for the natural-gas fired turbines located at the South Carlsbad Compressor Station, Enterprise has determined that it is not technically feasible or cost effective to implement any controls on equipment at this time, particularly given the expected insignificant impact at Carlsbad Caverns National Park.

Four Factor Analysis for Natural Gas Fired Turbines – NO_x

	Control Technology	Selective Catalytic Reduction (SCR)[a]	Water/Steam Injection[b]	Improved Combustion Technology (Low-NO_x Combustors, Ultra-Low NO_x Combustors and other improved combustion technology)	Good Combustion Technique
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_x to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.	Injected water/steam acts as a heat sink, lowering combustion zone peak temperatures, resulting in a decrease in thermal NO_x.	Low-NO_x burners (or SoloNOx) employ multi-staged combustion to inhibit the formation of NO_x. Primary combustion occurs at lower temperatures under oxygen-deficient conditions; secondary combustion occurs in the presence of excess air.	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. Primary combustion occurs at lower temperatures under oxygen-deficient conditions. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.
	Other Considerations	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.	Results in a small efficiency penalty but an increase in power output. May increase CO and VOC emissions. Not available in certain models.	N/A	N/A
	RBLC Database Information	Included in RBLC for the control of NO_X emissions from combustion turbines.	Included in RBLC for the control of NO_X emissions from combustion turbines.	Included in RBLC for the control of NO_X emissions from combustion turbines.	Included in RBLC for control of NOx emissions from combustion turbines.
ELIMINATE TECHNICALLY INFEASIBLE OPTIONS	Feasibility Discussion	Technically infeasible due to space limitations a the facilty.	Technically infeasible since this option is not available for the turbine model.	Technically feasible.	Base case.

After printing this label:
1. Use the 'Print' button on this page to print your label to your laser or inkjet printer.
2. Fold the printed page along the horizontal line.
3. Place label in shipping pouch and affix it to your shipment so that the barcode portion of the label can be read and scanned.

Warning: Use only the printed original label for shipping. Using a photocopy of this label for shipping purposes is fraudulent and could result in additional billing charges, along with the cancellation of your FedEx account number.
Use of this system constitutes your agreement to the service conditions in the current FedEx Service Guide, available on fedex.com.FedEx will not be responsible for any claim in excess of $100 per package, whether the result of loss, damage, delay, non-delivery,misdelivery,or misinformation, unless you declare a higher value, pay an additional charge, document your actual loss and file a timely claim.Limitations found in the current FedEx Service Guide apply. Your right to recover from FedEx for any loss, including intrinsic value of the package, loss of sales, income interest, profit, attorney's fees, costs, and other forms of damage whether direct, incidental,consequential, or special is limited to the greater of $100 or the authorized declared value. Recovery cannot exceed actual documented loss.Maximum for items of extraordinary value is $1,000, e.g. jewelry, precious metals, negotiable instruments and other items listed in our ServiceGuide. Written claims must be filed within strict time limits, see current FedEx Service Guide.

Re: NMED Follow-Up Letter Response
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC
South Carlsbad Compressor Station

Mr. Singleton:

Enterprise Field Services, LLC (Enterprise) submits herein to the New Mexico Environment Department (NMED) the enclosed responses to the follow-up questions contained in NMED correspondence dated December 23, 2019 for the Regional Haze Four-Factor Analysis submitted for the Enterprise South Carlsbad Compressor Station located in Eddy County, New Mexico.

Enterprise and Solar consider the information included in Appendix B of the enclosed response to be confidential business information (CBI) and request that it be treated as such to the full extent applicable.

Should you have questions or require further information regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828.

Thank you,
Enterprise Field Services, LLC

TABLE OF CONTENTS

1. RESPONSES TO THE NMED 1-3
   1. Selective Catalytic Reduction (SCR) Technology 1-3
   2. Cost Effectiveness 1-3
   3. Emissions Data 1-3
   4. Other Control Options 1-4

APPENDIX A: AERIAL MAP WITH SCR DIMENSIONS 1-6

APPENDIX B: VENDOR DOCUMENTATION 1-7

APPENDIX C: 2016 STACK TEST DATA 1-8

The NMED posed the following questions regarding the emissions control options Enterprise presented for the two (2) Solar Centaur T4702 Combustion Turbines located at the South Carlsbad Compressor Station.

1. SELECTIVE CATALYTIC REDUCTION (SCR) TECHNOLOGY

a. *You rejected consideration of SCR technology on account of space considerations; please provide more details on the specific dimensions and space required for the installation of SCR technology.*

Response: Enterprise received information from CECO-Peerless (Natalie Boone) on October 17, 2019, which stated that an area of approximately 40' by 20' is required for an SCR unit. This correspondence is included in Appendix B. As mentioned in our original report, space at the South Carlsbad Compressor Station is restricted. We have also included an aerial image in Appendix A of the facility with measurement overlays to demonstrate that the limited space precludes the option of installing an SCR.

b. *Please also provide an estimated NO_X control efficiency.*

Response: As discussed above, space limitations at the South Carlsbad Compressor Station would preclude the installation of an SCR, and the control technology is therefore technically infeasible, the control efficiency was not estimated. However, based on information provided in AP-42 Section 3.1.4.3, an SCR can control NO_X emissions from turbines with a minimum efficiency of approximately 65%.[1]

2. COST EFFECTIVENESS

a. *Please provide a vendor quote from Solar Turbines for the SoLoNO$_X$ packages.*

Response: A vendor quote from Solar for the SoloNO$_X$ conversion is attached. There are two components of the total cost considered: (1) the capital cost of the SoloNO$_X$ unit (which includes equipment cost from Solar, installation, engineering, and inspection) and (2) the incremental annual overhaul costs. The incremental annual overhaul costs are based on hourly overhaul rates for the gas producer and power turbine, which differ for units that are operating with or without SoloNO$_X$. This information was provided by Solar on October 22, 2019. The capital and overhaul costs are amortized with the specified interest rate to calculate an annualized total capital investment. This information is submitted with this response in Appendix B.

3. EMISSIONS DATA

a. *Adjacent to the turbine NOx emissions lb./hr. and ton/year (tpy) data in your 4- Factor analysis for SoLoNOx implementation is the statement, "from 2016 stack test data". Your 2016 Emissions Inventory submittal, however, does not match the data presented in your analysis (Unit 1: 7.59 lb./hr., 32.42 tpy; Unit 2: 9.55 lb./hr., 40.80 tpy). Further observation of your 2016-2018 Emissions Inventory submittals shows numerous stack test results for the years 2014-2018, none of which matches the lb./hr. values you used in the analysis. Please clarify.*

Response: The stack test conducted in 2016 at the facility which references the emissions is included with this submission. The stack tests are the most accurate representation of engine

[1] AP-42 Section 3.1.4.3 Stationary Gas Turbines, Control Technologies, Catalytic Reduction System.

emissions during 2016. These emissions, along with the hours of operation of each unit recorded that year, were used to represent the baseline emissions reported in the four-factor analysis report. The 2016 stack test data is included in Appendix C.

4. OTHER CONTROL OPTIONS

a. Have you considered other options not otherwise listed in your 4-Factor Analysis?

i. Staged Combustion

Response: AP-42 Section 3.1.2 provides a technical background on turbine combustion. The second paragraph of that section describes lean-premixed staged combustion.[2] That paragraph defines lean-premixed combustion as a synonym for dry low NO_X. SoloNO_X is Solar's proprietary dry low NO_X combustor, which would be synonymous with this option. If such a technology were to be implemented, it would not be appropriate to use a third-party vendor for Solar turbines. The SoloNO_X burners are specifically designed to work effectively with Solar turbines and have been widely implemented on Solar's units. While it may be possible to install a third-party burner on Solar turbines, the performance cannot be guaranteed and, as stated by Solar in correspondence dated October 21, 2019 (Attachment B), such a modification could void the turbines' warranty should damage be caused to the unit by third-party equipment.

ii. Ultra-Lean Combustion

Response: Ultra-lean combustion is informally defined as dry low NO_X technology that can achieve relatively low NO_X emissions compared to dry low NO_X. However, there is no formal definition of this technology that clearly delineates ultra-low NO_X or ultra-lean combustion from lean combustion. As part of the original four-factor analysis, Enterprise requested information on the most effective SoloNOx units available and used the information it received in preparing the analysis.

iii. Water-Steam Injection

Response: As discussed in Enterprise's original submission, and as Solar stated in correspondence dated October 21, 2019 (Appendix B), Solar does not offer water injection on the Centaur T4702 turbine. As noted in the correspondence, it may be possible to install a third-party water-steam injection system on Solar turbines, but such a modification could void the turbines' warranty should damage to the unit be caused by the third-party equipment.

iv. Post-Combustion other than SCR (e.g., XONON, SCONO$_X$, NSCR).

Response: XONON is not a post-combustion technology. The XONON combustor is completely contained within the combustion chamber of the turbine. As stated in the US EPA Environmental Technology Verification report, "The design of each XONON™ combustor is customized to the particular turbine model and operating conditions of the application and would typically be defined through a collaborative effort with the manufacturer of the turbine to integrate the hardware into the design."[3] Moreover, the Air Pollution Training Institute Manual for Controlling NO_X Formation in Gas Turbines states that, "Both GE and Solar Turbines have successfully

---

[2] AP-42 Section 3.1.2 Stationary Gas Turbines, Process Description.

[3] Environmental Technology Verification Report – NO_X Control Technologies: Catalytica Combustion Systems, Inc. Xonon™ Flameless Combustion System, at p. 2 (December 2000). https://archive.epa.gov/nrmrl/archive-etv/web/pdf/05_vr_xonon.pdf

operated on a 7.5 MW and a 10 MW engine using the XONON combustion system. Both engines demonstrated performance at less-than 2.5 ppmvd at 15% O2, but neither has yet made them commercially available, and it is not likely that they will."[4]

SCONOx was not identified in an exhaustive query of the RACT/BACT/LAER Clearinghouse and was not considered to be a widely implemented technology. Therefore, this technology was not considered. AP-42 Section 3.1.4.4 also states that the limited emission data available for SCONOx units cannot be used to robustly verify the manufacturer's claims for these units. Moreover, the technology is referred to as a "niche" technology, catering to a narrow range of turbines, in a DOE technical document evaluating the costs of NOx controls for turbines.[5] In this cost analysis, the cost per ton of NO_X controlled for the class of turbines installed at the South Carlsbad Compressor Station was greater than $16,000 (Table A-1). As that table in the cost anslysis indicates, this technology is only relatively cost effective for turbines of at least 150 MW, or those typically used for power generation.

NSCRs were not identified in either the RBLC or AP-42 Section 3.1 as a control option for turbines and were therefore not considered.[6]

Re: NMED Follow-Up Discussion Response
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC
South Carlsbad Compressor Station

Mr. Singleton:

Enterprise Field Services, LLC ("Enterprise") submits herein to the New Mexico Environment Department (NMED) its responses to the follow-up requests from a virtual meeting held on August 28, 2020 for the Regional Haze Four-Factor Analysis submitted for the Enterprise South Carlsbad Compressor Station located in Eddy County, New Mexico. The NMED requested information regarding six additional items identified as (a) through (f) in email correspondence dated September 2, 2020. Enterprise responded to each of the six items and committed to further developing and providing additional information for requests (b) and (c). The NMED follow-up requests and Enterprise responses for requests (b) and (c) are provided below.

Enterprise considers the information included in Attachment A of the enclosed response to be confidential business information (CBI) and requests that it be treated as such to the full extent of applicable law.

NMED Request (b): *We discussed an adjustment to the interest rate Enterprise originally used in its amortization of capital costs. You made an argument to use an interest rate higher than the adjusted rate of 3.25% NMED presented. Please provide in writing the reasoning for your higher interest rate (on top of the explanation provided in an email communication provided to NMED earlier this year), more precisely, the interest rate that would be specific to Enterprise for air pollution control projects. Note that no other New Mexico 4-factor submittal used an interest rate as high as the 8.38% you suggested would be appropriate to Enterprise. Providing official information from a potential lender would support your case when EPA and other entities review NMED's Regional Haze recommendations.*

www.enterpriseproducts.com

Enterprise Response: In our original Four-Factor Analysis, Enterprise used an annual interest rate of 8.38% based on its application of a 2018 FERC rulemaking that reflected an average capital structure for Enterprise's industry of 57% equity (with an average 10.55% annual return) and 43% debt (to which Enterprise applied the then-applicable prime rate of 5.5%). This approach tracked the basic manner in which Enterprise's industry raises funds, i.e. through a combination of investment equity and taking on debt. The NMED's response stated that Enterprise's proposed rate "is appropriate for pipeline operation and construction, not for air pollution control technologies. The prime rate [3.25%] or a rate specific to Enterprise should be used, and a rate representative of 2020 conditions."

Enterprise respectfully disagrees with the NMED's statement that the FERC methodology is only appropriate for pipeline construction and operation. As noted during our August 28, 2020 virtual meeting, Enterprise's cost of capital is based on the company's overall health and financial condition and generally is not sensitive to the specific purpose for which capital is raised. Put another way, Enterprise would not expect to obtain a lower interest rate on expenses for air pollution control equipment than for other types of expenses such as pipeline construction and operation. Accordingly, we continue to believe that the 8.38% rate derived from the FERC methodology would have been suitable for the Four-Factor Analysis. We also do not believe that the NMED's proposed prime rate of 3.25%, which reflects highly unusual but ultimately temporary conditions in the economy as the result of the COVID-19 pandemic, is a suitable basis for calculating the cost of control measures that would be implemented years in the future when interest rates are likely to return to higher levels more commensurate with their historical patterns.

Nonetheless, at the NMED's request, Enterprise has calculated a company-specific interest rate of 9.62% as of June 30, 2020 and requests that the NMED rely on this interest rate to calculate the cost-effectiveness of potential control measures on our facilities. This interest rate was calculated by Enterprise's Finance department using the Capital Asset Pricing Model. We emphasize that this interest rate reflects our company's overall cost of capital and is applicable to capital raised for a range of purposes, including air pollution control costs, construction of new facilities, or otherwise. The specific calculations behind this interest rate are described in the confidential white paper included as Attachment A. Enterprise consents to disclosure of the 9.62% rate and this explanation in the NMED's public record. However, we request that the NMED treat the white paper itself (i.e. Attachment A) as our confidential business information.

Enterprise has revised the cost-effectiveness calculations for potential retrofit control technologies for the combustion units subject to the Four-Factor Analysis at the South Carlsbad Compressor Station using the calculated company-specific interest rate of 9.62%. The revised cost-effectiveness calculations are enclosed as Attachment B.

NMED Request (c): *Replacing turbines with electric compressors has not been excluded from consideration; therefore, a technical feasibility analysis and cost analysis is required. Given the deadline of September 10 for NMED to submit information to WRAP for the 2nd round PAC photochemical grid modeling, a qualitative ballpark estimate will suffice if you cannot put together*

a comprehensive analysis within the next week. However, a more complete analysis would be appreciated by the end of the month.

Enterprise Response: To assess the potential conversion of combustion driven compressors to electric driven compressors, numerous significant considerations require evaluation. For the purposes of this discussion, Enterprise has evaluated existing electrical capacity to determine the additional electrical capacity that likely would be required to provide equivalent station horsepower for the units that are subject to the Four-Factor Analysis. The total added electric load that would be required if the two Solar Centaur T-4702 turbines (Units 1 and 2) were converted to electric driven units is approximately 5,400 kilowatts (KW). There is only minimal unused existing electrical capacity currently available at the South Carlsbad Compressor Station, and additional electricity demand would require utility infrastructure upgrades by the electricity provider and at the South Carlsbad Compressor Station; these costs would be borne by Enterprise. The electricity provider would have to modify its existing 12 kilovolt (kV) distribution system to provide the additional load. In addition to replacing the two combustion driven compressor packages with electric compressor packages, Enterprise would need to construct additional utility infrastructure within the South Carlsbad Compressor Station to distribute the energy needed to drive the electric compressors. Cost-effectiveness figures for electrification of each unit, including the cost estimation methodology used to estimate the total capital investment, is included in Attachment C. Please note that the electrification costs are based on best professional judgement and not reflective of an actual quoted facility-specific price.

Enterprise does not believe that any further evaluation of electrification of the two units at the South Carlsbad Compressor Station would be warranted. Redefining a source is not a retrofit control technology and is beyond the authority of the Regional Haze Rule.

Should you have any questions regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828.

Sincerely,
Enterprise Field Services, LLC

Subject: [EXTERNAL] Enterprise Regional Haze 4FA Follow-up Discussion

[Use caution with links/attachments]
Hello all,

Thank you for meeting with us to discuss your 4-Factor Analyses and our follow-up questions and requests. The information provided to us in the meeting is helpful and productive as we develop our Regional Haze SIP.

Below is a reiteration and post-discussion clarification of the items we discussed and information needed.

Enterprise: South Carlsbad CS, Blanco C&D CS, Chaco GP

a. Please provide a more detailed, itemized cost breakdown for capital and O&M costs. The example originally attached to the invite was a guideline only, but illustrates the detail NMED needs (as will EPA and other stakeholders) to vet and confirm appropriate categories of consideration. Please see the attached cost analyses for each facility that includes backup on how Total Capital Investment and O&M costs were estimated. Based on the guidance provided by NMED and discussion on 8/28/20, we revised our Total Capital Investment value for each unit and NOx reduction technology consistent with the methodology used in EPA Air Pollution Control Manual, Section 5.2, Chapter 1, Table 1.3. For water and steam injection technology, O&M costs were also updated since those values were estimated based on a percentage of the Total Capital Investment value.

b. We discussed an adjustment to the interest rate Enterprise originally used in its amortization of capital costs. You made an argument to use an interest rate higher than the adjusted rate of 3.25% NMED presented. Please provide in writing the reasoning for your higher interest rate (on top of the explanation provided in an email communication provided to NMED earlier this year), more precisely, the interest rate that would be specific to Enterprise for air pollution control projects. Note that no other New Mexico 4-factor submittal used an interest rate as high as the 8.38% you suggested would be appropriate to Enterprise. Providing official information from a potential lender would support your case when EPA and other entities review NMED's Regional Haze recommendations. Enterprise is preparing a response and will provide to NMED once available. As mentioned in email correspondence dated 3/26/20 and discussion on 8/28/20, Enterprise does not believe that a prime rate of 3.25% is appropriate and that actual interest rates would be significantly higher. It should be noted that EPA Air Pollution Control Cost Manual, Section 5.2, Chapter 1 suggests an interest rate of 7%.

c. Replacing turbines with electric compressors has not been excluded from consideration; therefore, a technical feasibility analysis and cost analysis is required. Given the deadline of September 10 for NMED to submit information to WRAP for the 2nd round PAC photochemical grid modeling, a qualitative ballpark estimate will suffice if you cannot put together a comprehensive analysis within the next week. However, a more complete analysis would be appreciated by the end of the month Enterprise is preparing an analysis that will be available by the end of the month. The analysis will generally include a comparison of the amount of available existing electrical capacity at each facility compared with the additional power capacity needed to maintain existing operational capacity at each facility. Based on preliminary review of available information, we expect that conversion of combustion engines to electric drivers will not be cost effective compared to other pollution control options.

d. The Blanco C&D CS T-D01 dry low NOx system capital cost reported in your 4-factor submittal is $8,205,400; whereas, the information provided in your follow-up CBI on page 4 of 4 is notably less. Please clarify. This is another example of where a more detailed breakdown/itemization of costs is required, per the itemization guidelines originally attached in the email invite. The cost provided in the follow-up CBI documentation (vendor cost) did not include all direct and indirect costs, please see the attached back-up that summarizes how the Total Capital Investment cost was estimated.

e. What is the control efficiency for the Chaco Gas Plant LEC controls on the Clark TLA-10 engines? As discussed on 8/28/20, the control efficiency is 50%.

f. What are the Chaco Gas Plant actual sulfur dioxide and H2S emissions from the sweetening process venting and flaring and how are they minimized Sweetening at the Chaco Gas Plant occurs on the NGL product stream, after the cryogenic process, for CO2 removal to meet pipeline specifications. Although the purpose of the sweetening unit at Chaco is generally to remove CO2, small quantities of H2S are also removed. CO2 and H2S are routed to a Callidus Thermal Oxidizer (Unit ID: 46) for destruction. Below are emissions for the TO (Unit ID: 46) as reported in annual emission inventories from CY 2015-2019:

Year	Volume Combusted (MMSCF)	tons/yr	
		H2S	SO2
2019	1,840.25	1.8	3.3
2018	1,798.33	1.7	1.7
2017	1,775.04	1.7	1.5
2016	1,832.21	1.8	1.6
2015	1,773.29	0.0	3.3

Stakeholder comments on Regional Haze can be found at: https://www.env.nm.gov/air-quality/rh-stakeholder-comments-2021/.
4-factor submittals can be found at: https://www.env.nm.gov/air-quality/four_factor_analysis-reports/

ETC Jal#3 is at least one facility that submitted information on electrification as a control measure option. Keep in mind that Jal's cost analysis was not correctly done.

We would appreciate any information that you can provide to us by September 8 so we may consider it before we submit information for the PAC #2 modeling run. The remainder of the information can be submitted by September 30, 2020 to the extent possible. We will be available to receive this information and answer any questions or address any comments you may have.

Please let me know if I missed anything or if you have any questions about this.

Thank you,

Re: NMED Regional Haze Four-Factor Analysis
Chaco Gas Plant; Blanco C&D and South Carlsbad Compressor Stations
Company-specific interest rate for Enterprise Field Services, LLC

Dear Mr. Jones:

On October 1, 2020, representatives of Enterprise Field Services, LLC submitted written statements to Kerwin Singleton of your office regarding the NMED's regional haze four-factor analysis for Enterprise's Chaco Gas Plant, Blanco C&D Compressor Station, and South Carlsbad Compressor Station. Each of these three submittals proposed use of a 9.62% company-specific interest rate (based on conditions as of June 30, 2020) for cost analysis of potential air emission controls. The supporting calculations were included in a confidential Attachment A to each submittal, which was titled "Enterprise Products Partners L.P. Capitalization and Cost of Capital Illustration."

By email to Enterprise's Tucker Jacobson on February 18, 2021, you requested additional documentation of this company-specific interest rate and indicated that acceptable documentation would be "in the form of a letter…from an official with your company (your company's CFO, for instance) that is in a position to know your company's costs of debt and equity."

In response to your request, I can confirm that this interest rate was calculated, and the associated document prepared, under my direction. I am familiar with the costs of debt and equity for Enterprise Products entities, including Enterprise Field Services, LLC and Enterprise Products Partners L.P. The attached document and resulting calculation accurately reflected both companies' cost of debt and equity as of June 30, 2020. Enterprise continues to regard the document as confidential.

Kind Regards,

Christian Nelly
Executive Vice President-Finance and Sustainability and Treasurer
Enterprise Field Services, LLC and Enterprise Products Holdings LLC, General Partner of Enterprise Products Partners L.P.

Re: Updated Cost-Effectiveness Estimates
Regional Haze Four-Factor Analysis
Enterprise Field Services, LLC

Dear Ms. Olson:

Enterprise Field Services, LLC (Enterprise) submits herein to the New Mexico Environment Department (NMED) updates for the Regional Haze Four-Factor Analysis submitted for the following Enterprise facilities:

- South Carlsbad Compressor Station located in Eddy County, New Mexico (South Carlsbad)
- Blanco C & D Compressor Station located in San Juan County, New Mexico (Blanco)
- Chaco Gas Plant located in San Juan County, New Mexico (Chaco)

Pursuant to a virtual meeting held with NMED on July 13, 2023, Enterprise is electing to provide revised cost-effectiveness estimates for previously evaluated retrofit control technologies for combustion units applicable to the Regional Haze Four-Factor Analysis at the three (3) facilities listed above based on 2023 conditions. Prior to this update, the last cost-effectiveness estimates were submitted to NMED on October 1, 2020. With this submittal, Enterprise is updating the cost-effectiveness estimates based on 2022 emissions data and 2023 cost-related factors including the Enterprise company-specific interest rate, cost of retrofit control technology equipment as provided by vendors, and incremental cost of equipment inspection and maintenance attributed to the installation of retrofit control technology. Additionally, at the request of NMED, additional facility-specific information regarding their utility electric supply is contained herein.

Enterprise considers the information included in **Attachment A** and **Attachment B** of this submittal to be **confidential business information (CBI)** and requests that it be treated as such to the full extent of applicable law.

This submittal includes the following attachments:

- Attachment A (**CBI**): Updated Company-Specific Interest Rate Calculation
- Attachment B (**CBI**): Updated Vendor-Provided Retrofit Cost Information

- Attachment C: Updated Cost-Effectiveness Estimates for South Carlsbad
- Attachment D: Updated Cost-Effectiveness Estimates for Blanco
- Attachment E: Updated Cost-Effectiveness Estimates for Chaco

Electrification Discussion

As requested by NMED in the virtual meeting held on July 13, 2023, responses to three questions related to the electrification of combustion units at each facility are provided below:

	Enterprise Response		
NMED Question	**South Carlsbad**	**Blanco**	**Chaco**
Is the facility currently served by utility power?	Yes	Yes	Yes
If yes, could one or more units be electrified without making upgrades to substations or off-site upgrades?	No	No	No
How many miles are we from a substation?	1.5 miles	2.5 miles	25 miles

Enterprise assessed the potential conversion of combustion-driven compressors to electric-driven compressors in correspondence dated October 1, 2020, for South Carlsbad, Blanco, and Chaco, respectively. The 2020 assessment still generally remains valid. Cost-effectiveness estimates for electrification of combustion units applicable to the Regional Haze Four-Factor Analysis have been updated and are included in Attachments C, D, and E for each facility, respectively. For the purposes of this discussion, Enterprise has evaluated existing on-site utility electrical capacity and infrastructure at each facility, respectively, to determine the additional electrical capacity and infrastructure that likely would be required to provide equivalent station horsepower for the units that are subject to the Four-Factor Analysis. Please note that the electrification costs are based on best professional judgment and are not reflective of an actual quoted facility-specific price. Estimated third-party (e.g. electric generating facility) costs that would be borne to serve additional electricity demand if combustion units were electrified are not included.

<u>South Carlsbad</u>
Enterprise confirmed with Xcel Energy, the electric provider for South Carlsbad, that there is not enough existing electrical capacity currently available to the facility, and additional electricity demand would require utility infrastructure upgrades.

<u>Blanco and Chaco</u>
Enterprise confirmed with Farmington Electric Utility System, the electric provider for Blanco and Chaco, that in addition to transmission upgrades that would be required for the electrification of these units, there is no existing spare generation capacity at existing power generating plants; therefore, approximately three (3)-150 megawatt combined cycle power plants would need to be constructed to serve the load required to drive electric motors for the compressors included in this analysis at Blanco and Chaco. The timeline to implement electrification at Blanco and Chaco would be five to eight years, depending on the new third-party generation plant siting requirements, environmental permitting, and right-of-way negotiations. No consideration has been given to potential nitrogen

oxide (NO_X) emissions as a result of generating additional electrical capacity necessary for the electrification of the combustion units at Blanco and Chaco. Electrification is not technically feasible because of the necessary additional power generation and utility infrastructure upgrades needed by the local utility over which Enterprise has no control.

Enterprise does not believe that any further evaluation of electrification of the units at the South Carlsbad, Blanco, and Chaco is warranted.

New Mexico Ozone Precursor Rule Discussion

On August 14, 2023, Enterprise submitted an Alternative Compliance Plan (ACP) in accordance with 20.2.50.113 NMAC (Ozone Precursor Rule) which included all the emission units being evaluated under the Regional Haze Rule along with other units in the Enterprise fleet throughout New Mexico. The ACP addresses NOx, carbon monoxide, and volatile organic compounds emissions and demonstrates how Enterprise will comply with allowable emission standards of NMED's Ozone Precursor Rule. NMED should consider Enterprise's emission reduction strategy proposed in the ACP, as well as other company strategies to comply with the Ozone Precursor Rule, when considering any subsequent control under the Regional Haze Rule.

Enterprise does not believe that implementing any of the evaluated controls for the Regional Haze Rule would meaningfully improve visibility in nearby Class I areas based on previously provided climatological data and ambient pollutant data. Should you have any questions regarding this submittal, please contact Tucker Jacobson at (713) 381-4313 (wtjacobson@eprod.com) or Bradley Cooley at (713) 381-5828 (bjcooley@eprod.com).

Sincerely,
Enterprise Field Services, LLC

D.5 ET Gathering & Processing

Supporting documentation for ET Gathering & Processing is provided below. Facility-specific documentation is provided first, followed by documentation pertaining to multiple facilities and/or the owner/operator. The following documents are included in this section (in reading order):

- Jal #3 Gas Plant:
    - Settlement Agreement and Stipulated Final Compliance Order (8/30/2021)
    - SRU Shutdown Certification (10/12/2021)
    - Administrative Permit Revisions (10/27/2021)
    - Application for Significant Revision to NSR Permit (6/10/2022)
    - NSR Permit No. 1092-M10 (11/7/2022)

STATE OF NEW MEXICO
SECRETARY OF ENVIRONMENT

ENVIRONMENTAL PROTECTION DIVISION OF THE NEW MEXICO ENVIRONMENT DEPARTMENT,

Complainant,

v. **No. AQB 20-63 (CO)**

ETC TEXAS PIPELINE, LTD.,

Respondent.

SETTLEMENT AGREEMENT AND STIPULATED FINAL COMPLIANCE ORDER

This Settlement Agreement and Stipulated Final Compliance Order ("Final Order") is entered into between the Environmental Protection Division ("Division") of the New Mexico Environment Department ("Department" or "NMED") and Respondent, ETC Texas Pipeline, Ltd., ("ETC") (collectively, the "Parties") to resolve alleged statutory, regulatory, and permit violations by ETC at its Jal No. 3 Gas Plant, located in Lea County, New Mexico. The Department alleges violations of the New Mexico Air Quality Control Act ("AQCA"), NMSA 1978, Sections 74-2-1 to -17; the Air Quality Control Regulations ("Regulations") at Title 20, Chapter 2 NMAC, and Air Quality Permit Number P090-R2M1 ("Permit").

I. BACKGROUND

A. PARTIES

1. The Division is an organizational unit of the Department and has been delegated the authority to issue compliance orders under the AQCA, NMSA 1978, 74-2-12.A (2006). The Air Quality Bureau ("Bureau") is an organizational unit of the Division.

2. ETC is a limited partnership doing business in New Mexico at the Jal No. 3 Gas

Plant Facility ("Facility"), located in Lea County, New Mexico. The Facility is a natural gas processing facility. At all times relevant to this Final Order, ETC owned and operated the Facility.

B. HISTORY AND ALLEGED VIOLATIONS

3. From December 23, 2014 to March 27, 2019, the Facility was authorized to operate under Title V Permit P090R2M1.

4. The following table from Title V Permit P090R2M1, Condition A106 lists the Facility emission units and their allowable emission limits. *See*: 40 CFR 50, 40 CFR 60, Subparts A, Db, and JJJJ, 40 CFR 63, Subparts A and ZZZZ, 40 CFR 64 CAM, 20.2.33 NMAC, 20.2.35 NMAC, 20.2.37 NMAC, and 20.2.72.210.A and B.1 NMAC and NSR Permit 1092-M8.

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2
2 "<" Indicates the application represented uncontrolled emissions are less than 1.0 pph or 1.0 tpy for this pollutant. Allowable limits are not imposed on this level of emissions, except for flares and pollutants with controls.
"-" Indicates the application represented emissions of this pollutant are not expected.
"*" Indicates hourly emission limits are not appropriate for this operating situation
3 FUG1 emissions are vented to Flares 8F or 10F; FUG2 emissions are vented to Flare 9F.

5. The following table from Title V Permit P090R2M1, Condition A107, lists the facility-wide startup, shutdown, and maintenance, and malfunction emission limits:

Table 107.A: Allowable SSM and Malfunction Units, Activities, and Emission Limits

Unit No.	Description	[1]NOx pph	NOx tpy	CO pph	CO tpy	VOC pph	VOC tpy	SO_2 pph	SO_2 tpy	H_2S pph	H_2S tpy
Flare Unit 9F SSM [4]	Flare Combustion of SSM Emissions	2.0	7.6	16.4	25.1	0.4	6.6	3,820.9	130.4[3]	40.6	1.5
Flare Unit 10F SSM [4]	Non-turbine Flare Combustion of SSM Emissions	430.1[2]		1,630.6[2]		1,008.6[2]		2,773.2[2]		29.5[2]	
Flare Unit 10F SSM	Turbine SSMs to 10F		12.0		26.4		25.6		70.0		4.7
C1 – C4 SSM [5]	C1 – C4 SSM			21.5	2.1	5.0	0.5				
Malfunc-tion	Malfunction Emissions	*[3]	10.0	*[3]	10.0	*[3]	10.0	*[3]	10.0	*[3]	10.0
Totals[6]			29.6		63.6		42.7		210.4		16.2

Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2.
Indicates that non-turbine and turbine to flare pph emissions shall not exceed this rate.
'*" Indicates that the Malfunction emission rates shall not exceed the combined pph SSM emission limits for Units 9F and 10F.

his allowable SSM emission limit does not supersede emission standards required by 40 CFR 60, Subpart JJJJ and/or 40 CFR 63, part ZZZZ.

6. Between January 1, 2017 and August 31, 2018, ETC reported 685 excess emissions events for the Facility via the NMED Air Quality Bureau's online Compliance Reporting System. The originally reported excess emissions totaled 3,131,006 pounds, which amount was later changed to 2,444,736 pounds based on ETC's submittal of corrected excess emissions reports.

7. ETC claimed that eleven (11) of these events qualified as malfunctions under the Environmental Improvement Board's excess emission rule, 20.2.7.111 NMAC. The Department accepted three (3) of these affirmative defense demonstrations ("ADDs"), and rejected the remaining eight (8).

8. On August 26, 2020, the Division issued an Administrative Compliance Order consolidating all the alleged violations identified in the five Notices of Violation issued from June 2017 to November 2018.

9. On September 11, 2020, the Division issued a Corrected Administrative Compliance Order ("ACO"). The recalculated penalty amount is $2,604,695.02.

10. On September 28, 2020, ETC filed its Request for Hearing and Answer to Administrative Compliance Order. ETC requested that the Secretary dismiss the ACO with prejudice.

11. On November 13, 2020, the Department issued a Notice of Docketing and the assignment of a hearing officer.

II. COMPROMISE AND SETTLEMENT

A. GENERAL

12. Following good faith settlement negotiations to resolve this matter without further costly litigation, the Parties agreed to a complete settlement of all the violations alleged in the

ACO, and have consented to the terms of this Final Order. ETC does not admit any of the violations alleged in the ACO, and the Department does not concede that ETC met its burden on the ADDs.

13. The Parties admit jurisdiction and consent to the relief specified herein.

B. CIVIL PENALTY AND ADDITIONAL INJUNCTIVE RELIEF

14. In compromise and settlement of the alleged violations in the ACO, and upon consideration of the seriousness of the alleged violations and ETC's efforts to address the causes of excess emissions at the Facility, the Parties agree that ETC shall: (1) pay a civil penalty of $1,302,347.51 in a cash payment to the State of New Mexico; (2) permanently shut down the sulfur recovery unit ("SRU") at the Facility; and (3) submit an application to revise the NSR and Title V permits for the Facility to remove authorization to operate the SRU.

Civil Penalty

15. ETC shall pay a civil penalty of $1,302,347.51 to the State of New Mexico within 30 calendar days after the effective date of this Final Order.

16. Payment shall be made to the ***State of New Mexico General Fund, New Mexico Environment Department, Air Quality Bureau, 525 Camino de los Marquez, Suite 1, Santa Fe, New Mexico,*** by certified or corporate check, or by ACH deposit. On the date that delivery of funds by check or ACH is confirmed, ETC shall notify the Air Quality Bureau Enforcement Manager by electronic mail sent to: cindy.hollenberg@state.nm.us.

Certified or corporate checks shall be sent to the following address:

New Mexico Environment Department
Air Quality Bureau
c/o Compliance and Enforcement Manager
525 Camino de los Marquez, Suite 1
Santa Fe, New Mexico 87505

ACH deposits shall be made to the order of the Wells Fargo Bank as follows:

Wells Fargo Bank, N.A.
100 W. Washington Street, Floor 20
Phoenix, AZ. 85003

Routing Transit Number: 121000248
Deposit Account Number: 4123107799
Descriptor: NMED-AQB-C&E

17. If ETC fails to make timely and complete payment of the civil penalty pursuant to paragraph 15, and unless the Parties agree to extend the time for payment of the civil penalty, ETC shall pay a stipulated penalty of $1,500.00 per day for each day the payment is not timely or complete.

Shutdown of SRU

18. Within 60 days of the effective date of this Final Order, ETC shall permanently shut down the sulfur recovery unit ("SRU") at the Facility. Upon completion of the shutdown of the SRU, ETC shall, within 30 days of such completion, submit a written certification to the Department that the SRU was properly and permanently decommissioned in accordance with applicable laws and rules. Certification shall include the following statement, signed by ETC's responsible official:

> *I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I have no personal knowledge that the information submitted is other than true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fines and/or revocation of air quality operating permits for knowingly and willfully submitting a materially false statement.*

19. If ETC fails to permanently shut down the SRU at the Facility within 60 days of the effective date of this Final Order, and unless the Parties agree to extend the time by which ETC

must permanently shut down the SRU, ETC shall pay a stipulated penalty of $1,500.00 per day for each day thereafter until the date the SRU is completely and permanently shut down.

20. If ETC fails to submit the written certification specified in paragraph 18 within 30 days of permanently shutting down the SRU, and unless the Parties agree to extend the time by which ETC must submit the written certification, ETC shall pay a stipulated penalty of $1,500.00 per day for each day thereafter until the date the required certification is submitted.

21. Within 60 days of the permanent shutdown of the SRU, ETC will submit an administrative revision pursuant to 20.2.72.219.A NMAC to the NSR and Title V permits to remove authorization to operate the SRU and any monitoring, recordkeeping, and reporting requirements related to operation of the SRU.

III. OTHER TERMS AND CONDITIONS

A. RESERVATION OF RIGHTS AND DEFENSES

22. This Final Order shall not be construed to prohibit or limit the Division in any way from requiring ETC to comply with any applicable state or federal requirement not resolved herein. This Final Order shall not be construed to prohibit or limit the Division in any way from seeking any relief authorized by the AQCA for violation of any state or federal requirement applicable to ETC not resolved herein. This Final Order shall not be construed to prohibit or limit in ETC in any way from raising any defense to a Department action seeking such relief.

B. MUTUAL RELEASE

23. The Parties mutually release each other from all claims that each Party raised or could have raised against the other regarding the facts and violations alleged in the NOVs and the ACO. Such release applies only to civil liability.

C. WAIVER OF STATE LIABILITY

24. ETC shall assume all costs and liabilities incurred in performing all obligations under this Final Order. The Division, on its own behalf and on behalf of the State of New Mexico, does not assume any liability for ETC's performance of any obligation under this Final Order.

D. EFFECTIVE DATE AND TERMINATION DATES

25. This Final Order and any modifications thereto shall be effective when the Final Order or modification has been executed by both of the Parties.

26. Except as otherwise provided in this Paragraph, the terms of this Final Order shall terminate when ETC has fulfilled the requirements of this Final Order. The reservations of rights and defenses and the mutual release in Paragraphs 22 and 23 shall survive the execution and performance of this Final Order, and shall remain in full force and effect as an agreement between the Parties.

E. INTEGRATION

27. This Final Order merges all prior written and oral communications between the Parties concerning the subject matter of this Final Order, contains the entire agreement between the Parties, and shall not be modified without the express written agreement of the Parties.

F. BINDING EFFECT

28. This Final Order shall be binding on the Parties and their officers, directors, employees, agents, subsidiaries, successors, assigns, trustees, or receivers.

G. AUTHORITY OF SIGNATORIES

29. The persons executing this Final Order on behalf of ETC and the Division, respectively, represent that they have the authority to execute this Final Order on behalf of ETC and the Department.

H. SIGNATURE AND COUNTERPARTS

30. This Final Order is intended to be executed on separate signature pages. Faxed, emailed, electronic, or digital signatures shall constitute original signatures binding on the signing party.

31. This Final Order may be executed in multiple counterparts, each of which shall be deemed an original, but all of which shall constitute one and the same agreement.

RE: **ETC Texas Pipeline, Ltd.**
Final Order No. AQB 20-63 (CO)
Jal #3 Gas Plant

In accordance with the Final Order between the Environmental Protection Division of the New Mexico Environment Department and ETC Texas Pipeline, Ltd. (ETC), dated August 30, 2021, ETC is hereby providing written certification to the Department that the Sulfur Recovery Unit (SRU) at the Jal #3 Gas Plant was properly and permanently decommissioned in accordance with applicable laws and rules. In accordance with section, "Shutdown of SRU" (Paragraph 18), the SRU was permanently shutdown on October 8, 2021, within 60 days of the effective date of the Final Order. This written certification is being submitted within 30 days of the shutdown. Pursuant to Paragraph 21 of the Final Order, ETC is currently working on the submittal of an administrative revision (20.2.72.219.A NMAC) to the NSR (1092-M8) and Title V (P090R3) permits to remove authorization to operate the SRU, including any monitoring, recordkeeping, and reporting requirements related to the operation of the SRU.

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I have no personal knowledge that the information submitted is other than true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fines and/or revocation of air quality operating permits for knowingly and willfully submitting a materially false statement.

RE: **Administrative Permit Revisions**
ETC Texas Pipeline, Ltd.
Jal #3 Gas Plant
NSR Permit No. 1092-M8R3
Title V Permit No. P090-R3

Dear Sir/Madam,

On August 25, 2021, ETC Texas Pipeline, Ltd (ETC) entered into the Settlement Agreement and Stipulated Final Compliance Order No. AQB 20-63 (CO) with the New Mexico Environment Department. Condition #21 of this agreement states the following:

> "Within 60 days of the permanent shutdown of the SRU, ETC will submit an administrative revision pursuant to 20.2.72.219.A NMAC to the NSR and Title V permits to remove authorization to operate the SRU and any monitoring, recordkeeping, and reporting requirements related to operation of the SRU."

To satisfy this requirement, ETC is hereby submitting the enclosed Permitting Administrative Multi-Forms requesting that unit numbers SRU and 9S and associated emissions be removed from NSR Permit No. 1092-M8R3 and Title V Permit No. P090-R3. Each form includes a notarized certification that has been signed by the site's Alternate Responsible Official. No changes to facility throughput or other permitted equipment result from the shutdown of these units.

Should you have any questions or require additional information, please do not hesitate to contact me at (432) 238-8421 or carolyn.blackaller@energytransfer.com.

Sincerely,

Carolyn J. Blackaller
Sr. Environmental Specialist

Section 2-D: Closing a Facility, Removing Units from a Permit, or Canceling an NOI

(Administrative Revision)

Check the appropriate boxes and provide complete information in the table. Closing the permit does not relieve the permittee from any outstanding permit fees.

If any of the units being removed are emission control equipment explain how a permit, federal regulation, or state regulation will not be violated by removal of the control equipment.

☐ Cease operations of the entire facility and cancel the construction permit (20.2.72.219.A(1)(c) NMAC).

Date the facility ceased operating:

☐ Retire an emissions unit and remove it from the construction permit (20.2.72.219.A(1)(c) NMAC).

Date unit(s) retired:
List all retired unit numbers to be removed from the permit:

☐ Cancel a construction permit for a facility or remove an emissions unit that has not and will not be constructed (20.2.72.219.A(1)(d) NMAC).

☐ Facility (plant) will not be constructed, or	☐ The following units will not be constructed and should be removed from the permit:

☒ Retire an emissions unit and remove it from the TV permit (20.2.70.404.A(1)(c) NMAC).

Date unit(s) retired: October 8, 2021
List all retired unit numbers to be removed from the permit: SRU, 9S

☐ Voluntary Discontinuation of the TV permit (20.2.70.400.I NMAC).

Date the TV permit was no longer required:
Explanation:

☐ Cancel a construction permit that is no longer required.

Explanation:

☐ Removal of minor NSR exempt equipment.

Explanation:

☐ Cancel a Notice of Intent (check one or explain):

☐ PER is now below 20.2.73.200 NMAC threshold.	☐ Date the facility ceased operating:

RE: Application for Significant Revision
NSR Permit No. 1092-M8R2
Jal No. 3 Gas Plant
Lea County, New Mexico
ETC Texas Pipeline, Ltd.

Dear Sir/Madam:

On behalf of ETC Texas Pipeline, Ltd. (ETC), Altamira-US, LLC (Altamira) is submitting the enclosed Application for a Significant Revision to NSR Permit No. 1092-M8R3 for the Jal No. 3 Gas Plant (Facility). The Facility is located approximately 4 miles north-northeast of Jal in Lea County, New Mexico.

With this application, ETC plans to remove ten (10) natural gas compressor engines, two (2) heaters, two (2) boilers, one (1) glycol dehydrator, one (1) thermal oxidizer, and supporting equipment. Two (2) Caterpillar 3606 engines, one (1) 28 MMBtu/hr amine system heater, one (1) glycol dehydration unit with associated reboiler and thermal oxidizer, one (1) AGI compressor, and (1) 10 MMBtu/hr condensate stabilizer heater will be added.

The enclosed application has been prepared in accordance with the requirements set forth in Title 20 New Mexico Administrative Code, Section 2.72.219. (NMAC 20.2.72.219.D.1.a.).

ETC has a payment credit of $4550 for GCP-OG application submitted to NMED March 2022, that NMED requested be withdrawn and replaced with this NSR application. ETC understands this monies will be applied to NSR Permit fee of $500 for this app and balance due after state finishes reviewing the application.

If you have any questions or comments, please contact Carolyn Blackaller of ETC at (432) 203-8920 or carolyn.blackaller@energytransfer.com.

Sincerely,
Altamira-US, LLC

Laura Worthen Lodes
VP-Mid Continent Operations

[3] To properly account for power conversion efficiencies, generator set rated capacity shall be reported as the rated capacity of the engine in horsepower, not the kilowatt capacity of the generator set.

[4] "4SLB" means four stroke lean burn engine, "4SRB" means four stroke rich burn engine, "2SLB" means two stroke lean burn engine, "CI" means compression ignition, and "SI" means spark ignition

Section 3

Application Summary

The **Application Summary** shall include a brief description of the facility and its process, the type of permit application, the applicable regulation (i.e. 20.2.72.200.A.X, or 20.2.73 NMAC) under which the application is being submitted, and any air quality permit numbers associated with this site. If this facility is to be collocated with another facility, provide details of the other facility including permit number(s). In case of a revision or modification to a facility, provide the lowest level regulatory citation (i.e. 20.2.72.219.B.1.d NMAC) under which the revision or modification is being requested. Also describe the proposed changes from the original permit, how the proposed modification will affect the facility's operations and emissions, de-bottlenecking impacts, and changes to the facility's major/minor status (both PSD & Title V).

The **Process Summary** shall include a brief description of the facility and its processes.

Startup, Shutdown, and Maintenance (SSM) routine or predictable emissions: Provide an overview of how SSM emissions are accounted for in this application. Refer to "Guidance for Submittal of Startup, Shutdown, Maintenance Emissions in Permit Applications (http://www.env.nm.gov/aqb/permit/app_form.html) for more detailed instructions on SSM emissions.

The ETC Texas Pipeline Ltd (ETC) Jal #3 Gas Plant (Jal 3) is a natural gas processing plant located near Jal, NM in Lea County. Lea County is attainment or non-classifiable for all criteria air pollutants. Jal 3 is currently a major source for the Prevention of Significant Deterioration (PSD) and Title V Operating Permit programs and is a major source of hazardous air pollutants (HAPs). ETC is submitting this application to apply for a Significant Revision (pursuant to NMAC 20.2.72.219.d.1.a) to its current Air Quality NSR Permit 1092-M8R2. As a result of this permit action, Jal 3 will no longer be a major source under the PSD program or a major source of HAPs.

With this application, ETC plans to remove ten (10) natural gas compressor engines, two (2) heaters, two (2) boilers, one (1) glycol dehydrator, one (1) thermal oxidizer, and supporting equipment. Two (2) Caterpillar 3606 engines, one (1) 28 MMBtu/hr amine system heater, one (1) glycol dehydration unit with associated reboiler and thermal oxidizer, one (1) AGI compressor, and (1) 10 MMBtu/hr condensate stabilizer heater will be added. The compressors and associated fugitive equipment components will be subject to NSPS OOOOa.

PART B GENERAL CONDITIONS (Attached)

PART C MISCELLANEOUS: Supporting On-Line Documents; Definitions; Acronyms (Attached)

PART A FACILITY SPECIFIC REQUIREMENTS

A100 Introduction

A. This permit, NSR 1092-M10, supersedes all portions of Air Quality Permit 1092-M8, issued August 01, 2013 and revision M8R1 thru M8R7, except portions requiring compliance tests. Compliance test conditions from previous permits, if not completed, are still in effect, in addition to compliance test requirements contained in this permit.

A101 Permit Duration (expiration)

A. The term of this permit is permanent unless withdrawn or cancelled by the Department.

A102 Facility: Description

A. The function of the facility is to treat and process natural gas. The facility consists of natural gas compression units, amine-sweetening units, an acid gas reinjection system, various storage tanks, fugitive emissions, and three flares.

B. This facility is located approximately 4 miles north northeast of Jal, New Mexico in Lea County.

C. This modification consists of removing ten (10) natural gas compressor engines, two (2) heaters, two (2) boilers, one (1) glycol dehydrator, one (1) thermal oxidizer, and supporting equipment and adding two (2) Caterpillar 3606 engines, one (1) 28 MMBtu/hr amine system heater (Unit Amine-2 is replacing Amine-1), one (1) glycol dehydration unit with associated reboiler and thermal oxidizer, one (1) AGI compressor, and (1) 10 MMBtu/hr condensate stabilizer heater. Also, added applicability to 20.2.50 NMAC, Oil and Gas Sector – Ozone Precursor Pollutants. The description of this modification is for informational purposes only and is not enforceable.

D. Tables 102.A and Table 102.B show the total potential emission rates (PER) from this facility for information only. This is not an enforceable condition and excludes emissions from Minor NSR exempt activities per 20.2.72.202 NMAC.

Table 102.A: Total Potential Emission Rate (PER) from Entire Facility

Pollutant	Emissions (tons per year)
Nitrogen Oxides (NOx)	105.5
Carbon Monoxide (CO)	88.2
Volatile Organic Compounds (VOC) [1]	163.6
Sulfur Dioxide (SO_2)	60.6

Malfunc-tions	Malfunctions	N/A	N/A	N/A	N/A	N/A

1. All TBD (to be determined) units and like-kind engine replacements must be evaluated for applicability to NSPS and MACT requirements.

A105 Facility: Control Equipment

A. Table 105 lists all the pollution control equipment required for this facility. Each emission point is identified by the same number that was assigned to it in the permit application.

Table 105.A: Control Equipment List:

Control Equipment Unit No.	Control Description	Pollutant being controlled	Control for Unit No.[1]
C1-C6	Oxidation Catalyst	CO, VOC, HCHO	C1-C4

Remainder of Permit Omitted for Brevity

D.6 Transwestern Pipeline Company

Supporting documentation for Transwestern Pipeline Company is provided below. Facility-specific documentation is provided first, followed by documentation pertaining to multiple facilities and/or the owner/operator. The following documents are included in this section (in reading order):

- Mountainair Compressor Station No. 7:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (10/30/2019)
    - Follow-Up Submittal (1/23/2020)
- Roswell Compressor Station No. 9:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (10/30/2019)
    - Follow-Up Submittal (1/23/2020)
- Multiple Facilities and/or Owner/Operator:
    - Follow-Up Submittal (9/10/2020)
    - Follow-Up Submittal (3/25/2021)
    - Follow-Up Submittal (8/11/2023)

NMED Final Cost Evaluation

4500	**Maximum Power Output Unit (hp/unit)**

Economic Evaluation

Cost Component		All Units	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	-	TWP 8.11.23 update explained that replacing 701, 702, and 703 with new CTs would require the replacement of 721 and 722 with microturbines to improve power reliability. TCI of the new CTs is $46.25M according to TWP. TWP did not include TCI of microturbines in its 8.11.23 update. TCI for the microturbines has been included as "Additional Capital" and estimated using Table 5-3 of the EPA CHP Catalog of Technologies - Microturbines, and CEPCI. This initial TCI (2023$) is over-estimated given that CHP installations are more complex and costly than their power generation only equivalents.
Other Direct Capital Costs 1 ($)	ODC1	$ -	-	
Other Direct Capital Costs 2 ($)	ODC2	$ -	-	
Indirect Capital Costs ($)	IDC	$ -	-	
Total Capital Costs - Direct ($)	TCC	$ 46,250,000	TWP 8.11.23 update	
Additional Capital ($)	AC	$ 2,471,898	TCI of 2x ~335 hp microturbines	
Total Capital Investment ($)	TCI	$ 48,721,898	TWP 8.11.23 update & ERG estimate	
Interest Rate (%)	R	7.50%	Bank prime rate as of December 2024	TWP used prime rate as of 7.11.23 (8%) in its 8.11.23 update
Useful Life (yr)	Y	30	ERG experience based on discussions with CT manufacturers	TWP indicated 25 years
Capital Recovery Factor	CRF	0.0847	-	Standard CRF calculation
Annualized Capital Costs ($/yr)	ACC	$ 4,125,343	-	TCI x CRF
Incremental Annual (O&M) Costs ($/yr)	OMC	$ (740,478)	Net change in O&M costs	OM1 - OM2 + OM3
New turbine O&M ($/yr)	OM1	$ 280,280	TWP 8.11.23 update	Based on TWP similar facility costs (2022$). Adjusted to 2023$ using CEPCI index of 0.98 (CEPCI 2023 (797.9)/ CEPCI 2022 (816.0))
Existing RICE O&M ($/yr)	OM2	$ 1,020,758	TWP 8.11.23 update	Estimated O&M for 721 and 722 using 701 O&M costs and adjusted using hp ratio
New microturbine O&M ($/yr)	OM3	$ -	-	Not specified by TWP
Other Indirect Annual Costs ($/yr)	OAC	$ -	-	4% of TCI for conventional pollution controls; EPA has not evaluated administrative and other ancillary costs associated with replacement with an equivalent/like-kind unit
Total Annualized Costs ($/yr)	TAC	$ 3,384,865	-	ACC + OMC + OAC
NOx Control Efficiency (%)	Eff	97%	-	ER/PAE
Baseline Actual NOx Emissions (ton/yr)	BAET	1,329.5	-	BAE1 + BAE2
	BAE1	1,263.5	CY 2022 emissions testing and average operating hours (2019-2021)	BAE of Units 701, 702 and 703
	BAE2	66.0	Average emission rate and 8760 hr/yr for 1 unit	BAE of Units 721 and 722
Future Utilization Adjustment (%)	FUA	0%	-	Not requested by TWP
Projected Actual Emissions (ton/yr)	PAE	1329.5	-	BAE x (1 + FUA)
Estimated Reductions (ton/yr)	ER	1284.5	-	PAE - CTE - MTE
	CTE	44.74	TWP 8.11.23 update	Post control estimated emissions (of new CT)
	MTE	0.26	Calculated	Microturbine emissions: 0.39 lb/MWh, assumed 60% load, 8760 hr/yr for 1 unit (other is backup)
2023$ Cost Effectiveness ($/ton)	**CE1**	**$ 2,635**	-	TAC/ER
Price Index	PI	1.00	-	2024 CEPCI* / 2023 CEPCI *Based on January-September values
2024$ Cost Effectiveness ($/ton)	**CE2**	**$ 2,635**	-	CE1 x PI

NMED Final Cost Evaluation
Transwestern Pipeline Company - Mountainair Compressor Station No. 7

Unit 701: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.78	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	246,631,018	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	6870	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	2.947	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.5894	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			
*The SRF value of 1.05 is a default value. User should enter actual value, if known.				
Number of SCR reactor chambers (n_{scr})			1	
Number of catalyst layers (R_{layer})			3	
Number of empty catalyst layers (R_{empty})			1	
Ammonia Slip (Slip) provided by vendor			2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)			UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)			UNK	acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours		
Estimated SCR equipment life	20	Years*		
* For industrial boilers, the typical equipment life is between 20 and 25 years.				
Gas temperature at the SCR inlet (T)			650	°F
*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.				
Base case fuel gas volumetric flow rate factor (Q_{fuel})			UNK	ft^3/min-MMBtu/hour
Concentration of reagent as stored (C_{stored})	29	percent*		
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14	days		

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 701: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,511,930	scf/Year
Actual Annual fuel consumption (Mactual) =		246,631,018	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.835	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7311	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	81.99	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	299.72	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.29	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.4	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	257.28	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	32	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	110	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	15	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	5,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.59	kW

Unit 701: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,676,009	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$91,970 in 2024 dollars
Indirect Annual Costs (IDAC) =	$265,305 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$357,275 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$13,380 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$56,768 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$15,053 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$6,768 in 2024 dollars
Direct Annual Cost =		$91,970 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,789 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$262,517 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$265,305 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$357,275 per year in 2024 dollars
NOx Removed =	300 tons/year
Cost Effectiveness =	$1,192 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Transwestern Pipeline Company - Mountainair Compressor Station No. 7

Unit 702: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.77	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	266,086,615	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	6870	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	3.359	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.6717	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Unit 702: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,426,964	scf/Year	
Actual Annual fuel consumption (Mactual) =		266,086,615	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.901	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7890	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	93.42	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	368.56	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.29		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.4	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	276.11	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	36	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	125	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	17	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	5,700	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.58	kW

Unit 702: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,675,509	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$106,687 in 2024 dollars
Indirect Annual Costs (IDAC) =	$265,256 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$371,943 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$13,378 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$69,805 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$16,241 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$7,264 in 2024 dollars
Direct Annual Cost =		$106,687 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,789 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$262,467 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$265,256 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$371,943 per year in 2024 dollars
NOx Removed =	369 tons/year
Cost Effectiveness =	$1,009 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Transwestern Pipeline Company - Mountainair Compressor Station No. 7

Unit 703: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	31.86	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	244,218,797	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	6870	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	3.401	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.6802	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Unit 703: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	32	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	270,701,843	scf/Year	
Actual Annual fuel consumption (Mactual) =		244,218,797	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.902	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7903	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	86.69	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	342.55	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.29		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.4	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	254.79	Cubic feet

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	18.86	kW

Unit 703: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,527,744	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$99,127 in 2024 dollars
Indirect Annual Costs (IDAC) =	$250,751 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$349,878 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,639 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$64,879 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$14,906 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$6,703 in 2024 dollars
Direct Annual Cost =		$99,127 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,780 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$247,972 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$250,751 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$349,878 per year in 2024 dollars
NOx Removed =	343 tons/year
Cost Effectiveness =	$1,021 per ton of NOx removed in 2024 dollars

Dear Mr. Jones:

Re: Four Factor Analysis
Mountainair Compressor Station
Transwestern Pipeline Company, LLC

GHD Services, Inc. (GHD) is submitting, on behalf of Transwestern Pipeline Company, LLC., a four-factor analysis of the Mountainair Compressor Station to the New Mexico Environment Department (NMED). This report is for the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309).

If you have any questions or concerns, please contact myself at (720) 974-0937 or Larry Campbell at (575) 625-8022.

Sincerely,

GHD

Sergio Guerra
Project Manager

SNCR ..... Selective Non-Catalytic Reduction
SO2 ..... Sulfur Dioxide
SSM ..... Startup, Shutdown, Maintenance
ULNB ..... Ultra Low NOx Burners
WRAP ..... Western Regional Air Partnership
VOC ..... Volatile Organic Compound

1. Executive Summary

In response to the New Mexico Environment Department (NMED) letter dated July 18, 2019, GHD Services, Inc. (GHD) was retained by ETC Texas Pipeline, LTD, the parent company of Transwestern Pipeline Company, LLC, to prepare a four-factor analysis for the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309). As a part of this Progress Analysis, NO_x and SO_2 emissions were evaluated at the Mountainair Compressor Station (Mountainair CS).

The four-factor analysis is codified in 40 CFR §51.308(d)(1)(i)(A) and is designated as a means for establishing reasonable progress goals towards achieving natural visibility conditions. The four factors to consider are:

1. The costs of compliance
2. The time necessary for compliance
3. The energy and non-air quality environmental impacts of compliance
4. The remaining useful life of any potentially affected sources

The purpose of the four-factor analysis is to identify control measures for reducing emissions that could be used to establish the long-term strategy for attaining the states visibility goals. The NMED has requested that evaluations be completed for individual equipment that have a potential to emit (PTE) greater than ten pounds per hour of NO_x or SO_2. The source categories identified at Mountainair CS for evaluation are three existing compressor engines (Units 701, 702, and 703). NMED also instructed to use actual emissions from reporting year 2016 as baseline emissions to calculate emission reductions for control options evaluated. The cost range for emission reductions reflects the range of operation time in 2016 between the two RICE compressor engines analyzed. The results of the subsequent four-factor analysis are in Table 1.1 below.

Table 1.1 Summary of Mountainair CS Four Factor Analysis Results

Source Category	Regional Haze Pollutant Analyzed	Average Cost in 2019 Dollars (dollars per ton of pollutant reduction)	Compliance Timeframe	Energy & Non-Air Quality Impacts	Remaining Useful Life
RICE Engines (Units 701, 702, and 703)	NO_x; Low Emission Controls (LEC)	$2,000 - $13,000	2-5 Years	None known for LEC	25 years for controls; Indefinite for RICE engines
	NO_x; Selective Catalytic Reduction (SCR)	$1,400 - $7,000	2-5 Years	Storage and handling of hazardous materials	25 years for controls; Indefinite for RICE engines

2. Source Category Analysis for RICE Engines

2.1 Source Category Description

Mountainair CS operates three (3) Reciprocating Internal Combustion Engines (RICE) that are subject to the requirements of the four-factor analysis. Mountainair CS's compression engines are 4,500-hp natural gas-fired Cooper-Bessemer LSV-16G compressor engines (Units 701, 702, and 703) used for transportation of natural gas.

Mountainair CS also operates two (2) 335-hp natural gas-fired Ingersoll-Rand PSVG-6 generator engines. These generators are already utilizing best available control technology (BACT) for NO_x as Units 721 and 722 are controlled by non-selective catalytic reduction (NSCR). According to recent engine performance tests, NO_x emission rates are reduced by over 85% with the installed catalysts.

2.2 Clean Air Act and State Regulations

The engines subject to this analysis are subject to the following state and federal regulations:

20.2.61.109 NMAC

This regulation limits opacity to 20% applies to Stationary Combustion Equipment, such as engines, boilers, heaters, and flares unless your equipment is subject to another state regulation that limits particulate matter such as 20.2.19 NMAC (see 20.2.61.109 NMAC). Units 701, 702, 703, 721 and 722 are subject to this regulation.

20.2.82 NMAC

This regulation applies to all sources emitting hazardous air pollutants, which are subject to the requirements of 40 CFR Part 63, as amended through August 29, 2013.

MACT 40 CFR 63, Subpart ZZZZ

Facilities are subject to this subpart if they own or operate a stationary RICE, except if the stationary RICE is being tested at a stationary RICE test cell/stand. The generator engines (Units 721 and 722) at this station are stationary RICE that are existing engines subject to this subpart.

2.3 NO_x Emissions and Control Options

NO_x is generated from the combustion of natural gas used to power the applicable compressor engines. The exhaust gases are released to the atmosphere through stacks associated with each engine.

There are several different categories of NO_x formation in combustion processes. The combustion process taking place in RICE predominantly produces thermal NO_x[1] which is formed when nitrogen and oxygen unite during high temperature and high pressure combustion.[2]

While neither engine currently utilizes NO_x emission controls, two control options were assessed for the applicable engines: Low Emission Controls (LEC) and Selective Catalytic Reduction (SCR).

2.3.1 Low Emission Controls (LEC)

LEC is a combination of combustion controls in which various engine modifications, upgrades, and tuning methods provide lower emission combustion.

One upgrade includes increasing the air-to-fuel ratio (AFR) to reduce thermal NO_x formation by diluting combustion gases and lowering peak flame temperature. Upgrades to the AFR controller and turbocharger would be required. Adjusting ignition timing is another modification associated with LEC. This control delays ignition in the power stroke when the chamber is below its maximum pressure. This causes ignition at a lower temperature, thus lowering thermal NO_x formation during combustion. Other LEC options include installing cylinder heads fitted with pre-combustion chambers, larger intercooling applications, enhanced mixing, bypass valves, and increased ignition energy.[3]

A quotation provided by Cooper Machinery Services[10] shows that these LEC upgrades can lower NO_x emission rates to 2.5 g/hp-hr.

2.3.2 Selective Catalytic Reduction (SCR)

SCR is a post-combustion control for lean-burn combustion in which ammonia or urea is mixed with exhaust gases over a catalyst to (ideally) convert NO_x to nitrogen gas (N_2) and water (H_2O). While SCR has been applied to large boilers and turbines in the power generation industry, its application on new RICE in the gas transmission industry has been rare, and retrofitted applications for existing lean burn RICE had not occurred as of 2014.[4]

There are several factors that make SCR difficult for this application. Technical concerns, such as reagent injection control, exhaust temperature requirements, and variations in the exhaust NO/NO_2 ratio, pose limitations on the effectiveness and feasibility of SCR. NOx reduction may not be achieved, or even more ammonium sulfates may be emitted if the reagent feed rate and/or operating temperature is not precisely tuned to the fluctuating exhaust properties.[4]

Another challenge is that combustion byproducts and engine oil carryover often contaminate the catalytic elements in SCR applications. Routine cleaning and replacement as well as greater management are required for effective use.[4]

For these reasons, LEC is the preferred control method for Units 701, 702, and 703.

Table 2.1 below summarizes the control technology options.

Table 2.1 Summary of Potential NO_x Control Options

Technology	Description	Applicability	Feasibility	Performance (% reduction)
Low Emission Combustion (LEC)	Engine tuning improvements to increase combustion efficiency.	Units 701, 702, and 703	Potentially feasible	58-75%[10]
Selective Catalytic Reduction (SCR)	Exhaust control for lean-burn combustion that converts NO_x to nitrogen and water using ammonia or urea.	Units 701, 702, and 703	Not feasible based on documented difficulty implementing technology on RICE engines	70-90%[5]

2.3.3 Four Factor Analysis of Potential NO_x Control Options

2.3.3.1 Factor 1: Cost of Compliance

A quotation was provided by Cooper Machinery Services[10] which outlined the proposed LEC upgrades to Units 701, 702, and 703. Modifications include:

- Installing new cylinder heads fitted with pre-combustion chambers;
- Replacing existing water-cooled pulse exhaust manifold with a dry constant pressure exhaust manifold;
- Adding turbocharger bypass valves to exhaust manifold;
- Upgrading turbocharger to increase air-to-fuel ratio;
- Replacing current intercoolers with larger intercoolers; and
- Adding pilot fuel lines and pressure control for pre-combustion chamber fuel.

Cost effectiveness estimates from these upgrades range from $2,000 to $13,000 per ton of NO_x removed. See Appendix A for cost estimate calculations.

The capital costs for SCR, if one were to assume this was an 'achievable technology' for this application, are varied. There are a number of published cost estimates for typical coal- oil- and gas-fired medium to large sized boilers. The same cannot be said for a retrofit of a natural gas-fired compressor engine. In addition, the cost to retrofit an engine with SCR is much higher than an original SCR installation, which would apply to this analysis. SCR systems used to retrofit an existing unit increase in costs by 30%.[5] O&M costs may also be substantial depending on reagent usage,

catalyst replacement, and increased electrical usage. The cost effectiveness of SCR was estimated from $1,400 to $6,600 per ton removed.

See Appendix A for emission reductions and cost calculations.

Table 2.2 Summary of Cost Effectiveness of Potential NO_x Control Options

Control Option	Specific Design Parameters	Cost Effectiveness (2019 $/ton)	Factors Affecting Cost	Potential Applicability to Specific Affected Units
Low Emissions Controls (LEC)	Power cylinder heads, upgraded water coolers, high efficiency turbocharger, and miscellaneous on-engine assemblies.	$2,000 - $13,000	Annual hours of operation, target NO_x emission factor	Potentially applicable to units 701, 702, and 703
Selective Catalytic Reduction (SCR)	Exhaust control that converts NO_x to nitrogen and water using ammonia or urea.	$1,400 - $6,600	Contamination from byproducts, excessive routine maintenance, reagent usage	Potentially applicable to units 701, 702, and 703

2.3.3.2 Factor 2: Time Necessary for Compliance

According to NMED guidance, sources are generally given between two and five years to implement changes for compliance with new regulations and implementation of this LEC would fall within that timeframe. Although no specific data was found, it would be reasonable to assume that a two to five year period would also be appropriate for the installation of SCR.

2.3.3.3 Factor 3: Energy and Non-Air Impacts

The LEC technology does not require the handling or storage of hazardous materials and does not require changes that could create an energy demand penalty.

As described above, SCR systems require ammonia (aqueous and/or anhydrous) or urea-to-ammonia reagents. Anhydrous ammonia is considered a hazardous material, and would be subject to storage, transportation, and operational regulations.

2.3.3.4 Factor 4: Remaining Useful Life of the Source

Although the engines were manufactured in the 1960s, they are planned for continuous operation until they are no longer functional. The estimated service life of the assessed control equipment (LEC and SCR) is 25 years.[6] Based on this information, the control options are considered the

limiting factor for useful life of the source. The cost effectiveness for applying the control options considers this as the minimum lifespan.

Dear Mr. Singleton:

Re: Additional Information for Four Factor Analysis
Mountainair Compressor Station
Transwestern Pipeline Company, LLC

GHD Services, Inc. (GHD) is submitting, on behalf of Transwestern Pipeline Company, LLC., responses to the New Mexico Environmental Department (NMED) request for additional information dated December 18, 2019 regarding the four-factor analysis completed for the Mountainair Compressor Station. These responses correspond to the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309).

If you have any questions or concerns, please contact myself at (720) 974-0937 or Larry Campbell at (575) 625-8022.

Sincerely,

GHD

Sergio Guerra
Project Manager

Attachments Index

Attachment A – Cooper Machinery Quote for Low Emission Controls Retrofit
Attachment B – Selected Pages from Chapter 2 SCR, EPA Cost Control Manual (updated June 2019)
Attachment C – Updated Electronic Cost Analysis Spreadsheet
Attachment D – NMED Additional Information Request Letter dated December 18, 2019

1. The source category identified for analysis should include all sources that have PTE of 10 lb/hr of NO_x or SO_2; therefore the two (2) 335-hp natural gas-fired Ingersoll-Rand PSVG-6 generator engines also need to be evaluated for potential control options.
These generators were discussed in Section 2.1 of the original Four-Factor Analysis Report submitted to NMED on October 30, 2019. The two (2) 335 hp generator engines already have Non-Selective Catalytic Reduction (NSCR) controls installed on them to reduce NOx emissions, which is considered BACT. Additionally, the permit for the facility states that only one generator may operate at a time except during start-up/shutdown transitions, so the generators are scheduled to operate for limited hours. We contacted Kerwin Singleton of NMED on 01/13/2020 to confirm that these generators will not need to be evaluated for further potential control options and he verbally agreed.

2. Provide the basis for the Operational and Maintenance (O&M) Costs used in the cost analysis.
The basis for O&M costs is that they are a percentage of the initial capital cost investment. The O&M percentage was calculated based on a four-factor cost analysis for a facility in North Dakota performed on similar controls for similar equipment. The primary reference for that North Dakota cost analysis is the EPA Air Pollution Control Cost Manual, 7th Edition, Sections 2.5 and 2.6.

3. Please provide the details regarding Good Combustion Practices (GCP) and the routine maintenance schedule and procedures that are currently used to mitigate NO_x emissions and are proposed as a feasible control.
Energy Transfer performs regular inspection and maintenance activities for the equipment on site. Maintenance schedule and procedures and the associated tracking, monitoring, testing, and recordkeeping are required in the facility operating permit.

4. Consider and include a discussion on the feasibility and cost of technology that limits engine capacity to reduce NO_x emissions. Also evaluate limiting operating hours or consider shutting down engines that are no longer needed to reduce emissions.
Energy Transfer cannot reduce the engine capacity or hours of operation for Units 701, 702, and 703 due to the operational needs of the site.

5. Please consider and include a discussion on the feasibility of replacing natural gas fueled engines with commercial electric powered compressors.
All electricity for this site is generated by the two (2) 335-hp natural gas-fired Ingersoll-Rand PSVG-6 generator engines, which are needed because the site does not have access to the electric grid. Since electricity is supplied by generators instead of the electric grid, it is not feasible to use electric powered compressors at this facility.

6. The four-factor analysis proposes a 2.5 grams per brake horsepower-hour (g/bhp-hr.) NO_X emission rate achievable by Low Emission Controls for Cooper Bessemer engines at the facility. Please provide a vendor quote with cost and control efficiency for Low Emission Controls.
Please see attached Cooper Machinery quote which includes a 2.5 g/hp-hr emission factor (Attachment A).

7. Consider and include a discussion of variations of Clean Burn Technology (CBT) used to reduce NO_X emissions that may be less expensive than the full CBT packages proposed. Please include cost and efficiencies in the analysis.
Please see correspondence with and quote from Cooper Machinery (Attachment A) which states that the full package of CBT is necessary to achieve emission reductions. The retrofit upgrades presented and quoted by Cooper include:

1) Install new cylinder heads fitted with precombustion chambers
2) Replace existing water-cooled pulse type exhaust manifold with a dry constant pressure manifold.
3) Add bypass valve to exhaust manifold to permit control of intake manifold pressure by bypassing some exhaust from the turbocharger.
4) Upgrade turbocharger to flow more air into combustion chamber
5) Remove existing expansion turbo-coolers.
6) Replace small intercoolers with larger intercoolers.
7) Add pilot fuel lines and pressure control for precombustion chamber fuel

8. Please verify and provide documentation that control systems have not yet been developed for selective catalytic reduction (SCR) controls that can handle variable load engines. This appears to be one main reason that SCR has not been implemented on two-stroke lean burn (2SLB) internal combustion engines in oil and gas midstream operations.
SCR technology was developed for combustion equipment and has been implemented on boilers which generally have lower emissions than compressor engines. Based on the INGAA source referenced in the Four Factor Analysis, SCR technology has been universally determined as not practical for engines due to the unreasonable cost of retrofitting (more expensive than a new installation) and the burdensome effort required to handle the hazardous materials involved (INGAA, Availability and Limitations of NOx Emission Control Resources, 2014). This includes the generation, capturing, disposal of, and replacing of catalytic reagants. Our understanding is that for these reasons and based on the information provided in Sections 2.3.2 and 2.3.3 of the Four-Factor Analysis dated October 30, 2019, SCR control systems are not a practical control measure for the compressor engines at this facility.

Chapter 2 of the EPA SCR cost manual (updated June 2019) (Attachment B) supports the information above. The only example provided for SCR technology used on a RICE engine occurred in 1994 on a new 1,800 hp diesel-fired engine but not for a natural gas engine. All other examples of SCR applications were for other types of combustion equipment often in industries other than oil & gas.

9. Please provide vendor quotes that include the cost information, recommendations, and equipment specifications for the engine control cost estimates.
Please see attached Cooper Machinery quote (Attachment A).

10. Provide any electronic spreadsheets used for control technology calculations.
Please see attached updated electronic spreadsheet (Attachment C).

Subject: RE: Engine Retrofit - Low Emission Controls - Roswell and Mountainair

Andrew, to achieve lower emissions the full package must be done.

Installing jetcell heads will definitely make the engines run with greater stability, however, this the improved combustion will result in lower exhaust temperatures as more fuel will go to providing effective work. The lower temperatures will reduce the energy needed to drive the turbocharger so there will not be sufficient air to lean out the air/fuel mixture necessary to reduce NOx emissions.

To achieve the leaner air/fuel mixture with jetcell heads requires a higher efficiency constant pressure turbocharger with a constant pressure exhaust manifold. To be able to control air fuel ratio, it is necessary to control the turbocharger speed. To do this we install a wastegate before the turbocharger which allows some of the exhaust gas to bypass the turbocharger. This is not possible with the pulse type manifold currently installed on the engine because it has individual pipes for each cylinder collecting into multiple inlets on the turbine casing.

The higher air flow from the turbocharger will require larger coolers to be installed to keep intake manifold temperature within limits.

We have provided a quick budget number with some consideration that this project may not be done for several years. Is there an estimated schedule for the job?

Best regards
Bob Bailey

Hi Bob,

Thanks for providing the general LEC quote below to my colleague Phil Horn back in October and hope 2020 is starting well for you.

The State of Mexico has asked for Cooper to now provide cost estimates for each of the individual upgrades mentioned below (i.e. install new cylinder heads, replace manifold, add bypass valve, etc.). They are interested in whether a “partial package” of upgrades might be more cost effective for controlling NOx emissions than the full $1,800,000 package. Would you be able to provide this for us?

Thanks very much for your help with this and please let me know any questions.

Best regards,

Andy White

Subject: RE: Engine Retrofit - Low Emission Controls - Roswell and Mountainair

Hello Phil

After doing some discussions we can upgrade these engines by doing following:

Install new cylinder heads fitted with precombustion chambers

Replace existing water cooled pulse type exhaust manifold with a dry constant pressure manifold.

Add bypass valve to exhaust manifold to permit control of intake manifold pressure by bypassing some exhaust from the turbocharger.

Upgrade turbocharger to flow more air into combustion chamber

Remove existing expansion turbo-coolers.

Replace small intercoolers with larger intercoolers.

Add pilot fuel lines and pressure control for precombustion chamber fuel.

Considering the age and condition of the engines, these changes will allow reliable operation with NoX emissions of 2.5 gm/bhp-hr at full load. This would be better stated in lb/hr and I will get you that value tomorrow.

Budget price for this is US$ 1,800,000 per engine.

I trust this will meet your needs for now (I will get you lb-hr value tomorrow).

Best regards
Bob Bailey

2. SELECTIVE CATALYTIC REDUCTION

2.1 Introduction

Selective catalytic reduction (SCR) has been applied to stationary source fossil fuel-fired combustion units for emission control since the early 1970s and is currently being used in Japan, Europe, the United States, and other countries. In the U.S. alone, more than 1,000 SCR systems have been installed on a wide variety of sources in many different industries, including utility and industrial boilers, process heaters, gas turbines, internal combustion engines, chemical plants, and steel mills [1]. Other sources include fluid catalytic cracking units (FCCUs), ethylene cracker furnaces, nitric acid plants, catalyst manufacturing processes, nitrogen fixation processes, and solid/liquid or gas waste incinerators [2, 3]. In the U.S., SCR has been installed on more than 300 coal-fired power plants ranging in size from less than 100 megawatt equivalent (MWe) to 1,400 MWe [1, 4]. Other combustion sources with large numbers of SCR retrofits include more than 50 gas-fired utility boilers ranging in size from 147 MWe to 750 MWe, more than 50 industrial boilers and process heaters (both field-erected and packaged units), and more than 650 combined cycle gas turbines [1]. SCR can be applied as a stand-alone nitrogen oxides (NO_x) control or with other technologies, including selective non-catalytic reduction (SNCR)[1] and combustion controls such as low NO_x burner (LNB) and flue gas recirculation (FGR) [2].

SCR is typically implemented on stationary source combustion units requiring a higher level of NO_x reduction than achievable by selective non-catalytic reduction (SNCR) or combustion controls. Theoretically, SCR systems can be designed for NO_x removal efficiencies up close to 100 percent. In practice, commercial coal-, oil-, and natural gas–fired SCR systems are often designed to meet control targets of over 90 percent. However, the reduction may be less than 90 percent when SCR follows other NO_x controls such as LNB or FGR that achieve relatively low emissions on their own. The outlet concentration from SCR on a utility boiler is rarely less than 0.04 lb/million British thermal units (MMBtu) [1].[2] In comparison, SNCR units typically achieve approximately 25 to 75 percent reduction efficiencies [5].

Either ammonia or urea may be used as the NO_x reduction reagent in SCR systems. Urea is generally converted to ammonia before injection. Results of a survey of electric utilities that operate SCR systems indicated that about 80 percent use ammonia (anhydrous and aqueous), and the remainder use urea [4]. A survey of coal-fired power plants that control NO_x emissions using either SCR or SNCR found anhydrous ammonia use exceeds aqueous ammonia use by a ratio of 3 to 1. Nearly half of these survey respondents also indicated that price is their primary consideration in the choice of reagent; safety is the primary consideration for about 25 percent of the operators [6].

SCR capital costs vary by the type of unit controlled, the fuel type, the inlet NO_x level, the outlet NO_x design level, and reactor arrangement. Capital costs also rose between 2000 and 2010 (at least for utility boiler applications), even after scaling all data to 2011 dollars (2011$).

[1] A hybrid SNCR/SCR system was demonstrated at the AES Greenidge Power Plant in 2006. However, no hybrid SNCR/SCR systems are currently known to be operating as of February 2016.

[2] Data in the Clean Air Markets Division (CAMD) database also suggest SCR units rarely achieve emissions less than 0.04 lb/MMBtu.

For a small number of early SCR retrofits on utility boilers prior to 2000, the average costs were about $100/kilowatt (kW), in 2011$, and there was little scatter in the data. From 2000 to 2007, the SCR costs for 32 utility boilers ranged from about $100/kW to $275/kW (2011$), and a slight economy of scale was evident (i.e., using a regression equation, costs ranged from about $200/kW for a 200 MW unit to $160/kW for an 800 MW unit). For 2008 to 2011, the average SCR costs exhibited great variability and again a modest economy of scale was evident (i.e., about $300/kW for a 200 MW unit to $250/kW for an 800 MW unit; 2011$). For eight utility boilers either installed in 2012 or projected to be installed by 2014, the SCR costs ranged from about $270/kW to $570/kW (2011$). The generating capacity for these units ranged from 400 MW to 800 MW [7]. Typical operation and maintenance costs are approximately 0.1 cents per kilowatt-hour (kWh) [8, 9]. Table 2.1a provides capital cost estimates for electric utility boilers, and Table 2.1b presents capital cost estimates for SCR applications of various sizes in several other industry source categories.

The procedures for estimating costs presented in this report are based on cost data for SCR retrofits on existing coal-, oil-, and gas-fired boilers for electric generating units larger than 25 MWe (approximately 250 MMBtu/hr). Thus, this report's procedure estimates costs for typical retrofits of such boilers. The methodology for utility boilers also has been extended to large industrial boilers by modifying the capital cost equations and power consumption (electricity cost) equations to use the heat input capacity of the boiler instead of electric generating capacity.[3] The procedures to estimate capital costs are not directly applicable to sources other than utility and industrial boilers. Procedures to estimate annual costing elements other than power consumption are the same for SCR units in any application. The cost of SCR as part of a new plant often is likely to be less than the cost for retrofitting an SCR at an existing plant. Appropriate factors to estimate the cost of a new plant SCR have been included. In addition, the cost procedures in this report reflect individual SCR applications. Retrofitting multiple boilers with SCR can allow for some economies of scale for installation, thus yielding some reduction in capital costs per SCR application. The cost methodology incorporates certain approximations; consequently, it should be used to develop study-level accuracy (±30 percent) cost estimates of SCR applications. Such accuracy in the cost methodology is consistent with the accuracy of the cost estimates for the other control measures found in this Cost Manual as stated in Section 1.

In the cement industry, pilot tests in the 1970s and 1990s showed that SCR could be a feasible control technology for cement kilns. Building on that experience, SCRs were first installed in Europe in 2001. Today, SCR has been successfully implemented at seven European cement plants in Solnhofer, Germany (operated from 2001 until 2006), Bergamo, Italy (2006), Sarchi, Italy (2007), Mergelstetten, Germany (2010), Rohrdorf, Germany (2011), Mannersdorf, Austria (2012), and Rezatto, Italy (2015) [10, 11, 12]. As of 2015, there is only one cement plant in the U.S. that has installed an SCR. This SCR began operation in 2013 and is installed after an electrostatic precipitator. The control efficiency for the system is reported to be about 80 percent, which is consistent with SCR applications on European kilns. SCRs have not seen widespread use in the U.S. cement industry mainly due to industry concerns regarding potential problems caused by high-dust levels and catalyst deactivation by high sulfur trioxide (SO_3) concentrations

[3] The term "industrial" boilers as used in the Control Cost Manual includes industrial, commercial, and institutional (or ICI) boilers, unless otherwise noted.

from pyritic sulfur found in the raw materials used by U.S. cement plants. The SO_3 could react with calcium oxide in the flue gas to form calcium sulfate and with ammonia to form ammonium bisulfate. The calcium sulfate could deactivate the catalyst, while the ammonium bisulfate could cause catalyst plugging. There have been concerns expressed about the potential for catalyst poisoning by sodium, potassium, and arsenic trioxide. Finally, other concerns expressed are that dioxins and furans may form in the SCR due to combustion gases remaining at temperatures between 450 degrees Fahrenheit (°F) and 750°F. These and other concerns regarding the implementation of SCR to the cement industry are discussed in detail in "Alternative Control Techniques Document Update – NO_x Emissions from New Cement Kilns" [10]. Due to the small number of SCRs installed at cement plants, information on capital and operating costs for SCRs at cement plants is limited. The installation and operating costs for the SCR installed at the U.S. plant in 2013 are not publicly available at this time. In general, we expect the capital and operating costs would be higher than for low-dust applications due to the need to install catalyst cleaning equipment for SCR systems installed in high-dust configurations and for heating the flue gas in low-dust, tail-end configurations.

Table 2.1a: Summary of SCR Cost Data for Utility Boilers

Source Category	Unit Size	Fuel Type	Capital Cost			$ Year	Comments	Reference
			Min	Avg	Max

Table 2.1b: Summary of SCR Cost Data for Miscellaneous Industrial Sources

Source Category	Unit Size	Fuel Type	Capital Cost: average (range)	$ Year	Actual, Vendor Quote, or Estimated?	Comments	Reference
Industrial-Commercial Boilers	350 MMBtu	Coal	NA ($10,000–$15,000/MMBtu/hr)	1999$	Estimated	Retrofit costs. Authors of referenced document estimated the low end of the range assuming a cost of about $100/kW for a 100 MW (1000 MMBtu/hr) utility boiler and assuming that economies of scale would be greater for utility boilers than for industrial boilers (so that the cost for a 350 MMBtu/hr industrial boiler would be comparable to or greater than the cost for a 1000 MMBtu/hr utility boiler on a $/MMBtu basis).	[19]
	100–1,000 MMBtu/hr	Coal	NA ($7,300–$14,600/MMBtu/hr)	1999$	Estimated	Retrofit costs. Generally costs available for one boiler with each type of fuel. Authors of referenced document estimated costs for other sizes assuming ratio of small-to-large $/MMBtu costs are related to ratio of large to small heat inputs raised to the 0.3 power.	[20]
	100–1,000 MMBtu/hr	Oil	NA ($5,550–$11,100/MMBtu/hr)	1999$	Estimated		[20]
	100–1,000 MMBtu/hr	Gas	NA ($4,010–$8,010/MMBtu/hr)	1999$	Estimated		[20]
	100 MMBtu/hr	Gas	NA ($7,500/MMBtu/hr)	1999$[b]	Vendor	Cited source in reference [15] is an unpublished letter from a vendor.	[19]
	350 MMBtu	Oil, Gas, or Wood	NA ($4,000–$6,000/MMBtu/hr)	1999$	Estimated		[21]
	57 MMBtu/hr	Wood	NA (>$560,000 and $9,500/MMBtu/hr)	1999$[c]	Actual/ Estimate	Costs for a new boiler.	[19]
	321 MMBtu/hr	Wood	NA ($1,980/MMBtu/hr)	2006$	Likely Estimated		[22]
Petroleum Refining – Steam Boilers	650 MMBtu/hr	Gas or refinery fuel gas	NA ($3,100–$25,800/MMBtu)	2004$ [c]	Estimated	Retrofit costs. Equipment costs based on range of costs found in literature search (references were not provided). Installation costs estimated using factors from the Control Cost Manual for thermal and catalytic incinerators.	[23]
Petroleum Refining – Process Heaters	350 MMBtu/hr	Gas/refinery fuel gas	NA ($3,100–$25,800/MMBtu)	2004$ [c]	Estimated	Same comment as above.	[23]
	350 MMBtu/hr	Refinery oil	NA ($3,100–$25,800/MMBtu)	2004$ [c]	Estimated	Same comment as above.	[23]

Source Category	Unit Size	Fuel Type	Capital Cost: average (range)	$ Year	Actual, Vendor Quote, or Estimated?	Comments	Reference
	10 MMBtu/hr	Gas or refinery fuel gas/NG combo	$19,200/MMBtu ($12,000–$26,500/MMBtu)	1999[b]	Vendor/ Estimated	Costs are based primarily on quotes from two vendors (and additional discussions). Authors of the referenced report added costs for fan, motor, and ductwork costs based on procedures in the Control Cost Manual.	[24]
	50 MMBtu/hr	Gas or refinery fuel gas/NG combo	$5,140/MMBtu ($4,020–$6,280/MMBtu)	1999[b]	Vendor/ Estimated	Same comment as above.	[24]
	75 MMBtu/hr	Gas or refinery fuel gas/NG combo	$4,190/MMBtu ($3,440–$4,950/MMBtu)	1999[b]	Vendor/ Estimated	Same comment as above.	[24]
	150 MMBtu/hr	Gas or refinery fuel gas/NG combo	$2,730/MMBtu ($2,570–$2,880/MMBtu)	1999[b]	Vendor/ Estimated	Same comment as above.	[24]
	350 MMBtu/hr	Gas or refinery fuel gas/NG combo	$1,550/MMBtu ($1,520–$1,570/MMBtu)	1999[b]	Vendor/ Estimated	Same comment as above.	[24]
	68 MMBtu/hr (Two 32 MMBtu/hr)	Refinery fuel gas	NA ($22,100/MMBtu)	1991	Actual	Retrofit costs.	[19]
Petroleum Refining – FCCU	70,000 barrels/stream day (bbl/stream day)	NA	NA ($9.0 million)	2004$[c]	Vendor	Estimated cost by vendor (for 90 percent reduction).	[3]
	27,000 bbl/stream day	NA	NA ($8-$12 million)	2009	Estimated		[25]

Source Category	Unit Size	Fuel Type	Capital Cost: average (range)	$ Year	Actual, Vendor Quote, or Estimated?	Comments	Reference
	<20,000->100,000 bbl/stream day	NA	NA (order of magnitude range; low end higher than two entries above)	2005 to 2010	Actual	Costs reported by 6 petroleum refining companies for 7 FCCUs in responses to EPA ICR. One new, 6 retrofits.	[26]
	NA	NA	NA ($20 million)	2006	Actual	Approximate average cost for SCR retrofits at several refineries	[27]
Portland Cement (dry kilns)	1.09 million short tpy clinker	NA	NA ($6.9 per short ton clinker)	2006[a]	Estimated	Retrofit cost. Estimate based primarily on SCR procedures for boilers in fifth edition of the Control Cost Manual. Clinker capacity obtained from the second reference.	[28,29]
	1.13 million short tpy clinker	NA	NA ($5.9 per short ton clinker)	2006[a]	Estimated	Same comment as above.	[28,29]
	2.16 million short tpy clinker	NA	NA ($3.9 per short ton clinker)	2006[a]	Estimated	Same comment as above.	[28,29]
	1.4 million short tpy clinker	NA	NA ($5.9 per short ton clinker)	2004	Not clear	Retrofit cost for European kiln. Cost in euros converted to dollars assuming a ratio of $1.3/euro.	[30]
	1.055 million tpy clinker	NA	NA ($4.4 per short ton clinker)	2004	Estimated	Cost for new kiln.	[31]
	1.095 million short tpy clinker	NA	NA ($4.4 per short ton clinker)	2011	Estimated	Cost for new kiln. Cost based on quote for the SCR equipment, and standard installation factors from the Control Cost Manual for other types of control devices.	[32]
Portland Cement (wet kilns)	0.3 million short tpy clinker	NA	NA ($17.5 per short ton clinker)	2006[a]	Estimated	Retrofit costs for 4 kilns. Rated clinker production capacity obtained from the second reference.	[28,33]
	0.320 million short tpy clinker		NA ($15.6-$16.6 per short ton clinker)	2006[a]	Estimated	Retrofit costs for 3 kilns. Rated clinker production capacity obtained from second reference.	[28,29]

Source Category	Unit Size	Fuel Type	Capital Cost: average (range)	$ Year	Actual, Vendor Quote, or Estimated?	Comments	Reference
Gas Turbine, Simple Cycle	NA	Gas	NA ($50-$70/kW)	1999$[a]	Vendor	Retrofit costs.	[19]
	80 MW	Gas	NA ($51/kW)	1999$[a]	Vendor	Retrofit cost, excluding balance of plant costs.	[19]
	2 MW	Gas	NA ($237/kW)	1999$[a]	Vendor	Retrofit cost.	[19]
	12 MW	Gas	NA ($167/kW)	1999$[a]	Vendor	Retrofit cost.	[19]
Internal Combustion Engine	1,800 hp[d]	Diesel (No. 2 fuel oil)	NA ($0.18 million)	1994	Actual	New cost	[19]

[a] Year of reference.

[b] Year analysis was conducted (assumed vendor contacts were made that year).

[c] Commission year of the SCR.

[d] Horsepower.

Subject: Request for Additional Information for Four-Factor Analyses under the Regional Haze Program

Dear Mr. Campbell:

This letter requests additional information for the Transwestern Mountainair No. 7 Compressor Station Four-Factor Analysis report that was received by the New Mexico Environment Department (NMED) Air Quality Bureau (AQB) on November 1st, 2019. Pursuant to NMED's Regional Haze Guiding Principles, the four-factor analysis must consider new ideas that potentially offer better solutions to problems and must evaluate the newest engineering methods and technology advances in potential control measures.

Based on our initial review, the NMED requires additional information, analyses and clarifications on Transwestern Pipeline's four-factor analysis as follows.

1. The source category identified for analysis should include all sources that have PTE of 10 lbs./hr. of NO_X or SO_2; therefore the two (2) 335-hp natural gas-fired Ingersoll-Rand PSVG-6 generator engines also need to be evaluated for potential control options.
2. Provide the basis for the Operational and Maintenance (O&M) Costs used in the cost analysis.
3. Please provide the details regarding Good Combustion Practices (GCP) and the routine maintenance schedule and procedures that are currently used to mitigate NO_X emissions and are proposed as a feasible control.
4. Consider and include a discussion on the feasibility and cost of technology that limits engine capacity to reduce NO_X emissions. Also evaluate limiting operating hours or consider shutting down engines that are no longer needed to reduce emissions.
5. Please consider and include a discussion on the feasibility of replacing natural gas fueled engines with commercial electric powered compressors.
6. The four-factor analysis proposes a 2.5 grams per brake horsepower-hour (g/bhp-hr.) NO_X emission rate achievable by Low Emission Controls for Cooper Bessemer engines at the facility. Please provide a vendor quote with cost and control efficiency for Low Emission Controls.

7. Consider and include a discussion of variations of Clean Burn Technology (CBT) used to reduce NO_X emissions that may be less expensive than the full CBT packages proposed. Please include cost and efficiencies in the analysis.
8. Please verify and provide documentation that control systems have not yet been developed for selective catalytic reduction (SCR) controls that can handle variable load engines. This appears to be one main reason that SCR has not been implemented on two-stroke lean burn (2SLB) internal combustion engines in oil and gas midstream operations.
9. Please provide vendor quotes that include the cost information, recommendations, and equipment specifications for the engine control cost estimates.
10. Provide any electronic spreadsheets used for control technology calculations.

Please note, NMED must document the cost and engineering information used to analyze potential control measures. If you feel that your supplemental information should be classified as confidential business information (CBI), it will need to be reviewed and approved as such by NMED and EPA. Submit CBI with the word 'confidential' included in the electronic file name and on each page of the document. Do not combine non-confidential business information and CBI in the same files. Also, the claimant must satisfy the conditions in 20.2.1.115.B(3)(a)-(d) NMAC when the CBI is submitted. Until NMED and EPA determines if the information qualifies as CBI, the information will not be disclosed to anyone other than those listed in 20.2.1.115 NMAC.

NMED respectfully requests that your company submit the additional information on four-factor analysis electronically as soon as possible to Kerwin Singleton and Mark Jones. Please contact NMED if you have questions about the additional information request. We encourage your questions in order to help expedite the technical analysis required under the Regional Haze Program. Staff would be happy to meet with you in person to discuss these requirements in more detail. Likewise, staff may further contact you with questions or require additional information during its review of your submittals.

Thank you for your assistance in this matter. If you have questions or need clarification, please contact me at (505) 476-4350, kerwin.singleton@state.nm.us, or Mark Jones at (505) 566-9746, mark.jones@state.nm.us.

Sincerely,

Kerwin Singleton
Planning Section Chief

Transwestern Pipeline Company - Roswell Compressor Station No. 9

Unit 903: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.43	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	278,211,765	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3620	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	3.233	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.6466	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Unit 903: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	34	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	292,538,118	scf/Year	
Actual Annual fuel consumption (Mactual) =		278,211,765	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.951	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8331	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	89.05	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	370.93	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.14		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	267.70	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	35	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	119	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	16	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	5,400	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.38	kW

Unit 903: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,354,033	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$106,048 in 2024 dollars
Indirect Annual Costs (IDAC) =	$233,700 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$339,748 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$11,770 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$70,254 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$16,981 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$7,042 in 2024 dollars
Direct Annual Cost =		$106,048 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,769 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$230,931 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$233,700 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$339,748 per year in 2024 dollars
NOx Removed =	371 tons/year
Cost Effectiveness =	$916 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Transwestern Pipeline Company - Roswell Compressor Station No. 9

Unit 904: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	36.06	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	267,984,210	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3620	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	1.521	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.3041	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			
Number of SCR reactor chambers (n_{scr})	1			
Number of catalyst layers (R_{layer})	3			
Number of empty catalyst layers (R_{empty})	1			
Ammonia Slip (Slip) provided by vendor	2	ppm		
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet		
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm		
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours		
Estimated SCR equipment life	20	Years*		
Gas temperature at the SCR inlet (T)	650	°F		
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour		
Concentration of reagent as stored (C_{stored})	29	percent*		
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14	days		

* For industrial boilers, the typical equipment life is between 20 and 25 years.

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 904: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	36	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	306,387,585	scf/Year	
Actual Annual fuel consumption (Mactual) =		267,984,210	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.875	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7662	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	43.86	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	168.04	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.14		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00

Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	21.35	kW

Unit 904: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,425,885	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$65,545 in 2024 dollars
Indirect Annual Costs (IDAC) =	$240,753 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$306,298 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,129 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$31,827 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$16,357 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$5,231 in 2024 dollars
Direct Annual Cost =		$65,545 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,774 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$237,979 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$240,753 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$306,298 per year in 2024 dollars
NOx Removed =	168 tons/year
Cost Effectiveness =	$1,823 per ton of NOx removed in 2024 dollars

Dear Mr. Jones:

Re: Four Factor Analysis
Roswell Compressor Station
Transwestern Pipeline Company, LLC

GHD Services, Inc. (GHD) is submitting, on behalf of Transwestern Pipeline Company, LLC., a four-factor analysis of the Roswell Compressor Station to the New Mexico Environment Department (NMED). This report is for the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309).

If you have any questions or concerns, please contact myself at (720) 974-0937 or Larry Campbell at (575) 625-8022.

Sincerely,

GHD

Sergio Guerra
Project Manager

VOC ..... Volatile Organic Compound

1. Executive Summary

In response to the New Mexico Environment Department (NMED) letter dated July 18, 2019, GHD Services, Inc. (GHD) was retained by ETC Texas Pipeline, LTD, the parent company of Transwestern Pipeline Company, LLC, to prepare a four-factor analysis for the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309). As a part of this Progress Analysis, NO_x and SO_2 emissions were evaluated at the Roswell Compressor Station (Roswell CS).

The four-factor analysis is codified in 40 CFR §51.308(d)(1)(i)(A) and is designated as a means for establishing reasonable progress goals towards achieving natural visibility conditions. The four factors to consider are:

1. The costs of compliance
2. The time necessary for compliance
3. The energy and non-air quality environmental impacts of compliance
4. The remaining useful life of any potentially affected sources

The purpose of the four-factor analysis is to identify control measures for reducing emissions that could be used to establish the long-term strategy for attaining the states visibility goals. The NMED has requested that evaluations be completed for individual equipment that have a potential to emit (PTE) greater than ten pounds per hour of NO_x or SO_2. The source categories identified at Roswell CS for evaluation are two existing compressor engines (Units 903 and 904). NMED also instructed to use actual emissions from reporting year 2016 as a baseline to calculate emission reductions for control options evaluated. However, permitted hourly NO_x emission rates were used for Unit 904 in this analysis due to the 2016 emissions inventory showing lower NO_x emission rates than what was feasible to obtain by the engine vendor. The cost range for emission reductions reflects the range of operation time in 2016 between the two RICE compressor engines analyzed. The results of the subsequent four-factor analysis are in Table 1.1 below.

Table 1.1 Summary of Roswell CS Four Factor Analysis Results

Source Category	Regional Haze Pollutant and Control Option Analyzed	Average Cost in 2019 Dollars (dollars per ton of pollutant reduction)	Compliance Timeframe	Energy & Non-Air Quality Impacts	Remaining Useful Life
RICE Engines	NO_x; Low Emission Controls (LEC)	$7,000 - $15,300	2-5 Years	None known for LEC	25 years for controls; Indefinite for RICE engines
	NO_x; Selective Catalytic Reduction (SCR)	$4,300- $5,500	2-5 Years	Storage and handling of hazardous materials	25 years for controls; Indefinite for RICE engines

2. Source Category Analysis for RICE Engines

2.1 Source Category Description

Roswell CS operates two (2) Reciprocating Internal Combustion Engines (RICE) that are subject to the requirements of the four-factor analysis. Both engines are 4,500-hp natural gas-fired Cooper-Bessemer LSV-16G compressor engines (Units 903 and 904) used for transportation of natural gas. Roswell CS operates two (2) electric-driven compressor engines that do not have associated emissions. Roswell CS also operates one (1) 408-hp natural gas-fired Ingersoll-Rand PSVG-6 generator engine that operates less than 100 hours per year and is therefore an exempt source, per NMAC 20.2.72.202.B.3.

2.2 Clean Air Act and State Regulations

The two compressor engines subject to this analysis are subject to the following state and federal regulations:

20.2.61.109 NMAC

This regulation limits opacity to 20% applies to Stationary Combustion Equipment, such as engines, boilers, heaters, and flares unless your equipment is subject to another state regulation that limits particulate matter such as 20.2.19 NMAC (see 20.2.61.109 NMAC). Units 903 and 904 are subject to this regulation.

20.2.82 NMAC

The listed units are subject to MACT standards. Roswell CS's engines (Units 903, 904) are subject to 40 CFR Part 63, Subpart ZZZZ and are therefore subject to this regulation.

MACT 40 CFR 63, Subpart ZZZZ

The station is a major source of hazardous air pollutant (HAP) emissions; therefore, this rule applies to the engines located at the station. Engines 903 and 904 are existing 4SLB engines of greater than 500 horsepower (hp). Per §63.6590(b)(3)(ii), these engines are subject to the regulation, but do not have any requirements under Subpart ZZZZ.

2.3 NO_x Emissions and Control Options

NO_x is generated from the combustion of natural gas used to power the applicable compressor engines. The exhaust gases are released to the atmosphere through stacks associated with each engine.

There are several categories of NO_x formation in combustion processes. The combustion process taking place in RICE predominantly produces thermal NO_x[1] which is formed when nitrogen and oxygen unite during high temperature and high pressure combustion.[2]

While neither engine currently utilizes NO_x emission controls, two control options were assessed for the applicable engines: Low Emission Controls (LEC) and Selective Catalytic Reduction (SCR).

2.3.1 Low Emission Controls (LEC)

LEC is a combination of combustion controls in which various engine modifications, upgrades, and tuning methods provide lower emission combustion.

One upgrade includes increasing the air-to-fuel ratio (AFR) to reduce thermal NO_x formation by diluting combustion gases and lowering peak flame temperature. Upgrades to the AFR controller and turbocharger would be required. Adjusting ignition timing is another modification associated with LEC. This control delays ignition in the power stroke when the chamber is below its maximum pressure. This causes ignition at a lower temperature, thus lowering thermal NO_x formation during combustion. Other LEC options include installing cylinder heads fitted with pre-combustion chambers, larger intercooling applications, enhanced mixing, bypass valves, and increased ignition energy.[3]

A quotation provided by Cooper Machinery Services shows that these LEC upgrades can lower NO_x emission rates to 2.5 g/hp-hr.[10]

2.3.2 Selective Catalytic Reduction (SCR)

SCR is a post-combustion control for lean-burn combustion in which ammonia or urea is mixed with exhaust gases over a catalyst to (ideally) convert NO_x to nitrogen gas (N_2) and water (H_2O). While SCR has been applied to large boilers and turbines in the power generation industry, its application on new RICE in the gas transmission industry has been rare, and retrofitted applications for existing lean burn RICE had not occurred as of 2014.[4]

There are several factors that make SCR difficult for this application. Technical concerns, such as reagent injection control, exhaust temperature requirements, and variations in the exhaust NO/NO_2 ratio, pose limitations on the effectiveness and feasibility of SCR. NOx reduction may not be achieved, or even more ammonium sulfates may be emitted if the reagent feed rate and/or operating temperature is not precisely tuned to the fluctuating exhaust properties.[4]

Another challenge is that combustion byproducts and engine oil carryover often contaminate the catalytic elements in SCR applications. Routine cleaning and replacement as well as greater management are required for effective use.[4]

For these reasons, LEC is the preferred control method.

Table 2.1 below summarizes the control technology options:

Table 2.1 Summary of Potential No_x Control Options

Technology	Description	Applicability	Feasibility	Performance (% reduction)
Low Emission Combustion (LEC)	Engine tuning improvements to increase combustion efficiency.	Potentially applicable to Units 903 and 904	Potentially feasible	33-80%
Selective Catalytic Reduction (SCR)	Exhaust control that converts NO_x to nitrogen and water using ammonia or urea.	Not applicable based on documented difficulty implementing technology on RICE engines	Not feasible based on documented difficulty implementing technology on RICE engines	70-90%[5]

2.3.3 Four Factor Analysis of Potential NO_x Control Options

2.3.3.1 Factor 1: Cost of Compliance

A quotation was provided by Cooper Machinery Services[10] which outlined the proposed LEC upgrades to Units 903 and 904. Modifications include:

- Installing new cylinder heads fitted with pre-combustion chambers;
- Replacing existing water-cooled pulse exhaust manifold with a dry constant pressure exhaust manifold;
- Adding turbocharger bypass valves to exhaust manifold;
- Upgrading turbocharger to increase air-to-fuel ratio;
- Replacing current intercoolers with larger intercoolers; and
- Adding pilot fuel lines and pressure control for pre-combustion chamber fuel.

Cost effectiveness estimates from these LEC upgrades range from $7,000 - $15,300 per ton of NO_x removed. See Appendix A for cost estimate calculations.

The capital costs for SCR, if one were to assume this was an 'achievable technology' for this application, are varied. There are a number of published cost estimates for typical coal- oil- and gas-fired medium to large sized boilers. The same cannot be said for a retrofit of a natural gas-fired compressor engine. In addition, the cost to retrofit and engine with SCR is much higher than an

original SCR installation, which would apply to this analysis. SCR systems used to retrofit an existing unit increase costs by 30%.[5] O&M costs may also be substantial depending on reagent usage, catalyst replacement, and increased electrical usage. The cost effectiveness of SCR was estimated from $4,300- $5,500 per ton removed.

See Appendix A for emission reductions and cost calculations.

Table 2.2 Summary of Cost Effectiveness of Potential No_x Control Options

Control Option	Specific Design Parameters	Cost Effectiveness (2019 $/ton)	Factors Affecting Cost	Potential Applicability to Specific Affected Units
Low Emissions Controls (LEC)	Power cylinder heads, upgraded water coolers, high efficiency turbocharger, and miscellaneous on-engine assemblies.	$7,000 - $15,300	Annual hours of operation, target NO_x emission factor	Potentially applicable to units 903 and 904
Selective Catalytic Reduction (SCR)	Exhaust control that converts NO_x to nitrogen and water using ammonia or urea.	$4,300- $5,500	Contamination from byproducts, excessive routine maintenance, reagent usage	Potentially applicable to units 903 and 904

2.3.3.2 Factor 2: Time Necessary for Compliance

According to NMED guidance, sources are generally given between two and five years to implement changes for compliance with new regulations and implementation of this LEC would fall within that timeframe. Although no specific data was found, it would be reasonable to assume that a two to five year period would also be appropriate for the installation of SCR.

2.3.3.3 Factor 3: Energy and Non-Air Impacts

The LEC technology does not require the handling or storage of hazardous materials and does not require changes that could create an energy demand penalty.

As described above, SCR systems require ammonia (aqueous and/or anhydrous) or urea-to-ammonia reagents. Anhydrous ammonia is considered a hazardous material, and would be subject to storage, transportation, and operational regulations.

2.3.3.4 Factor 4: Remaining Useful Life of the Source

Although engines 903 and 904 were manufactured in 1959, they are planned for continuous operation until they are no longer functional. The estimated service life of the assessed control equipment (LEC and SCR) is 25 years.[6] Based on this information, the control options are

considered the limiting factor for useful life of the source. The cost effectiveness for applying the control options considers this as the minimum lifespan.

PART B GENERAL CONDITIONS (Attached)

PART C MISCELLANEOUS: Supporting On-Line Documents; Definitions; Acronyms (Attached)

PART A FACILITY SPECIFIC REQUIREMENTS

A100 Introduction

A. Not Applicable

A101 Permit Duration (expiration)

A. The term of this permit is five (5) years. It will expire five years from the date of issuance. Application for renewal of this permit is due twelve (12) months prior to the date of expiration. (20.2.70.300.B.2 and 302.B NMAC)

B. If a timely and complete application for a permit renewal is submitted, consistent with 20.2.70.300 NMAC, but the Department has failed to issue or disapprove the renewal permit before the end of the term of the previous permit, then the permit shall not expire and all the terms and conditions of the permit shall remain in effect until the renewal permit has been issued or disapproved. (20.2.70.400.D NMAC).

A102 Facility: Description

A. This facility is a natural gas compressor station, providing compression of natural gas along a pipeline that transports the gas from production and processing areas to end users.

B. This facility is located approximately 5 miles north of Roswell, New Mexico in Chaves County. (20.2.70.302.A(7) NMAC)

C. This renewal consists of the following. The description of this renewal is for informational purposes only and is not enforceable:

- This Title V renewal incorporates the following equipment listed within NSR Permit 6742, issued May 27, 2016, into operating permit P154-R4: Two MIST extractors (MIST-1 and MIST-2) and six condensate tanks TK-1, TK-30, TK-31, TK-32, TK-33, and TK-34.
- This permit's allowable hourly NOx emission limits for Units 903, 904, and 921 are returned to those modeled for the 2009 Title V permit.
- The allowable annual operating hours for Units 903 and 904 are increased from the previous combined 13,248 total hours of operation per year to 8,760 hours of operation per year per engine.
- The allowable annual operating hours for Unit 921 is increased from 2,680 to 4,500 hours.

D. Tables 102.A and Table 102.B show the potential to emit (PTE) from this facility for information only. This is not an enforceable condition and excludes insignificant or trivial activities.

Table 102.A: Total Potential to Emit (PTE) from Entire Facility

Pollutant	Emissions (tons per year)
Nitrogen Oxides (NOx)	1,122.5
Carbon Monoxide (CO)	160.3
Volatile Organic Compounds (VOC) *	116.5
Sulfur Dioxide (SO_2)	0.8
Total Suspended Particulates (TSP)	4.0
Particulate Matter 10 microns or less (PM_{10})	4.0
Particulate Matter 2.5 microns or less ($PM_{2.5}$)	4.0
Greenhouse Gas (GHG) as CO_2e	72,123

* VOC total includes emissions from Fugitives, SSM and Malfunctions

Table 102.B: Total Potential to Emit (PTE) for *Hazardous Air Pollutants (HAPs) that exceed 1.0 ton per year

Pollutant	Emissions (tons per year)
Acetaldehyde	3.2
Acrolein	2.0
Formaldehyde	19.9
Total HAPs**	27.7

* HAP emissions are already included in the VOC emission total.

** The total HAP emissions may not agree with the sum of individual HAPs because only individual HAPs greater than 1.0 tons per year are listed here.

A103 Facility: Applicable Regulations and Non-Applicable Regulations

A. The permittee shall comply with all applicable sections of the requirements listed in Table 103.A.

Table 103.A: Applicable Requirements

Applicable Requirements	Federally Enforceable	Unit No.
NSR Permit No: **1776M1 & 1777M1** (Per 20.2.72 NMAC)	X	SVE-1 and SVE-2
NSR Permit No: **6742** (Per 20.2.72 NMAC)	X	MIST-1 MIST-2; TK-1, TK-30, TK-31, TK-32, TK-33 and TK-34
20.2.1 NMAC General Provisions	X	Entire Facility
20.2.7 NMAC Excess Emissions	X	Entire Facility

Table 103.A: Applicable Requirements

Applicable Requirements	Federally Enforceable	Unit No.
20.2.61 NMAC Smoke and Visible Emissions	X	903, 904, 921, SVE-1 and SVE-2
20.2.70 NMAC Operating Permits	X	Entire Facility
20.2.71 NMAC Operating Permit Emission Fees	X	Entire Facility
20.2.72 NMAC Construction Permit	X	Entire Facility
20.2.73 NMAC Notice of Intent and Emissions Inventory Requirements	X	Entire Facility
20.2.74 NMAC Permits – Prevention of Significant Deterioration (PSD)	X	Entire Facility
20.2.82 NMAC MACT Standards for Source Categories of HAPS	X	921
40 CFR 50 National Ambient Air Quality Standards	X	Entire Facility
40 CFR 63, Subpart A, General Provisions	X	921
40 CFR 63, Subpart ZZZZ	X	921
40 CFR 63, Subpart GGGGG, Site Remediation	X	SVE-1 and SVE-2

B. Table 103.B lists requirements that are **not** applicable to this facility. This table only includes those requirements cited in the application as applicable and determined by the Department to be not applicable, or the Department determined that the requirement does not impose any conditions on a regulated piece of equipment.

Table 103.B: Non-Applicable Requirements

Non-Applicable Requirements	(1)	(2)	Justification For Non-Applicability
N/A			

1. Not Applicable for This Facility: No existing or planned operation/activity at this facility triggers the applicability of these requirements.
2. No Requirements: Although these regulations may apply, they do not impose any specific requirements on the operation of the facility as described in this permit.

C. Compliance with the terms and conditions of this permit regarding source emissions and operation demonstrate compliance with national ambient air quality standards specified at 40 CFR 50, which were applicable at the time air dispersion modeling was performed for the facility's NSR Permit P154-R2M1.

A104 Facility: Regulated Sources

A. Table 104.A lists the emission units authorized for this facility. Emission units identified as insignificant or trivial activities (as defined in 20.2.70.7 NMAC) and/or equipment not regulated pursuant to the Act are not included.

Table 104.A: Regulated Sources List

Unit No.	Source Description	Make	Model	Serial No.	Construction/ Reconstruct Date	Manuf. Date	Manufacturer Rated Capacity /Permitted Capacity
903	4SLB RICE	Cooper-Bessemer	LSV-16SSG	7030	1959	1959	4500 hp / 4500 hp

SSM/M	Startup, Shutdown, Maintenance, and Malfunctions	N/A	N/A	N/A	N/A	N/A	N/A

1. All TBD (to be determined) units and like-kind engine replacements must be evaluated for applicability to NSPS and MACT requirements.

A105 Facility: Control Equipment

A. Table 105.A lists all the pollution control equipment required for this facility. Each emission point is identified by the same number that was assigned to it in the permit application.

Table 105.A: Control Equipment List:

Control Equipment Unit No.	Control Description	Pollutant being controlled	Control for Unit No.[1]
SVE-1	Thermal Oxidizer	VOCs & HAPs	SVE-1
SVE-2	Thermal Oxidizer	VOCs & HAPs	SVE-2

1 Control for unit number refers to a unit number from the Regulated Equipment List

B. Thermal Oxidizer (Units SVE-1 and SVE-2)

Requirement: (1) The off-gas from the SVE Systems shall be controlled by the Thermal Oxidizer. (2) The permittee shall maintain the units according to manufacturer's or supplier's recommended maintenance. (NSR Permits 1776M1 and 1777M1, condition A200.B)
Monitoring (1) The thermal oxidizer shall be operated in accordance with manufacturer's or supplier's recommendations and parameters. The SVE System shall not be operated without the thermal oxidizer except for periods of startup and shutdown as recommended by manufacturer or supplier. The permittee shall monitor times of maintenance and type of maintenance that occurred. (2) The permittee shall monitor the total hours of operation in either thermal or catalytic modes.
Recordkeeping: The permittee shall record the hours of operation in each mode daily and maintain records in accordance with Section B109.
Reporting: The permittee shall report in accordance with Section B110.

A106 Facility: Allowable Emissions

A. The following Section lists the emission units, and their allowable emission limits. (40 CFR 50; 40 CFR 63, Subparts A and ZZZZ, GGGGG, Paragraphs 1, 7, and 8 of 20.2.70.302.A NMAC; NSR Permits 1776M1, 1777M1, and 6742).

Table 106.A: Allowable Emissions

Unit No.	[1]NO_x pph	NO_x tpy	CO pph	CO tpy	VOC pph	VOC tpy
903	125.0	547.5	16.5	72.3	9.9	43.4

1 Nitrogen dioxide emissions include all oxides of nitrogen expressed as NO_2.
2 Title V annual fee assessments are based on the sum of allowable tons per year emission limits in Sections A106 and A107.
3 To report excess emissions for sources with no pound per hour and/or ton per year emission limits, see condition B110.E.
"-" indicates the application represented emissions are not expected for this pollutant.
"<" indicates that the application represented the uncontrolled mass emission rates are less than 1.0 pph or 1.0 tpy for this emissions unit and this air pollutant. The Department determined that allowable mass emission limits were not required for this unit and this pollutant.

A107 Facility: Allowable Startup, Shutdown, & Maintenance (SSM) and Malfunction Emissions

A. The maximum allowable SSM and Malfunction emission limits for this facility are listed in Table 107.A and were relied upon by the Department to determine compliance with applicable regulations.

Table 107.A: Allowable SSM and Malfunction Units, Activities, and Emission Limits

Unit No.	Description	VOC (tpy)
SSM/M from [901, 902, 903, 904, 921]	[1]Compressor & Associated Piping Blowdowns during Routine and Predictable Startup, Shutdown, and/or Maintenance (SSM); and Malfunctions.	10.0

1. This authorization does not include VOC combustion emissions.
2. Units 901 and 902 are electric engines that drive compressors and the emissions here are from the blow down of the compressors.
3. To report excess emissions for sources with no pound per hour and/or ton per year emission limits, see condition B110.E.

about GHD

GHD is one of the world's leading professional services companies operating in the global markets of water, energy and resources, environment, property and buildings, and transportation. We provide engineering, environmental, and construction services to private and public sector clients.

Dear Mr. Singleton:

Re: Additional Information for Four Factor Analysis
Roswell Compressor Station
Transwestern Pipeline Company, LLC

GHD Services, Inc. (GHD) is submitting, on behalf of Transwestern Pipeline Company, LLC., responses to the New Mexico Environmental Department (NMED) request for additional information dated December 23, 2019 regarding the four-factor analysis completed for the Roswell Compressor Station. These responses correspond to the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309).

If you have any questions or concerns, please contact myself at (720) 974-0937 or Larry Campbell at (575) 625-8022.

Sincerely,

GHD

Sergio Guerra
Project Manager

Attachments Index

Attachment A – Cooper Quote for Low Emission Controls retrofit
Attachment B – Selected Pages from Chapter 2 SCR, EPA Cost Control Manual (updated June 2019)
Attachment C – Selected Pages from Chapter 1 SNCR, EPA Cost Control Manual (updated April 2019)
Attachment D – Updated Electronic Cost Analysis Spreadsheet
Attachment E – NMED Additional Information Request Letter dated December 23, 2019

1. What options does the quotation from Cooper Machinery Services evaluate for emission reductions (i.e., upgrades to the air-to-fuel ratio (AFR) controller, turbocharger, adjusting ignition timing, installing cylinder heads fitted with pre-combustion chambers, larger intercooling applications, enhanced mixing, bypass valves, and increased ignition energy)? Please provide a copy of the quotation that shows the Low Emission Controls (LEC) upgrades presented can lower NO_x emission rates to 2.5 grams per horsepower-hour (g/hp-hr.). Consider and include a discussion of variations of LEC upgrades that might lower the cost of compliance while still achieving meaningful NO_x reductions.
Please see attached Cooper Machinery quote (Attachment A) that shows upgrades that lower NOx emission rates to 2.5 g/hp-hr. The vendor, Cooper Machinery, provided the LEC upgrades applicable to these engines to control NOx emissions from the engines at the Roswell facility and stated that the full package of CBT is necessary to achieve emission reductions. The retrofit upgrades presented and quoted by Cooper include:

1) Install new cylinder heads fitted with precombustion chambers
2) Replace existing water-cooled pulse type exhaust manifold with a dry constant pressure manifold.
3) Add bypass valve to exhaust manifold to permit control of intake manifold pressure by bypassing some exhaust from the turbocharger.
4) Upgrade turbocharger to flow more air into combustion chamber
5) Remove existing expansion turbo-coolers.
6) Replace small intercoolers with larger intercoolers.
7) Add pilot fuel lines and pressure control for precombustion chamber fuel

2. The referenced document indicating that selective catalytic reduction (SCR) retrofits have not occurred as of 2014 is dated 2014, so it may not reflect applications that may have occurred since that document was published. Please verify that there have been no SCR retrofits on RICE in the gas transmission industry and provide additional information on why this technology is not appropriate for your operation. This additional information is important, as the costs of control ($4,300-$5,500/ton NO_x removed) may be considered reasonable.
Chapter 2 of the EPA cost manual (updated June 2019) (Attachment B) supports the 2014 reference document cited in the Four Factor Analysis dated October 30, 2019. According to the EPA cost manual, the only example provided for SCR technology used on a RICE engine occurred in 1994 on a new 1,800 hp diesel-fired engine but not for a natural gas engine. All other examples of SCR applications were for other types of combustion equipment often in industries other than oil & gas.

3. Please include a discussion on the technical feasibility of non-selective catalytic reduction for the Cooper-Bessemer compressor engines. If it is determined that this option is technically feasible, please complete a four-factor analysis for this technology.
Based on Section 3.2 of the INGAA source referenced in the Four Factor Analysis, non-selective catalytic reduction (NSCR) is a control used on rich burn RICE engines and the Cooper-Bessemer compressor engines are four stroke lean burn RICE engines. Therefore, NSCR is not compatible and not a technically feasible control option (INGAA, Availability and Limitations of NOx Emission Control Resources, 2014).

Selective non-catalytic reduction (SNCR) is less effective in reducing NOx emissions than SCR and is only applied to similar equipment as SCR, such as industrial boilers. Chapter 1 of the EPA cost manual (updated April 2019) (Attachment C) supports this information and provides no examples or indication that this technology can be applied to engines. Please also see additional information provided in response 2 above.

4. Consider Good Combustion Practices (GCP) and routine maintenance as controls and provide details on how these would be achieved, including a maintenance schedule and operating procedures.
Energy Transfer performs regular inspection and maintenance activities for the equipment on site. Maintenance schedule and procedures and the associated tracking, monitoring, testing, and recordkeeping are required in the facility operating permit.

5. Please consider and include a discussion on the feasibility of replacing natural gas-fueled engines with commercial electric powered compressors.
Energy Transfer estimated the cost of a 4500 hp electric engine to replace each existing natural gas fired one at $6,512,932.09. This conservative cost estimate and an estimated O&M cost were used to calculate a cost per ton value in the attached spreadsheet (Attachment D).

6. Please provide a current quote on the installation of SCR on Units 903 and 904, as adjusting costs from a quote obtained in 1994 is not appropriate.
SCR is not a feasible technology for gas-fired engines based on Chapter 2 of the EPA cost manual (updated June 2019) (Attachment B) and a four-factor analysis should not have been completed for these engines. In 1994, the technology was being evaluated for feasibility on engines, which is why costs from that period are available, however, no other recent references were found.

7. Submit all electronic spreadsheets used for control technology calculations.
Please see attached electronic spreadsheet (Attachment D) which includes an updated cost analysis for electric replacement compressors.

Cc: Sergio Guerra; Phil Horn
Subject: RE: Engine Retrofit - Low Emission Controls - Roswell and Mountainair

Andrew, to achieve lower emissions the full package must be done.

Installing jetcell heads will definitely make the engines run with greater stability, however, this the improved combustion will result in lower exhaust temperatures as more fuel will go to providing effective work. The lower temperatures will reduce the energy needed to drive the turbocharger so there will not be sufficient air to lean out the air/fuel mixture necessary to reduce NOx emissions.

To achieve the leaner air/fuel mixture with jetcell heads requires a higher efficiency constant pressure turbocharger with a constant pressure exhaust manifold. To be able to control air fuel ratio, it is necessary to control the turbocharger speed. To do this we install a wastegate before the turbocharger which allows some of the exhaust gas to bypass the turbocharger. This is not possible with the pulse type manifold currently installed on the engine because it has individual pipes for each cylinder collecting into multiple inlets on the turbine casing.

The higher air flow from the turbocharger will require larger coolers to be installed to keep intake manifold temperature within limits.

We have provided a quick budget number with some consideration that this project may not be done for several years. Is there an estimated schedule for the job?

Best regards
Bob Bailey

Hi Bob,

Thanks for providing the general LEC quote below to my colleague Phil Horn back in October and hope 2020 is starting well for you.

The State of Mexico has asked for Cooper to now provide cost estimates for each of the individual upgrades mentioned below (i.e. install new cylinder heads, replace manifold, add bypass valve, etc.). They are interested in whether a “partial package” of upgrades might be more cost effective for controlling NOx emissions than the full $1,800,000 package. Would you be able to provide this for us?

Thanks very much for your help with this and please let me know any questions.

Best regards,

Andy White

Subject: RE: Engine Retrofit - Low Emission Controls - Roswell and Mountainair

Hello Phil

After doing some discussions we can upgrade these engines by doing following:

Install new cylinder heads fitted with precombustion chambers

Replace existing water cooled pulse type exhaust manifold with a dry constant pressure manifold.

Add bypass valve to exhaust manifold to permit control of intake manifold pressure by bypassing some exhaust from the turbocharger.

Upgrade turbocharger to flow more air into combustion chamber

Remove existing expansion turbo-coolers.

Replace small intercoolers with larger intercoolers.

Add pilot fuel lines and pressure control for precombustion chamber fuel.

Considering the age and condition of the engines, these changes will allow reliable operation with NoX emissions of 2.5 gm/bhp-hr at full load. This would be better stated in lb/hr and I will get you that value tomorrow.

Budget price for this is US$ 1,800,000 per engine.

I trust this will meet your needs for now (I will get you lb-hr value tomorrow).

Best regards
Bob Bailey

2. SELECTIVE CATALYTIC REDUCTION

2.1 Introduction

Selective catalytic reduction (SCR) has been applied to stationary source fossil fuel-fired combustion units for emission control since the early 1970s and is currently being used in Japan, Europe, the United States, and other countries. In the U.S. alone, more than 1,000 SCR systems have been installed on a wide variety of sources in many different industries, including utility and industrial boilers, process heaters, gas turbines, internal combustion engines, chemical plants, and steel mills [1]. Other sources include fluid catalytic cracking units (FCCUs), ethylene cracker furnaces, nitric acid plants, catalyst manufacturing processes, nitrogen fixation processes, and solid/liquid or gas waste incinerators [2, 3]. In the U.S., SCR has been installed on more than 300 coal-fired power plants ranging in size from less than 100 megawatt equivalent (MWe) to 1,400 MWe [1, 4]. Other combustion sources with large numbers of SCR retrofits include more than 50 gas-fired utility boilers ranging in size from 147 MWe to 750 MWe, more than 50 industrial boilers and process heaters (both field-erected and packaged units), and more than 650 combined cycle gas turbines [1]. SCR can be applied as a stand-alone nitrogen oxides (NO_x) control or with other technologies, including selective non-catalytic reduction (SNCR)[1] and combustion controls such as low NO_x burner (LNB) and flue gas recirculation (FGR) [2].

SCR is typically implemented on stationary source combustion units requiring a higher level of NO_x reduction than achievable by selective non-catalytic reduction (SNCR) or combustion controls. Theoretically, SCR systems can be designed for NO_x removal efficiencies up close to 100 percent. In practice, commercial coal-, oil-, and natural gas–fired SCR systems are often designed to meet control targets of over 90 percent. However, the reduction may be less than 90 percent when SCR follows other NO_x controls such as LNB or FGR that achieve relatively low emissions on their own. The outlet concentration from SCR on a utility boiler is rarely less than 0.04 lb/million British thermal units (MMBtu) [1].[2] In comparison, SNCR units typically achieve approximately 25 to 75 percent reduction efficiencies [5].

Either ammonia or urea may be used as the NO_x reduction reagent in SCR systems. Urea is generally converted to ammonia before injection. Results of a survey of electric utilities that operate SCR systems indicated that about 80 percent use ammonia (anhydrous and aqueous), and the remainder use urea [4]. A survey of coal-fired power plants that control NO_x emissions using either SCR or SNCR found anhydrous ammonia use exceeds aqueous ammonia use by a ratio of 3 to 1. Nearly half of these survey respondents also indicated that price is their primary consideration in the choice of reagent; safety is the primary consideration for about 25 percent of the operators [6].

SCR capital costs vary by the type of unit controlled, the fuel type, the inlet NO_x level, the outlet NO_x design level, and reactor arrangement. Capital costs also rose between 2000 and 2010 (at least for utility boiler applications), even after scaling all data to 2011 dollars (2011$).

[1] A hybrid SNCR/SCR system was demonstrated at the AES Greenidge Power Plant in 2006. However, no hybrid SNCR/SCR systems are currently known to be operating as of February 2016.

[2] Data in the Clean Air Markets Division (CAMD) database also suggest SCR units rarely achieve emissions less than 0.04 lb/MMBtu.

For a small number of early SCR retrofits on utility boilers prior to 2000, the average costs were about $100/kilowatt (kW), in 2011$, and there was little scatter in the data. From 2000 to 2007, the SCR costs for 32 utility boilers ranged from about $100/kW to $275/kW (2011$), and a slight economy of scale was evident (i.e., using a regression equation, costs ranged from about $200/kW for a 200 MW unit to $160/kW for an 800 MW unit). For 2008 to 2011, the average SCR costs exhibited great variability and again a modest economy of scale was evident (i.e., about $300/kW for a 200 MW unit to $250/kW for an 800 MW unit; 2011$). For eight utility boilers either installed in 2012 or projected to be installed by 2014, the SCR costs ranged from about $270/kW to $570/kW (2011$). The generating capacity for these units ranged from 400 MW to 800 MW [7]. Typical operation and maintenance costs are approximately 0.1 cents per kilowatt-hour (kWh) [8, 9]. Table 2.1a provides capital cost estimates for electric utility boilers, and Table 2.1b presents capital cost estimates for SCR applications of various sizes in several other industry source categories.

The procedures for estimating costs presented in this report are based on cost data for SCR retrofits on existing coal-, oil-, and gas-fired boilers for electric generating units larger than 25 MWe (approximately 250 MMBtu/hr). Thus, this report's procedure estimates costs for typical retrofits of such boilers. The methodology for utility boilers also has been extended to large industrial boilers by modifying the capital cost equations and power consumption (electricity cost) equations to use the heat input capacity of the boiler instead of electric generating capacity.[3] The procedures to estimate capital costs are not directly applicable to sources other than utility and industrial boilers. Procedures to estimate annual costing elements other than power consumption are the same for SCR units in any application. The cost of SCR as part of a new plant often is likely to be less than the cost for retrofitting an SCR at an existing plant. Appropriate factors to estimate the cost of a new plant SCR have been included. In addition, the cost procedures in this report reflect individual SCR applications. Retrofitting multiple boilers with SCR can allow for some economies of scale for installation, thus yielding some reduction in capital costs per SCR application. The cost methodology incorporates certain approximations; consequently, it should be used to develop study-level accuracy (±30 percent) cost estimates of SCR applications. Such accuracy in the cost methodology is consistent with the accuracy of the cost estimates for the other control measures found in this Cost Manual as stated in Section 1.

In the cement industry, pilot tests in the 1970s and 1990s showed that SCR could be a feasible control technology for cement kilns. Building on that experience, SCRs were first installed in Europe in 2001. Today, SCR has been successfully implemented at seven European cement plants in Solnhofer, Germany (operated from 2001 until 2006), Bergamo, Italy (2006), Sarchi, Italy (2007), Mergelstetten, Germany (2010), Rohrdorf, Germany (2011), Mannersdorf, Austria (2012), and Rezatto, Italy (2015) [10, 11, 12]. As of 2015, there is only one cement plant in the U.S. that has installed an SCR. This SCR began operation in 2013 and is installed after an electrostatic precipitator. The control efficiency for the system is reported to be about 80 percent, which is consistent with SCR applications on European kilns. SCRs have not seen widespread use in the U.S. cement industry mainly due to industry concerns regarding potential problems caused by high-dust levels and catalyst deactivation by high sulfur trioxide (SO_3) concentrations

[3] The term "industrial" boilers as used in the Control Cost Manual includes industrial, commercial, and institutional (or ICI) boilers, unless otherwise noted.

from pyritic sulfur found in the raw materials used by U.S. cement plants. The SO_3 could react with calcium oxide in the flue gas to form calcium sulfate and with ammonia to form ammonium bisulfate. The calcium sulfate could deactivate the catalyst, while the ammonium bisulfate could cause catalyst plugging. There have been concerns expressed about the potential for catalyst poisoning by sodium, potassium, and arsenic trioxide. Finally, other concerns expressed are that dioxins and furans may form in the SCR due to combustion gases remaining at temperatures between 450 degrees Fahrenheit (°F) and 750°F. These and other concerns regarding the implementation of SCR to the cement industry are discussed in detail in "Alternative Control Techniques Document Update – NO_x Emissions from New Cement Kilns" [10]. Due to the small number of SCRs installed at cement plants, information on capital and operating costs for SCRs at cement plants is limited. The installation and operating costs for the SCR installed at the U.S. plant in 2013 are not publicly available at this time. In general, we expect the capital and operating costs would be higher than for low-dust applications due to the need to install catalyst cleaning equipment for SCR systems installed in high-dust configurations and for heating the flue gas in low-dust, tail-end configurations.

Table 2.1a: Summary of SCR Cost Data for Utility Boilers

Source Category	Unit Size	Fuel Type	Capital Cost			$ Year	Comments	Reference
			Min	Avg	Max

1. SELECTIVE NONCATALYTIC REDUCTION

1.1 Introduction

Selective noncatalytic reduction (SNCR) is a post combustion emissions control technology for reducing NO_x by injecting an ammonia type reactant into the furnace at a properly determined location. This technology is often used for mitigating NO_x emissions since it requires a relatively low capital expense for installation, albeit with relatively higher operating costs. Japan originally developed SNCR for oil and gas units in the 1970s; Western Europe followed by applying the science to coal fired units in the late 1980s and the U.S electric power sector began installations on coal plants in the early 1990s. More than 45 gigawatts of coal-fired power capacity in the U.S. now have SNCR.[1] SNCR is now used beyond the electric power industry, and is currently being used to control NO_x emissions from a multitude of combustion sources, including industrial boilers, electric utility steam generators, thermal incinerators, cement kilns, pulp and paper power boilers, steel industry process units, refinery process units, and municipal solid waste energy recovery facilities [1, 2, 3]. It is being used on industrial boilers covering a wide range of sizes from <50 MMBtu/hr to more than 800 MMBtu/hr [2]. SNCR is also being used on a wide range of sizes of utility boilers from <50 MW to more than 900 MW. More than half of utility boilers with SNCR are relatively small (<50 – 200 MW) but about 24 percent are larger than 300 MW.[1] Over 70 percent of the utility boilers using SNCR burn coal as the primary fuel and most of the others burn biomass, but the other types of combustion sources are burning a wide range of materials [2].[1] SNCR can be applied as a standalone NO_x control or with other technologies such as combustion controls. The SNCR system can be designed for seasonal or year-round operations.

Reported SNCR reduction efficiencies vary over a wide range. Temperature, residence time, type of NO_x reducing reagent, reagent injection rate, uncontrolled NO_x level, distribution of the reagent in the flue gas, and CO and O_2 concentrations all affect the reduction efficiency of the SNCR [2]. Tables 1.1 and 1.2 and Figures 1.1a, 1.1b, and 1.1c summarize emission reductions for SNCR applications in a variety of industries [2]. Findings based on review of these data are as follows:

- Although installation of urea-based systems is more common than ammonia-based deployments, operating data reveal higher NO_x reductions occur with ammonia reagent. Table 1.1 shows the median (as a measure of average) reductions for urea-based SNCR systems in various industry source categories range from 25 to 60 percent, while median reductions for ammonia-based SNCR systems range from 61 to 65 percent. Note that most of the boilers with ammonia-based SNCR systems that are fired with solid fuels are fired with wood or municipal solid waste. Figure 1.1b shows nearly all ammonia-based systems have reduction efficiencies greater than 40 percent, while several urea-based systems have lower reduction efficiencies.

[1] Spreadsheet of information provided to EPA's Clean Air Market Division from query of SNL Energy data on 1/22/2015.

Table 1.1: Summary of NO_x Reduction Efficiencies Obtained Using SNCR on Different Types of Boilers in the U.S. [2]

Type of source category	Fuel	NO_x reduction reagent	Average boiler size	Median NO_x reduction (%)
Electric utility	Coal	Urea	320 MW	25
Co-generation	Primarily wood, some coal, biomass, and tires	Urea	360 MMBtu/hr	50
Pulp & paper (P&P)	Primarily bark and wood waste, supplemented with a variety of other fuels	Urea	410 MMBtu/hr	50
Municipal waste combustion (MWC)	Municipal solid waste (MSW)	Urea	270 MMBtu/hr	37
Refinery CO boilers	Typically refinery fuel gas	Urea	320 MMBtu/hr	60
Miscellaneous combustion units	Primarily wood, MSW, or coal	Ammonia	400 MMBtu/hr	65
Miscellaneous combustion units	Primarily crude oil or gas	Ammonia	110 MMBtu/hr	61

Table 1.2: SNCR NO_x Reduction Efficiency by Industry and Reagent Type [2, 4]

Industry and Units	**% Reduction**	
	Ammonia-Based	**Urea-Based**
Cement Kilns	12-77	25–90
Chemical Industry	NA[a]	35–80
Circulating Fluidized and Bubbling Bed Boilers	76–80	NA
Coal, Wood and Tire Fired Industrial and IPP/Co-Generations Boilers	NA	20–75
Coal-Fired Boilers	38–83	20–66
Gas- and Oil-Fired Industrial Boilers	30–75	NA
Glass Melting Furnaces	51–70	NA
Steel Products Industry	NA	42.9–90
Municipal Waste Combustors	45-70	16–87
Oil- and Gas-Fired Heaters	45–76	NA
Process Units	NA	40–85
Pulp and Paper Industry	NA	20–62
Refinery Process Units and Industrial Boilers	NA	20–75
Stoker-Fired and Pulverized Coal-Fired Boilers	50–83	NA
Stoker-Fired Wood-Fueled Boilers	40–75	NA

Subject: Request for Additional Information for Four-Factor Analysis under the Regional Haze Program

Dear Mr. Campbell:

This letter is to request additional information for the Transwestern Pipeline Company, LLC four-factor analysis for the Roswell Compressor Station. The four-factor analysis report was received by the New Mexico Environment Department (NMED) on November 1, 2019. Pursuant to NMED's Regional Haze Guiding Principles, the four-factor analysis must consider new ideas that potentially offer better solutions to problems and must evaluate the newest engineering methods and technology advances in potential control measures.

Please provide the following information for the reciprocating internal combustion engines (RICE) that were evaluated in four-factor analysis for potential nitrogen oxides (NO_X) controls.

1. What options does the quotation from Cooper Machinery Services evaluate for emission reductions (i.e., upgrades to the air-to-fuel ratio (AFR) controller, turbocharger, adjusting ignition timing, installing cylinder heads fitted with pre-combustion chambers, larger intercooling applications, enhanced mixing, bypass valves, and increased ignition energy)? Please provide a copy of the quotation that shows the Low Emission Controls (LEC) upgrades presented can lower NO_X emission rates to 2.5 grams per horsepower-hour (g/hp-hr.). Consider and include a discussion of variations of LEC upgrades that might lower the cost of compliance while still achieving meaningful NO_X reductions.
2. The referenced document indicating that selective catalytic reduction (SCR) retrofits have not occurred as of 2014 is dated 2014, so it may not reflect applications that may have occurred since that document was published. Please verify that there have been no SCR retrofits on RICE in the gas transmission industry and provide additional information on why this technology is not appropriate for your operation. This additional information is important, as the costs of control ($4,300-$5,500/ton NO_X removed) may be considered reasonable.
3. Please include a discussion on the technical feasibility of non-selective catalytic reduction for the Cooper-Bessemer compressor engines. If it is determined that this option is technically feasible, please complete a four-factor analysis for this technology.

4. Consider Good Combustion Practices (GCP) and routine maintenance as controls and provide details on how these would be achieved, including a maintenance schedule and operating procedures.
5. Please consider and include a discussion on the feasibility of replacing natural gas-fueled engines with commercial electric powered compressors.
6. Please provide a current quote on the installation of SCR on Units 903 and 904, as adjusting costs from a quote obtained in 1994 is not appropriate.
7. Submit all electronic spreadsheets used for control technology calculations.

Please note that per EPA's Guidance on Regional Haze State Implementation Plans for the Second Implementation Period (August 20, 2019), "as part of meeting the requirement of the Regional Haze Rule for the state to document the cost and engineering information on which the State is relying every source-specific cost estimate used to support an analysis of control measure must be documented in the SIP". If you feel that your supplemental information should be classified as confidential business information (CBI), it will need to be reviewed and approved as such by NMED and EPA. Submit CBI with the word 'confidential' included in the electronic file name and on each page of the document. Do not combine non-confidential business information and CBI in the same files. Also, the claimant must satisfy the conditions in 20.2.1.115.B(3)(a)-(d) NMAC when the CBI is submitted. Until NMED and EPA determines if the information qualifies as CBI, the information will not be disclosed to anyone other than those listed in 20.2.1.115 NMAC.

NMED respectfully requests that your company submit the additional information on four-factor analysis electronically as soon as possible to Mark Jones at mark.jones@state.nm.us and myself at kerwin.singleton@state.nm.us. Please contact NMED if you have questions about the additional information request. We encourage your questions in order to help expedite the technical analysis required under the Regional Haze Program. Staff would be happy to meet with you in person to discuss these requirements in more detail. Likewise, staff may further contact you with questions or require additional information during its review of your submittals.

Thank you for your assistance in this matter. Should you have questions or require clarification, please contact me at 505.476.4350, or Mark Jones at 505.566.9746.

Sincerely,

Kerwin C. Singleton
Planning Section Chief

Memorandum

09/10/2020

To:	Mark Jones, NMED	Ref. No.:	11203587
From:	Sergio Guerra, GHD, William Yenke, Larry Campbell, Kerry Egan- Transwestern Pipeline Company, LLC	Tel:	720-974-0937
CC:			

Subject: **Four Factor Analysis - Roswell and Mountainair Compressor Stations**

GHD Services, Inc. (GHD) is submitting, on behalf of Transwestern Pipeline Company, LLC (Transwestern) responses to the New Mexico Environmental Department (NMED) comments sent via email on August 27, 2020 regarding the four-factor analysis completed for the Mountainair and Roswell Compressor Stations. These responses correspond to the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to 51.309).

1. Responses to NMED Comments on the Roswell Compressor Station

1) NMED revised the cost estimate based on 2016 – 2018 average emissions and operating hours. Since Unit 904 performed better than the vendor's guarantee for NOX emissions, would the facility be willing to accept a lower permitted emission rate? This would ensure that the unit will continue to operate at that rate in the future. Otherwise, there is no guarantee that the utilization for this unit will not increase resulting in higher NOX emissions.

   Response: Transwestern is willing to work with NMED on looking at the option of reducing the current NOx permit limit. However, additional work will have to be done to identify an emission factor that is achievable.

2) The annualized cost did not consider an interest rate associated with the capital cost. NMED revised calculations assumed the current bank prime rate of 3.25%.

   Response: Comment is acknowledged. The revised calculations include the interest rate.

3) Replacing engines with electric compressors.

   Response: Electric compressor replacement cost estimates have been updated for the Roswell Compressor Station.

   The total capital investment (TCI) for electric compressor replacement at Roswell Compressor Station has been updated to approximately $12 million. This estimate includes the following factors:

   - *Removing and replacing gas engines with electric motors and VFD to existing compressor;*

- *Pouring and leveling foundation;*
- *Modifying gearbox, control buildings, oil coolers, gas piping; and*
- *Updating electrical components (substation build, conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.).*

In addition to this capital investment, monthly utility bills would be approximately doubled to account for the electric compressors. The average annual utility cost is estimated to increase by $2.3 million.

As shown in the Attachment A, the new cost estimates bring reduction costs to $12,310 per year-ton of reduced emissions for Unit 903 and $178,863 per year-ton of reduced emissions for Unit 904.

2. Responses to NMED Comments on the Mountainair Compressor Station

1) The annualized cost did not consider an interest rate associated with the capital cost. NMED revised calculations assumed the current bank prime rate of 3.25%.

   Response: Comment is acknowledged. The revised calculations include the interest rate.

2) Mountainair Compressor Station – Replacing engines with electric compressors. This cannot be eliminated at the feasibility step based on costs, so we will need to discuss feasibility and cost estimates further.

   Response: Electric compressor replacement cost estimates have been updated for those at the Mountainair Compressor Station.

   The total capital investment (TCI) for electric compressor replacement at Mountainair Compressor Station has been updated to approximately $24 million. This estimate includes the following factors:

   - *Constructing new compressor buildings, foundations, gas piping for 3 electric motors, VFDs and compressors;*
   - *Installing approximately 8.5 miles of 115kV transmission line;*
   - *Modifying gearbox, control buildings, oil coolers, gas piping; and*
   - *Updating electrical components (substation build, conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.).*

   In addition to this capital investment, the average annual utility cost is estimated to be $5.3 million.

   As shown in the Attachment B, the new cost estimates bring reduction costs to at least $16,888 per year-ton of emissions reduced for Unit 701, $10,641 per year-ton of emissions reduced for Unit 702, and $7,739 per year-ton of emissions reduced for Unit 703.

3. Additional Notes

Another impact of electric compressor replacement is the limited facility capacity during construction. This would impact pipeline capacity for existing customers with firm contract agreements.

These cost estimates come from Energy Transfer's senior planning engineer George Mayer who has overseen similar replacements at Roswell Compressor Station and Station 4 (a compressor station in Arizona). These are the best available estimates based on the previous projects. Note that these are minimum cost estimate values as we have not included maintenance or labor in our O&M costs. We will continue to refine costs as any additional information becomes available.

Subject: [EXT] RE: Mountainair Compressor Station / RE: Roswell Compressor Station 4-factor analysis

Mark,

Good afternoon. I appreciate your patience as we worked to collect the data necessary to provide you with the fuel gas costs for these facilities. We are presenting data that Transwestern has used to prepare and submit the Annual Form 2 filing to FERC for years 2016 – 2018. I'm presenting this information in as streamlined and usable fashion as possible.

	CY 2016 Annual Fuel Costs ($)	CY 2017 Annual Fuel Costs ($)	CY 2018 Annual Fuel Costs ($)		CY 2016 Average Fuel Cost per Compressor Engine* ($)	CY 2017 Average Fuel Cost per Compressor Engine * ($)	CY 2018 Average Fuel Cost per Compressor Engine* ($)
Station #7 Mountainair CS	570,945.00	865,835.00	1,003,748.00		190,315.00	288,611.67	334,582.67
Station #9 Roswell CS	255,657.00	300,864.00	334,370.00		127,828.5	150,432.00	167,185.00

Please review the presented data and let me know if you should have any questions. If you require any additional information, please let me know and I will work to respond as quickly as I can.

Respectfully,

Attn: Michael Baca, NMED-AQB

Mark Jones, NMED-AQB

Kenneth Miller, NMED-AQB

Mr. Baca,

Transwestern Pipeline Company, LLC (Transwestern) is providing the following response to the meeting held with New Mexico Environment Department – Air Quality Bureau (NMED) representatives and Transwestern on July 11, 2023. Specifically, Transwestern is addressing the questions and additional information requests raised by NMED (see Attachment A) regarding the Four Factor Analyses for the Mountainair and Roswell Compressor Stations.

These responses correspond to the NMED Regional Haze Second Planning Period Progress Analysis under the Clean Air Act (CAA) and Regional Haze Rule (40 CFR §51.300 to §51.309).

Please review at your earliest convenience and contact me with any questions concerning the submission.

Respectfully,

Kerry Egan

Four Factor Analysis

Roswell and Mountainair Compressor Stations

Transwestern Pipeline Company, LLC

Attachments Index:

Attachment A - 07-11-2023 Meeting Agenda and Additional Questions From NMED

Attachment B - Updated Cost Analysis Spreadsheets (v. 08-11-2023)

Attachment C – Supplemental Information For Cost Evaluations

1) Updated cost estimate for Cooper Low Emissions Control Technology installation on existing units.
2) Updated cost estimate for electrification of compressor stations and replacment of existing units.
3) Cost estimate for the replacement of existing units with Solar Turbines compressor packages

NMED Requests For Additional Information

1) What plans, if any, does ETC - Transwestern Pipeline have for retiring or replacing any of the Compressor Engines at either facility?

As discussed in the meeting on 7-11-2023, Transwestern currently has no definitive plans for the retirement or replacment of any units covered by the Four Factor Analysis (4FA). Given the current demand on Transwestern's pipeline system, retirement of units is not an option. The current firm shipping contracts with customers will require full utilization of compression at Transwestern mainline facilities. Transwestern's commercial and marketing groups anticipate this level of demand will remain in place for the foreseeable future.

In recent years Transwestern has evaluated the operational and economic feasibility of upgrading these compressor stations with new horsepower. In the most recent (CY2023) rate case submitted to the Federal Energy Regulatory Commission (FERC), Transwestern proposed a plan of modernization by replacement of existing units with new compressor packages. The proposal was not approved during the review and negotions of the rate case between Transwestern, FERC and the customers accessing Transwestern's pipeline system. The next regular rate case is not anticipated to occurr for at least five years. At that time the proposal for modernization may be taken up again. If approved at that time, the modernization project would be completed over several years (as defined in the rate case). Transwestern has no estimated timeline for the eventual replacement of the existing units.

2) How does ETC - Transwestern Pipeline plan to comply with the ozone precursor rule with respect to the compressor engines?

Transwestern is actively working to establish compliance programs for all applicable poritons of the Ozone Precursor Rule (NMAC 20.2.50). The Mountainair Compressor Station is not located in an affected county under the Ozone Precursor Rule. The Roswell Compressor Station is located in Chaves county, and is subject to the rule.

Currently the only engines accounted for in the 4FA subject to the rule, are units 903 and 904 at the Roswell Compressor Station. Transwestern is actively evaluating our options to achieve compliance with the newly established emissions limitations for existing gas driven engines.

The options for compliance mirror those that were established in the 4FA: 1) Cooper Low Emissions Control (LEC) technology installation, 2) Electrification of the station and replacment of gas driven engines with electric motors, 3) Replacement with new units (in this case Solar Turbines).

The Ozone Precursor Rule establishes the following emissions limitation for the existing units 903 and 904.

Table 1 - EMISSION STANDARDS FOR EXISTING NATURAL GAS-FIRED SPARK IGNITION ENGINES

NO_x	CO	NMNEHC (as propane)
0.5 g/bhp-hr.	0.60 g/bhp-hr.	0.70 g/bhp-hr.

As identified on the latest call between NMED and Transwestern, the Cooper LEC technology is not a suitable means of achieving compliance with the Ozone Precursor Rule. The guarantees provided by Cooper for emissions reductions do not meet the 0.5 g/bhp-hr limitation established by the Ozone Precursor Rule. As such, Transwestern is requesting the NMED recognize this is not a viable emissions reduction strategy for the Regional Haze Initiative, and should be excluded from the 4FA for these units.

This leaves the options of replacement of the existing units with electric motors or turbines. Transwestern continues to review and evaluate which course of action is the most ecnomical, conducive to current operations and in line with current business planning. In accordance with NMAC 20.2.50.113(B)(2), all existing natural gas-fired spark ignition engines must be in compliance with the emissions limitations found in Table 1, by January 1, 2029. Given the cost, complexity and integral nature units 903 and 904 to Transwestern's operations, we plan to address these units in the last grouping of engines from the entire affected fleet. Transwestern anticipates having the final plan to address these units in place on or before January 1, 2026. This should leave sufficient time to complete necessary work, prior to the January 1, 2029 deadline. At that time, Transwestern can provide updated information to the NMED if needed.

3) Is projected utilization of the Compressor Engines expected to be appreciably different than historical utilization?

Yes. The original 4FA prepared and presented to the NMED, utilized operational data from 2016 – 2018. Utilization has increased significantly at both compressor stations for the 2019 –

2022 time period. In 2022, utilization at the Mountainair compressor station was 261% of the utilization during 2016. At Roswell station, 2022 utilization was 366% of 2016 utilization.

Given the current firm shipping contracts in place, Transwestern anticipates both stations will remain at or near full utilization for the foreseeable future.

Unit	Annual Operating Hours					
	2019	2020	2021	2022		4-yr Avg
701	7084.3	7295.7	7553.2	8347.6		7570.2

	2019	2020	2021	2022		4-yr Avg
903	8079.4	8696.3	8217.4	8303.8		8324.2
904	6651.5	8489.7	7843.5	8476.5		7865.3
Total:	14730.9	17186.0	16060.9	16780.3		16189.5
% of 2016 Total Hours	322%	375%	351%	366%		

4) Is ETC- Transwestern Pipeline's cost-of-capital notably different than the current prime rate of ~8%?

In consultation with Energy Transfer's financial planning personnel, we've determined that 8% cost-of-capital is appropriate for the purposes of this analysis. This rate is subject to frequent change, and may not be appropriate for long term (greater than 1 year) planning or cost analysis.

5) Does ETC - Transwestern Pipeline plan to provide updated cost evaluations for any of the pollution control options it evaluated in its submitted Four Factor Analysis? If so, when should NMED expect to receive that information?

Transwestern has updated cost evaluations for the emissions reduction strategies presented in the 4FA. The updated evaluation spreadsheets are presented in Attachment B for your review. Transwestern attempted to update the evaluations based on best available information from vendors. Transwestern's Asset Management & Reliability, and Project Planning personnel worked to prepare the updated costs.

Given the short timeframe for response, and the complexity of work involved, Transwestern was not able to prepare a complete Request For Proposal (RFP), to provide to vendors. For large capital projects such as these, Transwestern would normally prepare a RFP, have job showings with vendors and allow them to develop detailed proposals.

The cost evaluations provided were prepared with the best information available at this time. Previous vendor quotes and costs associated with prior projects of a similar nature, were utilized to devleop the cost evaluations. Transwestern requests the NMED recognize that these numbers are not set in stone, and may not represent the full cost of the projects if we were to move forward. Additionally, Transwestern and our vendors are subject to the same extreme price volatility and material availability experienced by the entire engery and manufacturing industry. The cost evaluations provided today, will likely not be valid in one year's time. Certain vendors that were able to provide cost estimates have expressly stated that they will have minimum built in cost increases on an annual basis.

6) Does ETC - Transwestern Pipeline anticipate continued availability of maintenance parts for the Compressor Engines for 10 to 20 more years?

Transwestern does generally anticipate the ability to maintain these units in the near to medium term future. However, in general it is very difficult to estimate the availability of maintenance parts/components, and economic viabiltiy of maintaining these units, ten to 20 years from now.

As discussed on the initial call, material availability is a concern for the existing units. While Transwestern has not yet run into the issue of being unable to replace/repair components on the engines, the costs have been steadily increasing. Additionally, there have been instances where specific parts/components had to be specifically manufactured as no commercially

available options existed. Additionally, the significant supply chain disruptions cuased by the Covid-19 pandemic continue to be problematic.

Further complicating the matter is the effect proposed environmental regulations will have on the availability of materials. The EPA recently published the Good Neighbor Rule, affecting hundreds, if not thousands, of gas-fired reciprocating engines in the Natural Gas Transmission industry across the country (Note: The GNR proposal currently does not affect New Mexico). The effect of the rule may be the retirement of numerous engines similar to those operated by Transwestern. This may provide an opportunity to acquire surplus materials from these engines for the ongoing maintenance of our engines. Alternatively, the GNR may force numerous engines to adopt similar emissions reduction strategies as those evaluated here, causing the demand increases and subsequent price increases. Until the GNR has been implemented throughout the affected industry, it will be difficult to determine its ultimate effect on availability and pricing.

One of Transwestern's primary concerns with implementing the Cooper LEC technology on the existing units, is maintenance feasibility. While the LEC technology would be beneficial in the long term goal of NOx reductions, it would not alleviate the issues associated with ongoing maintenance. In fact the installation of additional equipment would increase the burden of maintenance, and potentially have a negative impact on Transwestern's long-term ability to maintain the overall unit. Accordingly, Transwestern considers the LEC technology as the least viable option, from an operational standpoint.

7) Estimates of maintenance costs for the units?

Transwestern has provided estimates of the operations and maintenance (O&M) costs for the various emissions reduction strategies, in the cost evaluation spreadsheet. The O&M costs were developed using actual costs realized at the Mountainair and Roswell stations, as well as similar costs at other stations, in the 2022 and 2023 budget years. The 2022 costs were based on year end totals. The 2023 costs were based on Year-To-Date (YTD) totals, and adjusted for a full year of operation.

The costs for electric units and turbines were taken from several other Transwestern stations operating similar equipment. It can be assume that due to similar equipment, operations, and utilization, the O&M costs should be similar as well.

8) Does ETC - Transwestern Pipeline plan to provide a cost evaluation for the replacement of the existing Compressor Engines with new, like-kind engines? If so, when should NMED expect to receive that information?

Transwestern did provide a cost evaluation for the replacement of existing engines in the cost evaluation spreadsheets. See Attachment B.

As previously mentioned (response to question #1), Transwestern has evaluated the potential to upgrade/modernize the compressor stations in question. As a part of that process Transwestern has determined that replacement with turbines would be preferable to replacement with new reciprocating engines. This is due to the nature of the operations at the mainline transmission compressor stations. Turbines better suite the need for continuous long term utilization, with minimal downtime interuptions for maintenance. Turbines generally require less maintenance outages than comparable reciprocating engines. The cost on a $/horsepower basis for a new turbine is comparable to that for a new reciprocating engine.

Finally, the NOx emissions reductions realized by installing new turbines would support the goals of NMED to reduce Regional Haze. Solar Turbines current fleet of gas compressor turbines are designed to have very low NOx emissions rates. They are certified to meet the new emissions limitations found in NMAC 20.2.50.113(B)(7) Table 2.

9) Does ETC - Transwestern Pipeline plan to provide a cost evaluation for the replacement of the existing Compressor Engines with electric motor equivalents? If so, when should NMED expect to receive that information?

Transwestern has provided a cost evaluation for the replacement of the existing engines with electric motors.

The cost was developed using information Transwestern had previously compiled for similar electrification projects. These costs were adjusted to current figures, using assumptions about inflation and general cost increases in the intervening years. Given the complexity involved with the electrification of the compressor station, significant input from the local utility providers would be needed to prepare a more accurate, current quote. Transwestern attempted to coordinate with utility providers to develop cost estimates for the large

expenditures such as running new electric transmission lines, constructing substations, and verifying the ability of the utility to meet the added load demand. However, project coordination with the utility providers can often take months or more than a year.

Transwestern requests the NMED recognize that the costs provided here are as accurate as we can provide at the current time. The ultimate costs may increase significantly depending on the manner in which the project proceeds, and the timeline for execution of the potential project.

10) Please provide documentation in support of estimated electrification costs. (For example, if a new electrical substation would be necessary to support increased facility demand, ETC - Transwestern Pipeline should provide details about how the estimated cost of the substation was determined.)

Transwestern has provided the best available documentation for the estimated cost of electrification. See Attachment C.

Transwestern's Asset Management & Reliability and Projects Planning groups have prepared the cost estimates using information available from other projects, previously scoped, and adjusted to current dollars. The cost evaluation spreadsheet details the particular work required for the electrification option.

A fully comprehensive Request For Proposal (RFP) would be required to develop a truly accurate and current cost estimate. As mentioned above, the truncated timeline provided for response, and the inability of utility providers to give detailed estimates in a short time frame, made an RFP infeasible.

Should the NMED have any questions regarding the cost evaluations, Transwestern will provide further information.

07-11-2023 Meeting Agenda and Additional Questions From NMED

Regional Haze: Energy Transfer Co. - Transwestern Pipeline

Draft Agenda

Date: Tuesday, July 11, 2023

Time: 2:00 pm – 4:00 pm (MT)

Virtual Teams Meeting (Link)

1. Introductions/welcome

2. NMED status update on Regional Haze State Implementation Plan revision (SIPr)

3. These are key units that previously have been included in **Energy Transfer Co.(ETC)- Transwestern Pipeline - Mountainair #7 Compressor Station (CS) and Roswell #9 CS** Four Factor Analysis as subject to analysis for Regional Haze, or are otherwise of interest for purposes of Regional Haze planning. For reference, the subset of units from the regulated source list table (Table 104.A) in the most recent facility operating permits (P153-R4, renewed on 10/14/2020) and (P154-R4, renewed 9/28/2018) are provided here.

   a. **Mountainair #7 CS**

Table 104.A: Regulated Sources List (subset of units from permit)

EI Unit ID No.	Permit Unit No.	Source Description	Make & Model	Yr of Manufacture	Operating Rate Max/Site	Operating Capacity Max/Site
EQPT1	701	4SLB Internal combustion engine	Cooper Bessemer Engine - LSV-16SG	01-JAN-60	4500 hp / 4500 hp	4500 hp / 365 rpm
EQPT2	702	4SLB Internal combustion engine	Cooper Bessemer Engine - LSV-16SG	01-JAN-60	4500 hp / 4500 hp	4500 hp / 365 rpm
EQPT3	703	4SLB Internal combustion engine	Cooper Bessemer Engine - LSV-16SG	01-JAN-67	4500 hp / 4500 hp	4500 hp / 365 rpm

EQPT5	921	4SRB RICE Generator	Ingersoll-Rand- PSVG-6	1959	1959	408 hp /408 hp

1. All TBD (to be determined) units and like-kind engine replacements must be evaluated for applicability to NSPS and MACT requirements.

4. General Topics
    a. What plans, if any, does **ETC - Transwestern Pipeline** have for retiring or replacing any of the Compressor Engines at either facility?
    b. How does **ETC - Transwestern Pipeline** plan to comply with the ozone precursor rule with respect to the compressor engines?
    c. Is projected utilization of the Compressor Engines expected to be appreciably different than historical utilization?
    d. Is **ETC- Transwestern Pipeline's** cost-of-capital notably different than the current prime rate of ~8%?
    e. Does **ETC - Transwestern Pipeline** plan to provide updated cost evaluations for any of the pollution control options it evaluated in its submitted Four Factor Analysis? If so, when should NMED expect to receive that information?

5. Operation and Maintenance Costs
    a. Does **ETC - Transwestern Pipeline** anticipate continued availability of maintenance parts for the Compressor Engines for 10 to 20 more years?
    b. Estimates of maintenance costs for the units?

6. Replacement
    a. Does **ETC - Transwestern Pipeline** plan to provide a cost evaluation for the replacement of the existing Compressor Engines with new, like-kind engines? If so, when should NMED expect to receive that information?

7. Electrification
    a. Does **ETC - Transwestern Pipeline** plan to provide a cost evaluation for the replacement of the existing Compressor Engines with electric motor equivalents? If so, when should NMED expect to receive that information?
    b. Please provide documentation in support of estimated electrification costs. (For example, if a new electrical substation would be necessary to support increased facility demand, **ETC - Transwestern Pipeline** should provide details about how the estimated cost of the substation was determined.)

8. Timeline of Four Factor Analysis determinations - draft proposal, required FLM formal consultation, hearing phase (NOI), etc.

9. Questions and answers/ Follow-ups /Next steps

NOTE: NMED requests that the basis of any cost figures provided in support of **ETC - Transwestern Pipeline's** Four Factor Analysis be adequately documented. (For example, the cost to replace an existing engine with a new engine should be accompanied with a vendor quote.)

LSV-16SG Model – 4 Cycle Scope of Supply Solution

- **Properly sized turbocharger, support systems and mounting hardware**
- **Aftercooling system (on engine)**
- **New cylinder heads with pre-combustion chambers with support system**
- **New constant pressure exhaust manifold**
- **ePCC™ System**
- **All engineering installation and commissioning of supplied systems**
- **Supplemental assemble drawings/BOM for new material only**
- **Post Commissioning Support**

AT RISK ITEMS NOT INCLUDED IN SCOPE

- Additional cooling capacity
- Compressed air capacity to handle turbocharger jet-assist during start-up
- High port power cylinders -GMW units (existing cylinders can be ground if not already converted)
- Ignition system must be CPU-2000 or comparable
- Control system upgrades
- Intake air silencer/filter
- Exhaust piping/silencer

$3,100,00 per unit for core LEC upgrade work

30% ($930,000) added for project at risk items

$4,000,000 estimate per unit for LEC

TW Station 7 Gearbox Estimate

Gearbox – Lufkin

$450,000 each / $1,350,000 total for qty 3 units

Labor

$117,000 total each / $350,000 for qty 3 units

Includes grout, per diem, travel, equipment

Total: $1,870,000 for Gearbox installation (includes 10% contingency)

TW Station 7 Controls Upgrade

Existing OPTO control system would need to be repalced with an Allen Bradely system for this project.

$1,000,000 cost for control system upgrade.

Total: $1,000,000 for Controls Upgrade

Total Station 7 Upgrade to LEC

$14,870,000 Total

$16,357,000 Total with 10% contingency

$5,452,333.33 per Unit

Note: This cost estimate is based on a current quote from Cooper for the LEC upgrades, and previous project estimates prepared for the gearbox replacemenet (adjusted for inflation to current dollars).

Electrification of Units 701, 702, 703

1) 2x: 7,500 HP Electric motor, VFD, compressor package, couplings, etc.
2) Foundation pouring and leveling, compressor building, PCR building, station piping, gas cooling
3) Electrical work- conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.
4) Contract and General Labor

-- Construction would have to occur adjacent to existing compression. Units 701, 702 & 703 cannot be taken out of service for the replacement. Current firm shipping contracts require full utilization of compression horsepower at Mountainair CS. This would requrie constructing significant amounts of new infrastructure, not allowing the use of some existing piping, buildings, foundations, coolers, etc..

-- Unknowns- Substation upgrade, transmission line upgrade, utility rate increases

These items would have to be supplied by the local utility. Attempts have been made to attain estimates from utility for station upgrade, without success. The substation upgrade would require an engineering and load study, which itself could result in extended lead times before any decision on technical feasibility.

- This facility is not served by any existing utility provider. Would require a minimum of 8 miles of transmission line. Utility provider has not guaranteed they could or would be willing to provide service to location. Installation of utility line and building a new substation could lead to significant cost increases in comparison to this estimate.

Total Station 7 Electrification Capital Cost

$36,000,000 **Total for station. Includes only items 1-4 above. Cost of third party infrastructure (i.e., substation, transmission line, etc.) and utility cost increases would be in addition to this.**

$12,000,000 **Per unit for electrification.**

Note: This cost estimate is based on previous electrification projects at Transwestern's Mountainair Compressor Station (Unit 901 & 902) and Klagetoh Compressor Station. Both projects were replacements of existing RICE units (similar to units 903 & 904) with electric motors. The project costs were carried forward and adjusted for inflation into current dollars. Given the complex nature of this project and reliance on third parties to provide for and conduct a significant amount of the work (i.e., installation of infrastructure outside of the facility), Transwestern was unable to compile a thorough Request For Proposal. Given the short response period allowed, no vendor proposals were received.

Station 7 Utility Cost & OM Estimate

Station 7 does not currently have electric units in operation, or serviced by a utility provider. O&M costs for the electric units and the projected utility costs were developed by averaging those costs incurred at the Roswell and Klagetoh stations. Both of which have units similar to those that would be installed. This assumes the local power provider is able to supply the necessary load to operate the station.

$112,500 **Projected Annual O&M Cost per unit (based of 2023 YTD expenses).**
$3,040,900 **Projected Annual Utility Cost per unit (based of 2023 YTD expenses).**

$3,153,400 **Projected total O&M plus utility cost, per unit (based on 2023 YTD expenses).**

Replacement of Units 701, 702 & 703 w/ Solar Mars 90 Turbines

1) Purchase two (2) Solar Mars 100 turbine driven gas compressor packages.
2) Foundation pouring and leveling, compressor building, PCR building, station piping, gas cooling
3) Electrical work- conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.
4) Contract and General Labor
5) Requires station control system upgrade for new units.
6) Requires replacement of existing generator Units 721 & 722 with new Capstone microturbine generators.
   - -- This is a requirement to meet the new demand and reliability requirements placed on the station with the installation of turbines.
   - -- Replacement of Untis 721 & 722 with microturbine generator, would result in additional emissions reductions.

-- Construction would have to occur adjacent to existing compression. Units 701, 702, 703 cannot be taken out of service for the replacement. Current firm shipping contracts require full utilization of compression horsepower at Mountainair CS. This would requrie constructing significant amounts of new infrastructure, not allowing the use of some existing piping, buildings, foundations, coolers, etc..

Total Station 7 Turbine Installation Capital Cost

$46,250,000 Total for station. Includes only items 1-5 above.

Note: This cost estimate is based on previously prepared project proposal for an installation of turbines at Mountainair Compressor Station. It should reflect the current cost of the project if completed today. Solar Turbines has instructed TW to anticipate a minimum of 6% cost increase per year for their products. The price increases on labor and other non Solar supplied materials are expected to be similar if not greater.

Station 7 Turbine O&M Estimate

The O&M cost of the turbines has been based on projected costs for other Transwestern stations operating similar (not identical) Solar turbines.

$143,000 Projected total O&M plus utility cost, per unit (based on 2022 expenses at similar station).

lbm/hr	4.61	4.68	2.68

Notes

1. For short-term emission limits such as lbs/hr., Solar recommends using "worst case" anticipated operating conditions specific to the application and the site conditions. Worst case for one pollutant is not necessarily the same for another.
2. Solar's typical SoLoNOx warranty, for ppm values, is available for greater than 0 deg F or -20 deg F, and between 50% and 100% load for gas fuel, and between 65% and 100% load for liquid fuel (except for the Centaur 40). An emission warranty for non-SoLoNOx equipment is available for greater than 0 deg F or -20 deg F and between 80% and 100% load.
3. Fuel must meet Solar standard fuel specification ES 9-98. Emissions are based on the attached fuel composition, or, San Diego natural gas or equivalent.
4. If needed, Solar can provide Product Information Letters to address turbine operation outside typical warranty ranges, as well as non-warranted emissions of SO2, PM10/2.5, VOC, and formaldehyde.
5. Solar can provide factory testing in San Diego to ensure the actual unit(s) meet the above values within the tolerances quoted. Pricing and schedule impact will be provided upon request.
6. Any emissions warranty is applicable only for steady-state conditions and does not apply during start-up, shut-down, malfunction, or transient event.

$10,048,500 Total with 10% contingency

$5,024,250 per Unit

Note: This cost estimate is based on a current quote from Cooper for the LEC upgrades, and previous project estimates prepared for the gearbox replacemenet (adjusted for inflation to current dollars).

Electrification of Units 903 & 904

1) 2x: 5000 HP electric motor, VFD, compressor package, couplings, etc.
2) Foundation pouring and leveling, compressor building, PCR building, station piping, gas cooling
3) Electrical work- conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.
4) Contract and General Labor

-- Construction would have to occur adjacent to existing compression. Units 903 and 904 cannot be taken out of service for the replacement. Current firm shipping contracts require full utilization of compression horsepower at Roswell CS. This would requrie constructing significant amounts of new infrastructure, not allowing the use of some existing piping, buildings, foundations, coolers, etc..

-- Unknowns- Substation upgrade, transmission line upgrade, utility rate increases

- These items would have to be supplied by the local utility. Attempts have been made to attain estimates from utility for station upgrade, without success. The substation upgrade would require an engineering and load study, which itself could result in extended lead times before any decision on technical feasibility.

Total Station 9 Electrification Capital Cost

$30,700,000 **Total for station. Includes only items 1-4 above. Cost of third party infrastructure (i.e., substation, transmission line, etc.) and utility cost increases would be in addition to this.**

$15,350,000 **Per unit for electrification.**

Note: This cost estimate is based on previous electrification projects at Transwestern's Roswell Compressor Station (Unit 901 & 902) and Klagetoh Compressor Station. Both projects were replacements of existing RICE units (similar to units 903 & 904) with electric motors. The project costs were carried forward and adjusted for inflation into current dollars. Given the complex nature of this project and reliance on third parties to provide for and conduct a significant amount of the work (i.e., installation of infrastructure outside of the facility), Transwestern was unable to compile a thorough Request For Proposal. Given the short response period allowed, no vendor proposals were received.

Station 9 Utility Cost & OM Estimate

Installation of two additional electric units is expected to double the utility expenses at the station. This assumes the local power provider is able to supply the necessary load to operate the unit, and the rate does not significantly increase for the additional demand.

$91,000 **Projected Annual O&M Cost per unit (based of 2023 YTD expenses).**
$1,788,000 **Projected Annual Utility Cost per unit (based of 2023 YTD expenses).**

$1,900,000 **Projected total O&M plus utility cost, per unit (based on 2023 YTD expenses).**

Replacement of Units 903 & 904 w/ Solar Mars 100 Turbine

1) Purchase one (1) Solar Mars 100 turbine driven gas compressor package.
2) Foundation pouring and leveling, compressor building, PCR building, station piping, gas cooling
3) Electrical work- conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.
4) Contract and General Labor
5) Requires station control system upgrade for new unit.

-- Construction would have to occur adjacent to existing compression. Units 903 and 904 cannot be taken out of service for the replacement. Current firm shipping contracts require full utilization of compression horsepower at Roswell CS. This would requrie constructing significant amounts of new infrastructure, not allowing the use of some existing piping, buildings, foundations, coolers, etc..

Total Station 9 Turbine Installation Capital Cost

$32,100,000 Total for station. Includes only items 1-5 above.

Note: This cost estimate is based on previously prepared project proposal for an installation of a turbine at Roswell Compressor Station. It should reflect the current cost of the project if completed today. Solar Turbines has instructed TW to anticipate a minimum of 6% cost increase per year for their products. The price increases on labor and other non Solar supplied materials are expected to be similar if not greater.

Station 9 Turbine O&M Estimate

The O&M cost of the turbines has been based on projected costs for other Transwestern stations operating similar (not identical) Solar turbines.

$143,000 Projected total O&M plus utility cost, per unit (based on 2022 expenses at similar station).

Notes

1. For short-term emission limits such as lbs/hr., Solar recommends using "worst case" anticipated operating conditions specific to the application and the site conditions. Worst case for one pollutant is not necessarily the same for another.
2. Solar's typical SoLoNOx warranty, for ppm values, is available for greater than 0 deg F or -20 deg F, and between 50% and 100% load for gas fuel, and between 65% and 100% load for liquid fuel (except for the Centaur 40). An emission warranty for non-SoLoNOx equipment is available for greater than 0 deg F or -20 deg F and between 80% and 100% load.
3. Fuel must meet Solar standard fuel specification ES 9-98. Emissions are based on the attached fuel composition, or, San Diego natural gas or equivalent.
4. If needed, Solar can provide Product Information Letters to address turbine operation outside typical warranty ranges, as well as non-warranted emissions of SO2, PM10/2.5, VOC, and formaldehyde.
5. Solar can provide factory testing in San Diego to ensure the actual unit(s) meet the above values within the tolerances quoted. Pricing and schedule impact will be provided upon request.
6. Any emissions warranty is applicable only for steady-state conditions and does not apply during start-up, shut-down, malfunction, or transient event.

To: Egan, Kerry L
Subject: RE: RE: Revived Four Factor Analysis Requests - Follow up

Kerry,

See below, this is very preliminary, but should work for this discussion. Expect cost to increase by end of year due to Good Neighbor Rule demand.

All LEC/controls/gear box numbers are preliminary. There have not been any site visits made to firm up costs, which are subject to change.

- **LSV-16SG Model – 4 Cycle Scope of Supply Solution**
  - **• Properly sized turbocharger, support systems and mounting hardware**
  - **• Aftercooling system (on engine)**
  - **• New cylinder heads with pre-combustion chambers with support system**
  - **• New constant pressure exhaust manifold**
  - **• ePCC™ System**
  - **• All engineering installation and commissioning of supplied systems**
  - **• Supplemental assemble drawings/BOM for new material only**
  - **• Post Commissioning Support**
    - **AT RISK ITEMS NOT INCLUDED IN SCOPE**
      - • Additional cooling capacity
      - • Compressed air capacity to handle turbocharger jet-assist during start-up
      - • High port power cylinders -GMW units (existing cylinders can be ground if not already converted)
      - • Ignition system must be CPU-2000 or comparable
      - • Control system upgrades
      - • Intake air silencer/filter
      - • Exhaust piping/silencer
    - **$3,100,00 per unit**
    - **30% adder for project at risk items**
    - **$4,000,000 estimate per unit for LEC**

- **TW Station 7 Controls Upgrade**
  - **Upgrade existing controls to Allen Bradley from obsolete OPTO**
  - **$1,000,000**

- **TW Station 7 Gearbox Estimate**
  - **Gearbox – Lufkin**
    - **$450,000 each**

        - **$1,350,000 total for qty 3 units**
    - **Labor**
        - **$350,000 total**
            - **Includes grout, per diem, travel, equipment**
    - **Spare Gear Set**
        - **$230,000**
            - **With gear and shaft assembly, bearings, seals, gaskets, ect.**
    - **Total**
        - **$1,870,000 with 10% contingency**
        - **$230,000 spare gear set**
- **Total Station 7 Qty 3 Cooper Bessemer LSV 16SG LEC package**
    - **$14,870,000 Total**
    - **$16,357,000 Total with 10% contingency**

Subject: RE: Revived Four Factor Analysis Requests - Follow up

Good afternoon,

I know I've already talked with several of you about this, but I wanted to send out a note, so everyone is on the same page. Sorry for the long email…

After our last call, I did follow up with the NMED regarding the suitability of the Cooper LEC technology. Unfortunately, we did not get the blanket approval to eliminate that option from the 4FA. According to NMED we must consider all technically feasible options to complete the 4FA. We are going to need numbers for the LEC modification.
In our narrative description of the 4FA we will make it clear that for Roswell we would not be installing these due to the more stringent requirements of the Ozone Precursor. I fully expect NMED will be accepting of this claim.
For Station #7 we're not able to make that claim, since it is not subject to the Ozone Precursor Rule. Although we can clarify the issues we're having with procuring the materials/parts to continue and the serious concerns we have with the ability to operate the units.

Matt is helping get updated costs from Cooper for the LEC upgrade.

If we are going assert this retrofit requires a replacement of the western gearbox, and/or any work on the compressor itself (or other attached equipment), to ensure long term operational viability of the unit, I think we can. We need to include those costs in capital outlay figure. We'll have to provide supporting documentation for the cost and justification in the narrative as to why this work would be required.
The same would hold true for the electrification option. If a new gear box and compressor are needed, let's capture those costs.

George/Collin, I believe you mentioned you'd be able to help provide these numbers based on quotes we had for a potential job at WT-1. Is that correct?
We're still needing the updated numbers for the electrification option. If you can put something together on that front it would be greatly appreciated.

Jafet/Tyler, I just wanted to verify that we are working on getting the numbers for the replacement together. If you have that send it my way when you can.

Remaining Action Items:

- Finalize quotes for LEC upgrade. Cooper's portion only.
- Determine full extent of equipment replacement/modification required for the LEC.
    - Provide numbers and supporting docs for necessary work to facilitate LEC upgrade (i.e., gear box replacement, etc.)
- Finalize updated electrification costs.
    - Include the costs for any necessary accessory work (i.e., gear box replacement, etc.)
- Finalize turbine replacement costs.

I've got to have everything put together in our response package by EOB on 8/11, so I'm hoping we can have all of the numbers back by 8/9 at the latest. That should give me some time to get everything compiled.

Please let me know what you think and if you have any questions for me.
I greatly appreciate the help (and patience!!).

Thanks,

Subject: Electrification Costs- Four Factor Analysis

Kerry,
From my memory the 2019 electrification costs were a small adjustment using basic inflation numbers and some adjustments for pricing differences. This is not sufficient for what we truly believe the cost would be to electrify Units 903 and 904 as well as Station 7. Below is a breakdown of what the costs would more closely relate to. I will say that we still have quite a few unknowns based on the limited timing to get these costs together. We have not received an answer from either utility at Station 9 or 7 whether they would be able to support additional load or what costs would be required to upgrade their system in order to do so. I've included those as unknowns below.

Station 9
Electrification would include installing two new electric 5,000 HP units. Based on our current pipeline conditions we are sold out moving west out of Roswell. We therefore cannot afford to simply replace units 903 and 904 and have 6-9 months of limited capacity while the LSVs get pulled out and replaced. There are also additional costs to keeping the existing gearboxes as Matt covered in his estimate.

Costs include:

- 2x: 5000 HP electric motor, VFD, compressor package, couplings, etc.
- Foundation pouring and leveling, compressor building, PCR building, station piping, gas cooling
- Electrical work- conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.
- Contract and General Labor
- Unknowns- Substation upgrade, transmission line upgrade, utility rate increases

Total Build Cost: $30.7M + Unknowns
Annual Utility Cost: $6.3M (an additional $3.2M)

- This assumes a similar load for the additional units and no changes to Central Valley Co-op's pricing.

Station 7:
This cost includes a full renovation of the station including a brand new compressor building, new units, substation, and roughly 8 miles of power line infrastructure to connect to PNM. Similar to Station 9 we do not have the ability to replace existing units and operate at limited capacity during planned construction. Instead we would build new facilities within the current station and switch over operation once construction is complete.

Costs include:

- 2x: 7,500 HP Electric motor, VFD, compressor package, couplings, etc.
- Foundation pouring and leveling, compressor building, PCR building, station piping, gas cooling
- Electrical work- conduit/cable install to PCR, VFD, motor, gearbox, control room, etc.
- Contract and General Labor
- Unknowns- Substation build, 8 miles of 69kv or 115kv transmission line, utility costs.

TOTal Build Cost: $36M + Unknowns

- This cost is similar to our East Mainline modernization project estimates

Annual Utility cost: $5.3 million

- Based on PNM Large Power Service Rates

D.7 Harvest Four Corners

Supporting documentation for Harvest Four Corners is provided below. Facility-specific documentation is provided first, followed by documentation pertaining to multiple facilities and/or the owner/operator. The following documents are included in this section (in reading order):

- Kutz Canyon Processing Plant:
    - NMED Final Cost Evaluation
    - Initial Four-Factor Analysis (11/2019)
    - Information Regarding Process & SSM Flaring (12/13/2019)
    - Follow-Up Submittal (3/2020)
    - Follow-Up Submittal (10/23/2020)
    - Follow-Up Submittal (2/26/2021)
    - Follow-Up Submittal (8/28/2023)
    - Follow-Up Submittal (2/22/2024)

NMED Final Cost Evaluation
Harvest Four Corners - Kutz Canyon Processing Plant

Facility Information

Harvest - Kutz Canyon PP	**Facility**
Six 1975 NG CT and two 1981 NG CT	**Units**
1, 2, 3, 4, 5, 6, 19, 20	**Unit IDs**
SCR	**Evaluated Pollution Control***
NA	**Target Emissions Rate (g NOx/bhp-hr)**

*This analysis assumes physical space is available for SCR. Harvest asserted physical space is not available.

NMED Final Cost Evaluation
Harvest Four Corners - Kutz Canyon Processing Plant

Unit 1: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.81	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	234,317,556	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.480	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0959	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours	
Estimated SCR equipment life	20	Years*	

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F	*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour	

Concentration of reagent as stored (C_{stored})	29	percent*	
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*	
Number of days reagent is stored ($t_{storage}$)	14	days	

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.

Interest Rate (Percent)	5.5	Default bank prime rate		Use known interest rate or use bank prime rate, available at https://www.federalreserve.gov/releases/h15/.

Unit 1: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,766,828	scf/Year	
Actual Annual fuel consumption (Mactual) =		234,317,556	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.792	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6940	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	13.36	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	46.36	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	144.14	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	18	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	900	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.61	kW

Unit 1: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,614	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$39,732 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,058 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$294,790 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,858 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$8,780 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$14,302 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,792 in 2024 dollars
Direct Annual Cost =		$39,732 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,058 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$294,790 per year in 2024 dollars
NOx Removed =	46 tons/year
Cost Effectiveness =	$6,359 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Harvest Four Corners - Kutz Canyon Processing Plant

Unit 2: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.81	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	181,477,934	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.508	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1016	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 2: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,766,828	scf/Year	
Actual Annual fuel consumption (Mactual) =		181,477,934	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.614	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	5375	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	14.15	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	38.03	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	145.45	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	19	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	900	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.61	kW

Unit 2: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,614	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$34,965 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,058 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$290,022 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,858 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$7,204 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$11,077 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,826 in 2024 dollars
Direct Annual Cost =		$34,965 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,058 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$290,022 per year in 2024 dollars
NOx Removed =	38 tons/year
Cost Effectiveness =	$7,625 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Harvest Four Corners - Kutz Canyon Processing Plant

Unit 3: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.81	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	174,725,267	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.361	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0722	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 3: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,766,828	scf/Year
Actual Annual fuel consumption (Mactual) =		174,725,267	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.591	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	5175	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	10.05	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	26.00	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	138.68	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	13	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	700	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.61	kW

Unit 3: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,614	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$32,095 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,058 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$287,153 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,858 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$4,924 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$10,665 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,648 in 2024 dollars
Direct Annual Cost =		$32,095 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,058 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$287,153 per year in 2024 dollars
NOx Removed =	26 tons/year
Cost Effectiveness =	$11,045 per ton of NOx removed in 2024 dollars

Unit 4: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.81	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	220,373,298	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	0.406	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0811	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024			
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI
Annual Interest Rate (i)	7.5	Percent		
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia		
Electricity ($Cost_{elect}$)	0.1000	$/kWh		
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst		
Operator Labor Rate	60.00	$/hour (including benefits)*		
Operator Hours/Day	4.00	hours/day*		

CEPCI = Chemical Engineering Plant Cost Index

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 4: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,766,828	scf/Year	
Actual Annual fuel consumption (Mactual) =		220,373,298	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.745	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6527	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.30	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	36.86	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	140.74	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	15	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	700	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.61	kW

Unit 4: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,614	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$36,993 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,058 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$292,051 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,858 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$6,982 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$13,451 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,702 in 2024 dollars
Direct Annual Cost =		$36,993 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,058 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$292,051 per year in 2024 dollars
NOx Removed =	37 tons/year
Cost Effectiveness =	$7,922 per ton of NOx removed in 2024 dollars

Unit 5: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.81	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	233,777,342	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.342	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0684	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Unit 5: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,766,828	scf/Year	
Actual Annual fuel consumption (Mactual) =		233,777,342	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.790	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6924	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	9.52	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	32.96	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	137.81	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	13	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	600	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.61	kW

Unit 5: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,614	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$36,995 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,058 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$292,052 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,858 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$6,242 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$14,269 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,625 in 2024 dollars
Direct Annual Cost =		$36,995 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,058 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$292,052 per year in 2024 dollars
NOx Removed =	33 tons/year
Cost Effectiveness =	$8,861 per ton of NOx removed in 2024 dollars

Unit 6: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	34.81	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	277,669,680	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.338	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0676	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 6: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	35	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	295,766,828	scf/Year	
Actual Annual fuel consumption (Mactual) =		277,669,680	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.939	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8224	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	9.41	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	38.69	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	137.62	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	13	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	600	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	20.61	kW

Unit 6: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,614	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$40,754 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,058 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$295,811 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,858 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$7,327 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$16,948 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,620 in 2024 dollars
Direct Annual Cost =		$40,754 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,058 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$295,811 per year in 2024 dollars
NOx Removed =	39 tons/year
Cost Effectiveness =	$7,647 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Harvest Four Corners - Kutz Canyon Processing Plant

Unit 19: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	27.41	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	127,931,057	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.570	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1140	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 19: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	27	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	232,891,950	scf/Year
Actual Annual fuel consumption (Mactual) =		127,931,057	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.549	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	4812	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	12.50	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	30.07	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	116.76	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	17	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	16.23	kW

Unit 19: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,201,603	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$27,583 in 2024 dollars
Indirect Annual Costs (IDAC) =	$218,737 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$246,320 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$11,008 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$5,694 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$7,808 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,072 in 2024 dollars
Direct Annual Cost =		$27,583 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,760 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$215,977 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$218,737 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$246,320 per year in 2024 dollars
NOx Removed =	30 tons/year
Cost Effectiveness =	$8,193 per ton of NOx removed in 2024 dollars

Unit 20: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	27.41	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	103,259,399	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5800	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.570	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1140	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 20: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	27	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	232,891,950	scf/Year
Actual Annual fuel consumption (Mactual) =		103,259,399	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.443	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	3884	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	12.50	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	24.27	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.24	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	11.9	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	116.76	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2

Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	16.23	kW

Unit 20: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,201,603	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$24,978 in 2024 dollars
Indirect Annual Costs (IDAC) =	$218,737 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$243,716 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$11,008 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$4,596 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$6,303 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,072 in 2024 dollars
Direct Annual Cost =		$24,978 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,760 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$215,977 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$218,737 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$243,716 per year in 2024 dollars
NOx Removed =	24 tons/year
Cost Effectiveness =	$10,043 per ton of NOx removed in 2024 dollars

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*
>
> The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long-Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed Harvest Four Corners, LLC (Harvest) that its Kutz Canyon Processing Plant (Kutz) facility was identified as one of the sources potentially contributing to regional haze at the Mesa Verde National Park Class I area.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to Harvest, it specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The subject equipment at Kutz, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Natural Gas-Fired Simple Cycle Turbine (Unit 1)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 2)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 3)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 4)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 5)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 6)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 19)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit 20)	15.5	67.9	Yes	0.029	0.13	No
Clark HRA-8 Reciprocating Compressor Engine (Unit 16)	37.1	162.0	Yes	0.007	0.031	No
Clark HRA-8 Reciprocating Compressor Engine (Unit 17)	37.1	162.0	Yes	0.007	0.031	No
Clark HRA-8 Reciprocating Compressor Engine (Unit 18)	37.1	162.0	Yes	0.007	0.031	No

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED[1], this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. Summaries of the result of this search are provided and discussed under Section 2 of this report. Harvest engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis is then conducted for those controls that are technically feasible.

[1] NMED 2021 Regional Haze Planning Website ("Links to other information"). https://www.env.nm.gov/air-quality/reg-haze/

NO_X is the only pollutant subject to evaluation in this four-factor analysis for the eight (8) turbines and three (3) engines located at Kutz. The turbines, Unit 1 through Unit 6, are Solar model Centaur 40-T4002 natural gas-fired, simple cycle turbines. Turbine Unit 19 and Unit 20 are Solar model Centaur 40-T4001 natural gas-fired, simple cycle turbines. The engines, Units 16, 17, and 18, are Clark model HRA-8 natural gas-fired, two-stroke lean-burn (2SLB) reciprocating compressor engines.

Units 1 through 6 are rated at 3,830 horsepower and were manufactured in 1975. Units 19 and 20 are rated at 3,016 horsepower and were manufactured in 1981. The engines are each rated at 830 horsepower and were manufactured prior to 1973. The units are de-rated in the 2016 Emission Inventory submittal to account for the altitude of the facility. Units 1 through 6 are rated at 3,692 hp, Units 19 and 20 at 2,907 hp, and Units 16 through 18 at 723 hp.

2.1. COMBUSTION TURBINES

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[2]

The treatment of the exhaust gases exiting the turbine dictate the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[3] The units at Kutz are simple cycle turbines.

NO_X is formed via three fundamentally different mechanisms. The principle NO_X formation mechanism, thermal NO_X, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_X forms in the highest temperature regions of the combustion chamber. The second NO_X formation mechanism, fuel NO_X, arises from the evolution and reaction of fuel bound nitrogen compounds with oxygen. The final NO_X formation mechanism, prompt NO_X, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_X is negligible in comparison to thermal and fuel NO_X. Fuel NO_X will also be negligible for Kutz's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_X.

[2] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[3] Ibid.

The PTE from each turbine is reported in the facility's New Source Review (0301M11) and Title V (P097R3) permits, as well as summarized in Table 1 of this report.

2.1.2. Potential NO_X Controls for Combustion Turbines

There are three general methods of controlling NO_X emission from gas turbines: (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation; (2) dry controls that use advanced combustor design to suppress NO_X formation; and (3) post-combustion, catalytic controls to selectively reduce NO_X.[4]

The retrofit control equipment that was identified for combustion turbines during a comprehensive review of the RBLC, available literature, and manufacturer's input is reported in Table 2. A more detailed table summarizing the RBLC review is provided in Appendix A. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible?	NO_X Control Efficiency
Good Combustion Practices	Yes	Base Case
Improved Combustion Technology	Yes	63%
Water/Steam Injection	No	N/A
Selective Catalytic Reduction	No	N/A

2.1.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at Kutz. However, these practices have been developed for and are currently in use at Kutz, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices is included in this report.

2.1.2.2. Improved Combustion Technology

The improved combustion technology control option, commonly referred to as Dry Low NO_X (DLN) control, seeks to reduce the combustion temperature and residence time of fuel in the combustor (thereby decreasing NO_X formation) by increasing the air-to-fuel ratio in the combustion chamber. There are several levels of

[4] Ibid.

improvements that can be made to the combustion chamber, which achieve this NO_X control at varying levels. The improved combustion technology available for the units at Kutz is produced by the manufacturer of the units, Solar, and is called SoLoNO$_X$. SoLoNO$_X$ utilizes lean-premixed combustion technology to ensure an extremely uniform air/fuel mixture and stringently controls the combustion process to prevent undesirable emissions from forming.

Based on communication with Solar, SoLoNO$_X$ is available for both the T4001 (Units 19 and 20) and T4002 (Units 1 through 6) Solar turbines located onsite. However, in order to support the technology each of the units would need to be uprated to model T4701 and T4702, respectively, because installation of SoLoNO$_X$ requires the turbine combustors to be capable of handling significantly higher temperatures. Uprating the units involves completely replacing the combustor section of the turbine with a much larger and more robust combustor.

Improved combustion technology, such as SoLoNO$_X$, was identified in this review of RBLC as a potential control of NO_X emissions from natural gas-fired combustion turbines, and AP-42 Section 3.1 also lists this as an available control technique for gas turbines.[5] Therefore, it has been determined that this control technology is technically feasible for the turbines located at Kutz. Solar can guarantee an output NO_X concentration of 25 parts per million (ppm) for uprated units with SoLoNO$_X$ installed. This is a resulting NO_X emissions reduction of approximately 63%, based on the currently permitted hourly emission rate and turbine stack parameters.

2.1.2.3. Water/Steam Injection

Water injection is a control technology for gas turbines that has been demonstrated to effectively suppress NO_X emissions. Injection of water has the effect of increasing the thermal mass by dilution and thereby reducing the peak temperature in the flame zone. Additionally, the latent heat of vaporization from the flame zone is absorbed when water injection is utilized, further reducing the combustion temperature. Water is typically injected at a water-to-fuel weight ratio of less than one.[6] Steam injection is not discussed as an option because Solar does not manufacture turbines with steam injection technology.

The capability of these units to be retrofit for water injection is dependent on the number of shafts employed in the unit, per communications with Solar. The shaft is the piece of equipment in the unit that connects the turbine to the generator and turns to generate the power output. Solar has indicated that turbine units with one shaft are mechanically capable of installing water injection, while two-shaft units are not. The Solar T4002 turbines (Units 1 through 6) located at Kutz are two-shaft units and the Solar T4001 turbines (Units 19 & 20) are one-shaft units. Therefore, the model T4002 turbines are not mechanically capable of being retrofit for water injection, while the model T4001 turbines are.

Despite the Solar T4001 units being mechanically capable of supporting water injection, Solar has stated that they do not offer water injection retrofits for any of the Centaur 40 conventional combustion line of turbines. This is primarily due to the design of the combustor housing of the conventional Centaur 40. The injectors on this style of combustor intersect directly into the combustor without using direct air flow for the direction of fuel. The style of injector needed to implement water injection technology is referred to by Solar as a Dual Lined Injector. This type of injector introduces fuel laterally into the front of a combustor and utilizes a controlled flow to disperse fuel.

Solar considers the control technique to be antiquated technology in comparison to the other control methods they have available, such as SoLoNO$_X$. Solar has retired this control option and does not recommend water

[5] Ibid.
[6] Ibid.

injection be installed to control emissions from their turbine units. They have stated that if there were direct modifications made to the turbine engine or it's supporting hardware, it could affect the unit's warranty with Solar.

Furthermore, approximately 5 gallons per minute (gpm) of de-ionized or de-mineralized water is needed to properly implement this control, per conversations with Solar. For a continuously operating turbine, this represents a total water usage of approximately 2.6 million gallons per year, per unit, without taking into account leaks and evaporative losses that would occur during transport. Kutz is located in San Juan County, in the northwestern part of the state. The National Drought Mitigation Center currently classifies this region as experiencing severe drought conditions.[7] The New Mexico Office of the State Engineer projects that the water demand in the San Juan region will exceed the drought-adjusted available water supply before 2030.[8] The implementation of this control may pose an unsustainable burden on this region's watershed.

Based on the communication with the turbine manufacturer detailed above, as well as the lack of available water in the region, it has been determined that water and steam injection are technically infeasible for the Solar turbines located at Kutz.

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[9] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituent, thermal sintering, or compacting, of active sited due to high temperatures in the reactor, fouling caused by ammonia-sulfur salts and particulate matter in the gas, and erosion due to high gas velocities.[10]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams can blind the catalyst and may necessitate the application of a soot blower.[11]

For an SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the

[11] Ibid.

upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[12] The exhaust temperature of the turbines assessed here is approximately 1,271 °F. It is unlikely that SCR control would function effectively on the Solar turbines due to the high exhaust temperature of these units. In addition, there are site-specific space limitations associated with the building and stack orientations that will prevent installation of the necessary equipment for this control method (i.e., SCR module and reagent storage systems).

Furthermore, Harvest does not anticipate that the current electricity availability at Kutz will be sufficient to support the substantial energy burden associated with SCR control. Installation of this control will require the facility to expand its current power generation.

Communication with Solar has indicated that SCR controls are available for each of the turbine models assessed here. However, it is not anticipated that the exhaust temperature, space, and energy limitations can be overcome; therefore, it has been determined that SCR is not a technically feasible control option for the turbines located at Kutz.

2.2. TWO-STROKE LEAN-BURN ENGINES

2.2.1. Two-Stroke Lean-Burn Engines Background

A reciprocating internal combustion engine (RICE) is a device that uses the combustion of fuel and air in an internal chamber to generate a reciprocating motion and convert heat energy into mechanical work. The units use a piston to draw air and fuel into the combustion chamber and compress it. The compressed air/fuel mixture is then ignited, generating combustion in the chamber. The energy of combustion pushes out the piston, turning a crankshaft and producing mechanical work. In the same cycle, the products of combustion remaining in the chamber are released and exhausted from the unit.

Natural gas-fired RICE are separated into multiple design classes, including 2-stroke lean-burn (2SLB), 4-stroke lean-burn (4SLB), and 4-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1) with exhaust oxygen levels less than 4%, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12% or more.[13]

NO_X is formed in reciprocating engines via the same three mechanisms applicable to the turbines:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Kutz engines also use natural gas fuel; therefore, the formation of prompt and fuel NO_X will again be insignificant, and this analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[14]

[12] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[13] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[14] Ibid.

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:[15]

(1) Operational control methods, such as adjusting the timing or other operating parameters.
(2) Combustion control techniques, for example reducing the peak flame temperature or introducing inerts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.

The PTE from each engine is reported in the facility's New Source Review (0301M11) and Title V (P097R3) permits, as well as summarized in Table 1 of this report.

2.2.2. Potential NO_X Controls for 2SLB Engines

Retrofit control options identified for 2SLB RICE were identified via comprehensive review of the RBLC and available technical literature and are summarized in Table 3. A detailed description and discussion of the technical feasibility and anticipated performance of each control is provided below.

Table 3. Potential Control Equipment for 2SLB RICE

Control Equipment	Technically Feasible?	NO_X Control Efficiency
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**
Clean Burn Technology	**Yes**	**80% - 93%**
Selective Catalytic Reduction	**No**	**N/A**
Non-Selective Catalytic Reduction	**No**	**N/A**

2.2.2.1. Good Combustion Practices and Fuel Selection

By following the same concepts from engineering knowledge, experience, and manufacturer's recommendations referenced above, good combustion practices for operation of engines can be developed and maintained. This is achieved by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from 2SLB engines; therefore, it has been determined that this method of NO_X control is feasible for the engines at Kutz. However, these practices have been developed for and are currently in use at Kutz, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices is included in this report.

2.2.2.2. Clean Burn Technology

Clean Burn Technology (CBT) is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding or enhancing an air-to-fuel ratio controller, making the unit capable of operating at more desirable ratios.

[15] Ibid.

Rich-burn engines are normally designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio of 16:1, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1). A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. 2SLB engines are typically designed to operate at the high air-to-fuel ratios employed in CBT; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease the NO_X emissions.[16]

In order to avoid derating the engine, combustion air must be increased at constant fuel flow. To achieve this, the engine would need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel ratio controller.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[17]

There is limited manufacturer support available to provide input on the potential effect installation of these controls could have on the engines. As such, a third-party control vendor with significantly less unit-specific experience and familiarity would need to be employed to install this control. Harvest is concerned that the addition of this control equipment by a third-party vendor could negatively affect the units and ultimately be operationally detrimental due to their limited historical knowledge of the engines.

Despite the potential drawbacks to installation of CBT control on these units discussed above, 2SLB engines are mechanically capable of being retrofit to support the combustor modifications and more sensitive air-to-fuel ratio controllers necessary to employ CBT. Therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Kutz. On 2SLB RICE, CBT is estimated to achieve an 80 to 93% reduction in NO_X emissions; however, this reduction is specific to each engine and typical loading.[18]

2.2.2.3. Selective Catalytic Reduction

Implementation of SCR controls for engines follows the same process and has the same technical drawbacks as discussed in Section 2.1.2.4 of this report.

For engines that typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed.[19] Kutz does typically operate with variable loads; therefore, the facility expects to have periods of ammonia slip or insufficient ammonia.

In order for the chemical reactions necessary for SCR to occur effectively, the exhaust streams injected with the reagent must be fairly oxygen rich. The exhaust oxygen levels for 2SLB engines are sufficient to support these reactions; therefore, this technology can be used on lean-burn engines.

---

[16] State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines, State of New Jersey Department of Environmental Protection, 2003.
[17] Ibid.
[18] U.S. EPA, Office of Air Quality Planning and Standards, "Alternative Control Techniques Document – NO_X Emissions from Stationary Reciprocating Internal Combustion Engines", EPA-453/R-93-032, Section 5.2.5.4, July 1993
[19] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"

AP-42 Section 3.2 does list SCR as an available control technology for 2SLB engines; however, the RBLC does not identify SCR as a control for these specific engine models.[20] This is likely because there is limited operating experience to date with the use of SCR on 2SLB RICE. Additionally, there is historical precedent that installation of SCR on 2SLB engines can result in significant technical complications, including a necessity to derate the engines and unreliable operation post-retrofit. The engines at Kutz are currently de-rated to account for the altitude of the facility. It is not operationally appropriate to de-rate the units further, as would be necessary if SCR control is implemented.

An engine control vendor contacted indicated that the Clark HRA-8 model of engines are poorly suited for installation of SCR controls and they do not typically recommend this for control due to the availability of more suitable options, such as CBT. The control vendor stated that significant challenges would need to be overcome to install this equipment on the units. Primarily, the poor air-to-fuel ratio employed in these units will make it difficult to regulate the SCR and greatly affect the NO_X reduction capability out of the engine. Additionally, a turbocharger and intercooler would need to be installed in the units to support the SCR equipment. As SCR control technology is not listed in the RBLC tables for 2SLB engines, has not been a proven as an effective method of controlling NO_X, and has significant operating challenges, Harvest has determined this control is technically infeasible for the Clark HRA-8 engines at Kutz.

2.2.2.4. Non-Selective Catalytic Reduction

Non-Selective Catalytic Reduction (NSCR) is a control technique that uses residual hydrocarbons and carbon monoxide (CO) in engine exhaust as a reducing agent for NO_X. In an NSCR system, hydrocarbons and CO are oxidized by oxygen (O_2) and NO_X. The excess hydrocarbons, CO, and NO_X pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_X to N_2.[21] This technique does not require additional reagents to be injected because the unburnt hydrocarbons in the engine exhaust are used as the reductant. The chemical reactions for this process are shown in the equations below.[22]

Phase 1:
$$\left.\begin{array}{l} 2CO + O_2 \rightarrow 2CO_2 \\ 2H_2 + O_2 \rightarrow 2H_2O \\ HC + O_2 \rightarrow CO_2 + H_2O \end{array}\right\}$$

Phase 2:
$$\left.\begin{array}{l} NO_X + CO \rightarrow CO_2 + N_2 \\ NO_X + H_2 \rightarrow H_2O + N_2 \\ NO_X + HC \rightarrow CO_2 + H_2O + N_2 \end{array}\right\}$$

The reactions in Phase 1 of the chemical process above function to remove excess oxygen from the exhaust stream. This step is necessary because if the oxygen is not removed, it will react more readily with the CO and hydrocarbons than the NO_X, thus reducing the potential for NO_X removal.

Despite this oxygen removal step in the chemical process, the engine exhaust gas stream must already have low levels of excess oxygen, or the oxygen will not be fully removed in Phase 1 and the NO_X removal will not be efficient. Consequently, application of the NSCR control technique is effectively limited to engines with normal exhaust

[20] Ibid.
[21] Ibid.
[22] U.S. EPA, "Compliance Assurance Monitoring Technical Guidance Document", Appendix B Review Draft, 2005

oxygen levels of 4% or less. This does not include lean-burn engines, which typically have an exhaust excess oxygen level around 8%, ranging from 4% to 17%.[23]

The exhaust oxygen levels for 2SLB engines are not sufficiently low to support the reactions described above; therefore, this technology is not a method used to control NO_X emissions from lean-burn engines. Furthermore, NSCR was not identified in the review of the RBLC as a potential control of NO_X emissions from large natural gas-fired lean-burn stationary RICE and AP-42 Section 3.2 does not list NSCR as an available control technique for 2SLB engines.[24] For these reasons, it has been determined that this method of NO_X control is infeasible for the 2SLB engines at Kutz.

[23] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[24] Ibid.

Harvest has evaluated the costs of implementing the technologically feasible control technologies as thoroughly as possible in the time provided to complete this assessment. These cost estimates are calculated according to the methods and recommendations in the EPA Air Pollution Control Cost Manual.[25] Cost effectiveness considerations for each unit and control technology are discussed below.

These cost estimates have been developed based on the actual emissions from each unit assessed here, using the 2016 Emission Inventory submittal for Kutz. The full cost estimation for each unit, including the EPA Air Pollution Control Cost Spreadsheet, are included in Appendix B of this report.

3.1. COMBUSTION TURBINES

Cost effectiveness for each combustion turbine control option are summarized Table 4.

Table 4. Cost Analysis Summary of Technically Feasible Control Options for Combustion Turbines at Kutz

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Improved Combustion Technology	1	467,300	61,603	27.4	2,246
	2	467,300	61,603	25.5	2,412
	3	467,300	61,603	31.1	1,983
	4	667,300	78,339	3.4	23,111
	5	667,300	78,339	36.5	2,145
	6	667,300	78,339	41.0	1,910
	19	467,300	61,603	12.9	4,779
	20	467,300	61,603	30.1	2,043

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

3.1.1. Improved Combustion Technology

Harvest has received an estimated direct capital cost for the equipment and vendor labor associated with implementing SoLoNO$_X$ on the turbines located at Kutz from Solar. Solar has also provided an estimated annual cost necessary to operate and maintain the units post-retrofit.

This cost estimate assumes that SoLoNO$_X$ will reduce NO$_X$ emissions to an outlet concentration of 25 ppm, based on manufacturer's estimations.

[25] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

3.2. 2SLB ENGINES

Cost effectiveness for each engine control option are summarized Table 5.

Table 5. Cost Analysis Summary of Technically Feasible Control Options for Engines at Kutz

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Clean Burn Technology	16	1,000,000	123,679	121.1	1,021
	17	1,000,000	123,679	71.7	1,725
	18	1,000,000	123,679	70.0	1,767

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

3.2.1. Clean Burn Technology

Harvest has estimated the capital cost for the equipment and labor associated with implementing CBT on the 2SLB engines located at Kutz, as well as the annual costs necessary to operate and maintain the units.

This cost estimate assumes that the CBT control will reduce NO_X emissions by 80%, per the EPA's Alternative Control Techniques document on NO_X emissions from stationary RICE.[26]

[26] U.S. EPA, Office of Air Quality Planning and Standards, "Alternative Control Techniques Document – NO_X Emissions from Stationary Reciprocating Internal Combustion Engines", EPA-453/R-93-032, Section 5.2.5.4, July 1993

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of Harvest's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

4.1. COMBUSTION TURBINES

4.1.1. Improved Combustion Technology

Harvest estimates that approximately 2-3 years will be needed to implement the improved combustion technology control equipment. Factors that have been considered for this anticipated timeline include budgeting, design, uprating the combustors, procuring the equipment, and installing the control.

4.2. 2SLB ENGINES

4.2.1. Clean Burn Technology

Harvest estimates that approximately 2-3 years will be needed to budget, design, procure, and construct the clean burn technology control equipment. For this anticipated timeline, Harvest has considered the time necessary to identify a control vendor, budget and plan the project, and order and install the equipment.

This section addresses the potential energy and non-air environmental impacts that installation of the technically feasible control options poses on a source. The consideration of energy impacts involves assessing the impact of a control measure on the energy that is consumed by the source. Non-air environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

5.1. COMBUSTION TURBINES

5.1.1. Improved Combustion Technology

It is not anticipated that installation of the improved combustion technology (SoLoNO$_X$) on the turbines at Kutz will have any significant energy or non-air environmental impacts.

5.2. 2SLB ENGINES

5.2.1. Clean Burn Technology

Clean burn technology control employs a combustion mixture with a higher air-to-fuel ratio, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. This will reduce NO$_X$ emissions; however, a reduction in combustion temperature also tends to increase emissions of CO, due to incomplete combustion.[27]

[27] Solar Turbines, "Developments in Dry Low Emissions Technology", 2006

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system. Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.[28]

6.1. COMBUSTION TURBINES

Based on their current age and operating efficiency, it is estimated that the remaining useful life of the turbines will be longer than the control units. The turbines have operated for more than 35 years without any significant deterioration in operating efficiency; therefore, this analysis of the remaining useful life of the equipment will be based on the anticipated useful life of the control device considered.

6.1.1. Improved Combustion Technology

It is anticipated that the estimated useful life of the improved combustion technology, SoLoNO$_X$, will be similar to the useful life of an SCR system. The useful life is estimated to be 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[29]

6.2. 2SLB ENGINES

The 2SLB engines at Kutz have similarly been operating for more than 45 years without any significant deterioration in operating efficiency; therefore, this analysis of the remaining useful life of the equipment will be based on the anticipated useful life of the control device considered.

6.2.1. Clean Burn Technology

The useful life of a clean burn technology control system is conservatively estimated to be 20 years.

[28] 40 CFR 51, Appendix Y, Section II.B.4.f

[29] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input of the available control technologies for the natural-gas fired turbines and 2SLB engines located at Kutz, Harvest has determined that SoLoNO$_X$ is the only technically feasible control option for the Solar turbine units. The cost of compliance to install the control on each of these units has been estimated based on manufacturer's input and EPA guidance. The estimated cost effectiveness and NO$_X$ emission reduction for each turbine unit are summarized in Table 6.

Table 6. Summary of Cost Effectiveness and NO$_X$ Reduction for Control of the Turbines at Kutz

Control Equipment	Unit	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Improved Combustion Technology (SoLoNO$_X$)	1	27.4	2,246
	2	25.5	2,412
	3	31.1	1,983
	4	3.4	23,111
	5	36.5	2,145
	6	41.0	1,910
	19	12.9	4,779
	20	30.1	2,043

It is projected that the useful life of these units will be 20 years, based on the life expectancy of the SoLoNO$_X$ control. Harvest estimates that an achievable compliance timeline to implement this control is 2-3 years.

Harvest has further determined that Clean Burn Technology is the only technically feasible control option for the 2SLB engines located at Kutz. The cost of compliance to install this control on each of these units has been estimated by Harvest. The estimated cost effectiveness and NO$_X$ emission reduction for each engine unit are summarized in Table 7.

Table 7. Summary of Cost Effectiveness and NO$_X$ Reduction for Control of the Engines at Kutz

Control Equipment	Unit	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Clean Burn Technology	16	121.1	1,021
	17	71.7	1,725
	18	70.0	1,767

It is projected that the useful life of these units will be 20 years, based on the life expectancy of the CBT control. The only anticipated energy and non-air impact of the CBT control will be an increase in CO emissions. Harvest estimates that 2-3 years would be an achievable compliance timeline to implement this control technology.

At this time, Harvest would like to reiterate their concerns regarding the limited manufacturer support available for these engines. It would be necessary to employ a third-party control vendor with significantly less unit-specific experience and familiarity to install this control. Harvest is concerned that the addition of this control equipment will be operationally detrimental due to this third-party involvement.

Furthermore, Harvest would like to advise the NMED of their judgement that the Kutz facility's potential contribution to regional haze at the Mesa Verde National Park Class I area is such that it does not justify their facility being selected for this assessment. There are hundreds of sources, both major and minor, located closer to the Class I area whose contribution has not been considered. Harvest would argue that only assessing high emitting sources at a limited number of facilities will not effectively address the visibility impairment problem, as required by the State under the RHR.

8. SUPPORTING DOCUMENTATION

Appendix A – RBLC Tables
Appendix B – Cost Analysis Calculations

APPENDIX A - RBLC TABLES

RBLC Analysis for Natural Gas Fired Turbines – NO_X Control

	Control Technology	Good Combustion Technique	Improved Combustion Technology (Low-NO_X Combustors, Ultra-Low NO_X Combustors and other improved combustion technology)[a]	Water/Steam Injection[b]	Selective Catalytic Reduction (SCR)[c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. Primary combustion occurs at lower temperatures under oxygen-deficient conditions. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.	Low-NO_x burners employ multi-staged combustion to inhibit the formation of NO_X. Primary combustion occurs at lower temperatures under oxygen-deficient conditions; secondary combustion occurs in the presence of excess air. This category includes Improved Combustion Technology Lean Head End Liners for the GE turbines assessed here.	Injected water/steam acts as a heat sink, lowering combustion zone peak temperatures, resulting in a decrease in thermal NO_X.	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_X to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.
	Other Considerations	N/A	N/A	Results in a small efficiency penalty but an increase in power output. May increase CO and VOC emissions. Not available in certain models.	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.

RBLC Analysis for Natural Gas-Fired Lean-Burn RICE – NO_X Control

	Control Technology	Good Combustion Practices and Fuel Selection	Clean Burn Technology [a]	Selective Catalytic Reduction (SCR) [b,c]	Non-Selective Catalytic Reduction (NSCR) [c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.	Natural gas fueled engines that operate with a fuel-lean air/fuel ratio are capable of low NO_X emissions.	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_x to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.	This technique uses residual hydrocarbons and CO in rich-burn engine exhaust as a reducing agent for NO_x. In an NSCR, hydrocarbons and CO are oxidized by O_2 and NO_x. The excess hydrocarbons, CO, and NO_x pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_x to N_2.[b]
	Other Considerations	N/A	N/A	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.	N/A
ELIMINATE TECHNICALLY INFEASIBLE OPTIONS	RBLC Database Information	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.
	Feasibility Discussion	Technically feasible.	Technically feasible.	Technically infeasible. Site and unit-specific complications exclude SCR as a control option for the 2SLB engines at this facility.	Technically infeasible. The NSCR technique is limited to engines with normal exhaust oxygen levels of 4 percent or less. This includes 4-stroke rich-burn naturally aspirated engines and some 4-stroke rich-burn turbocharged engines. Lean-burn engines could not be retrofitted with NSCR control because of the reduced exhaust temperatures.

RE: Submittal Requirements for Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring as part of the Regional Haze Four-Factor Analyses

Dear Mr. Singleton:

Harvest Four Corners, LLC is repsonding to the November 14, 2019 request from New Mexico Environment Department for the review of process flaring and Startup, Shutdown, and Maintenance (SSM) flaring as part of the Regional Haze four-factor analyses.

Harvest Four Corners submitted a four-factor analysis for both the Kutz Canyon Processing Plant and San Juan Gas Plant on October 31, 2019. These analyses were conducted in accordance with the federal Clean Air Act, 42 U.S.C. §7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule) as well as the guidance provided by New Mexico Environment Department as received in the July 18, 2019 request to perform four-factor reasonable progress analyses.

Per NMED Guidance from July 18, 2019, *"In accordance with the Regional Haze Rule, NMED requested that a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis."*

The Kutz Canyon Processing Plant has two flares, units 28 and 36. Unit 28 is the plant flare and unit 36 is a control for the TEG dehydrator. The San Juan Gas Plant also has two flares, units 9 and 16. Unit 9 is a plant safety system flare and unit 16 is a staged blowdown flare that works in conjunction with the system flare.

After an extensive review of the equipment at both Kutz Canyon Processing Plant and San Juan Gas Plant it was determined that none of the flares have a potential to emit (PTE) above the de minimus thesholds of 10 pounds per hour and 5 tons per year for either NO_X or SO_2.

PO Box 61229
Houston, TX 77208

1111 Travis Street
Houston, TX 77002
Phone: 713/209-2400
Fax 713/209-2478
harvestmidstream.com

Furthermore, Harvest would like to advise the NMED of their judgement that the flares at both Kutz Canyon and San Juan facilities' potential contribution to regional haze at the Mesa Verde National Park Class I area are such that it does not justify either facility being selected for this assessment for further evaluations of flares. Neither facility has a PTE associated with flares for SO_2 emisions and the NO_X emissions for each flare are below the de minimus thesholds for evaluation. Furthermore, NO_X emissions are not the dominant visibility impairing pollutant at Mesa Verde, and, for that reason, further reductions in NO_X emissions are unlikely to have a significant effect on visibility conditions.

Harvest appreciates the opportunity to present its views on the issues concerning possible reasonable progress assessments for the second planning period of the regional haze program with respect to Harvest Four Corners' Kutz Canyon Processing Plant and San Juan Gas Plant.

If you have questions or require additional information, please contact me at (505) 632-4625 or by e-mail at msmith@harvestmidstream.com.

Sincerely,

Monica Smith

TABLE OF CONTENTS

1. RESPONSES TO THE NMED 1-3
Natural Gas Fired Simple Cycle Turbines....1-3
Two Stroke Lean-Burn Engines (2SLB) 1-4

APPENDIX A: VENDOR DOCUMENTION 1-8

APPENDIX B: GOOD COMBUSTION PRACTICES MANUAL 1-9

The NMED posed the following questions regarding the emissions control options Harvest presented for the turbines and engines located at the Kutz Canyon Processing Plant.

NATURAL GAS FIRED SIMPLE CYCLE TURBINES

i. Provide details of the Good Combustion Practices utilized at the plant including routine inspections, maintenance and training schedules. It is unclear if these practices are fully optimized or conform to permit conditions alone.

Harvest complies with the periodic testing pursuant to A205.A. in order to monitor NOX and CO emissions and A205.D for Maintenance and Repair Monitoring of the current Title V operating permit, P097-R3. A copy of the current SSM Plan includes maintenance and inspection schedules and is included within Appendix B.

Harvest implements good combustion practices as prescribed by the manufacturer and required permit conditions. These include, but are not limited to:

- Manufacturer recommended maintenance
- Training of personnel in proper equipment maintenance and operations
- Routinely scheduled inspections
- Overhauls as required or recommended by the manufacture
- Use of pipeline quality natural gas

i. Provide vendor specifications for the Solar SoLoNOx (i.e., Dry Low NOx (DLN)) combustion technologies to include the guaranteed NOx emission rates used in cost analysis, the cost information, recommendations, and equipment specifications for the turbine control estimates.

These are included in Appendix A.

ii. How will upgrading the turbine combustors with Solar SoLoNOx affect the turbine capacities and the emission rates of NOx and CO?

According to documentation received from Solar, the SoLoNO$_X$ unit would reduce the NO$_X$ exhaust concentration to 15 ppm. According, to AP-42, CO emissions would be increased from the implementation of this control, but Solar has not provided any guidance on the magnitude of the emission increase.[1]

iii. Provide the statement by the turbine vendor stating why water injection is not technically feasible for these units.

This is included in Appendix A.

[1] AP-42 Section 3.1.4.2 Stationary Gas Turbines, Control Technologies, Dry Controls.

iv. Provide supporting data and information for the determination that Selective Catalytic Reduction (SCR) systems are a technically infeasible control measure. Please consider and discuss temperature control devices and catalysts with higher operating temperatures (e.g., zeolites). Additionally, provide clarifying information regarding the additional energy demand SCR would require and expansion of current power generation capacity. Provide a cost analysis if this determination is based on cost and not technical feasibility.

This is included in Appendix A. SCR is not supported by Solar and neither are other proposed technologies – Solar only supports the use of SoLoNO$_X$ for emission reductions on their turbines. Kutz would also need to install additional sources of electricity to meet the power demand required to support SCR.

v. Please consider and include a discussion on limiting turbine operating hours or shutting down turbines that are no longer needed to reduce emissions.

Harvest cannot commit to decreasing turbine capacity as the facility has contractual obligations to process specific amounts of gas. Shutting down units or limiting hours of operation would reduce the facility's capacity and have substantial effects on both producers and consumers of natural gas. Decreases in the maximum capacity could impose a strain on facilities located in the San Juan and this is not something that Harvest can commit to.

vi. Include a discussion of additional control measures for NOx emissions including catalytic combustion and DLN technology available from other manufacturers. A four-factor analysis should be completed for all technically feasible options.

Solar has communicated to Harvest that the only appropriate technology for their turbines is SoLoNO$_X$. Other technologies are not supported by the manufacturer and could impose a serious threat to equipment operation and lead to issues in the future that could lead to more frequent malfunction events. All other DLN technologies are considered technically infeasible for these turbines.

vii. Provide the electronic spreadsheets used for control technology cost calculations.

These have been provided to the NMED.

TWO STROKE LEAN-BURN ENGINES (2SLB)

i. Provide details of the Good Combustion Practices utilized at the plant including routine inspections, maintenance and training schedules.

Harvest complies with Maintenance and Repair Monitoring pursuant to A201.A. and Period Emissions Testing pursuant to A201.B. of the current Title V operating permit, P097-R3. A copy of the current SSM Plan includes maintenance and inspection schedules and is included within Appendix B.

Harvest implements good combustion practices as prescribed by the manufacturer and required permit conditions. These include, but are not limited to:

- Manufacturer recommended maintenance
- Training of personnel in proper equipment maintenance and operations
- Routinely scheduled inspections

- Overhauls as required or recommended by the manufacture
- Use of pipeline quality natural gas

ii. Please consider and include a discussion on the feasibility and cost of technology that limits engine capacity to reduce NOx emissions. Also evaluate limitations on engine operating hours or shutting down engines that are no longer needed to reduce emissions.

Harvest cannot commit to decreasing engine capacity as the facility has contractual obligations to process specific amounts of gas. Shutting down units or limiting hours of operation would reduce the facility's capacity and have substantial effects on both producers and consumers of natural gas. Decreases in the maximum capacity could impose a strain on facilities located in the San Juan and this is not something that Harvest can commit to.

iii. Please consider and include a discussion on the feasibility of replacing the 2SLB engines with commercial electric powered compressors.

40 CFR 51 Appendix Y, states the following: "We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis." Moreover, there are concerns regarding the power supply in the San Juan Basin that present some major obstacles in converting these units to electric. This option is therefore not considered.

iv. Consider and include a discussion of variations of Clean Burn Technology (CBT) used to reduce NOx emissions that may be less expensive than the full CBT packages proposed. Please include cost and efficiencies in analysis.

There is limited manufacturer support available to provide input on the potential effect installation of these controls could have on the engines. As such, a third-party control vendor with significantly less unit-specific experience and familiarity would need to be employed to install this control. Harvest is concerned that the addition of this control equipment by a third-party vendor could negatively affect the units and ultimately be operationally detrimental due to their limited historical knowledge of the engines. Despite the potential drawbacks to installation of CBT control on these units discussed above, 2SLB engines are mechanically capable of being retrofit to support the combustor modifications and more sensitive air-to-fuel ratio controllers necessary to employ CBT. Therefore, as stated in the original four factor analysis submitted to NMED it has been determined that this method of NOX control is feasible for the 2SLB engines at Kutz. On 2SLB RICE, CBT is estimated to achieve an 80 to 93% reduction in NOX emissions; however, this reduction is specific to each engine and typical loading.

As the units at Kutz Canyon are two-stroke lean burn engines (2SLB), the technology for reducing NOX emissions are limited. Harvest has requested additional vendor support regarding Clean Burn Technologies (CBT) and is currently still waiting on a response to determine if any other package options would be viable technology for these units.

v. Provide vendor quotes and estimates that include equipment specifications, installation cost information, recommendations, as well as operation and maintenance costs for the engine control estimates in section 3.

Harvest has requested additional vendor support regarding Clean Burn Technologies (CBT) and is currently still waiting on a response for these units.

The cost estimate assumes that the CBT control will reduce NOX emissions by 80%, per the EPA's Alternative Control Techniques document on NOX emissions from stationary RICE.[2]

Provide the technical justification and basis that supports the determination that Clark HRA-8 2SLB are poorly suited for SCR controls resulting in technical complications and unreliable operation. When would the engine control vendor contacted recommend this control?

Harvest has requested additional vendor support regarding SCR and is waiting on a response. Please refer to the discussion within the four-factor analysis section 2.2.2.3. Selective Catalytic Reduction.

For engines that typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed.[3] Kutz does typically operate with variable loads; therefore, the facility expects to have periods of ammonia slip or insufficient ammonia.

In order for the chemical reactions necessary for SCR to occur effectively, the exhaust streams injected with the reagent must be fairly oxygen rich. The exhaust oxygen levels for 2SLB engines are sufficient to support these reactions; therefore, this technology can be used on lean-burn engines.

AP-42 Section 3.2 does list SCR as an available control technology for 2SLB engines; however, the RBLC does not identify SCR as a control for these specific engine models.[4] This is likely because there is limited operating experience to date with the use of SCR on 2SLB RICE. Additionally, there is historical precedent that installation of SCR on 2SLB engines can result in significant technical complications, including a necessity to derate the engines and unreliable operation post-retrofit. The engines at Kutz are currently de-rated to account for the altitude of the facility. It is not operationally appropriate to de-rate the units further, as would be necessary if SCR control is implemented.

An engine control vendor contacted indicated that the Clark HRA-8 model of engines are poorly suited for installation of SCR controls and they do not typically recommend this for control due to the availability of more suitable options, such as CBT. The control vendor stated that significant challenges would need to be overcome to install this equipment on the units. Primarily, the poor air-to-fuel ratio employed in these units will make it difficult to regulate the SCR and greatly affect the NO_X reduction capability out of the engine. Additionally, a turbocharger and intercooler would need to be installed in the units to support the SCR equipment. As SCR control technology is not listed in the RBLC tables for 2SLB engines, has not been a proven as an effective method of controlling NO_X, and has significant operating challenges, Harvest has determined this control is technically infeasible for the Clark HRA-8 engines at Kutz.

---

[2] U.S. EPA, Office of Air Quality Planning and Standards, "Alternative Control Techniques Document – NO_X Emissions from Stationary Reciprocating Internal Combustion Engines", EPA-453/R-93-032, Section 5.2.5.4, July 1993

[3] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"

[4] Ibid.

vi. Please provide more information on what could be done to improve the poor air to fuel ratio for SCR to work properly, including the installation of a turbo charger and intercooler. Provide vendor quotes and specifications received on installing SCR for these engines, if any.

Please refer to the discussion within the four-factor analysis section 2.2.2.3. Selective Catalytic Reduction.

The Clark HRA-8 model of engines are poorly suited for installation of SCR controls and the vendor does not typically recommend this for control due to the availability of more suitable options, such as CBT. The control vendor stated that significant challenges would need to be overcome to install this equipment on the units. Primarily, the poor air-to-fuel ratio employed in these units will make it difficult to regulate the SCR and greatly affect the NO_X reduction capability out of the engine. Additionally, a turbocharger and intercooler would need to be installed in the units to support the SCR equipment. As SCR control technology is not listed in the RBLC tables for 2SLB engines, has not been a proven as an effective method of controlling NO_X, and has significant operating challenges, Harvest has determined this control is technically infeasible for the Clark HRA-8 engines at Kutz.

vii. Provide the electronic spreadsheets used for control technology cost calculations.

These have been provided to the NMED.

APPENDIX A: VENDOR DOCUMENTION

Solar® Turbines

A Caterpillar Company

Powering the Future Through Sustainable, Innovative Energy Solutions

SOLONOX DRY LOW EMISSIONS TECHNOLOGY

Solar Turbines is a leader in pollution-prevention technology. Since the introduction of SoLoNOx™ in 1992, our dry low emissions technology advancements have prevented the production of more than 5.8 MM tons of NOx emissions. This represents a reduction of 75-90% from conventional combustion baselines for natural gas fuel.

Solar has unrivaled experience within the industry with more than 3500 SoLoNOx gas turbines with over 312 million operating hours located around the world.

Fuel options include natural gas, ultra low sulfur diesel (ULSD), associated gases, LPG and kerosene.

Low NOx Emissions Warranty: Pipeline natural gas emissions avalable at 9, 15, 25 or 38 ppm NOx @15% O2 on select models. ULSD emissions levels range from 58 to 96 ppm NOx @15% O2 on select models.

Wide Low NOx Emissions Operating Range: Single shaft 50-100% load, two shaft 40-100% load down to low ambient temperatures.

Available warranty emissions levels, operating range, and ambient temperature range vary by product and rating. Please contact Solar for more information.

Dry Low Emissions 101

DLE (dry low emissions) or lean-premix combustion reduces the conversion of atmospheric nitrogen to NOx by reducing the combustor's flame temperature. Since NOx formation rates are strongly dependent on flame temperature, lowering this temperature is an effective strategy for reducing NOx emissions. Lean combustion is enhanced by premixing the fuel and combustor airflows upstream of the combustory primary zone. DLE eliminates the need for water or steam injection or exhaust cleanup, which benefits the environment at a lower cost.

Subject: [EXTERNAL] RE: Harvest - 4 Factor San Juan and Kutz

HI Monica,

Please see the attached Product Info Letters (PIL) and Spec Sheets on both the Centaur Generator Set and Compressor set. As well as combustion technology.

As far as wet NOx systems go, it is clearly stated on our spec sheets we no longer offer this technology. It is an outdated technology that requires more parts, maintenance and extremely clean water which equals additional cost for our customer and does not preform as well as our current SoLoNOx technology. Instead we continue to improve on this technology and pass the savings along to our customers from having to maintain additional systems that do not do as well in lowering emissions.

Solar's current stance on SCR's is on a case by case business. However as we are not SCR manufacturers we will currently not warranty or maintain these systems. Being that there are too many ways to construct these types of systems or standardize them based on customer needs, it makes it a difficult avenue for our company to pursue. We stand firm on our SoLoNOx technology being the best solution to lower emissions. It's the most environmentally friendly, cost effective and quickest way to reduce emissions.

FYI I'll be in the FCA office tomorrow morning if you'd like to chat about it. Let me know if this helps. I think I may need to provide you with performance runs to show the emissions guarantees mentioned. However I was waiting to get some clarification from one of our applications engineers before I send that information over.

Thanks!

Cheers,
Joey Guillen

October 23, 2020

Mr. Michael Baca
Control Strategies Manager
New Mexico Environment Department Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, New Mexico, 87505-1816

Harvest Four Corners, LLC is submitting this response to your August 31, 2020 follow-up email regarding the 4-Factor Analyses for the Kutz Canyon Processing Plant (Kutz) and the San Juan Gas Plant (SJGP). The attachments have been labeled to correspond with each item outlined in your email.

0. Harvest used the 5.5% interest rate based on the default rate at the time of the analysis to estimate costs (2016 year) and you are not opposed to NMED using an updated interest rate (e.g., 3.25%) in our cost analysis.

   While responses to the following items are based on a 5.5% interest rate, Harvest Corporate has recommended that analyses should be based on a 7.5% interest rate, the rate at which money has recently been borrowed.

1. Electronic spreadsheets (i.e., Excel files) and vendor quotes for cost calculations. Harvest indicated that vendor quotes have been difficult to obtain (i.e., CBT for engines) and may not be available, but will provide more information on their efforts to obtain these and the basis to estimate costs.

   See the attached spreadsheet and vendor quotes (*Att1K (filename)*) for the Solar SoLoNOx upgrades for Kutz Canyon. Solar is preparing quotes for the SJGP upgrades. The attached spreadsheet is based the 2019 4-Factor packet submittal, but the vendor quotes were requested after August 31, 2020 conference call.

2. Information for the Kutz Canyon facility (Kutz I) that was shared with our permitting group regarding future plans for permitting, facility operations, shutdowns, etc. With the continuing decline in natural gas production in the San Juan Basin, it is no longer economically viable to operate all equipment at the Kutz Canyon Processing Plant, and thus Harvest will discontinue operation of the Kutz I lean oil plant portion of the facility. The equipment to be decommissioned includes:

   a. Unit 16 – Clark HRA8 refrigerant compressor R4;
   b. Unit 17 – Clark HRA8 refrigerant compressor R5;
   c. Unit 18 – Clark HRA8 refrigerant compressor R6;
   d. Unit 22 – 23.1 MMBtu/hr Wheco heater H1;

PO Box 61229
Houston, TX 77208

1111 Travis Street
Houston, TX 77002
Phone: 713/209-2400
Fax 713/209-2478
harvestmidstream.com

e. Unit 23 – 9.57 MMBtu/hr Alcorn heater H2;
f. Unit 24a – Kutz I EG dehydrator;
g. Unit 24b – Kutz I dehydrator reboiler;
h. Unit 37a – Waukesha 5794LT refrigerant compressor;
i. Unit 37b – Waukesha 7042GL refrigerant compressor (never installed);
j. Unit 39 – cooling tower; and
k. Tank T6438 – Blanco/Hare condensate tank and associated EVRU

3. Clarification about the use and generation of electricity at each plant including a list of the units used for compression and generating electricity.
   a. At Kutz, as currently permitted, Units 1 through 8, 16, 17 and 18 compress inlet or residue gas, while Units 37a or 37b compress propane for the Kutz 1 lean oil plant. Units 29 and 30 (Gen A and Gen B) generate electricity.
   b. At SJGP, Units 1, 2 and 3 compress inlet and residue gas, while electricity is generated by Units 4, 5, 6 and 7.

4. Technically feasibility of installing line electricity to the plants and replacing compression units with electric motors. Attachments *Att4K Kutz Electrical 9.8.2020* and *Att4S SJ Electrical Conversion* provide the cost estimate of replacing gas-fired compressor drivers with electrical motors.
   Adding 3 VFD motors to replace the units used for compression only, would require 15,000 hp motor variable speed for each. A building housing the three VFD motors of that size would have to be built across the road with land purchase. The power currently produced wouldn't be near enough for one VFD motor, much less all three. This would require a substation to be built across the road also. Modifications to the plant would have to be made, and real estate found to have heaters installed for heating the hot oil, which currently uses the waste heat from the turbines. Without the hot oil, the plant cannot make product spec. Additionally, these type and size of motors with a substation to start them would probably require very high voltage technicians that are qualified to work on them; nobody currently working at SJGP is line voltage qualified.

5. Confirmation that retrofit costs were included in your SCR analysis for the Solar turbines at San Juan GP.
   The SCR cost were derived using the EPA Cost Control Manual for SCRs. Within this calculation is an option for retrofit which was chosen and a designation of a Retrofit Factor (RF). An RF of 1.o was chosen for this calculation which is incorporated for the cost. Based on the Chapter 2 Selective Catalytic Reduction" from June 2019 , "a retrofit factor of 1 should be used for average retrofits. The equations may overestimate costs for

PO Box 61229
Houston, TX 77208

1111 Travis Street
Houston, TX 77002
Phone: 713/209-2400
Fax 713/209-2478
harvestmidstream.com

some simple retrofits of existing plants. For retrofits that are more complicated than average, a retrofit factor of greater than 1 can be used to estimate capital costs provided the reasons for using a higher retrofit factor are appropriate and fully documented."

6. Clarification on the basis and use of incremental costs for SCR.
   Upon evaluating the calculation for incremental cost this appears to only be the difference in cost between the installation of SoloNox versus SCR and does not change the individual evaluation of the cost of the SCR.

7. Additional information about the space limitations for installing SCR.
   As with conversion to electricity, installation of SCR for turbine exhaust controls would also require purchase of real estate across the road. Routing the turbine exhaust to the ammonia/urea reagent storage across the road is technically infeasible the exhaust temperature would fall below reaction temperatures. Therefore, it would be necessary to pump the reagent to the existing exhaust stacks that have been retrofitted to accommodate the catalyst. In addition to the costs of remotely storing the reagent, there is also a significant safety hazard moving the reagent from storage and across the road to the exhaust stacks.

Thank you for your assistance with this analysis. Please email or call me (msmith@harvestmidstream.com, (505) 632-4625) if we can provide any additional information.

Sincerely,

Monica Smith

Michael,

Please see the attached items as well as the responses provided below.

1.) Harvest used a 5.5% interest rate in their responses and indicated that Harvest Corporate recommends a 7.5% interest rate for use in the 4-Factor Analyses. We have to document company specific interest rates in the form of a letter from the chief financial officer for the institution that lends to your company, or from an official with your company (your company's CFO, for instance) that is in a position to know your company's costs of debt and equity. Otherwise, we plan to use the current prime rate of 3.25% in the cost calculations. – Harvest – Pricing Term Sheet, attached

2.) Have you received quotes from Solar for the SJGP upgrades? – (5) attachments included from Solar for San Juan Gas Plant, (all 5 docs start with OD)

3.) Harvest indicates that equipment associated with the lean oil plant of Kutz I will be decommissioned. Under the Regional Haze Rule, emission limitations and reductions must be permanent and federally enforceable. Our review of Air Quality Bureau's permitting records does not show a recent New Source Review permit application for this action. Please provide more information about your plans to modify your permits including any recent communications with AQB permitting staff indicating your commitment to permanently discontinue operation of the Kutz I lean oil plant. – We just started internal discussions about the removal of the Kutz I equipment. We felt that we needed to wait before proceeding with the permit application to ensure that the plant could operate without any issues before de-permitting the equipment. Internal discussions have begun, and communications with NMED will be upcoming as well as the application submittal. We are currently working through our Annual Reports, such as Emissions Inventory and Green House Gas, which take precedent based on the submittal deadlines.

This is the current list of equipment that we plan on removing from the Kutz Permit, we may be adding a couple more items, in the permit application.

EU	Equipment Name
16	Clark Reciprocating Engine (R4)
17	Clark Reciprocating Engine (R5)
18	Clark Reciprocating Engine (R6)
22	Wheco Heater (H1)

23	Alcorn Heater (H2)
24	Kutz I EG Dehydrator
37a	Waukesha L5794LT Engine refrigerant compressor
37b	Waukesha L7042GL Engine (never installed)
39	Cooling Tower
T6438	Blanco-Hare Condensate Tank (& EVRU)

4.) Do the Operation and Maintenance (O&M) costs provided for in your Four Factor evaluation of applicable equipment reflect the incremental cost of O&M for additional control? In other words, are these costs over and above those already realized for the units? – Both Plant Foreman feel as though the numbers provide are correct. They did not feel that the numbers provided were over and above the cost already realized for the units.

Please let me know if you have any additional questions or need additional information.

Thank you,

Monica Smith

Subject: RE: [EXTERNAL] Follow up on Kutz Canyon and the regional haze program
Attachments: Harvest - Pricing Term Sheet (Final).pdf; Att4k Kutz Electrical 9.8.2020 (2).xlsx

My apologies for the delayed follow up to our conference call.

After speaking with upper management, they have advised that we still have the same pricing sheet previously provided with a 7.5% interest rate. I have attached the letter that was previously provided.

The same for the electrification after further review of what was submitted, Harvest will not be revising the cost elevation. Also attached.

Below are the updated cost of capital associated with the Solar turbines currently located at Kutz Plant.

Conventional units
4 year overhaul costs per unit- $513,282.00

Maintenance cost per year-$128,320.00 per unit

Solonox upgrade- 750k per unit

Solonox units
4 year overhaul costs- $630,000 per unit

Maintenance cost per year-$157,520 per unit

Please let me know if you have any additional questions or need anything else.

Thank you,

Subject: RE: [EXTERNAL] Question Regarding Status of Kutz Canyon Processing Plant Units 4-6, Other Facility Changes

Kirby,

My apologies for the delay in getting back to you. Units 4-6 remain inactive with no plans to bring those units online or make the necessary changes needed to get them up and running. No final decision has been made to remove the no longer operating equipment from the permit. Units 19-20 are still providing power for the facility, communications and progress on the purchase power route have been unsuccessful and may be a few years out. The flare is being looked at per Ozone rule requirements, so no decision has been made there. With all this said I feel like it will still be a year or two before we are able to re-permit the facility as a minor source.

Please let me know if you have any additional questions.

Thank you,

Monica Smith

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 1: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	123.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,007,467,701	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.1610	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0322	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F		*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour		

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.

Unit 1: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	123	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,046,781,765	scf/Year	
Actual Annual fuel consumption (Mactual) =		1,007,467,701	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.962	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8431	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	15.86	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	66.87	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	458.30	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	21	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	72.94	kW

Unit 1: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$5,803,002	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$115,230 in 2024 dollars
Indirect Annual Costs (IDAC) =	$572,251 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$687,481 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$29,015 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$12,666 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$61,492 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$12,057 in 2024 dollars
Direct Annual Cost =		$115,230 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,976 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$569,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$572,251 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$687,481 per year in 2024 dollars
NOx Removed =	67 tons/year
Cost Effectiveness =	$10,280 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 2: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	123.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,017,146,848	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.1724	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0345	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F		*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour		

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.
Electricity Cost ($/kWh)	0.0676	U.S. Energy Information Administration. Electric Power Monthly. Table 5.3. Published December 2017. Unit 2: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	123	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,046,781,765	scf/Year
Actual Annual fuel consumption (Mactual) =		1,017,146,848	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.972	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8512	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	16.99	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	72.32	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

Not applicable; factor applies only to coal-fired boilers

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	460.16	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	7	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	23	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,100	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	72.94	kW

Unit 2: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$5,803,002	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$116,901 in 2024 dollars
Indirect Annual Costs (IDAC) =	$572,251 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$689,151 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$29,015 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$13,697 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$62,083 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$12,106 in 2024 dollars
Direct Annual Cost =		$116,901 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,976 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$569,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$572,251 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$689,151 per year in 2024 dollars
NOx Removed =	72 tons/year
Cost Effectiveness =	$9,529 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 3: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	123.2	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	1,022,165,664	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.1578	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0316	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 3: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	123	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	1,046,781,765	scf/Year	
Actual Annual fuel consumption (Mactual) =		1,022,165,664	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.976	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8554	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	15.55	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	66.52	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	457.79	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	6	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	21	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	3	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	1,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	72.94	kW

Unit 3: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$5,803,002	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$116,046 in 2024 dollars
Indirect Annual Costs (IDAC) =	$572,251 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$688,296 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$29,015 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$12,598 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$62,389 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$12,043 in 2024 dollars
Direct Annual Cost =		$116,046 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,976 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$569,275 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$572,251 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$688,296 per year in 2024 dollars
NOx Removed =	67 tons/year
Cost Effectiveness =	$10,348 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 4: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	23.9	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	185,613,288	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.5812	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1162	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours	
Estimated SCR equipment life	20	Years*	

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F	*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour	

Concentration of reagent as stored (C_{stored})	29	percent*	
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*	
Number of days reagent is stored ($t_{storage}$)	14	days	

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 4: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	24	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	203,068,865	scf/Year
Actual Annual fuel consumption (Mactual) =		185,613,288	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.914	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8007	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.11	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	44.49	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	102.16	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	15	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	700	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	14.15	kW

Unit 4: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$1,998,547	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$32,435 in 2024 dollars
Indirect Annual Costs (IDAC) =	$198,805 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$231,241 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$9,993 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$8,426 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$11,329 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$2,688 in 2024 dollars
Direct Annual Cost =		$32,435 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,748 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$196,057 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$198,805 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$231,241 per year in 2024 dollars
NOx Removed =	44 tons/year
Cost Effectiveness =	$5,198 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 5: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	23.9	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	186,772,357	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.5715	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1143	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours	
Estimated SCR equipment life	20	Years*	

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F	*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour	

Concentration of reagent as stored (C_{stored})	29	percent*	
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*	
Number of days reagent is stored ($t_{storage}$)	14	days	

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent

Unit 5: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	24	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	203,068,865	scf/Year	
Actual Annual fuel consumption (Mactual) =		186,772,357	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.920	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8057	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	10.93	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	44.02	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units

Unit 5: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$1,998,547	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$32,410 in 2024 dollars
Indirect Annual Costs (IDAC) =	$198,805 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$231,216 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$9,993 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$8,338 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$11,400 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$2,680 in 2024 dollars
Direct Annual Cost =		$32,410 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,748 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$196,057 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$198,805 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$231,216 per year in 2024 dollars
NOx Removed =	44 tons/year
Cost Effectiveness =	$5,252 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 6: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	23.9	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	185,845,102	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.6360	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1272	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 6: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	24	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	203,068,865	scf/Year
Actual Annual fuel consumption (Mactual) =		185,845,102	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.915	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8017	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	12.16	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	48.74	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	103.89	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	16	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	14.15	kW

Unit 6: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$1,998,547	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$33,301 in 2024 dollars
Indirect Annual Costs (IDAC) =	$198,805 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$232,107 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$9,993 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$9,232 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$11,343 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$2,733 in 2024 dollars
Direct Annual Cost =		$33,301 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,748 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$196,057 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$198,805 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$232,107 per year in 2024 dollars
NOx Removed =	49 tons/year
Cost Effectiveness =	$4,762 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Hilcorp Energy Company - San Juan Basin Gas Plant

Unit 7: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	23.9	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	182,692,435	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	5595	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.6033	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.1207	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 7: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	24	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	203,068,865	scf/Year
Actual Annual fuel consumption (Mactual) =		182,692,435	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.900	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7881	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.54	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	45.46	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm

Unit 7: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$1,998,547	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$32,459 in 2024 dollars
Indirect Annual Costs (IDAC) =	$198,805 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$231,265 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$9,993 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$8,610 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$11,151 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$2,706 in 2024 dollars
Direct Annual Cost =		$32,459 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,748 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$196,057 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$198,805 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$231,265 per year in 2024 dollars
NOx Removed =	45 tons/year
Cost Effectiveness =	$5,087 per ton of NOx removed in 2024 dollars

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*
>
> The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long-Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed Harvest Four Corners, LLC (Harvest) that its Harvest Pipeline - San Juan Gas Plant (San Juan) facility was identified as one of the sources potentially contributing to regional haze at the Mesa Verde National Park Class I area.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to Harvest, it specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The subject equipment at San Juan, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Rolls-Royce Avon 1535 Natural Gas Turbine (Unit 1)	56.3	246.4	Yes	0.060	0.26	No
Rolls-Royce Avon 1535 Natural Gas Turbine (Unit 2)	56.3	246.4	Yes	0.060	0.26	No
Rolls-Royce Avon 1535 Natural Gas Turbine (Unit 3)	56.3	246.4	Yes	0.060	0.26	No
Rolls-Royce Avon 1535 Natural Gas Turbine (Unit Rotating Spare)	56.3	246.4	Yes	0.060	0.26	No
Solar Centaur T4501 Natural Gas Turbine (Unit 4)	15.9	69.8	Yes	0.010	0.050	No
Solar Centaur T4501 Natural Gas Turbine (Unit 5)	15.9	69.8	Yes	0.010	0.050	No
Solar Centaur T4501 Natural Gas Turbine (Unit 6)	15.9	69.8	Yes	0.010	0.050	No
Solar Centaur T4501 Natural Gas Turbine (Unit 7)	15.9	69.8	Yes	0.010	0.050	No

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED[1], this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. Summaries of the result of this search are provided and discussed under Section 2 of this report. Harvest engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis is then conducted for those controls that are technically feasible.

[1] NMED 2021 Regional Haze Planning Website ("Links to other information"). https://www.env.nm.gov/air-quality/reg-haze/

NO_X is the only pollutant subject to evaluation in this four-factor analysis for the eight turbines located at San Juan. Unit 1 through 3 and Unit Rotating Spare are Rolls-Royce Avon model 1535 natural gas-fired, simple cycle turbines. Units 4 through 7 are Solar model Centaur T4501 natural gas-fired, simple cycle turbines.

Unit 1 through 3 and Unit Rotating Spare are rated at 15,000 horsepower and were manufactured in 1985 or 1986. Units 4 through 7 are rated at 3,735 horsepower and were manufactured in 1986.

Per NMED Guidance received on 9/23/2019, the four-factor analysis is to be completed only for units which are a steady state source of emissions. Unit Rotating Spare is a backup unit, which only operates when Unit 1, 2 or 3 are down for maintenance or repair. The unit is kept in a warehouse and is not a source of emissions unless it is commissioned to replace one of the primary turbines. Due to the intermittent nature of emissions and non-steady state operation, no further assessment of Unit Rotating Spare will be included in this four-factor analysis.

2.1. COMBUSTION TURBINES

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[2]

The treatment of the exhaust gases exiting the turbine dictate the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[3] The units at San Juan are simple cycle turbines.

NO_X is formed via three fundamentally different mechanisms. The principle NO_X formation mechanism, thermal NO_X, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_X forms in the highest temperature regions of the combustion chamber. The second NO_X formation mechanism, fuel NO_X, arises from the evolution and reaction of fuel bound nitrogen compounds with oxygen. The final NO_X formation mechanism, prompt NO_X, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_X is negligible in comparison to thermal and fuel NO_X. Fuel NO_X will also be negligible for San Juan's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_X.

[2] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[3] Ibid.

The PTE from each turbine is reported in the facility's New Source Review (0613-M10R2) and Title V (P124-R3) permits, as well as summarized in Table 1 of this report.

2.1.2. Potential NO_X Controls for a Combustion Turbines

There are three general methods of controlling NO_X emission from gas turbines: (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation; (2) dry controls that use advanced combustor design to suppress NO_X formation; and (3) post-combustion, catalytic controls to selectively reduce NO_X.[4]

The retrofit control equipment that was identified for combustion turbines during a comprehensive review of the RBLC, available literature, and manufacturer's input is reported in Table 2. A more detailed table summarizing the RBLC review is provided in Appendix A. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible for Rolls-Royce (Units 1 through 3)?	Technically Feasible for Solar (Units 4 through 7)?	NO_X Control Efficiency
Good Combustion Practices	Yes	Yes	Base Case
Improved Combustion Technology	No	Yes	65% - 75%
Water/Steam Injection	No	No	N/A
Selective Catalytic Reduction	No	Yes	65% - 75%

2.1.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at San Juan. However, these practices have been developed and are currently in use at San Juan, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices is included in this report.

2.1.2.2. Improved Combustion Technology

The improved combustion technology control option, commonly referred to as Dry Low Emissions (DLE) control, seeks to reduce the combustion temperature and residence time of fuel in the combustor (thereby decreasing NO_X

[4] Ibid.

formation) by increasing the air-to-fuel ratio in the combustion chamber. There are several levels of improvements that can be made to the combustion chamber, which achieve this NO_X control at varying levels.

2.1.2.2.1 Rolls-Royce Avon Units

The Rolls-Royce Avon energy gas turbine and compressor business is currently owned and operated by Siemens. Based on communication with Siemens, there are no DLN control options for the model of turbines located at San Juan. The units were designed and manufactured prior to the enhanced environmental awareness present today; and therefore, were not designed to suitably implement emissions control measures. The unavailability is also likely due to lack of market demand to improve the control efficiency of these older units.

Per conversations with a Siemens representative, a small number of these turbine models were retrofit with DLN emissions controls as a pilot study, but the units did not function properly after installation of the control. Therefore, testing of DLN controls for these turbines was halted and the control eliminated as a viable option. DLN controls were not offered to the market to control emissions from these units.

Per 40 CFR Part 51, Appendix Y, "a technology is considered 'available' if the source owner may obtain it through commercial channels, or it is otherwise available within the common sense meaning of the term."[5] Further, source owners are not expected to "construct a process or control device that has not already been demonstrated in practice."[6]

DLN controls are not currently offered on the market for these turbines; therefore, this control is not considered to be available as described above. Additionally, there is historical precedent which indicates that installation of these controls would result in decreased functionality of the units. For these reasons, it has been determined that this control technology is infeasible for the Rolls-Royce turbines located at San Juan.

2.1.2.2.2 Solar Units

The improved combustion technology available for the units at San Juan is produced by the manufacturer of the units, Solar, and is called SoLoNO$_X$. Based on communication with Solar, SoLoNO$_X$ is available for the T4501 Solar turbines located onsite; however, each of the units would need to be uprated to model Centaur T4701 in order to support the technology. The uprate is necessary because installation of SoLoNO$_X$ requires the turbine combustors to be capable of handling significantly higher temperatures. Uprating the units involves replacing the combustor section of the turbine with a much larger and more robust combustor. Solar can guarantee an output NO_X concentration of 25 parts per million (ppm) for uprated units with SoLoNO$_X$ installed, resulting in a NO_X emissions reduction of approximately 65 - 75%, based on the 2016 hourly emission rate and turbine stack parameters of each unit.

Improved combustion technology was identified in this review of RBLC as a potential control of NO_X emissions from natural gas-fired combustion turbines, and AP-42 Section 3.1 also lists this as an available control technique for gas turbines.[7] Therefore, it has been determined that this control technology is technically feasible for the Solar turbines located at San Juan.

[5] 40 CFR 51, Appendix Y, Section IV.D.2
[6] 40 CFR 51, Appendix Y, Section IV.D.1
[7] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"

2.1.2.3. Water/Steam Injection

Water or steam injection is a control technology for gas turbines that has been demonstrated to effectively suppress NO_X emissions. Injection of steam and water has the effect of increasing the thermal mass by dilution and thereby reducing the peak temperature in the flame zone. Additionally, the latent heat of vaporization from the flame zone is absorbed when water injection is utilized, further reducing the combustion temperature. Water or steam is typically injected at a water-to-fuel weight ratio of less than one.[8]

2.1.2.3.1 Rolls-Royce Avon Units

Water/steam injection was identified in this review of RBLC as a potential control of NO_X emissions from natural gas-fired combustion turbines, and AP-42 Section 3.1 also lists water/steam injection as an available control technique for gas turbines.[9] However, communication with Siemens has indicated that water/steam injection is not currently offered for the model of turbines located at San Juan, and is therefore not considered available. Additionally, as this technology has not been installed on this model of turbine, there is no historical data to support that installation of these controls would result in significant reductions of NO_X emissions. For these reasons, it has been determined that this control technology is infeasible for the Rolls-Royce turbines located at San Juan.

2.1.2.3.2 Solar Units

Steam injection is not discussed as an option for these units because Solar does not manufacture turbines with steam injection technology. The capability of these units to be retrofit for water injection is dependent on the number of shafts employed in the unit, per communication with Solar. The shaft is the piece of equipment in the unit that is turned by the turbine to generate work. Solar has indicated that turbine units with one shaft are mechanically capable of installing water injection, while two-shaft units are not. The Solar Model T4501 turbines located at San Juan are one-shaft units and are, therefore, capable of being retrofit with water injection controls.

Despite the Solar T4501 being mechanically capable of supporting water injection, Solar has stated that they do not offer water injection retrofits for any of the Centaur 40 conventional combustion line of turbines. This is primarily due to the design of the combustor housing of the conventional Centaur 40. The injectors on this style of combustor intersect directly into the combustor without using direct air flow for the direction of fuel. The style of injector needed to implement water injection technology is referred to by Solar as a Dual Lined Injector. This type of injector introduces fuel laterally into the front of a combustor and utilizes a controlled flow to disperse fuel.

Solar considers the control technique to be antiquated technology in comparison to the other control methods they have available, such as $SoLoNO_X$. Solar has retired this control option and does not recommend water injection be installed to control emissions from their turbine units. They have stated that if there were direct modifications made to the turbine engine or it's supporting hardware, it could affect the unit's warranty with Solar.

Furthermore, per conversations with Solar, approximately 5 gallons per minute (gpm) of de-ionized or de-mineralized water will be needed to properly implement this control. For a continuously operating turbine, this represents a total water usage of approximately 2.6 million gallons per year, per unit, without taking into account leaks and evaporative losses that would occur during transport. The facility is located in San Juan County, in the northwestern part of the state. The National Drought Mitigation Center currently classifies this region as

[8] Ibid.
[9] Ibid.

experiencing severe drought conditions.[10] The New Mexico Office of the State Engineer projects that the water demand in the San Juan region will exceed the drought-adjusted available water supply before 2030.[11] The implementation of this control may pose an unsustainable burden on this region's watershed.

Based on the communication with the turbine manufacturer detailed above, as well as the lack of available water in the region, it has been determined that water injection control is technically infeasible for the Solar turbines located at San Juan.

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[12] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO_X emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituent; thermal sintering, or compacting, of active sites due to high temperatures in the reactor; fouling caused by ammonia-sulfur salts and particulate matter in the gas; and erosion due to high gas velocities.[13]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams can blind the catalyst and may necessitate the application of a soot blower.[14]

For an SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[15]

2.1.2.4.1 Rolls-Royce Avon Units

As provided by site engineers, the exhaust temperature of the Rolls-Royce Avon turbines is 1,250 °F, and is therefore outside of the temperature range necessary to support SCR control. It is unlikely that SCR control would function effectively on the Rolls-Royce turbines due to the high exhaust temperature of these units. Additionally,

there are potential site-specific space limitations that prevent the installation of the necessary equipment for this control method (i.e., SCR module and reagent storage systems).

Furthermore, Harvest does not anticipate that the current electricity availability at San Juan will be sufficient to support the substantial energy burden associated with SCR control. Installation of this control will require the facility to expand its current power generation.

Communication with Siemens has indicated that SCR controls are available for the turbine model assessed here. However, it is not anticipated that the exhaust temperature, space, and energy limitations can be overcome. Therefore, it has been determined that this control technology is infeasible for the Rolls-Royce turbines located at San Juan.

2.1.2.4.2 Solar Units

The exhaust temperature of the turbines assessed here is within the necessary operating range for SCR control, at approximately 827 °F. However, the site-specific space and energy limitations discussed above apply to these units as well.

Communication with Solar has indicated that SCR controls are available for the Solar turbines assessed here. Therefore, assuming that the space limitations can be overcome, SCR is considered a technically feasible control option for the turbines located at San Juan. Solar has estimated that installation of SCR control on these units will result in an output NO_X concentration of 25 parts per million (ppm), resulting in a NO_X emissions reduction of approximately 65 - 75%, based on the 2016 hourly emission rate and turbine stack parameters of each unit.

Harvest has evaluated the costs of implementing the technologically feasible control technologies as thoroughly as possible in the time provided to complete this assessment. These cost estimates are calculated according to the methods and recommendations in the EPA Air Pollution Control Cost Manual.[16] Cost effectiveness considerations for each unit and control technology are discussed below.

These cost estimates have been developed based on the actual emissions from each unit assessed here, using the 2016 Emission Inventory submittal for San Juan. The full cost estimation for each unit, including the EPA Air Pollution Control Cost Spreadsheet, is included in Appendix B of this report.

3.1. SOLAR TURBINES

Cost effectiveness for each technically feasible Solar combustion turbine control option are summarized Table 3.

Table 3. Cost Analysis Summary of Technically Feasible Control Options for Solar Turbines

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Improved Combustion Technology (SoLoNO$_X$)	4	563,300	69,637	35.7	1,952
	5	563,300	69,637	28.9	2,412
	6	563,300	69,637	36.8	1,894
	7	563,300	69,637	46.4	1,500
Selective Catalytic Reduction **(SCR)**	4	4,000,000	457,586	35.7	12,824
	5	4,000,000	456,964	28.9	15,825
	6	4,000,000	457,827	36.8	12,455
	7	4,000,000	458,936	46.4	9,883

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

3.1.1. Improved Combustion Technology

Harvest has received an estimated direct capital cost for the equipment and vendor labor associated with implementing SoLoNO$_X$ on the turbines located at San Juan from Solar. Solar has also provided an estimated annual cost necessary to operate and maintain the units post-retrofit.

This cost estimate assumes that SoLoNO$_X$ will reduce NO$_X$ emissions to an outlet concentration of 25 ppm, based on manufacturer's estimations.

[16] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

3.1.2. SCR

Harvest has received an estimated direct capital cost for the equipment and vendor labor associated with implementing an SCR system on the model of turbines located at San Juan from the manufacturer.

The EPA Air Pollution Control Cost Spreadsheet for SCR is used to estimate the direct annual costs (maintenance, operating labor, reagent cost, electricity cost, and catalyst cost) and indirect annual costs associated with Harvest's internal labor, overhead and capital recovery for the project.

This cost estimate assumes that the SCR will reduce NO_X emissions to an outlet concentration of 25 ppm, based on manufacturer's estimations.

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of Harvest's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

4.1. SOLAR TURBINES

4.1.1. Improved Combustion Technology

Harvest estimates that approximately 2-3 years will be needed to implement the improved combustion technology control equipment (SoLoNO$_X$). Factors that have been considered for this anticipated timeline include budgeting, design, uprating the combustors, procuring the equipment, and installing the control.

4.1.2. SCR

Harvest estimates that approximately 2-3 years will be needed to budget, plan, order, deliver and install the SCR control equipment.

This section addresses the potential energy and non-air environmental impacts that installation of the technically feasible control options poses on a source. The consideration of energy impacts involves assessing the impact of a control measure on the energy that is consumed by the source. Non-air environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

5.1. SOLAR TURBINES

5.1.1. Improved Combustion Technology

It is not anticipated that installation of the improved combustion technology (SoLoNO$_X$) on the Solar turbines at San Juan will have any significant energy or non-air environmental impacts.

5.1.2. SCR

The implementation of SCR on the turbines at San Juan would result in several energy and non-air environmental impacts. The primary impact of this control would be a significant increase in energy consumption, which would be necessary to power the units. The estimated energy consumption for each unit is summarized in Table 4, and is based on the EPA Air Pollution Control Cost Manual.[17] The calculation for these values is included in Appendix C of this report. Harvest does not anticipate that the current electricity availability at San Juan will be sufficient to support this increased energy burden. Installation of this control will require the facility to expand its current power generation. The costs of this associated power expansion are not accounted for in the SCR cost estimates included in Table 3.

Table 4. Turbine SCR Energy Consumption Analysis Summary

Unit	Annual Energy Consumption (MWh/yr)
4	95.8
5	100.1
6	99.2
7	97.3
Total	392.4

In addition to the increased energy burden, there are several non-air environmental impacts associated with the handling and storage of the reagent used in the SCR system, typically ammonia or urea. Ammonia is a Toxic Air Pollutant (TAP) regulated under 20.2.72.502 NMAC with an occupational exposure limit (OEL) of 18 mg/m^3. In both soil and water, urea is hydrolyzed quickly to ammonia and carbon dioxide by urease, an extracellular enzyme that originates from microorganisms and plant roots.[18] Short-term inhalation exposure to high levels of ammonia

[17] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

[18] U.S. EPA, EPA/635/R-10/005F, "Toxilogical Report of Urea", July 2011

in humans can cause irritation and serious burns in the mouth, lungs, and eyes. Chronic exposure to airborne ammonia can increase the risk of respiratory irritation, cough, wheezing, tightness in the chest, and impaired lung function in humans. Animal studies also suggest that exposure to high levels of ammonia in air may adversely affect other organs, such as the liver, kidney, and spleen.[19]

Unavoidable releases of ammonia could have significant and irreversible impacts on the living and physical environment affected. Storage and handling of urea or ammonia onsite would result in an increased risk to the health and safety of facility operators. San Juan is a natural gas processing plant, which already maintains a high level of health and safety risk. Harvest considers any increase to this risk unacceptable.

[19] U.S. EPA, EPA/635/R-16/163Fc, "Toxicological Review of Ammonia Noncancer Inhalation: Executive Summary", September 2016

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system. Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.[20]

Based on their current age and operating efficiency, it is estimated that the remaining useful life of the Solar turbines will be longer than the control units. The turbines have operated for more than 30 years without any significant deterioration in operating efficiency; therefore, this analysis of the remaining useful life of the equipment will be based on the anticipated useful life of the control device considered.

6.1. SOLAR TURBINES

6.1.1. Improved Combustion Technology

It is anticipated that the estimated useful life of the improved combustion technology, SoLoNO$_X$, will be similar to the useful life of an SCR system. The useful life is estimated to be 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[21]

6.1.2. SCR

The estimated useful life of the SCR equipment is 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[22]

[20] 40 CFR 51, Appendix Y, Section II.B.4.f
[21] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual
[22] Ibid.

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input of the available control technologies for the natural-gas fired turbines located at San Juan, Harvest has determined that there are no technically feasible control options for the Rolls-Royce turbines that are not currently implemented at the facility due to the age of the units.

At this time, Harvest would like to advise the NMED of additional concerns regarding the retrofit of the Rolls-Royce turbines. The manufacturer of these turbines, Siemens, is based out of Switzerland. Harvest is required to ship the turbines overseas for any necessary retrofits, repairs, or advanced maintenance requirements. This requires the turbine to be decommissioned and shipped via rail or truck across the country to an eastern port. From there, the turbine must be shipped via cargo ship to a port in Europe where it is then transferred via truck or rail again to Siemens for the applicable repairs/retrofits. Altering these turbines will undoubtedly increase operational complexity and will necessitate additional support from Siemens, contributing to severe cost implications.

Harvest has further determined that SoLoNO$_X$ and SCR are the only technically feasible control options for the Solar turbines. The cost of compliance to install the controls on each of these units has been estimated based on manufacturer's input, as well as the EPA Air Pollution Control Cost Manual.[23] The estimated cost effectiveness and NO$_X$ emission reduction for each unit are summarized in Table 5.

Table 5. Cost Effectiveness and NO$_X$ Reduction for Control of the Solar Turbines at San Juan

Control Equipment	Unit	NO$_X$ Reduction (tpy)	Cost Effectiveness ($/ton)
Improved Combustion Technology (SoLoNO$_X$)	4	35.7	1,952
	5	28.9	2,412
	6	36.8	1,894
	7	46.4	1,500
Selective Catalytic Reduction	4	35.7	12,824
	5	28.9	15,825
	6	36.8	12,455
	7	46.4	9,883

It is projected that the useful life of these units will be 20 years, based on the life expectancy of the SoLoNO$_X$ and SCR controls. The primary energy and non-air impacts from the SCR control method is increased energy consumption and health and safety risks associated with ammonia usage. Harvest estimates an achievable compliance timeline to implement either the SoLoNO$_X$ or SCR controls is 2-3 years.

[23] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

Furthermore, Harvest would like to advise the NMED of their judgement that the San Juan facility's potential contribution to regional haze at the Mesa Verde National Park Class I area is such that it does not justify their facility being selected for this assessment. There are hundreds of sources, both major and minor, located closer to the Class I area whose contribution has not been considered. Harvest would argue that only assessing high emitting sources at a limited number of facilities will not effectively address the visibility impairment problem, as required by the State under the RHR.

8. SUPPORTING DOCUMENTATION

Appendix A – RBLC Tables
Appendix B – Cost Analysis Calculations
Appendix C – SCR Energy Consumption Calculation

APPENDIX A - RBLC TABLES

RBLC Analysis for Natural Gas Fired Turbines – NO_X Control

	Control Technology	Good Combustion Technique	Improved Combustion Technology (Low-NO_X Combustors, Ultra-Low NO_X Combustors and other improved combustion technology)[a]	Water/Steam Injection[b]	Selective Catalytic Reduction (SCR)[c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. Primary combustion occurs at lower temperatures under oxygen-deficient conditions. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.	Low-NO_x burners employ multi-staged combustion to inhibit the formation of NO_X. Primary combustion occurs at lower temperatures under oxygen-deficient conditions; secondary combustion occurs in the presence of excess air. This category includes Improved Combustion Technology Lean Head End Liners for the GE turbines assessed here.	Injected water/steam acts as a heat sink, lowering combustion zone peak temperatures, resulting in a decrease in thermal NO_X.	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_X to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.
	Other Considerations	N/A	N/A	Results in a small efficiency penalty but an increase in power output. May increase CO and VOC emissions. Not available in certain models.	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.
	RBLC Database Information	Included in RBLC for control of NO_X emissions from combustion turbines.	Included in RBLC for the control of NO_X emissions from combustion turbines.	Not included in RBLC for the control of NO_X emissions from combustion turbines; identified as a control option based on AP-42 Section 3.1. Unit 4: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

Is the SCR for a new turbine or retrofit of an existing turbine?

What type of fuel does the unit burn?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty.: 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)? 23.66 MMBtu/hour

What is the higher heating value (HHV) of the fuel? 1,000 Btu/scf

What is the estimated actual annual fuel consumption? 186,400,000 scf/Year

Enter the net plant heat input rate (NPHR) 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 5600 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Select for Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,943
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.83	6,656

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR}): 365 days

Number of days the turbine operates (t_{plant}): 365 days

Inlet NO_x Emissions (NOx_{in}) to SCR: 0.54 lb/MMBtu

Outlet NO_x Emissions (NOx_{out}) from SCR: 0.159 lb/MMBtu

Stoichiometric Ratio Factor (SRF): 1.050

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Estimated operating life of the catalyst ($H_{catalyst}$): 24,000 hours

Estimated SCR equipment life: 20 Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored}): 29 percent*

Density of reagent as stored (ρ_{stored}): 56 lb/cubic feet*

Number of days reagent is stored ($t_{storage}$): 14 days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Select the reagent used

Number of SCR reactor chambers (n_{scr}): 1

Number of catalyst layers (R_{layer}): 3

Number of empty catalyst layers (R_{empty}): 1

Ammonia Slip (Slip) provided by vendor: 2 ppm

Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known): UNK Cubic feet

Flue gas flow rate ($Q_{Flue gas}$) (Enter "UNK" if value is not known): UNK acfm

Gas temperature at the SCR inlet (T): 650 °F

Base case fuel gas volumetric flow rate factor (Q_{fuel}): 484 ft^3/min-MMBtu/hour

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Enter the cost data for the proposed SCR:

Desired dollar-year: 2018

CEPCI for 2018: 603.1 Enter the CEPCI value for 2018 | 603.1 | 2018 CEPCI

CEPCI = Chemical Engineering Plant Cost Index

Annual Interest Rate (i): 5.5 Percent*

* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/ .)

Reagent ($Cost_{reag}$): 0.293 $/gallon for 29% ammonia*

* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.

Electricity ($Cost_{elect}$): 0.0676 $/kWh

* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.

Catalyst cost ($CC_{replace}$): 227.00 $/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst

* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.

Operator Labor Rate: 60.00 $/hour (including benefits)*

* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.

Operator Hours/Day: 4.00 hours/day*

* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) = 0.005

Administrative Charges Factor (ACF) = 0.03

Unit 4: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	24	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	207,295,163	scf/Year	
Actual Annual fuel consumption (Mactual) =		186,400,000	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.899	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	7877	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	70.6	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	9.06	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	35.68	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.88		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	10,960	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	120.19	/hour	
Residence Time	$1/V_{space}$	0.01	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyst}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	91.18	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	11	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	4	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	13	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	3.6	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	52	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	12	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	600	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	12.17	kW

Unit 4: Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$4,000,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$120,001	in 2018 dollars
Indirect Annual Costs (IDAC) =	$337,668	in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$457,669	in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$20,000	in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600	in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$3,743	in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$6,479	in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$2,178	in 2018 dollars
Direct Annual Cost =		$120,001	in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,868	in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$334,800	in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$337,668	in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$457,669	per year in 2018 dollars
NOx Removed =	35.68	tons/year
Cost Effectiveness =	$12,826	per ton of NOx removed in 2018 dollars

Unit 5: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

Is the SCR for a new turbine or retrofit of an existing turbine?

What type of fuel does the unit burn?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty.: 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)? 23.52 MMBtu/hour

What is the higher heating value (HHV) of the fuel? 1,000 Btu/scf

What is the estimated actual annual fuel consumption? 194,600,000 scf/Year

Enter the net plant heat input rate (NPHR) 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation 5600 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Select for Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,943
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.83	6,656

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR}) 365 days

Number of days the turbine operates (t_{plant}) 365 days

Inlet NO_x Emissions (NOx_{in}) to SCR 0.46 lb/MMBtu

Outlet NO_x Emissions (NOx_{out}) from SCR 0.160 lb/MMBtu

Stoichiometric Ratio Factor (SRF) 1.050

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr}) 1

Number of catalyst layers (R_{layer}) 3

Number of empty catalyst layers (R_{empty}) 1

Ammonia Slip (Slip) provided by vendor 2 ppm

Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known) UNK Cubic feet

Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known) UNK acfm

Estimated operating life of the catalyst ($H_{catalyst}$) 24,000 hours

Estimated SCR equipment life 20 Years*

* For industrial turbines, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T) 650 °F

Base case fuel gas volumetric flow rate factor (Q_{fuel}) 484 ft^3/min-MMBtu/hour

Concentration of reagent as stored (C_{stored}) 29 percent*

Density of reagent as stored (ρ_{stored}) 56 lb/cubic feet*

Number of days reagent is stored ($t_{storage}$) 14 days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

Enter the cost data for the proposed SCR:

Unit 6: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

Is the SCR for a new turbine or retrofit of an existing turbine?

What type of fuel does the unit burn?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty.: 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)? 22.78 MMBtu/hour

What is the higher heating value (HHV) of the fuel? 1,000 Btu/scf

What is the estimated actual annual fuel consumption? 192,900,000 scf/Year

Enter the net plant heat input rate (NPHR) 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 5600 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Select or Enter Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,943
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.93	6,656

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365 days	Number of SCR reactor chambers (n_{scr})	1
Number of days the turbine operates (t_{plant})	365 days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOx_{in}) to SCR	0.55 lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOx_{out}) from SCR	0.165 lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050	Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
		Flue gas flow rate ($Q_{Flue gas}$) (Enter "UNK" if value is not known)	UNK acfm

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000 hours		
Estimated SCR equipment life	20 Years*	Gas temperature at the SCR inlet (T)	650 °F
		Base case fuel gas volumetric flow rate factor (Q_{fuel})	484 ft^3/min-MMBtu/hour
Concentration of reagent as stored (C_{stored})	29 percent*		
Density of reagent as stored (ρ_{stored})	56 lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14 days		

* For industrial turbines, the typical equipment life is between 20 and 25 years.

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

Enter the cost data for the proposed SCR:

Desired dollar-year	2018		
CEPCI for 2018	603.1 Enter the CEPCI value for 2018	603.1 2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5 Percent*		* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293 $/gallon for 29% ammonia*		* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0676 $/kWh		* $0.0676/kWh is a default value for electrity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00 $/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst		* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00 $/hour (including benefits)*		* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00 hours/day*		* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit 6: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	23	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	199,551,724	scf/Year	
Actual Annual fuel consumption (Mactual) =		192,900,000	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.967	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8468	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	69.7	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	8.68	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	36.76	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.87		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	10,550	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	121.13	/hour	
Residence Time	$1/V_{space}$	0.01	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyst}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	87.10	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	11	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	4	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	13	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	3.6	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	52	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	3	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	12	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	600	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	11.71	kW

Unit 6: Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$4,000,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$120,242	in 2018 dollars
Indirect Annual Costs (IDAC) =	$337,668	in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$457,910	in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$20,000	in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600	in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$3,856	in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$6,705	in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$2,081	in 2018 dollars
Direct Annual Cost =		$120,242	in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,868	in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$334,800	in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$337,668	in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$457,910	per year in 2018 dollars
NOx Removed =	36.76	tons/year
Cost Effectiveness =	$12,457	per ton of NOx removed in 2018 dollars

Unit 7: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial turbine?

Is the SCR for a new turbine or retrofit of an existing turbine?

What type of fuel does the unit burn?

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty.: 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)? 23.03 MMBtu/hour

What is the higher heating value (HHV) of the fuel? 1,000 Btu/scf

What is the estimated actual annual fuel consumption? 189,200,000 scf/Year

Enter the net plant heat input rate (NPHR) 8.2 MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation: 5600 Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned:

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fuel Mix % Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,943
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.83	6,656

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired turbines, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- Method 1
- Method 2
- Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365 days	Number of SCR reactor chambers (n_{scr})	1
Number of days the turbine operates (t_{plant})	365 days	Number of catalyst layers (R_{layer})	3
Inlet NO_x Emissions (NOX_{in}) to SCR	0.65 lb/MMBtu	Number of empty catalyst layers (R_{empty})	1
Outlet NO_x Emissions (NOX_{out}) from SCR	0.158 lb/MMBtu	Ammonia Slip (Slip) provided by vendor	2 ppm
Stoichiometric Ratio Factor (SRF)	1.050	Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK Cubic feet
*The SRF value of 1.05 is a default value. User should enter actual value, if known.		Flue gas flow rate ($Q_{Flue gas}$) (Enter "UNK" if value is not known)	UNK acfm
Estimated operating life of the catalyst ($H_{catalyst}$)	24,000 hours		
Estimated SCR equipment life	20 Years*	Gas temperature at the SCR inlet (T)	650 °F
* For industrial turbines, the typical equipment life is between 20 and 25 years.		Base case fuel gas volumetric flow rate factor (Q_{fuel})	484 ft^3/min-MMBtu/hour
Concentration of reagent as stored (C_{stored})	29 percent*		
Density of reagent as stored (ρ_{stored})	56 lb/cubic feet*		
Number of days reagent is stored ($t_{storage}$)	14 days		

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used

Enter the cost data for the proposed SCR:

Desired dollar-year	2018		
CEPCI for 2018	603.1 Enter the CEPCI value for 2018	603.1 2018 CEPCI	CEPCI = Chemical Engineering Plant Cost Index

Unit 7: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	23	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	201,751,917	scf/Year	
Actual Annual fuel consumption (Mactual) =		189,200,000	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.938	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8215	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	75.6	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.31	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	46.44	tons/year	
NO_x removal factor (NRF) =	EF/80 =	0.95		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	10,667	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	110.64	/hour	
Residence Time	1/V_{space}	0.01	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired turbines
Elevation Factor (ELEVF) =	14.7 psia/P =	1.23		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.0	psia	
Retrofit Factor (RF)	Retrofit to existing turbine	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyst}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	13	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	3.6	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	53	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	4	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	15	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	700	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial turbines.	11.84	kW

Unit 7: Cost Estimate

Total Capital Investment (TCI)

TCI for Natural Gas-Fired Turbines		
Total Capital Investment (TCI) =	$4,000,000	in 2018 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$121,351	in 2018 dollars
Indirect Annual Costs (IDAC) =	$337,668	in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$459,019	in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Operating Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$20,000	in 2018 dollars
Annual Operating Cost =	Operator Labor Rate x Hours/Day x t_{SCR} =	$87,600	in 2018 dollars
Annual Reagent Cost =	m_{sol} x $Cost_{reag}$ x t_{op} =	$4,872	in 2018 dollars
Annual Electricity Cost =	P x $Cost_{elect}$ x t_{op} =	$6,577	in 2018 dollars
Annual Catalyst Replacement Cost =	n_{scr} x Vol_{cat} x ($CC_{replace}$/R_{layer}) x FWF	$2,303	in 2018 dollars
Direct Annual Cost =		$121,351	in 2018 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,868	in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$334,800	in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$337,668	in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$459,019	per year in 2018 dollars
NOx Removed =	46.44	tons/year
Cost Effectiveness =	$9,885	per ton of NOx removed in 2018 dollars

Kerwin C. Singleton
Planning Section Chief
New Mexico Environment Department
Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, NM 87505

RE: Submittal Requirements for Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring as part of the Regional Haze Four-Factor Analyses

Dear Mr. Singleton:

Harvest Four Corners, LLC is repsonding to the November 14, 2019 request from New Mexico Environment Department for the review of process flaring and Startup, Shutdown, and Maintenance (SSM) flaring as part of the Regional Haze four-factor analyses.

Harvest Four Corners submitted a four-factor analysis for both the Kutz Canyon Processing Plant and San Juan Gas Plant on October 31, 2019. These analyses were conducted in accordance with the federal Clean Air Act, 42 U.S.C. §7491, and implementing regulations at 40 CFR §§ 51.300 to 51.309 (Regional Haze Rule) as well as the guidance provided by New Mexico Environment Department as received in the July 18, 2019 request to perform four-factor reasonable progress analyses.

Per NMED Guidance from July 18, 2019, *"In accordance with the Regional Haze Rule, NMED requested that a four-factor analysis of all potential new control measures for nitrogen oxides (NO_X) and sulfur dioxide (SO_2) on individual equipment that has the potential to emit (PTE) greater than ten (10) pounds per hour of NO_X or SO_2. A separate analysis is required for each pollutant with a PTE greater than ten (10) pounds per hour of NO_X or SO_2. Individual emission points that total less than five (5) tons per year for either pollutant do not need to undergo this analysis."*

The Kutz Canyon Processing Plant has two flares, units 28 and 36. Unit 28 is the plant flare and unit 36 is a control for the TEG dehydrator. The San Juan Gas Plant also has two flares, units 9 and 16. Unit 9 is a plant safety system flare and unit 16 is a staged blowdown flare that works in conjunction with the system flare.

After an extensive review of the equipment at both Kutz Canyon Processing Plant and San Juan Gas Plant it was determined that none of the flares have a potential to emit (PTE) above the de minimus thesholds of 10 pounds per hour and 5 tons per year for either NO_X or SO_2.

PO Box 61229
Houston, TX 77208

1111 Travis Street
Houston, TX 77002
Phone: 713/209-2400
Fax 713/209-2478
harvestmidstream.com

Furthermore, Harvest would like to advise the NMED of their judgement that the flares at both Kutz Canyon and San Juan facilities' potential contribution to regional haze at the Mesa Verde National Park Class I area are such that it does not justify either facility being selected for this assessment for further evaluations of flares. Neither facility has a PTE associated with flares for SO_2 emisions and the NO_X emissions for each flare are below the de minimus thesholds for evaluation. Furthermore, NO_X emissions are not the dominant visibility impairing pollutant at Mesa Verde, and, for that reason, further reductions in NO_X emissions are unlikely to have a significant effect on visibility conditions.

Harvest appreciates the opportunity to present its views on the issues concerning possible reasonable progress assessments for the second planning period of the regional haze program with respect to Harvest Four Corners' Kutz Canyon Processing Plant and San Juan Gas Plant.

If you have questions or require additional information, please contact me at (505) 632-4625 or by e-mail at msmith@harvestmidstream.com.

Sincerely,

Monica Smith

TABLE OF CONTENTS

1. RESPONSES TO THE NMED 1-3
Natural Gas Fired Simple Cycle Turbines 1-3
APPENDIX A: VENDOR DOCUMENTION 1-5
APPENDIX B: GOOD COMBUSTION PRACTICES MANUAL 1-6

The NMED posed the following questions regarding the emissions control options Harvest presented for the turbines and engines located at the San Juan Gas Plant.

NATURAL GAS FIRED SIMPLE CYCLE TURBINES

Provide details of the Good Combustion Practices utilized at the plant including routine inspections, maintenance and training schedules. It is unclear if these practices are fully optimized or conform to permit conditions alone.

Harvest complies with the periodic testing pursuant to A205 in order to monitor NOX and CO emissions of the current Title V operating permit, P124R2. A copy of the current SSM Plan includes maintenance and inspection schedules and is included within Appendix B.

Harvest implements good combustion practices as prescribed by the manufacturer and required permit conditions. These include, but are not limited to:

- Manufacturer recommended maintenance
- Training of personnel in proper equipment maintenance and operations
- Routinely scheduled inspections
- Overhauls as required or recommended by the manufacture
- Use of pipeline quality natural gas

i. Provide documentation of your communications with Siemens to support the determination that dry low-NO_X (DLN) control options are technically infeasible for Units 1-3 and Rotating Spare.

These are included in Appendix A.

ii. Include a discussion of additional control measures for NO_X emissions including catalytic combustion and DLN technology available from other manufacturers. A four factor analysis should be completed for all technically feasible options.

These are included in Appendix A.

iii. Provide vendor specifications for the Solar SoLoNO$_X$ (i.e., DLN control) combustion technology to include the guaranteed NO_X emission rates used in cost analysis, the cost information, recommendations, and equipment specifications for the turbine control estimates.

These are included in Appendix A.

iv. How will upgrading units 4-7 with SoLoNO$_X$ affect the turbine capacities and the emission rates of NO_X and CO?

According to documentation received from Solar, the SoLoNO$_X$ unit would reduce the NO$_X$ exhaust concentration to 15 ppm. According, to AP-42, CO emissions would be increased from the implementation of this control, but Solar has not provided any guidance on the magnitude of the emission increase.[1]

v. Provide documentation of your communications with Siemens and Solar that supports the conclusion that water injection is not technically feasible for these units.

These are included in Appendix A.

vi. Provide supporting data and information for the determination that Selective Catalytic Reduction (SCR) systems are a technically infeasible control measure. Include documentation from site engineers verifying exhaust gas temperatures and space limitations at the facility. Consider and discuss exhaust gas temperature control devices and catalysts with higher operating temperatures (e.g., zeolites). Additionally, provide clarifying information regarding the additional energy demand SCR would require and expansion of current power generation capacity. Provide a cost analysis if this determination is based on cost and not technical feasibility.

This is included in Appendix A. SCR is not supported by Solar or Siemens and neither are other proposed technologies – Solar only supports the use of SoLoNO$_X$ for emission reductions on their turbines. San Juan would also need to install additional sources of electricity to meet the power demand required to support SCR.

vii. Please consider and include a discussion on limiting turbine operating hours or shutting down turbines that are no longer needed to reduce emissions.

Harvest cannot commit to decreasing turbine capacity as the facility has contractual obligations to process specific amounts of gas. Shutting down units or limiting hours of operation would reduce the facility's capacity and have substantial effects on both producers and consumers of natural gas. Decreases in the maximum capacity could impose a strain on facilities located in the San Juan and this is not something that Harvest can commit to.

viii. Provide the electronic spreadsheets used for control technology cost calculations.

These have been provided to the NMED.

[1] AP-42 Section 3.1.4.2 Stationary Gas Turbines, Control Technologies, Dry Controls.

APPENDIX A: VENDOR DOCUMENTION

From: McMahon, Jay
To: Monica Smith
Subject: [EXTERNAL] Avon Emissions Options
Date: Monday, September 23, 2019 9:47:42 AM

As per our discussion.

Right now there are no emissions reductions system available at this this point. That said, there are two (future) options for on emissions reduction.

1. Dry Low Emission Fuel and Combustion System
2. Water Injection System

The unfortunate part is neither are available yet.

DLE System

There have been a few DLE A20's built, but we really don't know much about them. Siemens has launched a project for a MK2 version of the DLE system. At this point I am not at liberty to give details on emissions levels but I can say their emissions target levels are a substantial reduction to what you have now. Right now it looks like this mod is 2-3 years out.

The mod will obviously include substantial engine, package and controls modifications. The DLE conversion would only be available from Siemens licensed overhaul shops for the engine mod and Siemens themselves on the package and controls mods.

Water Injection

There are no water injected A20's right now but Siemens recognizes the need for emissions reduction and is not looking at the development of a water injection mod. On other engine models I have experience with, the engine mods are normally consigned to fuel burners and flame tubes, but there are substantial package mods required as the water you inject must be absolutely pure so you would need a water treatment system. I am sure there would be controls modifications required as well. As for time line, we do not have one at this time.

As with the DLE system, water injection conversion would only be available from Siemens licensed overhaul shops for the engine mod and Siemens themselves on the package and controls mods.

Solar® Turbines

A Caterpillar Company

Powering the Future Through Sustainable, Innovative Energy Solutions

SOLONOX DRY LOW EMISSIONS TECHNOLOGY

Solar Turbines is a leader in pollution-prevention technology. Since the introduction of SoLoNOx™ in 1992, our dry low emissions technology advancements have prevented the production of more than 5.8 MM tons of NOx emissions. This represents a reduction of 75-90% from conventional combustion baselines for natural gas fuel.

Solar has unrivaled experience within the industry with more than 3500 SoLoNOx gas turbines with over 312 million operating hours located around the world.

Fuel options include natural gas, ultra low sulfur diesel (ULSD), associated gases, LPG and kerosene.

Low NOx Emissions Warranty: Pipeline natural gas emissions avalable at 9, 15, 25 or 38 ppm NOx @15% O2 on select models. ULSD emissions levels range from 58 to 96 ppm NOx @15% O2 on select models.

Wide Low NOx Emissions Operating Range: Single shaft 50-100% load, two shaft 40-100% load down to low ambient temperatures.

Available warranty emissions levels, operating range, and ambient temperature range vary by product and rating. Please contact Solar for more information.

Dry Low Emissions 101

DLE (dry low emissions) or lean-premix combustion reduces the conversion of atmospheric nitrogen to NOx by reducing the combustor's flame temperature. Since NOx formation rates are strongly dependent on flame temperature, lowering this temperature is an effective strategy for reducing NOx emissions. Lean combustion is enhanced by premixing the fuel and combustor airflows upstream of the combustory primary zone. DLE eliminates the need for water or steam injection or exhaust cleanup, which benefits the environment at a lower cost.

Subject: [EXTERNAL] RE: Harvest - 4 Factor San Juan and Kutz

HI Monica,

Please see the attached Product Info Letters (PIL) and Spec Sheets on both the Centaur Generator Set and Compressor set. As well as combustion technology.

As far as wet NOx systems go, it is clearly stated on our spec sheets we no longer offer this technology. It is an outdated technology that requires more parts, maintenance and extremely clean water which equals additional cost for our customer and does not preform as well as our current SoLoNOx technology. Instead we continue to improve on this technology and pass the savings along to our customers from having to maintain additional systems that do not do as well in lowering emissions.

Solar's current stance on SCR's is on a case by case business. However as we are not SCR manufacturers we will currently not warranty or maintain these systems. Being that there are too many ways to construct these types of systems or standardize them based on customer needs, it makes it a difficult avenue for our company to pursue. We stand firm on our SoLoNOx technology being the best solution to lower emissions. It's the most environmentally friendly, cost effective and quickest way to reduce emissions.

FYI I'll be in the FCA office tomorrow morning if you'd like to chat about it. Let me know if this helps. I think I may need to provide you with performance runs to show the emissions guarantees mentioned. However I was waiting to get some clarification from one of our applications engineers before I send that information over.

Thanks!

Cheers,
Joey Guillen

October 23, 2020

Mr. Michael Baca
Control Strategies Manager
New Mexico Environment Department Air Quality Bureau
525 Camino de los Marquez, Suite 1
Santa Fe, New Mexico, 87505-1816

Harvest Four Corners, LLC is submitting this response to your August 31, 2020 follow-up email regarding the 4-Factor Analyses for the Kutz Canyon Processing Plant (Kutz) and the San Juan Gas Plant (SJGP). The attachments have been labeled to correspond with each item outlined in your email.

0. Harvest used the 5.5% interest rate based on the default rate at the time of the analysis to estimate costs (2016 year) and you are not opposed to NMED using an updated interest rate (e.g., 3.25%) in our cost analysis.

   While responses to the following items are based on a 5.5% interest rate, Harvest Corporate has recommended that analyses should be based on a 7.5% interest rate, the rate at which money has recently been borrowed.

1. Electronic spreadsheets (i.e., Excel files) and vendor quotes for cost calculations. Harvest indicated that vendor quotes have been difficult to obtain (i.e., CBT for engines) and may not be available, but will provide more information on their efforts to obtain these and the basis to estimate costs.

   See the attached spreadsheet and vendor quotes (*Att1K (filename)*) for the Solar SoLoNOx upgrades for Kutz Canyon. Solar is preparing quotes for the SJGP upgrades. The attached spreadsheet is based the 2019 4-Factor packet submittal, but the vendor quotes were requested after August 31, 2020 conference call.

2. Information for the Kutz Canyon facility (Kutz I) that was shared with our permitting group regarding future plans for permitting, facility operations, shutdowns, etc. With the continuing decline in natural gas production in the San Juan Basin, it is no longer economically viable to operate all equipment at the Kutz Canyon Processing Plant, and thus Harvest will discontinue operation of the Kutz I lean oil plant portion of the facility. The equipment to be decommissioned includes:

   a. Unit 16 – Clark HRA8 refrigerant compressor R4;
   b. Unit 17 – Clark HRA8 refrigerant compressor R5;
   c. Unit 18 – Clark HRA8 refrigerant compressor R6;
   d. Unit 22 – 23.1 MMBtu/hr Wheco heater H1;

PO Box 61229
Houston, TX 77208

1111 Travis Street
Houston, TX 77002
Phone: 713/209-2400
Fax 713/209-2478
harvestmidstream.com

e. Unit 23 – 9.57 MMBtu/hr Alcorn heater H2;
f. Unit 24a – Kutz I EG dehydrator;
g. Unit 24b – Kutz I dehydrator reboiler;
h. Unit 37a – Waukesha 5794LT refrigerant compressor;
i. Unit 37b – Waukesha 7042GL refrigerant compressor (never installed);
j. Unit 39 – cooling tower; and
k. Tank T6438 – Blanco/Hare condensate tank and associated EVRU

3. Clarification about the use and generation of electricity at each plant including a list of the units used for compression and generating electricity.
   a. At Kutz, as currently permitted, Units 1 through 8, 16, 17 and 18 compress inlet or residue gas, while Units 37a or 37b compress propane for the Kutz 1 lean oil plant. Units 29 and 30 (Gen A and Gen B) generate electricity.
   b. At SJGP, Units 1, 2 and 3 compress inlet and residue gas, while electricity is generated by Units 4, 5, 6 and 7.

4. Technically feasibility of installing line electricity to the plants and replacing compression units with electric motors. Attachments *Att4K Kutz Electrical 9.8.2020* and *Att4S SJ Electrical Conversion* provide the cost estimate of replacing gas-fired compressor drivers with electrical motors.
   Adding 3 VFD motors to replace the units used for compression only, would require 15,000 hp motor variable speed for each. A building housing the three VFD motors of that size would have to be built across the road with land purchase. The power currently produced wouldn't be near enough for one VFD motor, much less all three. This would require a substation to be built across the road also. Modifications to the plant would have to be made, and real estate found to have heaters installed for heating the hot oil, which currently uses the waste heat from the turbines. Without the hot oil, the plant cannot make product spec. Additionally, these type and size of motors with a substation to start them would probably require very high voltage technicians that are qualified to work on them; nobody currently working at SJGP is line voltage qualified.

5. Confirmation that retrofit costs were included in your SCR analysis for the Solar turbines at San Juan GP.
   The SCR cost were derived using the EPA Cost Control Manual for SCRs. Within this calculation is an option for retrofit which was chosen and a designation of a Retrofit Factor (RF). An RF of 1.o was chosen for this calculation which is incorporated for the cost. Based on the Chapter 2 Selective Catalytic Reduction" from June 2019 , "a retrofit factor of 1 should be used for average retrofits. The equations may overestimate costs for

PO Box 61229
Houston, TX 77208

1111 Travis Street
Houston, TX 77002
Phone: 713/209-2400
Fax 713/209-2478
harvestmidstream.com

some simple retrofits of existing plants. For retrofits that are more complicated than average, a retrofit factor of greater than 1 can be used to estimate capital costs provided the reasons for using a higher retrofit factor are appropriate and fully documented."

6. Clarification on the basis and use of incremental costs for SCR.
   Upon evaluating the calculation for incremental cost this appears to only be the difference in cost between the installation of SoloNox versus SCR and does not change the individual evaluation of the cost of the SCR.

7. Additional information about the space limitations for installing SCR.
   As with conversion to electricity, installation of SCR for turbine exhaust controls would also require purchase of real estate across the road. Routing the turbine exhaust to the ammonia/urea reagent storage across the road is technically infeasible the exhaust temperature would fall below reaction temperatures. Therefore, it would be necessary to pump the reagent to the existing exhaust stacks that have been retrofitted to accommodate the catalyst. In addition to the costs of remotely storing the reagent, there is also a significant safety hazard moving the reagent from storage and across the road to the exhaust stacks.

Thank you for your assistance with this analysis. Please email or call me (msmith@harvestmidstream.com, (505) 632-4625) if we can provide any additional information.

Sincerely,

Monica Smith

Michael,

Please see the attached items as well as the responses provided below.

1.) Harvest used a 5.5% interest rate in their responses and indicated that Harvest Corporate recommends a 7.5% interest rate for use in the 4-Factor Analyses. We have to document company specific interest rates in the form of a letter from the chief financial officer for the institution that lends to your company, or from an official with your company (your company's CFO, for instance) that is in a position to know your company's costs of debt and equity. Otherwise, we plan to use the current prime rate of 3.25% in the cost calculations. – Harvest – Pricing Term Sheet, attached

2.) Have you received quotes from Solar for the SJGP upgrades? – (5) attachments included from Solar for San Juan Gas Plant, (all 5 docs start with OD)

3.) Harvest indicates that equipment associated with the lean oil plant of Kutz I will be decommissioned. Under the Regional Haze Rule, emission limitations and reductions must be permanent and federally enforceable. Our review of Air Quality Bureau's permitting records does not show a recent New Source Review permit application for this action. Please provide more information about your plans to modify your permits including any recent communications with AQB permitting staff indicating your commitment to permanently discontinue operation of the Kutz I lean oil plant. – We just started internal discussions about the removal of the Kutz I equipment. We felt that we needed to wait before proceeding with the permit application to ensure that the plant could operate without any issues before de-permitting the equipment. Internal discussions have begun, and communications with NMED will be upcoming as well as the application submittal. We are currently working through our Annual Reports, such as Emissions Inventory and Green House Gas, which take precedent based on the submittal deadlines.

This is the current list of equipment that we plan on removing from the Kutz Permit, we may be adding a couple more items, in the permit application.

EU	Equipment Name
16	Clark Reciprocating Engine (R4)
17	Clark Reciprocating Engine (R5)
18	Clark Reciprocating Engine (R6)
22	Wheco Heater (H1)

23	Alcorn Heater (H2)
24	Kutz I EG Dehydrator
37a	Waukesha L5794LT Engine refrigerant compressor
37b	Waukesha L7042GL Engine (never installed)
39	Cooling Tower
T6438	Blanco-Hare Condensate Tank (& EVRU)

4.) Do the Operation and Maintenance (O&M) costs provided for in your Four Factor evaluation of applicable equipment reflect the incremental cost of O&M for additional control? In other words, are these costs over and above those already realized for the units? – Both Plant Foreman feel as though the numbers provide are correct. They did not feel that the numbers provided were over and above the cost already realized for the units.

Please let me know if you have any additional questions or need additional information.

Thank you,

Monica Smith

Subject: Electrifying Three 17,000 horsepower Motors at the Hilcorp Facility

Dear Mr. Harris,

I hope this letter finds you well. This is a response to your recent request. You had approached the Farmington Electric Utility System (FEUS) in late June requesting a cost estimate to electrify three (3) 17,000 horsepower (hp) motors at the Hilcorp facility located on the corner of Saiz Lane and Arizona Ave in Bloomfield, New Mexico. First of all, thank you for your inquiry. As I was contemplating a response to your request, it was suddenly obvious that the present configuration of the Farmington electric system can in no way provide service for load of this magnitude without significant additional infrastructure.

A 17,000 horsepower motor is effectively 17MVA of electrical load when motor efficiency and power factor are considered. Three of these motors would then represent a minimum of 51MVA electrical load. This does not account for motor starting, which would require deeper investigation. For reference, the all-time maximum FEUS system peak demand was 206MVA back in 2006. In 2022, the system peak was 193MVA. Thus, the additional 50MVA represents roughly a 25% increase in system demand. Although FEUS would be delighted to serve this load, it would be a bad business model for the Utility to have an additional 25% of system capacity "just lying around".

As mentioned above, accommodating this amount of load would require significant infrastructure upgrade to the 115kV system in addition to the installation of a new substation facility required to serve it. Presently the transmission line traversing east and west just to the north of the Hilcorp facility is built to FEUS maximum standards. Specifically, the conductor is made of 795kcmil conductor, good for up to 135MVA, but it is routinely modeled at near maximum loading conditions. The electric utility must design for and build to the anticipated system peak loads under various outage scenarios (called "contingencies") which is why the T-line, despite having seemingly adequate capacity, does not actually have that capacity available. Therefore, effectively, an additional 50MVA of transmission capacity would need to be built into the existing 115kV transmission line by adding a second 795kcmil conductor.

For your information, 795kcmil ACSR "Drake" conductor has a diameter of slightly more than 1 inch. ACSR stands for Aluminum Conductor Steel Reinforced. It has a core made of seven strands of steel, overlaid with 26 strands of aluminum alloy conductor and weighs about a pound per foot. It would seem that adding this second conductor is overkill, needlessly doubling the existing 135MVA to 270MVA, when only an additional 50MV is required. Multipronged reasons exist as to why this second conductor needs to be 795ACSR, and I am prepared to discuss them with you in person. Outlining them here would make this long letter even longer. Suffice it to say that several entire industries filled with many lifetime careers have been made off of electrical cable design, testing, installation, and operation.

Also, building a new transmission line could be investigated, but easement issues typically constitute "deal breakers" for transmission line projects now days. Either way the T-line would need to terminate near a power source (a power plant or grid interconnection point on the cusp of the FESU Service Territory) that could provide the additional 50MVA of load. In today's market, building a new 115kV transmission line could easily top $1,000,000 per mile. Upgrading the existing T-line could cost about 80% of that or $800,000 per mile. The length of the line depends on where the interconnection point or power source would be. In the extreme case, the line would have to be rebuilt all the way back to the Shiprock Substation, or approximately 40 miles for a total cost of about $40M. That is just for the transmission line.

As for the substation, there are a number of possible configurations. Let me just give you the worst-case estimate. A five-breaker ring bus would be required. This would serve as a terminus for the 1) input and the 2) output of the transmission line. It would also provide the point of service for the three (3) motors individually [3), 4) and 5)]. Each motor would be served by a three-phase 20MVA transformer, 115 to 13.8kV. The metering point would be at the 13.8kV level indicating that Hilcorp would own all facilities thereafter. If Hilcorp can serve its motors at 13.8kV, then no further transformation would be necessary. If a different voltage is required – again, worst-case – then three additional 20MVA transformers are needed to convert 13.8kV to that specific service voltage.

So, a five-breaker ring bus substation facility to include grading, foundations, conduits, control cable, ground grid, gravel, steel supports, twelve disconnect switches, five breakers, fifteen voltage transformers (for instrumentation), fence and security, the control building, relays, SCADA, communications, battery backup, AC/DC lighting and control, and HVAC installed would cost around $8 million. Then you will need six (6) 20 MVA transformers at a cost of just under $1M each, or about $6M. Add all substation components together and along with 30% for testing and commissioning, the sum is slightly more than $18 million. That is just for the substation.

Thus, the total cost of 115kV T-line upgrade plus substation could be as high as $58 million. And before all this takes place, we will need to discuss power purchase agreements, construction agreements, ownership and maintenance agreements, environmental and archeological permitting, perhaps some easements, etc. Make no mistake: Requesting to serve a load of this magnitude from this utility – and I would guess from MOST utilities – would be a very expensive endeavor.

I hope this letter provides you with the information you need. Please contact me on my cell phone any time, 505-860-4104, voice or text (text preferred) should you wish to discuss this further.

Thank you for your attention.

Solar maintenance costs

Current T4501's (hrs)	8,760	17,520	26,280	35,040	43,800	52,560	
Year	1	2	3	4	5	6	
T4501 Annual	$ 15,000	$ 15,000	$ 15,000	$ 15,000	$ 15,000		$ 75,000
T4501 Exchange						$ 410,084	$ 410,084
							$ 485,084
							div. by 6
							$ 80,847 maintenance cost per year/unit

T4501 Annual = Borescope, coupling parts & grease, gaskets, filters, misc. parts, materials and 3rd party labor. Not including company labor.
T4501 Exchange 45,000 to 50,000 hours = Annual parts and labor plus exchange, transportation, 3rd party labor for swapping turbine engine. Not including company labor.
T4501 no additional charge if run past agreed upon hours unless exchanged unit is damaged.

Proposed T4701S (hrs)	8,760	17,520	26,280	35,040		
Year	1	2	3	4		
T4701S Annual	$ 15,000	$ 15,000	$ 15,000		$ 45,000	
T4701S Exchange				$ 655,000	$ 655,000	
					$ 61,488	Hrs over 30K charge
					$ 761,488	
					div. by 4	
					$ 190,372	**maintenance cost per year/unit**

T4701S Annual = Borescopr, coupling parts & grease, gaskets, filters, misc. parts, materials and 3rd party labor. Not including company labor.
T4701 Exchange 35,040 hours = Annual parts and labor plus exchange, transportation, 3rd party labor for swapping turbine engine. Not including company labor.
T4701S Fired Hour rate for each hour above 30,000 is $12.20

Conversion to Centaur T4701S SoLoNox for all 4 units **$6,962,486** Based on costs calculated to possibly convert first 2 units in early 2024.

Hilcorp is considering converting 2 standard Solar Centaur units to low emissions Solonox units in early 2024 and then the next 2 in 2027.

Introduction

Hilcorp Energy Co. owns and operates the San Juan Gas Plant located at UTM Zone 13, UTMH 235.7 km, UTMV 4069 km, approximately 2 miles northeast of Bloomfield, New Mexico in San Juan County. The function of this facility is a natural gas processing plant that extracts and processes natural gas liquids and residue gas products from field gas.

Units C-101 (1), C-201 (2), and C-301 (3) are used to compress and transport gas throughout the facility. Units G-1300A (4), G-1300B (5), G-1300C (6), and G-1300D (7) are used for the production of electricity used at the plant.

Exhaust emissions tests for the effluents of nitrogen oxides (NO_X defined as NO + NO_2) and carbon monoxide (CO) were conducted on the seven turbines to prove compliance with Title 20, New Mexico Administrative Code, Chapter 2, Part 70, (20 NMAC 2.70), Operating Permits. The State of New Mexico Environment Department, Air Quality Bureau (AQB) Operating Permit Number P124-R3 is the regulating permit in place for this facility. The testing followed the protocol submitted to the NMED-AQB which outlined the procedures set forth in the Code of Federal Regulations, Title 40, Part 60, Appendix A, Methods 3A, 7E, 10, and 19. The results of the testing will show that the turbines passed the annual emission tests.

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*
>
> The uniform rate of progress or improvement is sometimes referred to as the glidepath and is part of the state's Long Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Region Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed IACX Roswell, LLC (IACX) that its Bitter Lake Compressor Station (Bitter Lake) was identified as one of the sources contributing to regional haze at the Salt Creek WA Class I area.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to IACX, it specifies that any single piece of equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at Bitter Lake, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability of the Four-Factor Analysis

Equipment	NO_X PTE (lb/hr)	NO_X PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 PTE (lb/hr)	SO_2 PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Cooper-Bessemer / GMVH-10C 2SLB RICE / Unit C-891	20.0	87.6	Yes	--	--	No
Cooper-Bessemer / GMVH-10C 2SLB RICE / Unit C-893	20.0	87.6	Yes	--	--	No

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED,[1] this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. Summaries of the result of this search are provided and discussed under Section 2 of this report. IACX engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis is then conducted for those controls that are technically feasible.

2.1. TWO-STROKE LEAN-BURN ENGINES

Bitter Lake has two (2) natural gas-fired two-stroke lean-burn (2SLB) reciprocating internal combustion engines (RICE), Units C-891 and C-893, that are subject to this four-factor analysis. The only pollutant subject to evaluation for these units is NO_X.

2.1.1. Two-Stroke Lean-Burn Engines Background

Natural gas-fired RICE are separated into multiple design classes, including 2SLB, 4-stroke lean-burn (4SLB), and 4-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1) with exhaust oxygen levels less than 4 %, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12 % or more.[2]

NO_X is formed in reciprocating engines via three mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Bitter Lake engines use natural gas fuel, which contains a negligible amount of nitrogen compounds. Therefore, the formation of prompt and fuel NO_X will be insignificant. This analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio.[3]

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:

(1) Operational control methods, such as adjusting the timing or other operating parameters.
(2) Combustion control techniques, for example reducing the peak flame temperature by introducing inerts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.

The PTE from each engine is reported in the facility's Title V permit P047-R3, as well as above in Table 1.

[3] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"

2.1.2. Potential NO_X Controls for 2SLB Engines

Retrofit control options identified for 2SLB RICE were identified via comprehensive review of the RBLC and available technical literature and are summarized in Table 2. A detailed description and discussion of the technical feasibility and anticipated performance of each control is provided below.

Table 2. Potential Control Options for 2SLB RICE

Control Equipment	Technically Feasible	NO_X Control Efficiency
Selective Catalytic Reduction	**No**	**N/A**
Clean Burn Technology	**Yes**	**25% - 57%**
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**

2.1.2.1. Selective Catalytic Reduction

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust stream of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[4] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, reagent storage tank, reagent injector, reagent pump, pressure regulator, and electronic controls to accurately meter the quantity of reagent injected as a function of engine load, speed, temperature, and NOx emissions to be achieved. The lifespan of the catalyst is primarily determined by the erosion caused by the flue gas, deactivation caused by ammonium bisulfate (NH_4HSO_4) poisoning, as well as the build-up and fouling by the catalyst.

In order for an SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted reagent in the exhaust can form ammonium sulfates, which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.

For engines that typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia

[4] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

injection to gain the reductions needed.[5] In the case of Bitter Lake, the two engines run at ongoing variable loads. Therefore, an SCR is technically infeasible for the engines at Bitter Lake.

Finally, there has been no application of SCR on this model of Cooper engines (see attached RBLC results). A thorough twenty-year review of the RBLC tables was conducted and there were no examples of an SCR being used as a control for 2SLB engines. The lack of availability or comparable use of an SCR on these Cooper engines presents the case that this control technology is considered technically infeasible. Consequently, SCR is not evaluated further in this four-factor analysis.

2.1.2.2. Clean Burn Technology

Clean Burn Technology (CBT) is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding or enhancing an air-to-fuel ratio controller, making the unit capable of operating at more desirable ratios.

As described in Section 2.1.1 of this report, rich-burn engines are normally designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio of 16:1, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1). A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. 2SLB engines are typically designed to operate at the high air-to-fuel ratios employed in CBT; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease the NO_X emissions.[6]

In order to avoid derating the engine, combustion air must be increased at constant fuel flow. To achieve this, the engine will need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel ratio controller.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high-energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[7]

2SLB engines are mechanically capable of being retrofitted with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NO_X emissions. Therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Bitter Lake. Air-to-fuel ratio adjustment generally achieves a 5 to 30% reduction in NO_X emissions; however, this reduction is very specific to each engine and typical loading[8].

The two units at Bitter Lake are currently equipped with turbochargers and efficient combustion air intercoolers. Based on manufacturer guidance, the addition of these clean burn technologies allows the engines to range from 1.74 to 3.04 g/hp-hr, which allows for a 25% to 57% reduction in NO_X emissions; thus, no further assessment of these control practices is included in this report.

[7] Ibid
[8] Ibid

2.1.2.3. Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from large natural gas-fired lean-burn stationary internal combustion engines; therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Bitter Lake. With that being said, these practices are currently in use at Bitter Lake. No further assessment of these control practices is included in this report.

3. SUMMARY & CONCLUSIONS

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input of available control technologies for the natural gas fired engines located at Bitter Lake, IACX has determined that clean burn technology and good combustion practices are the only technically feasible control options for the two units. As IACX already deploys these control technologies, there are no further factors to evaluate.

Based upon actual emissions at the site, IACX will be modifying its permit this year to more closely match the actual emissions of the clean burn technologies that exist at the facility, which will remove the facility from Title V permit status.

4. SUPPORTING DOCUMENTATION

Appendix A – RBLC Analysis Table and Raw RBLC Review Table

Appendix A

RBLC Analysis for Natural Gas-Fired Lean-Burn Stationary Internal Combustion Engines – NO_x

	Control Technology	Selective Catalytic Reduction (SCR) [a,b]	Non-Selective Catalytic Reduction (NSCR) [b]	Clean Burn Technology	Good Combustion Practices and Fuel Selection [c]
IDENTIFY AIR POLLUTION CONTROL TECHNOLOGIES	Control Technology Description	A nitrogen-based reagent (e.g., ammonia, urea) is injected into the exhaust stream downstream of the combustion unit. The reagent reacts selectively with NO_x to produce molecular N_2 and water in a reactor vessel containing a metallic or ceramic catalyst.	This technique uses residual hydrocarbons and CO in rich-burn engine exhaust as a reducing agent for NO_x. In an NSCR, hydrocarbons and CO are oxidized by O_2 and NO_x. The excess hydrocarbons, CO, and NO_x pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_x to N_2.[b]	Natural gas fueled engines that operate with a fuel-lean air/fuel ratio are capable of low NO_x emissions.	NO_x emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following EPA's "Good Combustion Practices" guidance document, good combustion practices can be maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices the unit will operate as intended with the optimal NO_x emissions.
	Other Considerations	Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as "ammonia slip." Unreacted reagent may form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams may blind the catalyst and may necessitate the application of a soot blower.	N/A	N/A	N/A
ELIMINATE TECHNICALLY INFEASIBLE OPTIONS	RBLC Database Information	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Not included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.	Included in RBLC for the control of NO_x emissions from large natural gas-fired lean-burn stationary internal combustion engines.
	Feasibility Discussion	Technically infeasible. For engines which typically operate at variable loads, such as engines on gas transmission pipelines, an SCR system may not function effectively, causing either periods of ammonia slip or insufficient ammonia to gain the reductions needed.	Technically infeasible. The NSCR technique is limited to engines with normal exhaust oxygen levels of 4 percent or less. This includes 4-stroke rich-burn naturally aspirated engines and some 4-stroke rich-burn turbocharged engines. Lean-burn engines could not be retrofitted with NSCR control because of the reduced exhaust temperatures.	Technically feasible.	Technically feasible.

RE: Response to the Request for Additional Information for Four-Factor Analyses under the Regional Haze Program

Dear Mr. Jones and Mr. Singleton:

This letter addresses the additional information request for the IACX Roswell LLC – Bitter Lake Compressor Station Four-Factor Analysis report received on December 23, 2019. For the Bitter Lake Compressor Station (Bitter Lake) there were a total of three item requests pertaining to the NO_X emissions for both engines. Please see the responses for each item request below.

1. *Provide the details regarding Good Combustion Practices (GCP) and the routine maintenance schedule and procedures that are currently used to mitigate nitrogen oxide (NO_X) emissions that are employed as the base case.*
   Response: Bitter Lake complies with the routine maintenance schedule pursuant to A201.A in TV Permit No. P047-R3. Bitter Lake complies with periodic testing pursuant to A201.B in order to monitor NO_X, CO, and VOC emissions. IACX operates the units per the manufacturer guidelines in order to mitigate NO_X emissions.
2. *Please provide an analysis of the technical feasibility of Non-Selective Catalytic Reduction (NSCR) as a retrofit control option for all engines that were evaluated in the Bitter Lake Compressor Station four-factor analysis for NO_X. Should it be determined that SCR is technically feasible, please complete a four-factor analysis for this technology.*
   Response: U.S. EPA, Ap-42, Section 3.2 "Natural Gas-Fired Reciprocating Engines" currently states, "To achieve effective NO_X reduction performance, the engine may need to be run with a richer fuel adjustment than normal. This exhaust excess oxygen level would probably be closer to 1 percent. Lean-burn engines could not be retrofitted with NSCR control because of the reduced exhaust temperatures." Also, in the report submitted on November 1, 2019, we included an RBLC table that further explains the infeasibility of NSCR on 2SLB engines.
3. *Please consider and include a discussion on the feasibility of replacing natural gas-fueled engines/turbines with commercial electric powered compressors.*
   Response: Per Appendix Y to Part 51—Guidelines for BART Determinations Under the Regional Haze Rule Section IV.D.1.5, "We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis." This report is essentially a BART analysis with only 4 factors which are reviewed. IACX will only submit alternative control options and will not assess replacing equipment.

Please feel free to contact either myself at (505) 266-6611 or Tony Hines, Senior VP of Operations at IACX Roswell LLC at (972) 960-3219 if you have any questions regarding this response.

Sincerely,

MacKenzie Russell
Consultant

IACX_Bitter Lake_4FA Cost Estimate_2020-1104.xlsx

Good evening Neal,

Responses to your follow-up questions on the IACX Bitter Lake 4FA are below in blue and the cost effectiveness calculations are attached. Please feel free to reach out if you have any questions.

1. Bitter Lake already has Clean Burn Technology in use, specifically turbochargers and efficient combustion air intercoolers. However, we would like more information on the technical feasibility and cost numbers for additional CBT retrofit technologies.

   Based on conversations with the engine manufacturer, IACX has determined that some upgrades to the CBT retrofit technologies are technically feasible for the engines at Bitter Lake, but would have little to no reduction in emissions based on the stack test data recorded for the 2019 Emission Inventory due to the existing controls already in place. Cost effectiveness calculations are attached based on the quotes and emission guarantees provided by Cooper; however, the estimated emissions reductions and costs are based on a series of assumptions and it will be necessary to complete a thorough engineering study of the engines to determine what is truly feasible. Due to the overly conservative calculation methodology applied for Emission Inventories prior to IACX obtaining the site, the potential emission reduction has been calculated using the 2019 emission inventory submitted. The cost effectiveness of additional CBT on each engine is summarized below.

Unit	Total Capital Cost ($)	Annual O&M Cost ($)	Total Annual Cost ($)	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
C-891	$ 701,500	$ 174,750	$ 222,998	1.92	$ 116,063
C-893	$ 701,500	$ 174,750	$ 222,998	0.00	$ 222,998

2. We have values for the permitted allowable emissions for the engines at Bitter Lake, but we would like to know more about the actual NOx emissions and current operating hours for 2019; as well as the representativeness of those emissions in the future.

   The 2019 emission inventory was completed based on the most recent available stack test data at the time. Operating hours for each unit in 2019 are anticipated to be representative for future years.

Thank you,

Rachel Reese

Subject: RE: [EXT] RE: IACX 4FA
Importance: High

Good Afternoon Rachel,

I would like to follow up with you on your submitted analysis.

1. 1. I think the calculations for "Estimated Controlled Emissions" at 2g/hp-hr may be incorrect. Your Excel formula (=2*'C-891'!B11*'C-891'!B12/2000/453.6) references the cell for "Maximum Horsepower" rating (i.e. Cell B-12) rather than the "Requested Horsepower" (i.e. Cell B-13) (as done for other calculations; e.g. "Heat Input Rating", " Hourly Fuel Usage", "Uncontrolled Emissions for Criteria Pollutants, VOCs, and HAPs"). If Requested hp is used, this would reduce the "Estimated Controlled Emissions (tpy)" from 39.62 tpy to 23.70 tpy for C-891; and from 36.76 to 22.73 tpy for C-893. This would then improve the cost effectiveness from $116,063/yr-ton to $14,002/yr-ton for

engine C-891; but did not change the cost effectiveness for engine C-893 ($222,998/yr-ton), which brings up the following question.

I have updated the cost estimates per your notes in the attached spreadsheet.

2. You indicate that for engine C-893, "2018 stack test recorded emissions less than Cooper guarantee. No anticipated reduction possible." It seems counterintuitive to me that adding additional pollution-control equipment would increase emissions.

   You're correct that the additional equipment would not increase emissions; however, the guaranteed output NOx emissions from Cooper for the available additional pollution control equipment are higher than the emissions recorded for stack testing. Therefore, there's no guarantee that the available control will be able to reduce emissions further.

3. What is the estimated "Compliance Time (yr)" for the CBT upgrades?

   The anticipated compliance time is 24 months to budget, plan, and install the control equipment, provided the supplier can guarantee a reduction in emissions below historically tested levels.

4. What is the anticipated "Energy / Non-Air Impacts" for the CBT upgrades?

   Clean burn technology control employs a combustion mixture with a higher air-to-fuel ratio, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. This could reduce NO_X emissions; however, a reduction in combustion temperature also tends to increase emissions of CO due to incomplete combustion [Solar Turbines, "Developments in Dry Low Emissions Technology", 2006].

5. While not an issue here necessarily, I think your GHG Emissions Inventory calculations (e.g. for CO2 tpy, "=D51*B12/2000") is incorrect, with a cell reference to B-12 (i.e. "Maximum hp") instead of B-11 (i.e. "Hours of Operation").

   Thank you for your note. This will be updated for future Inventory calculations.

Thank you for your help on this,

Neal

Purchased equipment costs ($)	PEC	$ -		Oxy did not provide an estimate for electrification. As a result, the TCC of an EMD unit is based on a cost metric of 2,084 $/hp installed (2023$) derived from cost estimates provided by other facilities. Oxy indicated that there is insufficient power available to support additional electrical demands at the facility, but did not provide a cost estimate for upgrades to the electric substation and distribution lines. As a result, NMED included a $5M infrastructure cost estimate. This value is believed to underestimate the respective cost based on information provided by other facilities.
Other Direct Capital Costs 1 ($)	ODC1	$ -		
Other Direct Capital Costs 2 ($)	ODC2	$ -

2024$ Cost Effectiveness ($/ton)	**CE2**	**$ 25,426**	-	CE1 x PI

Unit ES-06/07: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	39	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	252,573,230	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3821	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.3790	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0758	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit ES-06/07: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	39	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	331,367,604	scf/Year	
Actual Annual fuel consumption (Mactual) =		252,573,230	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.762	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6677	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.82	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	39.47	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	156.30	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	16	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	23.09	kW

Unit ES-06/07: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,739	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$39,863 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,070 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$294,933 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,859 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$7,476 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$15,416 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$4,112 in 2024 dollars
Direct Annual Cost =		$39,863 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,288 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,070 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$294,933 per year in 2024 dollars
NOx Removed =	39 tons/year
Cost Effectiveness =	$7,472 per ton of NOx removed in 2024 dollars

Unit ES-08/09: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	39	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	242,170,708	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3821	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.3790	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0758	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.

Unit ES-08/09: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	39	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	331,367,604	scf/Year
Actual Annual fuel consumption (Mactual) =		242,170,708	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	0.731	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	6402	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	11.82	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	37.85	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.00	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	156.30	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	5	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	16	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	2	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^n/(1+ i)^n - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	23.09	kW

Unit ES-08/09: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,571,739	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$38,920 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,070 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$293,990 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,859 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$7,169 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$14,781 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$4,112 in 2024 dollars
Direct Annual Cost =		$38,920 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,288 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,070 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$293,990 per year in 2024 dollars
NOx Removed =	38 tons/year
Cost Effectiveness =	$7,768 per ton of NOx removed in 2024 dollars

NMED Final Cost Evaluation
Oxy USA WTP Limited Partnership - Indian Basin Gas Plant

Unit ES-10/11: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	39.01	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	331,452,570	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3821	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.2543	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0509	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours	
Estimated SCR equipment life	20	Years*	

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F	*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour	

Concentration of reagent as stored (C_{stored})	29	percent*	
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*	
Number of days reagent is stored ($t_{storage}$)	14	days	

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.

Unit ES-10/11: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	39	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	331,452,570	scf/Year	
Actual Annual fuel consumption (Mactual) =		331,452,570	scf/Year	
Heat Rate Factor (HRF) =	NPHR/10 =	1.14		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	1.000	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8760	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	7.94	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	34.76	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour	
Residence Time	1/V_{space}	#VALUE!	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.15		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	12.8	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	149.92	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet

SCR Reactor Data:

Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole
Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	3	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	11	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	1	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	500	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0981

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	23.09	kW

Unit ES-10/11: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$2,572,168	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$43,619 in 2024 dollars
Indirect Annual Costs (IDAC) =	$255,112 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$298,731 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$12,861 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$6,584 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$20,231 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$3,944 in 2024 dollars
Direct Annual Cost =		$43,619 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,782 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$252,330 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$255,112 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$298,731 per year in 2024 dollars
NOx Removed =	35 tons/year
Cost Effectiveness =	$8,594 per ton of NOx removed in 2024 dollars

Re: Requirement to Perform a Four-Factor Analysis on Control Measures Under the Clean Air Act Regional Haze Program- OXY USA WTP Limited Partnership (OXY); Indian Basin Gas Plant

Dear Mr. Singleton:

OXY USA WTP Limited Partnership (OXY) is submitting this Four-Factor Analysis Report per request of the New Mexico Environment Department in the letter dated July 18, 2019. The Indian Basin Gas Plant Four-Factor Analysis is attached to this letter.

This submittal includes one hard copy and one electronic copy. Please feel free to contact me at (713) 366-5331 if you have any questions regarding this analysis.

Sincerely,

Femi Serrano
Environmental Advisor Sr.
OXY USA WTP Limited Partnership

1. EXECUTIVE SUMMARY

In the 1977 amendments to the Clean Air Act (CAA), Congress set a nation-wide goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR). The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Federal Class I areas. The CAA defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> This is known as a four-factor analysis.
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*
>
> The uniform rate of progress or improvement is sometimes referred to as the glide path and is part of the state's Long Term Strategy (LTS).

The second implementation planning period (2018-2028) for national regional haze efforts is currently underway. There are a few key distinctions from the processes that took place during the first planning period (2004-2018). Most notably, the second planning period analysis distinguishes between natural or biogenic and manmade or anthropogenic sources of emissions. Using a Photochemical Grid Model (PGM), the Western Regional Air Partnership (WRAP), in coordination with the EPA, is tasked with comparing anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), the states are responsible for identifying the sources that contribute to the most impaired days in the Class I areas. To accomplish this, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for major sources and assessed each facility's impact on visibility in Class I areas with a "Q/d" analysis, where "Q" is the magnitude of emissions that impact ambient visibility and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 18, 2019 the NMED informed OXY USA WTP Limited Partnership (OXY) that its Indian Basin Gas Plant (IBGP) facility was identified as one of the sources contributing to regional haze at the Carlsbad Caverns National Park Class I area.

In coordination with WRAP, the NMED devised criteria to determine specific equipment that is subject to the four-factor analysis. In the NMED's July 18, 2019 notification letter to OXY, it specifies that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The subject equipment at IBGP, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant are reported in Table 1.

Table 1. Summary of Equipment and Applicability to a Four-Factor Analysis

Equipment	NO_X Hourly PTE (lb/hr)	NO_X Annual PTE (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 Hourly PTE (lb/hr)	SO_2 Annual PTE (tpy)	SO_2 Subject to Analysis? (Yes/No)
Natural Gas-Fired Simple Cycle Turbines (Units ES-06/07 & ES-08/09)	15.5	67.9	Yes	0.029	0.13	No
Natural Gas-Fired Simple Cycle Turbine (Unit ES-10/11)	23.7	104	Yes	0.029	0.13	No
Amine Gas Treating Units (Unit AMINE-1 & SELEXOL)[a]	-	-	No	-	-	Yes

[a] This unit is controlled by an acid gas injection well and flare. No emissions from this unit vent directly to the atmosphere.

Once the applicability of equipment and pollutants has been determined, potential retrofit control technologies must be identified. In accordance with 40 CFR 51 Appendix Y and at the recommendation of the NMED[1], this is primarily achieved by utilizing the Reasonably Available Control Technology (RACT) / Best Available Control Technology (BACT) / Lowest Achievable Emission Reduction (LAER) Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC is queried for the previous ten years. Summaries of the result of this search are provided and discussed under Section 2 of this report. OXY engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The four-factor analysis is then conducted for those controls that are technically feasible.

[1] NMED 2021 Regional Haze Planning Website ("Links to other information"). https://www.env.nm.gov/air-quality/reg-haze/

NO_X is the only pollutant subject to evaluation in this four-factor analysis for the three turbines. The turbines, Unit ES-06/07 and Unit ES-08/09, are Solar model Centaur 40-4002 natural gas-fired, simple cycle turbines. Turbine Unit ES-10/11 is a Solar model Centaur 40-4702 natural gas-fired, simple cycle turbine. Units ES-06/07 and ES-08/09 are rated at 4,000 horsepower and were manufactured in 1980. Unit ES-10/11 is rated at 4,700 horsepower and was manufactured in 1980.

SO_2 is the only pollutant subject to the evaluation in this four-factor analysis for the two amine units. The amine units, AMINE-1 and SELEXOL, are both currently controlled by an acid gas injection well and an acid gas flare.

2.1. COMBUSTION TURBINES

2.1.1. Combustion Turbine Background

A gas turbine is an internal combustion engine that operates with a rotary, rather than reciprocating, motion and is composed of three primary components: a compressor, a combustor, and a power turbine. The compressor draws in ambient air and compresses it up to 30 times the ambient pressure, then directs it into the combustor where fuel is introduced, ignited, and burned. Exhaust gas from the combustor is then diluted with additional air and sent to the power turbine at temperatures up to 2600 °F. The hot exhaust gas expands in the power turbine section, generating energy in the form of shaft horsepower.[2]

The treatment of the exhaust gases exiting the turbine dictate the cycle designation of these units. The heat content can either be discarded without heat recovery (simple cycle); recovered with a heat exchanger to preheat combustion air entering the combustor (regenerative cycle); recovered in a heat recovery steam generator to raise process steam, with or without supplementary firing (cogeneration); or recovered, with or without supplementary firing, to raise steam for a steam turbine Rankine cycle (combined cycle or repowering).[3] The units at IBGP are simple cycle turbines.

NO_X is formed via three fundamentally different mechanisms. The principle NO_X formation mechanism, thermal NO_X, arises from the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion. Most thermal NO_X forms in the highest temperature regions of the combustion chamber. The second NO_X formation mechanism, fuel NO_X, arises from the evolution and reaction of fuel bound nitrogen compounds with oxygen. The final NO_X formation mechanism, prompt NO_X, arises from early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The significance of prompt NO_X is negligible in comparison to thermal and fuel NO_X. Fuel NO_X will also be negligible for IBGP's turbines assessed here, as these combustion turbines fire natural gas, which contains a negligible amount of nitrogen compounds. Therefore, this analysis will focus on thermal NO_X.

The PTE from each turbine is reported in the facility's New Source Review (PSD0295M11) and Title V (P103R2) permits, as well as summarized in Table 1 of this report.

[2] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[3] Ibid.

2.1.2. Potential NO_X Controls for a Combustion Turbines

There are three general methods of controlling NO_X emission from gas turbines; (1) wet controls, which use steam or water injection to reduce combustion temperatures and NO_X formation, (2) dry controls that use advanced combustor design to suppress NO_X formation, and (3) post-combustion, catalytic controls to selectively reduce NO_X.[4]

The retrofit control equipment that was identified for combustion turbines during a comprehensive review of the RBLC, available literature, and manufacturer's input is reported in Table 2. A more detailed table summarizing the RBLC review is provided in Appendix A. A detailed discussion, including a description, the technical feasibility, and the anticipated performance of each control is provided below.

Table 2. Potential Control Options for Combustion Turbines

Control Equipment	Technically Feasible for 4002 (Units ES-06/07 & ES-08/09)?	Technically Feasible for 4702 (Units ES-10/11)?	NO_X Control Efficiency
Good Combustion Practices	Yes	Yes	Base Case
Improved Combustion Technology	Yes	Yes	25 ppm
Water Injection	No	No	60%
Selective Catalytic Reduction	No	No	25 ppm

2.1.2.1. Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from combustion turbines; therefore, it has been determined that this method of NO_X control is feasible for the units at IBGP. However, these practices are currently in use at IBGP, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices is included in this report.

2.1.2.2. Improved Combustion Technology

The improved combustion technology control option, commonly referred to as Dry Low NO_X (DLN) control, seeks to reduce the conversion of atmospheric nitrogen to NO_X by reducing the combustion temperature and residence time of fuel in the combustor. There are several levels of improvements that can be made to the combustion chamber, which achieve this NO_X control at varying levels. The improved combustion technology available for the units at IBGP is produced by the manufacturer of the units, Solar, and is called SoLoNO_X.

[4] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"

SoLoNO$_X$ utilizes lean-premixed combustion technology to ensure an extremely uniform air/fuel mixture and stringently controls the combustion process to prevent excess NO$_X$ emissions from forming.

Based on communication with Solar, SoLoNO$_X$ is available for both the 4002 (Units ES-06/07 and ES-08/09) and 4702 (Unit ES-10/11) Solar turbines located onsite. However, in order to support the technology each of the 4002 units would need to be uprated to model 4702, respectively, because installation of SoLoNO$_X$ requires the turbine combustors to be capable of handling significantly higher temperatures. Uprating the units involves completely replacing the combustor section of the turbine with a much larger and more robust combustor.

Improved combustion technology was identified in this review of RBLC as a potential control of NO$_X$ emissions from natural gas-fired combustion turbines, and AP-42 Section 3.1 also lists this as an available control technique for gas turbines.[5] Therefore, it has been determined that this control technology is technically feasible for the turbines located at IBGP. Solar can guarantee output NO$_X$ emissions of 25 parts per million (ppm) for units with SoloNO$_X$ installed.

2.1.2.3. Water Injection

Water injection is a control technology for gas turbines that has been demonstrated to effectively suppress NO$_X$ emissions. Injection of water has the effect of increasing the thermal mass by dilution and thereby reducing the peak temperature in the flame zone. There is an additional benefit of absorbing the latent heat of vaporization from the flame zone when water injection is utilized. Water is typically injected at a water-to-fuel weight ratio of less than one.[6] Steam injection is not discussed as an option since Solar does not manufacture turbines with steam injection technology.

The capability of these units to be retrofit for water injection is dependent on the make and model of the turbine, per communications with Solar. Solar has indicated that the turbine models at IBGP are unable to be retrofitted with water injection; Therefore it has been determined that water injection control is technically infeasible for the Solar turbines located at IBGP (Units ES-06/07, ES-08/09, and ES-10/11).

2.1.2.4. Selective Catalytic Reduction Systems

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO$_X$ in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[7] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of turbine load, speed, and temperature, so NO$_X$ emissions reductions can be achieved. The lifespan of the catalyst is primarily determined by poisoning of active sites by flue gas constituent, thermal

[5] U.S. EPA, AP-42, Section 3.1, "Stationary Gas Turbines"
[6] Ibid.
[7] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

sintering, or compacting, of active sited due to high temperatures in the reactor, fouling caused by ammonia-sulfur salts and particulate matter in the gas, and erosion due to high gas velocities.[8]

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams can blind the catalyst and may necessitate the application of a soot blower.[9]

In order for an SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), dependent on the material of the catalyst. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[10] Communication with Solar has indicated that SCR controls are available for each of the turbine models assessed here but the facility engineers have determined the additional power demands required to install SCR controls on the turbines are infeasible. The power at the plant would need to be upgraded significantly and re-designed in order to power the SCR controls. Therefore, SCR is considered a technically infeasible control option for the turbines located at IBGP and are not assessed further in this report.

2.2. AMINE TREATING UNITS

2.2.1. Amine Treating Unit Background

Concentrations of H_2S or CO_2 are unfavorable in natural gas since they both can form a corrosive acid when in the presence of water.[11] H_2S is also highly toxic. Gas processing plants use amine treating units to remove H_2S and CO_2 from natural gas since amines such as Monoethanolamine (MEA), Diglycolamine (DGA), Diethanolamine (DEA) and Methyldiethanolamine (MDEA) are able to form salts with H_2S and CO_2 in an aqueous solutions.

An amine treating unit operates by feeding natural gas into the bottom of a contactor and simultaneously feeding a lean amine solution at the top of the contactor. The two streams interact in the counter flow, resulting in CO_2 and H_2S being stripped from the natural gas stream. The lean amine solution must be kept at a higher temperature than the gas feeding into the contactor, or condensation of heavier hydrocarbons could occur.[12] Trays or packing along the contactor walls provide a place for the lean amine solution to interact with the natural gas. The natural gas leaving the contactor will be "sweet gas."[13]

The rich amine leaving the contactor is usually sent to a flash tank which reduces the pressure of the stream and causes dissolved hydrocarbons to be removed.[14] The rich amine will then pass through a heat exchanger and enter a solvent regenerator. The heated vapor generated at the bottom of the regenerator flows upward through the trays or packing where it comes in contact with the rich amine and removes the acid gases from the amine. The lean amine is then cooled and reenters the first contactor to start the process over. The acid gas that is

[11] KIDNAY, A. J.; PARRISH, W. R.; MCCARTNEY, D. G. Fundamentals of natural gas processing. CRC Press, 2011;

[12] Ibid

[13] Ibid

[14] Ibid

dissolved in the vapor is then sent to a control device such as a sulfur recover unit with a tail gas incinerator, a flare, or an acid gas injection (AGI) well.

2.2.2. Potential SO_2 Controls for an Amine Treater

As listed above, potential controls for amine treating systems are a sulfur recovery unit with a tail gas incinerator, a flare, or an AGI well. In addition, the aforementioned controls will also have an associated acid gas flare as a standby control device when the main controls are being maintenanced. Sulfur recovery units are not discussed in this report since the facility has an AGI well installed.

2.2.2.1. Acid Gas Flare

Acid gas flares can be used as a backup control to sulfur recovery units with tail gas incinerators or acid gas injection (AGI) wells or they can be a main control for an amine system. Acid Gas flares are used to destroy H_2S emissions by converting H_2S to SO_2 during the combustion process. For a flare to operate properly, a heat content of 300 BTUs per standard cubic feet must be met. When this heat content is met, a flare will have at least a 98% control efficiency.[15] Since acid gas can have a very low heat content (less than 300 BTU per standard cubic feet), assist gas may be added to the stream to increase the heat content over this threshold. At gas plants, assist gas usually consists of mixing the acid gas stream with the residue gas from the facility.

IBGP currently operates an acid gas flare that operates when the AGI well is down for maintenance. Please see Section 2.2.2.2 for information on the acid gas injection well operation at the facility.

2.2.2.2. Acid Gas Injection Well

An AGI well will necessitate a geological study to be completed in order to determine if there are carbonate or sandstone reservoirs deep underground that can store the acid gas. If there is such a geological formation near the facility that will support the injection of acid gas, an AGI well can be drilled. An electrically driven compressor will pressurize the acid gas and pump it into the well to be stored in the underground reservoir. When the AGI well is operating there are no emissions vented to the atmosphere except for a fugitive emissions since all emissions are stored underground.

IBGP currently operates an AGI well to control amine emissions at the facility. To further improve the control of amine units at the facility, a redundant acid gas electrically driven compressor can be added to the AGI well system. This will reduce flaring emissions at the facility by having less downtime from performing maintenance on the acid gas compressor. This is the only additional control the facility can employ to reduce SO_2 emissions further.

[15] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Flare)," EPA-452/F-03-019.

OXY has evaluated the costs of implementing the technologically feasible control technologies as thoroughly as possible in the time provided to complete this assessment. These cost estimates are calculated according to the methods and recommendations in the EPA Air Pollution Control Cost Manual.[16] Cost effectiveness considerations for each unit and control technology are discussed below.

3.1. COMBUSTION TURBINES

Cost effectiveness for each combustion turbine control option are summarized Table 3.

Table 3. Cost Analysis Summary of Technically Feasible Control Options for Combustion Turbines at IBGP

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Improved Combustion Technology	ES-06/07	$1.51 M	$156.8 K	41.16	$3.81 K
	ES-08/09	$1.51 M	$156.8 K	37.94	$4.13 K
	ES-10/11	$1.36 M	$147.2 K	80.33	$1.83 K

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

3.1.1. Improved Combustion Technology

The equipment and installation labor cost discussed in this section was based on vendor data received for a similar replacement unit from Solar. The EPA Air Pollution Control Cost Spreadsheet was used to estimate all other costs completed in this section. The NO_X emissions are based on an outlet concentration of 25ppm. The costs are shown in Table 3 above. These cost estimates have been developed based on the actual emissions from each unit using the 2016 Emission Inventory submittal for IBGP. The full cost estimation for each unit is included in Appendix B of this report.

Please note that unit ES-10/11 was uprated in 2018 and the emissions for the unit increased. Per communication with the NMED, the actual emissions for calculating cost effectiveness should be based on 2016 actual emissions. Since the emissions for ES-10/11 were changed after the 2016 baseline date, PTE emissions along with a recent stack test were used to calculate the cost effectiveness of the unit.

[16] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

3.2. AMINE TREATING UNITS

Cost effectiveness for the redundant electric compression control is summarized in Table 4.

Table 4. Cost Analysis Summary of Technically Feasible Control Options for Engines at IBGP

Control Equipment	Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Redundant Compression	$11.0 M	$1.04 M	37.7	$27.6 K

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

3.2.1. Redundant Compression

OXY obtained a total cost estimate for installing redundant electric compression associated with the AGI well. The estimate incorporates direct capital cost for equipment and vendor labor, indirect costs associated with OXY's internal labor, and overhead and contingency costs for the project. According to this estimate, the redundant compressor would cost $11 M with $120 K per year for operating costs. The addition of this unit will reduce SO_2 emissions by 90% resulting in an emission rate reduction of 37.7 tpy. Emission effectiveness is therefore expected to be approximately $27.6 K per ton of reduced emissions. These cost estimates have been developed based on the actual emissions from each unit assessed here, using the 2016 Emission Inventory submittal for IBGP. The full cost estimation for each unit is included in Appendix B of this report.

4. TIME NECESSARY FOR COMPLIANCE

The second factor in this analysis is the time necessary for compliance. Consideration of this factor involves estimating the time required for a source to implement a potential control measure. This information is provided here in order to advise the NMED of OXY's projection of a reasonable compliance timeline based on the equipment and site-specific considerations that could affect the time necessary to comply.

4.1. COMBUSTION TURBINES

4.1.1. Improved Combustion Technology

OXY estimates that approximately 4-5 years will be needed to implement the improved combustion technology control equipment. Factors that have been considered for this anticipated timeline include permitting, budgeting, design, uprating the combustors, procuring the equipment, and installation of the control.

4.2. AMINE TREATING UNIT

4.2.1. Redundant Electric Compression

OXY estimates that approximately 5 years will be needed to budget, design, procure, and construct the redundant compressor. Factors that have been considered for this anticipated timeline include permitting, budgeting, design, procuring the equipment, and installation of the control.

5. ENERGY AND NON-AIR ENVIRONMENTAL IMPACTS

This section addresses the potential energy and non-air environmental impacts that installation of the technically feasible control options pose on a source. The consideration of energy impacts involves assessing the impact of a control measure on the energy that is consumed by the source. Non-air environmental impacts are assessed based on the effect of the control on non-air environmental media. Some examples of non-air environmental impacts include water resource depletion, solid waste generation, increased noise and odor pollution, and increased land usage.

5.1. COMBUSTION TURBINES

5.1.1. Improved Combustion Technology

It is not anticipated that installation of the improved combustion technology SoLoNO$_X$ on the turbines at IBGP will have any significant energy or non-air environmental impacts.

5.2. AMINE TREATING UNIT

5.2.1. Redundant Compression

There are no anticipated unique or site-specific energy or non-air impacts imposed by the installation of the redundant compression.

6. REMAINING USEFUL LIFE OF SOURCES

The anticipated remaining useful life of each source is addressed here for the NMED's consideration. The assessment of this factor involves estimating how long the sources analyzed will remain in operation and the lifetime of potential control measures, accounting for equipment and site-specific limitations.

40 CFR Part 51, Appendix Y includes guidance on the characterization of this factor, stating that the remaining useful life of a source will typically be longer than the useful life of the emission control system. Therefore, it is appropriate to annualize compliance costs based on the useful life of the control equipment, rather than the life of the source.[17]

6.1. COMBUSTION TURBINES

Based on their current age and operating efficiency, it is estimated that the remaining useful life of the turbines will be longer than the control units. Two of the turbines have operated for more than 35 years without any significant deterioration in operating efficiency and one of the turbines was installed in the last year; therefore, this analysis of the remaining useful life of the equipment will be based on the anticipated useful life of the control device considered.

6.1.1. Improved Combustion Technology

It is anticipated that the estimated useful life of the improved combustion technology, SoLoNO$_X$, will be similar to the useful life of an SCR system. The useful life is estimated to be 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[18]

6.2. AMINE TREATING CONTROL

6.2.1. Redundant Compression

The estimated useful life of the redundant compressor is about 20 years. Since the unit will be operating in acid gas service, the life span of the compressor will not be longer than 20 years.

[17] 40 CFR 51, Appendix Y, Section II.B.4.f

[18] U.S. EPA, "Air Pollution Control Cost Manual", available at: https://www.epa.gov/economic-and-cost-analysis-air-pollution-regulations/cost-reports-and-guidance-air-pollution#cost%20manual

7. SUMMARY & CONCLUSIONS

Based on a comprehensive review of the RBLC, available literature, and manufacturer's input of the available control technologies for the natural-gas fired turbines, OXY has determined that the SoloNOx controls are the only technically feasible control option for the turbines under review in this analysis. The marginal reduction in NO_X emissions to install the SoLoNOx controls on each of these units does not support the high investment cost of the control. The only option to further control SO_2 emissions from the amine systems would be to install redundant electric compression to support the AGI well. There is an extremely high initial investment cost to add this compression due to infrastructure changes needed in order to complete the modification. With such a high investment cost, OXY believes the minimal reduction in SO_2 emissions does not support the high cost for installing the redundant compression. With a calculated Q/d below 10, IBGP will not impact the visibility of Carlsbad Caverns. Furthermore, the analysis does not support additional controls due to the costs of the controls.

APPENDIX A: RBLC TABLES

The RBLC tables for the turbines are shown in the attached Table A-1.

Table A-1 RBLC Search for Small Turbines – NO_X

PROCESS_NAME	THROUGHPUT		POLLUTANT	CONTROL_METHOD_DESCRIPTION
Five (5) Natural Gas Fired Combustion Turbines	37.6	MMBTU/H	Nitrogen Oxides (NOx)	Selective Catalytic Reduction
Cogeneration gas turbine	4.37	MW	Nitrogen Oxides (NOx)	SoLoNOx burner (Ultra lean Premix)
Aeroderivative Simple Cycle Combustion Turbine	263	MM BTU/h	Nitrogen Oxides (NOx)	Selective Catalytic Reduction (SCR), exclusive combustion of fuel gas, and good combustion practices.
FG-PEAKERS: 2 natural gas fired simple cycle combustion turbines	171	MMBTU/H	Nitrogen Oxides (NOx)	Dry low-NOx combustors
FG-TURBINES	10504	HP	Nitrogen Oxides (NOx)	Dry ultra-low NOx burners
FGTURNBINES (5 Simple Cycle CTs: EUTURBINE1, EUTURBINE2, EUTURBINE3, EUTURBINE4, EUTURBINE5)	10504	HP	Nitrogen Oxides (NOx)	Dry ultra-low NOx burners.
TURBINE GENERATORS - UNITS CC007 AND CC008 AT CITY CENTER	4.6	MMBTU/H	Nitrogen Oxides (NOx)	LEAN PRE-MIX TECHNOLOGY AND LIMITING THE FUEL TO NATURAL GAS ONLY
Small Combustion Turbines (<25MW)	10179	Horsepower	Nitrogen Oxides (NOx)	Dry-Low NOx Combustion

Total Annual Costs:	$	1,040,473		
Emissions Reduction:			37.72 tpy	
Cost Effectiveness:	**$**	**27,581.01**	**$/ton**	

REGIONAL HAZE FOUR-FACTOR ANALYSIS ADDENDUM

OXY USA WTP Limited Partnership
Indian Basin Gas Plant

Prepared By:

TRINITY CONSULTANTS
9400 Holly Ave NE
Building 3, Suite 300
Albuquerque, NM 87122
(505) 266-6611

February 2020

Project 193201.0194

Environmental solutions delivered uncommonly well

Oxy appends the Four-Factor Analysis for Indian Basin Gas Plant with the following information provided in this addendum. In Oxy's original Four-Factor Analysis report submitted on October 31, 2019, any unit from each facility which had NO_x or SO_2 emissions greater than 10 lb/hr and 5 tpy was analyzed. Below in blue and italicized are Oxy's responses to the NMED's letter dated December 23, 2019 for additional information on the 4FA submitted on November 1, 2019 to the NMED.

1. Sour Gas Amine Treating Units

a. Consider and discuss adding a secondary control to the acid gas injection (AGI) system to reduce flaring emissions, such as LO-CAT sulfur recovery technology. If technically feasible, include a four-factor analysis.

Oxy Response: The AGI system is a fully enclosed system, with no clear/viable way Oxy could add a new system such as LO-CAT technology. The Indian Basin Plant does have a Sulfur Recovery Unit that removes H_2S from the acid gas flow to create elemental sulfur. This unit has been shut down since the AGI well was installed and operational but was known to have very poor reliability. The installation of a LO-CAT system would be technically infeasible.

2. **Flaring:** Please provide the following information for the flare Units at the IBGP Unit ES-42 Startup, Shutdown & Maintenance (SSM) (NOX and SO2), ES-50-SSM (SO2):
   a. Provide a description of each flare, the design and type, and its purpose.
   b. List and describe the reasons that trigger each type of flaring event. This is to identify and clarify the causes to help find potential solutions to reduce flaring emissions.
   c. Complete a review and include an analysis about how the entire facility and/or source specific operations can be improved to reduce the frequency of SSM flaring events. If it is not possible to make any improvements to the facility or its processes to reduce SSM flaring events, then please explain why.
   d. Include a discussion of any potential alternative control options or operational changes that could reduce flaring NOX and/or SO2 emissions, including but not limited to,
      i. infrastructure that allows re-routing or recirculating the gas within the facility or outside of the facility until an SSM event is over;
      ii. sulfur absorbent technology used to remove sulfur from pipelines and other auxiliary equipment to reduce inlet or plant flaring SO2 emissions;
      iii. Gas Capture Plans with facilities located downstream and upstream similar to those required for producers to better synchronize upstream and downstream services with the IBGP;
      iv. use of remote capture equipment; and
      v. better infrastructure planning and changes to existing infrastructure that connects the downstream and upstream operations to the IBGP to ensure that there is adequate processing capacity to move produced gas to market.
   e. For any technically feasible solutions, complete and submit a four-factor analysis. For additional information regarding potential alternative controls to flaring see the New Mexico Methane Strategy webpage.

Oxy Response: The majority of SSM events are related to startup and shutdown of the Turbines at the Plant. The Plant has worked to implement Solar Turbotronics controls on the Solar Turbines at the Plant. These controls help to minimize downtime of the units and provide the units with a longer lifespan before they need to be overhauled. During SSM events, Oxy reduces emissions through work

practice standards and good air pollution control practices. The flares at the facility are permitted with the least amount of emissions due to the fact Oxy has already reduced flaring emissions as low as the plant can possibly operate with. The acid gas flare is only used during maintenance or an upset of the AGI well. There are no further ways to reduce emissions from the acid gas flare other than those stated in the original 4FA submittal on November 1, 2019.

As for the inlet residue flare, this flare has minimal emissions associated with it. This flare is only used during maintenance events and when the plant has a turnaround. There are no further ways to reduce emissions from this flare. When maintenance or turnaround events are scheduled, Oxy makes every effort to schedule these events along with downstream and upstream facilities. This will help to mitigate emissions further during these types of events.

The NMED also listed a "remote gas capture system" as an alternative to flaring but this technology would be technically infeasible for the facility. The remote gas capture system would have to be able to remove acid gas from the stream and be able to accommodate 200 MMSCFD of inlet gas. Oxy is also contractually obligated to meet certain natural gas specifications before the gas can be sent to downstream facilities. If these specifications are not met, the downstream facilities will not accept the gas. At this time, Oxy does not know of any system that is capable of handling this amount of gas and removing the acid gas from the stream.

Oxy has the infrastructure needed to accommodate the gas the facility processes. There are no further infrastructure changes that could mitigate SSM emissions further for the facility.

3. **Simple Cycle Natural Gas Fueled Turbines**

Please provide the following information for Four Factor Analyses for NOX from Simple Cycle Turbines Unit Numbers ES-06/07, EP-08/09, and ES-10/11:

a. Provide the Good Combustion Practices and the routine maintenance schedule and procedures that are currently used to help mitigate NOx emissions and are proposed as a feasible control.
Oxy Response: Oxy has a maintenance contract with Solar for routine maintenance. Solar provides field support and performs all needed maintenance on Oxy's Turbines. The maintenance procedures followed are the ones Solar provides for the facility turbines.

b. Provide vendor specifications for the SoLoNOX Dry Low NOx (DLN) combustion technology that includes the guaranteed NOX emission rates used in cost analysis, the cost information, recommendations, and equipment specifications for the turbine control estimates.
Oxy Response: The NOx emission rate guarantee is attached. The cost recommendation was based on a similar unit that was installed at the facility and the invoice log is provided. This cost is considered confidential business information and is being submitted as a separate document.

c. How will upgrading the turbine combustors with SoLoNOX affect the turbine capacities and the emission rates of NOX and CO?
Oxy Response: The NOx and CO for the units will be reduced but the turbine capacities will be increased and then derated to the permitted limit in order to not increase capacity for the unit.

d. Provide the documentation from the turbine vendor stating why water injection is not technically feasible for Solar Turbines.
Oxy Response: Per correspondence with Solar, the turbines were not designed for water injection. Solar does not offer this older technology on the turbines. The only technology provided in Solar technical data sheets is for dry low NOx. None of the data sheets provide information on wet NOx which would be associated with water injection.

e. Provide the basis for the following statement; "communication with Solar has indicated that SCR *[selective catalytic reduction]* controls are available for each of the turbine models assessed here

but the facility engineers have determined the additional power demands required to install SCR controls on the turbines are infeasible". Is the increase in power demand not technically feasible or too costly? If this determination is based on cost, then a cost analysis that includes the increase in energy demand, must be provided.

Oxy Response: The increase in power is not technically feasible. There is no extra power at the facility to operate the SCR equipment. Oxy believes the major modification that would need to be completed in order to add a substation and add the control is outside the scope of this analysis. A full engineering redesign of the facility would need to take place to determine if a new substation and the SCR controls could be added to the facility. This engineering redesign would take months to determine the cost needed to modify the facility and if the redesign is even feasible. Oxy believes this redesign cost would be more expensive than the SoloNOx cost estimate that was provided since the addition of the SoloNOx would not require a redesign of the facility.

f. Consider and include a discussion on the feasibility and cost of load management including limited operating hours to reduce emissions.

Oxy Response: Oxy has contracts in place that require the current loads and hours permitted for the units. This is not an option for the units at the site.

g. Provide the electronic spreadsheets used for control technology cost calculations.

Oxy Response: These have been attached to the documents.

h. Please include a discussion of the following control options to reduce NO_X emissions:

   i. catalytic combustion such as a XONON^{TM} developed by Catalytic Combustion Systems, Incorporated (CESI);

   Oxy Response: This control option was not provided by Oxy as an option to control the turbines at the site. When completing an RBLC search over the last ten years, XONON has not been installed on turbines. The most notable control was a dry low NOx burner which Oxy discussed in the original submittal. Oxy has historically had issues with Solar turbines that were operated with different equipment that was not from Solar. There were more instances of downtime and overhauls had to be completed more often.

   ii. lean and staged (DLN) combustors from turbine manufacturers other than Solar and complete a Four-Factor analysis on technically feasible options. That Solar does not manufacturer a particular control method or turbine combustor is not grounds for eliminating an option for technical reasons.

   Oxy Response: SoloNOx is a dry low NOx combustor manufactured by Solar. Therefore, this method was discussed in the original 4FA submittal and will not be provided further in this document. Please note that adding aftermarket combustors to the turbines would void the warranty Oxy has with Solar. There would be no reason to install aftermarket controls when Solar manufactures controls specifically designed for the Solar Turbines.

APPENDIX A: SUPPORTING INFORMATION

Solar Turbines
A Caterpillar Company

PREDICTED EMISSION PERFORMANCE

Customer	Engine Model: CENTAUR 40-4700S CS/MD 59F MATCH
Job ID	
Inquiry Number	Fuel Type: SD NATURAL GAS; Water Injection: NO

lbm/(MW-hr)	2.05	1.48	0.43
(gas turbine shaft pwr) lbm/hr	7.15	5.18	1.48

Notes

1. For short-term emission limits such as lbs/hr., Solar recommends using "worst case" anticipated operating conditions specific to the application and the site conditions. Worst case for one pollutant is not necessarily the same for another.
2. Solar's typical SoLoNOx warranty, for ppm values, is available for greater than 0 deg F or -20 deg C, and between 50% and 100% load for gas, fuel, and between 65% and 100% load for liquid fuel (except f or the Centaur 40). An emission warranty for non-SoLoNOx equipment is available for greater than 0 deg F or -20 deg C and betwee
3. Fuel must meet Solar standard fuel specification ES 9-98. Emissions are based on the attached fuel composition, or, San Diego natural gas or equivalent.
4. If needed, Solar can provide Product Information Letters to address turbine operation outside typical warranty ranges, as well as non-warranted emissions of SO2, PM10/2.5, VOC, and formaldehyde.
5. Solar can provide factory testing in San Diego to ensure the actual unit(s) meet the above values within the tolerances quoted. Pricing and schedule impact will be provided upon request.
6. Any emissions warranty is applicable only for steady-state conditions and does not apply during start-up, shut-down, malfunction, or transient event.

Subject: [EXTERNAL] RE: Call to Discuss Regional Haze Four-factor Analysis for OXY - Indian Basin Gas Plant

WARNING - This message is from an EXTERNAL SENDER - be CAUTIOUS, particularly with links and attachments.

Good Afternoon Femi,

Thank you for your responses. In terms of your company-specific interest rate for the cost of capital for the installation of air pollution equipment, I appreciate that you have verified this with the Oxy Treasury Team that an appropriate cost is approximately 10 – 12%. You stated that this was based on a recent analysis provided to Technical Accounting and KPMG from Treasury where they calculated that a reasonable WACC is 10 – 12%.

EPA has indicated to us that they are expecting documentation to defend the interest rate used for submitted four factor analyses. Therefore we request that you provide documentation to support your proposed interest rate. This could be a letter from the chief financial officer for the institution that lends to your company, or from an official with your company (your company's CFO, for instance) that is in a position to know your company's costs of debt and equity.

Regards,

Neal

Hi Femi – good morning. Yes, as discussed, it would be more appropriate to use Oxy's WACC as the cost to fund capital projects.
An appropriate cost is ~10%. Recent analysis provided to Technical Accounting and KPMG from Treasury calculated that a reasonable WACC is 10-12%.
Let me know if you need anything else.
Regards,
Jason

Good morning Jason,
Thank you very much for your explanation regarding the use of a weighted average cost to capital of 10-12% from a recent analysis in June. If you have any additional details to buttress this, please reply to this email.
I plan respond to NMED sometime today. Have a wonderful day!
Kind Regards,

Hi Femi – thanks for the note, happy to discuss. Let me know if you have time this afternoon; I'm available starting at 4:30pm.

If not, I'm available tomorrow morning starting at 10:00am.
Let me know what works best, just call my cell. Talk soon.

Regards,
Jason

Subject: FW: Call to Discuss Regional Haze Four-factor Analysis for OXY - Indian Basin Gas Plant

Hi Jason,

I had a question from NMED about interest rates and was directed to you by James Holtz. Please see NMED's comments below. Do you have a few minutes to discuss? Please advise.

- OXY has indicated that the interest rate was 5.5% at the time of the analysis. However, NMED's intention is to use a bank prime rate of 3.25% for its cost analysis unless OXY can provide information on a percentage rate OXY would potentially be able to borrow at for the purchase of control equipment. If you have a company-specific interest rate for the cost of capital for the installation of air pollution equipment, please provide it, and any documentation that supports this rate.

Kind Regards,

Hello Michael,

Sorry for the late response, I was out of office when your email came and it has taken me some time to catch up on all the missed messages.

To answer your question below, there are currently no plans to replace those equipment that were removed from the site.

Thank you for your patience, and please let me know if there are any other questions.

Hi Femi,

During our meeting, you stated that the permitted equipment had been removed and put in use at a different facility. What is your company's plan for replacing the equipment?

In the absence of any other information regarding the facilities operation, we plan on finalizing the Four Factor Analysis for your facility as it is permitted and presented in the original 4FA submittal.

Thank you,

Michael Baca | CS Manager | NMED AQB

San Juan Generating Station
NSR Permit No. 0063-M12R3
Agency Interest No. 1421 - PRT20220002
AIRS No: 350450902

Dear Justine Vaivai:

The Air Quality Bureau (ABQ) is in receipt of Public Service Company of New Mexico (PNM)'s December 27, 2022, request to voluntarily discontinue the San Juan Generating Station Title V Operating Permit No. P062-R4M1 and Acid Rain Permit P062A-R4M1, pursuant to 20.2.70.400.I NMAC.

On December 27, 2022, the AQB received Public Service Company of New Mexico (PNM)'s request to close the New Source Review permit 0063-M12R3 for the facility located in San Juan County, New Mexico at latitude and longitude decimal degrees: 36.802056, -108.43875. The request to close the NSR permit was effective upon receipt per 20.2.72.219.A(3) NMAC.

With the closure of the NSR permit, the actions required to reduce the potential to emit of this facility to below Major Source thresholds have been met. Therefore, the Department has voluntarily discontinued Title V Operating Permit No. P062-R4M1 for the San Juan Generating Station as of December 28, 2022, and this facility will be removed from the list of major Title V sources in New Mexico.

If you have any questions, please contact me at 505-269-2718 or joseph.kimbrell@env.nm.gov.

Sincerely,

Elizabeth Kuehn

Economic Evaluation

Cost Component		B-01	B-02	Source	Methodology/Note
Purchased equipment costs ($)	PEC	$ -	$ -	-	According to Targa, the estimated TCC is an adjusted average from several vendors and includes burner modifications, engineering, installation and related field services. Targa estimated TCI by increasing a vendor estimate (Combustion Control Systems, CBI) by 16% to presumably account for additional installation costs. This is reasonably consistent with the EPA Control Cost Manual.

NMED Final Cost Evaluation
Targa Midstream Services - Eunice Gas Processing Plant

Unit B-01: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	62.1	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	527,639,185	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3415	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.0960	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0096	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	$0.293/gallon 29% ammonia solution 'ammonia cost for 29% solution	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.
Electricity Cost ($/kWh)	0.0676	U.S. Energy Information Administration. Electric Power Monthly. Table 5.3. Published December 2017. Unit B-01: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	527,639,185	scf/Year
Actual Annual fuel consumption (Mactual) =		527,639,185	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	1.000	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8760	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	90.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	5.37	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	23.50	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.13	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.13	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.0	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	246.76	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	#VALUE!	feet
		#VALUE!	

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	#VALUE!	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	#VALUE!	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	#VALUE!	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	2	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	7	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	1	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	400	gallons (storage needed to store a 14 day reagent supply rounded to t
		2,024	
		797.6	
		7.5	

Capital Recovery Factor:

Parameter	Equation	0.529
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 =	0.0981
	Where n = Equipment Life and i= Interest Rate	255

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	36.76	kW

Unit B-01: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,427,850	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$60,287 in 2024 dollars
Indirect Annual Costs (IDAC) =	$339,106 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$399,393 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$17,139 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$4,451 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$32,205 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$6,492 in 2024 dollars
Direct Annual Cost =		$60,287 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,834 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$336,272 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$339,106 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$399,393 per year in 2024 dollars
NOx Removed =	24 tons/year
Cost Effectiveness =	$16,995 per ton of NOx removed in 2024 dollars

Unit B-02: Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

What type of fuel does the unit burn? Natural Gas

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the maximum heat input rate (QB)?	62.1	MMBtu/hour
What is the higher heating value (HHV) of the fuel?	1,031	Btu/scf
What is the estimated actual annual fuel consumption?	527,639,185	scf/Year
Enter the net plant heat input rate (NPHR)	11.38	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3415	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days		
Number of days the boiler operates (t_{plant})	365	days		
Inlet NO_x Emissions (NOx_{in}) to SCR	0.0960	lb/MMBtu		
Outlet NO_x Emissions (NOx_{out}) from SCR	0.0096	lb/MMBtu		
Stoichiometric Ratio Factor (SRF)	1.050			

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	650	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	UNK	ft^3/min-MMBtu/hour

*The SCR inlet temperature of 650 deg.F is a default value. Enter actual temperature, if known.

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2024				
CEPCI for 2024	797.6	Enter the CEPCI value for 2024	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	7.5	Percent			
Reagent ($Cost_{reag}$)	0.529	$/gallon for 29% ammonia			
Electricity ($Cost_{elect}$)	0.1000	$/kWh			
Catalyst cost ($CC_{replace}$)	255.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Unit B-02: SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	62	MMBtu/hour
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	527,639,185	scf/Year
Actual Annual fuel consumption (Mactual) =		527,639,185	scf/Year
Heat Rate Factor (HRF) =	NPHR/10 =	1.14	
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	1.000	fraction
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8760	hours
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	90.0	percent
NOx removed per hour =	NOx_{in} x EF x Q_B =	5.37	lb/hour
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	23.50	tons/year
NO_x removal factor (NRF) =	EF/80 =	1.13	
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	#VALUE!	acfm
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	#VALUE!	/hour
Residence Time	1/V_{space}	#VALUE!	hour
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00	
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =		Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.13	
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.0	psia
Retrofit Factor (RF)	Retrofit to existing boiler	1.00	

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3095	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	246.76	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	#VALUE!	ft^2

Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	36.76	kW

Unit B-02: Cost Estimate

Total Capital Investment (TCI)

TCI for Oil and Natural Gas Boilers

For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW:

$$TCI = 86{,}380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$$

For Oil and Natural Gas-Fired Utility Boilers >500 MW:

$$TCI = 62{,}680 \times B_{MW} \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour :

$$TCI = 7{,}850 \times (2{,}200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour :

$$TCI = 10{,}530 \times (1{,}640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$$

For Oil-Fired Industrial Boilers >5,500 MMBtu/hour:

$$TCI = 5{,}700 \times Q_B \times ELEVF \times RF$$

For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour:

$$TCI = 7{,}640 \times Q_B \times ELEVF \times RF$$

Total Capital Investment (TCI) =	$3,427,850	in 2024 dollars

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$60,287 in 2024 dollars
Indirect Annual Costs (IDAC) =	$339,106 in 2024 dollars
Total annual costs (TAC) = DAC + IDAC	$399,393 in 2024 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$17,139 in 2024 dollars
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$4,451 in 2024 dollars
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$32,205 in 2024 dollars
Annual Catalyst Replacement Cost =	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$	$6,492 in 2024 dollars
Direct Annual Cost =		$60,287 in 2024 dollars

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,834 in 2024 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$336,272 in 2024 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$339,106 in 2024 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$399,393 per year in 2024 dollars
NOx Removed =	24 tons/year
Cost Effectiveness =	$16,995 per ton of NOx removed in 2024 dollars

1. EXECUTIVE SUMMARY

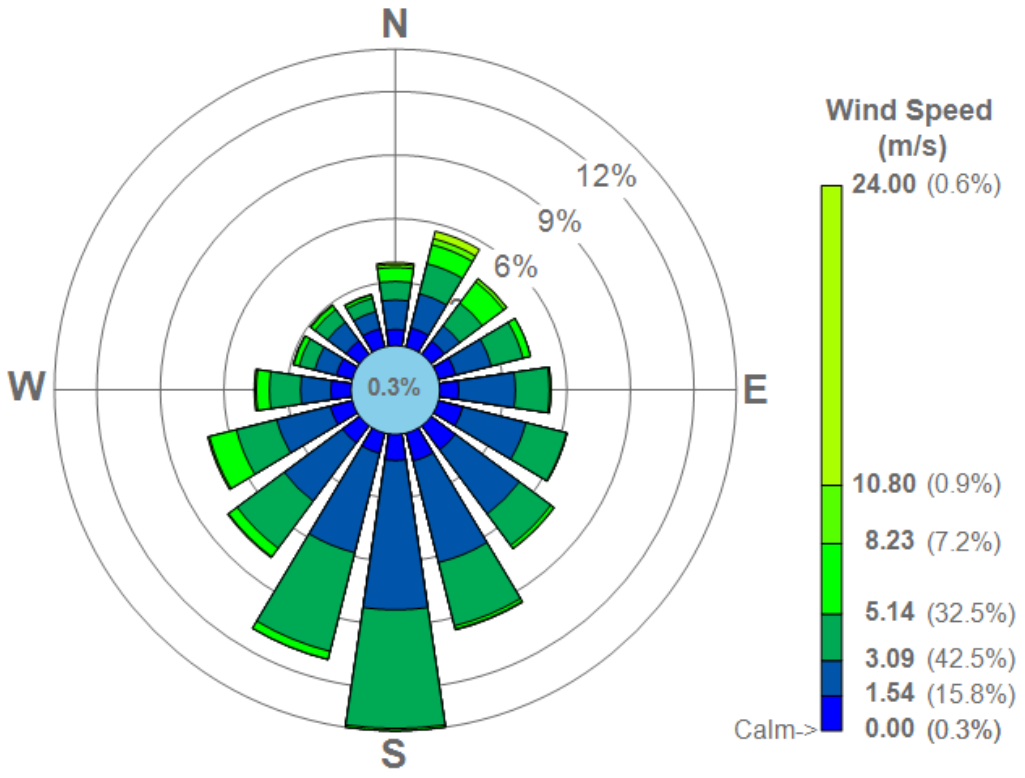
In the 1977 amendments to the Clean Air Act (CAA), Congress set a national goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR).[1] The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Class I areas. The Clean Air Act defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*

Currently, we are in the second planning period for national regional haze efforts. There are a few key distinctions from the processes that took place during the first planning period. Most notably, the second planning period analysis will distinguish between "natural" and "anthropogenic" sources. Using a Photochemical Grid Model (PGM), the Western Regional Air Partnership (WRAP) in coordination with the EPA will compare anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), "The State must identify all anthropogenic sources of visibility impairment considered by the State in developing its long-term strategy. The State should consider major and minor stationary sources, mobile sources, and area sources." To accomplish this for major stationary sources, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for Title V sources and screened each facility's potential impact on visibility in Class I areas using a "Q/d" analysis, where "Q" is the magnitude of emissions that could impact ambient visibility, and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 19, 2019 the NMED informed Targa Midstream Services LLC (Targa) that its Eunice Gas Plant was identified as one of the sources potentially contributing to regional haze at the Carlsbad Caverns National Park Class I Area.



[1] Federal Register / Vol. 64, No. 126 /Thursday, July 1, 1999 (https://www.govinfo.gov/content/pkg/FR-1999-07-01/pdf/99-13941.pdf).

1.1. CONTRIBUTION TO VISIBILITY

1.1.1. Lack of Contribution to Visibility Impairment Due To Prevailing Winds

The NMED did not consider actual contribution to visibility impairment when selecting sources for the Four-Factor Analysis, but this is a critical factor in establishing realistic reasonable progress goals for Class I areas. In Figure 1-1 below, the prevailing wind from Hobbs, NM, can be used to estimate this facility's potential impact on the nearest Class I Area, Carlsbad Caverns National Park. Targa's Eunice Gas Plant is located approximately 73.5 miles northeast at a wind vector of 76.5 degrees from the Carlsbad Caverns. The 2015 meteorological data from the NMED website at the Hobbs, NM meteorological station shows that wind blows from 56.3 to 78.8 degrees at a frequency of approximately 4.5%.[2] Based off this infrequent amount of time the wind blows from Targa's Eunice Gas Plant toward Carlsbad Caverns, Targa believes that it is unlikely that the facility's potential emissions impact visibility at Carlsbad Caverns. Therefore, when balancing retrofit costs and visibility improvements, NMED should remain mindful that emissions from this facility are unlikely to contribute to regional haze at Carlsbad Caverns.

Figure 1-1. Hobbs, NM Meteorological Data, 2015 Wind rose

[2] https://www.env.nm.gov/air-quality/meteorological-data/

1.1.2. Already Effective SO_2 Controls

Further, with respect to SO_2 emissions, Targa controls H_2S emissions from the amine unit through operation of an acid gas injection (AGI) well and is in the process of adding redundant electric compression to the AGI well system to further reduce SO_2 emissions from the flare during SSM and malfunction events. The addition of the redundant electric compression is solely required by a Settlement Agreement and Stipulated Final Compliance Order between the Environmental Protection Division of the New Mexico Environment Department and Targa Midstream Services LLC. Targa expects this project to reduce SO_2 flaring emissions at Eunice Gas Plant by approximately 200-250 tons per year. The installation of the redundant compression constitutes effective emission control technology to meet emission reductions required under the Settlement Agreement. This project will be complete by December 31, 2020; therefore, occurring during the 2nd Planning Period. There are no further SO_2 control options for the amine unit. Thus, the only equipment at this facility subject to this regional haze evaluation emit NOx.

Per 40 CFR 51.308(f)(2) of the Regional Haze rule, the NMED must determine emission reduction measures that are necessary to make reasonable further progress. The NMED, in an outreach webinar on Regional Haze Planning held on October 2, 2019, presented data on the most impaired days. This presentation identified ammonium sulfate as the largest contributor of visibility impairment in the National Parks of New Mexico. Ammonium sulfate is a byproduct of gaseous sulfur dioxide which becomes oxidized in the atmosphere to form sulfate particulate matter. This sulfate particulate matter is composed of sulfuric acid and corresponding salts such as ammonium sulfate.[3] Since this information indicates the major contribution to regional haze is from sulfur dioxide emissions, not nitrogen dioxide emissions, the NMED should ensure that any required NO_X reductions show significant contribution to improving visibility prior to requiring capital expenditures. Because emissions from Targa's Eunice Gas Plant are not expected to impact visibility in the Carlsbad Caverns National Park Class I Area based on predominant wind direction (see Section 1.1), the NMED should find all technically feasible NO_X controls for the Eunice Gas Plant economically unreasonable.

1.2. EQUIPMENT ANALYSIS

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four factor analysis. In the NMED's notification letter to Targa, they specify that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility that is subject to this analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant, are reported in Table 1.

AM-01/ F-01	Amine Gas Treating Unit [a]	-	-	No	5176.6	776.5	Yes

[a] This unit is controlled by an acid gas injection well during normal operations and a flare during SSM or malfunction activities. Hydrogen sulfide emissions from this unit are combusted to form sulfur dioxide at flare F-01.

[b] This unit is inoperable and therefore permanently shutdown. Targa intends to remove it from the NSR permit in its next permitting action. It is not further reviewed in this report but should be noted for emission reductions at the site.

[c] Units C-09 and C-12 were restricted to 500 hrs/yr operation in permit 67-M8R1 and C-10 and C-11 were restricted to 500 hr/yr operation in permit 67-M7.

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified in accordance with 40 CFR 51 Appendix Y. At the recommendation of the NMED,[4] this is primarily achieved by utilizing RACT/BACT/LAER Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC was queried for the two-stroke lean-burn engines over the past 20 years and the last ten years for the boilers. Summaries of the search results are provided and discussed in Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The required four-factor analysis is then conducted for those controls that are technically feasible.

Targa has reduced NO_X emissions prior to this analysis but after the 2016 baseline date by reducing hours of operation on several units, replacing natural gas combustion units with electrically driven sources and removing units from service. Below is a summary the NO_X reduction from engines at the facility since 2016:

- Targa replaced unit C-15 (natural gas internal combustion engine) with three (3) screw compressors driven by electric motors in the 2019 NSR Permit 067-M9R2.
- Targa has also since reduced the operating hours on Unit C-09, C-10, C-11, and C-12 to 500 hours. These four units were replaced with compressors driven by electric motors in NSR permits 067-M8R1 and 067-M7.
- Targa has permanently shutdown Unit C-08 and Targa intends to remove it from the NSR permit in its next permitting action. It is not further reviewed in this report but should be noted for emission reductions at the site.

Targa conducted the required Four Factor Analysis for engines and boilers listed in Table 1 above. Based on a comprehensive review of the RBLC and control vendor's input of available control technologies, Targa determined the only feasible additional control option for natural gas fired two-stroke lean burn (2SLB) engines is installation of clean burn technology and the only feasible additional control option for boilers is flue gas recovery.

2.1. SO_2 EMISSIONS

Targa controls H_2S emissions from the amine unit through operation of an acid gas injection (AGI) well at the site and is in the process of adding redundant electric compression to the AGI well system to further reduce SO_2 emissions during SSM and malfunction flaring events. The addition of the redundant electric compression is solely required by a Settlement Agreement and Stipulated Final Compliance Order between the Environmental Protection Division of the New Mexico Environment Department and Targa Midstream Services LLC. Targa expects this project to reduce SO_2 flaring emissions at Eunice Gas Plant by approximately 200-250 tons per year. The installation of the redundant compression constitutes effective emission control technology to meet emission reductions required under the Settlement Agreement. This project will be complete by December 31, 2020 and therefore occurs during the 2nd Planning Period.

There are no further control options for the amine unit. No further analysis should be necessary to evaluate SO_2 emissions from the amine treater since no additional control equipment can be added to reduce SO_2 emissions at the site. Therefore, Targa will not assess any further control technology for this process unit.

2.2. NO_X EMISSIONS

Eunice Gas Plant has twelve (12) natural gas-fired two-stroke lean-burn engines are subject to review under this analysis. There are also two (2) natural gas boilers that are subject to review under this analysis. The only pollutant subject to evaluation for these units is nitrogen oxides (NO_X). More detailed information on each engine and boiler units is listed in Table 2 below:

2.2.1. Two-Stroke Lean-Burn Engines

Table 3. Potential Control Equipment for Two-Stroke Lean-Burn RICE

Control Equipment	Technically Feasible?	NO_x Control Efficiency
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**
Clean Burn Technology	**Yes**	**70% to 90%**
Selective Catalytic Reduction	**No**	**N/A**
Non-Selective Catalytic Reduction	**No**	**N/A**

2.2.1.1. Two-Stroke Lean-Burn Engines Background

A reciprocating internal combustion engine (RICE) is a device that uses the combustion of fuel and air in an internal chamber to generate a reciprocating motion and convert heat energy into mechanical work. The units use a piston to draw air and fuel into the combustion chamber and compress it. The compressed air/fuel mixture

is then ignited, generating combustion in the chamber. The energy of combustion pushes out the piston, turning a crankshaft and producing mechanical work. In the same cycle, the products of combustion remaining in the chamber are released and exhausted from the unit.

Natural gas-fired RICE are separated into multiple design classes, including 2-stroke lean-burn (2SLB), 4-stroke lean-burn (4SLB), and 4-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1) with exhaust oxygen levels less than 4%, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12% or more.[5] .

NO_X is formed in reciprocating engines by the following mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Eunice engines also use natural gas fuel; therefore, the formation of prompt NO_X and fuel NO_X will again be insignificant, and this analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio[6].

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:[7]

(1) Operational control methods, such as adjusting the timing or other operating parameters.
(2) Combustion control techniques, for example reducing the peak flame temperature or introducing inerts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.

The potential to emit (PTE) from each engine is reported in the Eunice Gas Plant's NSR (0067M9R2) and Title V (P109-R2M1) permits as well as summarized in Table 1. Additionally, the NOx emission rates from the RICE are calculated using stack test data.

2.2.1.2. Potential NO_X Controls for 2SLB Engines

Retrofit control options identified for 2SLB RICE were identified via comprehensive review of the RBLC and available technical literature and are summarized in Table 3. A detailed description and discussion of the technical feasibility and anticipated performance of each control is provided below.

2.2.1.2.1 Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's

[5] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[6] Ibid.
[7] Ibid.

recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from large natural gas-fired lean-burn stationary internal combustion engines; therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Eunice Gas Plant. However, these practices are currently in use at Eunice Gas Plant. No further assessment of these control practices has been included in this report.

Eunice Gas Plant conducts routine maintenance on all engines at the site per manufacture recommendations using trained maintenance personnel and using pipeline quality natural gas.

2.2.1.2.2 Clean Burn Technology

Clean Burn Technology (CBT) is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding an air-to-fuel ratio controller so that they are capable of operating at more desirable ratios.

As described in Section 2.1.1 of this report, lean-burn engines operate at air-to-fuel ratios ranging from 20:1 to 50:1. A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. 2SLB engines are typically designed to operate at the high air-to-fuel ratios employed in CBT; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease the NO_X emissions.[8]

In order to avoid derating the engine, combustion air must be increased at constant fuel flow. To achieve this, the engine would need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel ratio controller.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[9]

2SLB engines are mechanically capable of being retrofit with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NO_X emissions. Therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Eunice. On 2SLB RICE, air-to-fuel ratio adjustment generally achieves a 5 to 30% reduction in NO_X emissions; however, this reduction is very specific to each engine and typical loading.[10]

Targa was able to request potential NO_X reduction options from their engine control vendor including Clean Burn technology. The Clean Burn technology will reduce NO_X emissions between 70% and 90%. The units could be modified to operate with pre-combustion chambers and pilot fuel systems with Jet Cells which are needed to

[8] State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines, State of New Jersey Department of Environmental Protection, 2003.
[9] Ibid.
[10] Ibid.

significantly lean the combustion mixture with the required capacity air source. The 2SLB engines will also need turbochargers or externally driven blowers added as well. If a 2SLB engine does need an externally driven blower, this will be an electric blower and require electricity to operate. At this time, Eunice Gas Plant would have to significantly upgrade the power substation at the plant to operate blowers associated with these controls. The cost provided in Section 3 of this report does not include the cost to upgrade the electrical substation at the facility. An engineering design assessment would need to be completed before a total cost for the upgrade can be provided but is estimated at $1 million to $3 million.

Even with the power concerns, Targa has determined that this method of NO_X control is feasible for the 2SLB engines at the facility.

2.2.1.2.3 Selective Catalytic Reduction

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[11] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of engine load, speed, and temperature, so NO_X emissions reductions can be achieved. The catalyst effectiveness can reduce over time and ultimately become inactive. This inactivity can be caused by the following: [12]

- Poisoning of the active sites by flue gas constituents;
- Thermal sintering of active sites due to high temperatures within the catalyst reactor;
- Blinding/plugging/fouling of active sites by ammonia-sulfur salts and particulate matter; and
- Erosion due to high gas velocities.

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams can blind the catalyst and may necessitate the application of a soot blower.[13]

For an SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), the material of the catalyst will affect the specific temperature range the exhaust must operate within. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[14]

---

[11] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.
[12] Ibid.
[13] Ibid.
[14] U.S. EPA, AP-42, Section 3.2, "Natural Gas-fired Reciprocating Engines"

In order for the chemical reactions necessary for SCR to occur effectively, the exhaust streams injected with the reagent must be fairly oxygen rich. The exhaust oxygen levels for 2SLB engines are sufficient to support these reactions; therefore, this technology can be used on lean-burn engines.

That said, the RBLC does not identify SCR as a control for these specific engine models.[15] This is likely because there is limited operating experience to date with the use of SCR on 2SLB RICE. Additionally, there is a historical precedent that installation of SCR on 2SLB engines can result in significant technical complications, including a necessity to derate the engines and unreliable operation post-retrofit.

The engine control vendors did not offer or suggest SCR as a suitable control option as there are significant challenges to install this equipment on the 2SLB units at Eunice. The main challenge is most 2SLB engines have a poor air-to-fuel ratio that will not support the SCR control. The vendors provided CBT technology as the technically feasible option to control NO_X emissions from 2SLB engines. As SCR control technology is not listed in the RBLC tables for 2SLB engines, has not been a proven as an effective control of NO_X emissions for 2SLB engines and has significant operating challenges for 2SLB engines, Targa has determined this control is technically infeasible.

2.2.1.2.4 Non-Selective Catalytic Reduction

Non-Selective Catalytic Reduction (NSCR) is a control technique that uses residual hydrocarbons and carbon monoxide (CO) in engine exhaust as a reducing agent for NO_X. In an NSCR system, hydrocarbons and CO are oxidized by oxygen (O_2) and NO_X. The excess hydrocarbons, CO, and NO_X pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_X to N_2.[16] This technique does not require additional reagents to be injected because the unburned hydrocarbons in the engine exhaust are used as the reductant. The chemical reactions for this process are shown in the equations below.[17]

Phase 1:
$$2CO + O_2 \rightarrow 2CO_2$$
$$2H_2 + O_2 \rightarrow 2H_2O$$
$$HC + O_2 \rightarrow CO_2 + H_2O$$

Phase 2:
$$NO_X + CO \rightarrow CO_2 + N_2$$
$$NO_X + H_2 \rightarrow H_2O + N_2$$
$$NO_X + HC \rightarrow CO_2 + H_2O + N_2$$

The reactions in Phase 1 of the chemical process above function to remove excess oxygen from the exhaust stream. This step is necessary because if the oxygen is not removed, it will react more readily with the CO and hydrocarbons than the NO_X, thus reducing the NO_X removal.

Despite this oxygen removal step in the chemical process, the engine exhaust gas stream must already have low levels of excess oxygen, or the oxygen will not be fully removed in Phase 1 and the NO_X removal will not be efficient. Consequently, application of the NSCR control technique is effectively limited to engines with normal exhaust oxygen levels of 4% or less. This includes naturally aspirated 4SRB engines and some turbocharged

[15] Ibid.
[16] Ibid.
[17] U.S. EPA, "Compliance Assurance Monitoring Technical Guidance Document", Appendix B Review Draft, 2005

4SRB engines. In order to achieve effective NO_X reduction performance, the engine may need to be run with a richer fuel adjustment than normal, resulting in an exhaust excess oxygen level closer to 1%.[18]

The exhaust oxygen levels for 2SLB engines are not sufficiently low to support the reactions described above; therefore, this technology is not a method used to control NO_X emissions from lean-burn engines. Furthermore, NSCR was not identified in the review of the RBLC as a potential control of NO_X emissions from large natural gas-fired lean-burn stationary RICE and AP-42 Section 3.2 does not list NSCR as an available control technique for 2SLB engines.[19] For these reasons, it has been determined that this method of NO_X control is infeasible for the 2SLB engines at Eunice.

2.2.2. Industrial Boilers

2.2.2.1. Industrial Boilers Background

Similar to natural gas engines, boilers have three NO_X formation mechanisms and both fuel and prompt NO_X formations are negligible for natural gas fired industrial boilers. Thermal NO_X results from the oxidation of atmospheric nitrogen in the high-temperature, post-flame region of a combustion system. The major factors that influence thermal NO_X formation are temperature, concentrations of oxygen and nitrogen, and residence time. If the temperature or the concentration of oxygen or nitrogen can be reduced quickly after combustion, thermal NO_X formation can be suppressed. This includes controlling the conditions within and immediately following the flame zone where most combustion reactions occur. In utility boilers, temperature, residence time, and turbulence are determined by factors associated with boiler and burner design, fuel characteristics, and boiler operating conditions.

2.2.2.2. Potential NO_X Controls for Industrial Boilers

The retrofit control equipment identified for industrial boilers during a comprehensive review of the RBLC are reported in Table 4Table 4. Potential Control Equipment for Industrial Boilers. A detailed discussion including a description, the technical feasibility, and the estimated performance of each control, is provided below.

Table 4. Potential Control Equipment for Industrial Boilers

Control Equipment	Technically Feasible	NO_X Control Efficiency
Good Combustion Practices	**Base Case**	**N/A**
Low NO_X	**Yes**	**N/A**
Flue Gas Recirculation	**Yes**	**45 ppm**
Selective Catalytic Reduction	**No**	**N/A**
Selective Non-Catalytic Reduction	**No**	**N/A**

[18] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[19] Ibid.

2.2.2.2.1 Good Combustion Practices

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the combustion chamber where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, tuning of the boilers, as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from boilers; therefore, it has been determined that this method of NO_X control is feasible for the units at Eunice. However, these practices are currently in use at Eunice, as required by various conditions in its Title V and NSR permit authorizations. No further assessment of these control practices has been included in this report.

2.2.2.2.2 Low NO_X Burner

The low NO_X (LN) burner control, seeks to reduce the combustion temperature and residence time of fuel in the combustor (thereby decreasing NO_X formation) by increasing the air-to-fuel ratio in the combustion chamber. This is usually accomplished by staging techniques that supply excess air to cool the combustion process (fuel-lean combustion zone) and by reducing the concentration of oxygen in the flame zone (fuel-rich combustion zone). There are several levels of improvements that can be made to the combustion chamber, which achieve this NO_X control at varying levels. NO_X emission reductions of 40% to 85% have been observed with low NO_X burners. [20]

Targa has determined that this method of NO_X control is feasible for the boilers at the facility. The boilers at Eunice already have LN burners installed. The next step of control for the burners is to replace the current burners with ultra-low NO_X (ULN) burners. The vender for the boilers stated that it will be technically infeasible to run the boilers at times with the ULN burners because the fuel gas for the boilers is rich (i.e. has a higher Btu content). Due to the age of the boilers and the venders concerns with the fuel, Targa considers adding the ULN burners technically infeasible, as the boilers will not be able to operate under current conditions. No further assessment of these control practices has been included in this report.

2.2.2.2.3 Flue Gas Recirculation

In a Flue Gas Recirculation (FGR) system, a portion of the flue gas is recycled from the stack to the burner or combustion zone. Upon entering the wind box, the recirculated gas is mixed with combustion air prior to being fed into the burner. The recycled flue gas consists of combustion products which act as inerts during combustion of the fuel/air mixture. The FGR system reduces NO_X emissions by two mechanisms. Primarily, the recirculated gas acts as a diluent to reduce combustion temperatures, thus suppressing the thermal NO_X formation mechanism. To a lesser extent, FGR also reduces NO_X formation by lowering the oxygen concentration in the primary flame zone. The amount of recirculated flue gas is a key operating parameter influencing NO_X emission reduction potential for these systems.

Targa has determined that this method of NO_X control is technically feasible for the boilers at the facility.

---

[20] U.S. EPA, AP-42, Section 1.4, "Natural Gas Combustion"

2.2.2.2.4 Selective Catalytic Reduction

The selective catalytic reduction (SCR) system for industrial boilers is similar to the process explained in Section 2.1.2.3 and involves injecting ammonia (NH_3) into the flue gas in the presence of a catalyst to reduce NOx emissions. The Alternative Control Techniques (ACT) document for utility boilers estimates NO_X reduction efficiencies for SCR control ranging from 70% to 90%.[21], [22] Historically, retrofitting SCR controls on boilers is difficult and affects the reliability of the boilers.[23] Additionally, SCR controls have significant electrical power requirements. The power at the plant would need to be upgraded significantly and re-designed in order to provide the necessary power for SCR controls. Therefore, SCR controls are considered a technically infeasible control option for the boilers located at Eunice and are not assessed further in this report.

2.2.2.2.5 Selective Non-Catalytic Reduction

The selective non-catalytic reduction (SNCR) system for industrial boilers is a chemical reaction that will reduce NO_X emissions by the NO_X reacting with a reagent, such as ammonia or urea, to create nitrogen and water. This reaction only takes place during a very specific temperature range of 1600 °F and 2100 °F. If the reaction takes place outside this temperature range, the NO_X reaction will not be favored.[24] The reagent is injected into the combustion chamber to promote the mixing of the reagent with the flue gas. The process of where and how the injection will happen depends on the specific boiler model and operation. The disadvantages to this control system is the specific operating temperature in which the reaction to reduce NO_X occurs. Low-loads will especially affect the temperature profile and optimum operating temperature of the control. Due to the specific operating parameters including temperature of the boilers at Eunice, Targa has deemed this control option as technically infeasible and will not assess it any further in this report.

3. COST OF COMPLIANCE

According to the EPA Control Cost Manual, there are five steps associated with evaluating the control cost effectiveness:

1. Obtain the facility parameters and regulatory options for a given facility;
2. Draft the control system design;
3. Size the control system components;
4. Estimate the costs of these individual components; and
5. Estimate the capital and annual costs of the entire system.

The cost effectiveness discussion and summary tables for the engines and boilers applicable to this analysis are provided in this section. Detailed cost control estimates are provided in Appendix B.

3.1. TWO-STROKE LEAN-BURN ENGINE CONTROLS

Table 5. Cost analysis summary of technically feasible controls for two-stroke lean-burn engines.

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)[a, b]	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Clean Burn Technology	C-01	**950,000[c]**	**179,495**	**118.28**	**1,517.53**
	C-02	**950,000[c]**	**179,495**	**40.82**	**4,396.91**
	C-03	**950,000[c]**	**179,495**	**30.12**	**5,959.33**
	C-04	**950,000[c]**	**179,495**	**77.27**	**2,323.09**
	C-05	**950,000[c]**	**179,495**	**74.04**	**2,424.14**
	C-06	**950,000[c]**	**179,495**	**121.00**	**1,483.48**
	C-07	**950,000[c]**	**179,495**	**100.97**	**1,777.73**
	C-09	**950,000[c]**	**179,495**	**10.09**	**17,797.69**

	C-12	**950,000[c]**	**179,495**	**6.91**	**25,969.35**
	C-13	**950,000[c]**	**179,495**	**199.09**	**901.58**

[a] Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

[b] This cost does not include annual operating costs for upgrade to the electrical substation that would incur. A full engineering assessment would need to be completed in order to know the full annual cost of this upgrade.

[c] The Capital Cost does not include the $1 million to $3 million required to upgrade the electrical substation at the site needed to power blowers for the CTB technology. A full engineering assessment would need to be completed in order to know the full cost of this upgrade.

3.1.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. There is no further cost to assess for this control technology.

3.1.2. Clean Burn Technology

Targa has received an estimated direct capital costs for the equipment and vendor labor associated with implementing a CBT on the 2SLB models located at Eunice from the engine control vendor. Based on prior knowledge of the equipment, Targa estimated the direct annual costs (maintenance, operating labor, reagent cost, electricity cost, and catalyst cost) and indirect annual costs associated with Targa's internal labor, overhead and capital recovery for the project. Please note that the cost in Table 5 does not include the significant upgrade to the power substation at the plant to operate the blowers associated with these CTB controls as discussed in Section 2.2.12.2. The upgrade to the substation would require a Capital Cost of at least $1 million to $3 million. A full engineering design assessment would need to be completed before a final full cost can be provided.

This cost estimate assumes that the CBT will reduce NO_X emissions to an outlet concentration of 2 g/hp-hr, based on information provided by the engine control vender. The cost effectiveness for each engine control option are summarized in Table 5. The full cost estimation for each unit is included in Appendix B of this report. To calculate the emission reductions, Targa used the 2016 Emission Inventory (EI) data. This was compared to the maximum PTE emission rate of the equipment post-control to get an Emission Reduction (tpy) value. The Total Annual Cost was then divided by the Emission Reduction to come up with a Cost Effectiveness ($/ton) amount. Please note that since 2016, engines C-09, C-10, C-11, and C-12 are now operated as standby, backup units. They were replaced with electric driven compressors. Targa revised the emission limits for these engines reducing their annual operation to a maximum of 500 hours per year for each engine. Therefore, the 2016 emission inventory rates were reduced to a maximum of 500 hours per year for these engines multiplied by the emission rate of the unit used in the 2016 EI.

3.2. INDUSTRIAL BOILER CONTROLS

Cost effectiveness for each engine control option are summarized in Table 6.

Table 6. Cost Analysis Summary of Technically Feasible Controls for Industrial Boilers.

Control Equipment		Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Flue Gas Recirculation	B-01	**300,000**	**39,104**	**2.42**	**16,138.92**
	B-02	**300,000**	**39,104**	**2.02**	**19,371.44**

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

3.2.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. There is no further costs to asses for this control technology.

3.2.2. Low NO_X Burner

Targa has already employed LN burners on the boilers. There is no further costs to asses for this control technology.

3.2.3. Flue Gas Recirculation

Targa has received an estimated direct capital costs for the equipment and vendor labor associated with implementing a FGR on the boilers located at Eunice from the control vendor. Based on prior knowledge of the equipment, Targa estimated the direct annual costs (maintenance, operating labor, reagent cost, electricity cost, and catalyst cost) and indirect annual costs associated with Targa's internal labor, overhead and capital recovery for the project.

This cost estimate assumes that the FGR will reduce NO_X emissions to an outlet concentration of 45 ppm. The cost effectiveness for each engine control option are summarized in Table 4. To calculate the emission reductions, Targa used the 2016 Emission Inventory (EI) data. This was compared to the maximum PTE

emission rate of the equipment post-control to get an Emission Reduction (tpy) value. The Total Annual Cost was then divided by the Emission Reduction to come up with a Cost Effectiveness ($/ton) amount. The full cost estimation for each unit is included in Appendix B of this report.

4.1. TWO-STROKE LEAN-BURN ENGINE CONTROLS

4.1.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. There is no further time for compliance to assess for this control technology.

4.1.2. Clean Burn Technology

Targa estimates that approximately 7 years will be needed to budget, design, procure, permit, and install the CBT equipment from the time the facility is required to add this control.

4.2. INDUSTRIAL BOILERS

4.2.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. There is no further time for compliance to assess for this control technology.

4.2.2. Low NO_X Burners

Targa already employs LN burners. There is no further time for compliance to assess for this control technology.

4.2.3. Flue Gas Recirculation

Targa estimates that approximately 5 years will be needed to budget, design, procure, permit, and install, the FGR control equipment from the time the facility is required to add this control.

5.1. TWO-STROKE LEAN-BURN ENGINES

5.1.1. Good Combustion Practices and Fuel Selection

There are no anticipated unique or site-specific energy or non-air impacts imposed by continuing to use good combustion practices and fuel selection.

5.1.2. Clean Burn Technology

Clean burn technology control employs a combustion mixture with a higher air-to-fuel ratio, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. This will reduce NO_X emissions; however, a reduction in combustion temperature increases emissions of CO, due to incomplete combustion. The blowers associated with this control will require electrical power to operate. This additional power will cause additional strain on the electrical grid and require an upgrade to the electrical substation at the site.

5.2. INDUSTRIAL BOILERS

5.2.1. Good Combustion Practices and Fuel Selection

There are no anticipated unique or site-specific energy or non-air impacts imposed by continuing to use good combustion practices and fuel selection.

5.2.2. Low NOX Burner

There are no anticipated unique or site-specific energy or non-air impacts imposed by continuing to use LN burners.

5.2.3. Flue Gas Recirculation

There are no anticipated unique or site-specific energy or non-air impacts imposed by installing FGR.

6.1. TWO-STROKE LEAN-BURN ENGINE CONTROLS

6.1.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. No further information needs to be assessed in this section.

6.1.2. Clean Burn Technology

The estimated useful life of the CTB equipment is 20 years, based on industry standards for life of the controls.

6.2. INDUSTRIAL BOILERS

6.2.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. No further information needs to be assessed in this section.

6.2.2. Low NO_X Burners

Targa already employs LN burners. No further information needs to be assessed in this section.

6.2.3. Flue Gas Recirculation

The estimated useful life of the FGR equipment is 20 years, based on default values from the EPA Air Pollution Control Cost Manual.[25]

[25] Ibid.

7. RESULTS & CONCLUSION

Based on a comprehensive review of the RBLC, and engine control vendor's input of available control technologies for the natural-gas fired engines and boilers located at Eunice Gas Plant, Targa has determined that CBT and good combustion practices for the 2SLB engines and flue gas recovery for the boilers are the only technically feasible NO_X control options for the units being reviewed under this analysis. However, retrofitting with these technologies would require Targa to spend significant amounts of time (for design and installation) and capital. In addition, based on the predominant wind direction and that SO_2, not NOx, is the contaminant of interest for visibility impairment in Carlsbad Caverns, NOx emissions from these pieces of equipment are inconsequential for regional haze purposes. Thus, retrofitting the Eunice Gas Plant engines or boilers would be uneconomical and unnecessary for improving visibility.

APPENDIX A: RBLC TABLES

Attached are the RBLC tables, Table A-1 for the 2SLB Clark engines and Table A-2 for the natural gas boilers.

RBLCID	FACILITY_NAME	THROUGHPUT	POLLUTANT	CONTROL_METHOD_DESCRIPTION
TX-0678	FREEPORT LNG PRETREATMENT FACILITY	130 MMBTU/H	Nitrogen Oxides (NOx)	ultra-low NOx burners
TX-0682	GALENA PARK TERMINAL	129 MMBTU/H	Nitrogen Oxides (NOx)	low-NOx burners and SCR
TX-0708	LA PALOMA ENERGY CENTER	150 MMBTU/H	Nitrogen Oxides (NOx)	low-NOx burners, limited use
TX-0712	TRINIDAD GENERATING FACILITY	110 MMBTU/H	Nitrogen Oxides (NOx)	ultra-low NOx burners, limited use
TX-0811	LINEAR ALPHA OLEFINS PLANT	217 MM BTU / H	Nitrogen Oxides (NOx)	Low-NOX burners and Selective Catalytic Reduction (SCR). Ammonia slip limited to 10 ppmv (corrected to 3% O2) on a 1-hr block average.
VA-0325	GREENSVILLE POWER STATION	185 MMBTU/HR	Nitrogen Oxides (NOx)	ultra low-NOâ€ž burners
VA-0328	C4GT, LLC	902 mmcf/y	Nitrogen Oxides (NOx)	Low NOx burners
WV-0025	MOUNDSVILLE COMBINED CYCLE POWER PLANT	100 mmBtu/hr	Nitrogen Oxides (NOx)	Ultra Low-NOx Burners, Flue-Gas Recirculation, & Good Combustion Practices

APPENDIX B: COST ANALYSIS SUPPORTING INFORMATION

The cost analysis was based on information received from engine or boiler control vendors or knowledge on the particular equipment and is provided in Table B-1 below.

Table B-1. Engine and Boiler Cost Information.

Equipment	Model	Control Type	Purchased Equipment Cost [a] ($)	Direct & Indirect Installation Cost [b] ($)	Capital Cost ($)
Clark	BA-8	CBT	800,000	150,000	950,000
Clark	HBA-8	CBT	800,000	150,000	950,000
Clark	HBA-T8	CBT	800,000	150,000	950,000
Wicker	Type A	Flue Gas Recirculation	300,000	*	300,000

[a] The cost in this column is based on a control vendor estimated quote. This cost does not include the $1 million to $3 million required to upgrade the electrical substation at the site needed to power blowers for the CTB technology. A full engineering assessment would need to be completed in order to know the full cost of this upgrade.

[b] The cost in this column is based on Targa's knowledge of the equipment but does not include the additional costs of operating the upgraded electrical substation.

*The flue gas recirculation control includes piping in the cost and modifications to the facility which is accounted for under purchased equipment.

REGIONAL HAZE FOUR-FACTOR ANALYSIS
SSM FLARING ADDENDUM

Targa Midstream Services LLC – Eunice Gas Plant

SSM FLARING ADDENDUM

Targa appends the Four-Factor Analysis for Eunice Gas Plant with the following additional information on process and SSM flaring at our Eunice Gas Plant as requested in Liz Bisbey-Kuehn's November 14, 2019 emailed letter titled "Submittal Requirements for Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring as part of the Regional Haze Four-Factor Analyses".

In Targa's original Four-Factor Analysis report submitted on October 31, 2019, flaring associated with F-01, Acid Gas Flare, was discussed in Section 1.1.2. As such, we do not intend to include additional information about this flaring. Targa maintains that the redundant compression unit to be installed by December 30, 2020 constitutes effective emission control technology to meet emission reductions required under the Settlement Agreement and therefore, does not require additional review.

Table 1A below shows the flare emission rates permitted in the current NSR permit for Eunice Gas Plant.

Table 1A. Summary of Flaring Emissions at Eunice Gas Plant.

Unit	Equipment	NO_X (lb/hr)	NO_X (tpy)	SO_2 (lb/hr)	SO_2 (tpy)
F-01	Acid Gas Flare (Allowable Emissions)	0.3	0.12	--	--
F-01	Acid Gas Flare (Allowable SSM Emissions)	68.5	10.3	5,176.6	776.5[1]
F-02	Inlet and Residue Flare (Allowable Emissions)	0.03	0.12	0.06	0.2
F-02	Inlet and Residue Flare (Allowable SSM Emissions)	563.5	9.1	4,064.0	63.4

Targa does not have process streams that vent to flare during normal operations. Targa's authorized flaring is associated with startup, shutdown, and maintenance (SSM) events. As required under 20.2.7.14, Targa developed and implemented a plan to minimize emissions during routine and predictable startup, shutdown, and scheduled maintenance through work practice standards and good air pollution control practices. Targa has followed these requirements while continuing to look for ways to reduce and minimize emissions at the Eunice Gas Plant.

Targa minimizes emissions during startups, shutdowns, and maintenance activities through the use of industry standards and/or manufacturer recommended operating practices. In addition, equipment at the facility is equipped with safety devices that will aid in minimizing excess emissions during non-routine operating conditions. The following summarizes Targa's operational plans for minimizing excess emissions.

After reviewing options for minimizing emissions associated with flaring at Targa's Eunice Gas Plant, Targa has not identified any new options to lower flared emission rates beyond what it is already doing. Below is a more detailed explanation of what Targa already does to minimize emissions at the gas plant.

[1] Permit amendment for redundant AGI compressor has not been submitted and will lower annual PTE for SSM emissions significantly from EPN F-01. See Section 1.1.2 of Eunice's Four-Factor Analysis Report submitted 10/31/2019.

1.1. MAINTENANCE

Targa takes a pro-active approach to facility and equipment maintenance. Operations personnel are aware of the importance of proper and efficient operation of equipment. Moreover, Targa recognizes the economic incentives to maintain and operate equipment efficiently. Malfunctioning equipment wastes resources and costs money.

Equipment at the facility is maintained in accordance with manufacturers' recommendations, industry best operating practices, and Targa's own practices designed to minimize downtime and non-routine operations. Procedures exist for maintenance of each major piece of equipment; personnel are trained in proper procedures; and Targa's own internal review processes ensure that procedures are followed. As a result, non-routine operational events and consequent excess emissions are minimized.

1.2. STARTUP AND SHUTDOWN

Targa's Eunice Gas Plant is shutdown annually, in conjunction with required third party pipeline maintenance outages. During this downtime, Targa conducts annual inspections and maintenance of its equipment to minimize downtime. However, due to the nature of oil and natural gas production, natural gas production rates cannot be easily turned on and off when a gas plant needs to be offline for maintenance activities. When natural gas cannot be processed, the gas must be vented or combusted.

During startup of the gas plant some flaring is necessary and cannot be avoided. The first processing step at the plant involves removal of carbon dioxide (CO_2) and hydrogen sulfide (H_2S) followed by the removal of water from the gas. This processing is necessary because Eunice utilizes a cryogenic process to split out methane from the heavier hydrocarbons found in raw natural gas. The cryogenic process operates at approximately -150°F. Due to this very cold temperature, the gas must meet very low specifications for water, CO2 and H2S content. Additionally, the natural gas, methane, produced from the cryogenic process must meet several specifications for BTU value as well as ethane content prior to the pipeline accepting the gas.

During startup, the gas will not initially meet the specifications required to go onto the next step in the process. Therefore, there is a period of time flaring of the gas prior to being able to introduce it into the next step of the process. Therefore, the gas must be flared initially until the stream reaches the specifications and can be routed to the next step in the process.

1.3. MINIMIZING EMISSIONS

To reduce emissions during equipment shutdowns for maintenance or operational outages, procedures are designed to minimize the duration of events. Such procedures include the following:

- Compression and other operational loads may be shifted to other units.
- Maintenance may be scheduled for periods of low load.
- Use of spare equipment to maintain operating rates during routine maintenance downtime of certain equipment, like natural gas fired engines.
- Multiple maintenance activities may be scheduled to occur simultaneously.
- Gas may be routed to other nearby gas plants.
- Producers may be asked to shut-in production to minimize gas flow to the plant.
- Startup is conducted with lower H_2S gas streams. Higher H_2S streams are not introduced to the gas plant inlet until the plant is operating normally.

- Compressors are first blown down to lower pressure process equipment prior to venting to reduce volume of process gas emitted (for example blowdown higher stage compressors to first stage suction at approximately 5 psig rather than venting from operating pressure that can be over 100 psig).
- Startup procedures for the turbines and engine are normally completed in less than five minutes, and shutdown procedures are normally completed in less than two minutes.

Targa believes the Eunice Gas Plant already utilizes efficient processes and mitigation strategies to reduce flaring emissions through the use of an acid gas injection system as well as by the techniques explained in this addendum. Targa is not aware of control technology that could further reduce emissions from the gas plant.

1. EXECUTIVE SUMMARY

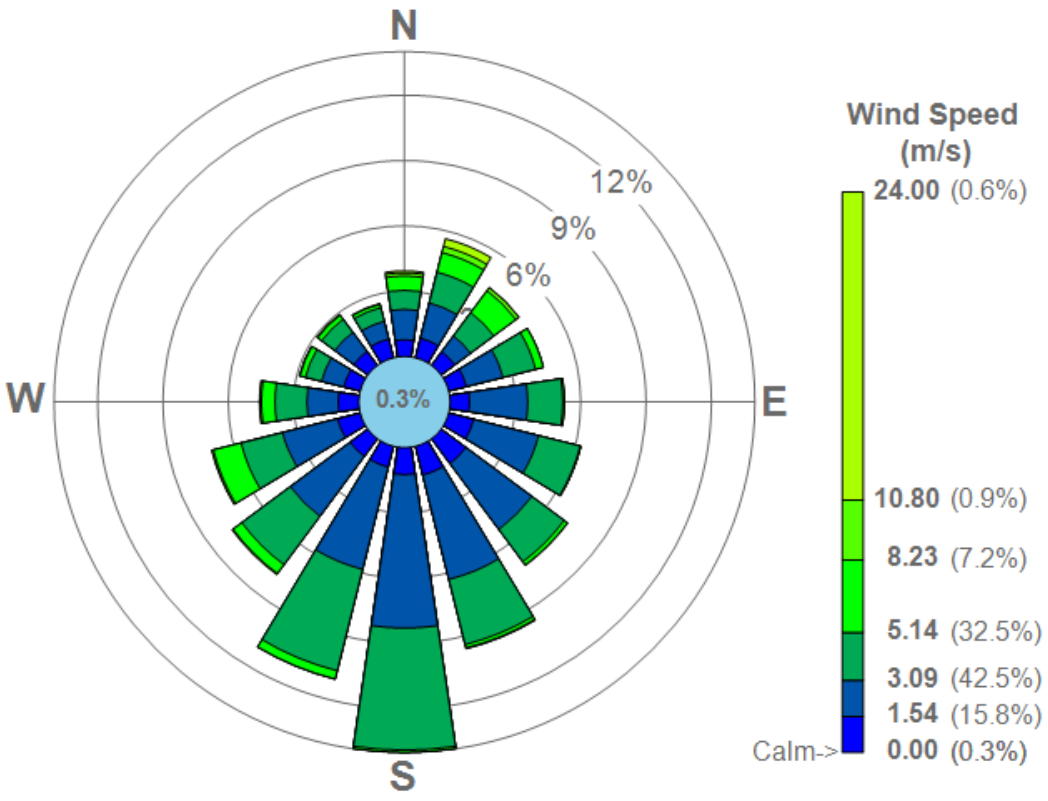
In the 1977 amendments to the Clean Air Act (CAA), Congress set a national goal to restore national parks and wilderness areas to natural conditions by remedying existing, anthropogenic visibility impairment and preventing future impairments. On July 1, 1999, the U.S. Environmental Protection Agency (EPA) published the final Regional Haze Rule (RHR).[1] The objective of the RHR is to restore visibility to natural conditions in 156 specific areas across the United States, known as Class I areas. The Clean Air Act defines Class I areas as certain national parks (over 6,000 acres), wilderness areas (over 5,000 acres), national memorial parks (over 5,000 acres), and international parks that were in existence on August 7, 1977.

The RHR requires states to set goals that provide for reasonable progress towards achieving natural visibility conditions for each Class I area in their jurisdiction. In establishing a reasonable progress goal for a Class I area, each state must:

> *(A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, and include a demonstration showing how these factors were taken into consideration in selecting the goal. 40 CFR 51. 308(d)(1)(i)(A).*
>
> *(B) Analyze and determine the rate of progress needed to attain natural visibility conditions by the year 2064. To calculate this rate of progress, the State must compare baseline visibility conditions to natural visibility conditions in the mandatory Federal Class I area and determine the uniform rate of visibility improvement (measured in deciviews) that would need to be maintained during each implementation period in order to attain natural visibility conditions by 2064. In establishing the reasonable progress goal, the State must consider the uniform rate of improvement in visibility and the emission reduction. 40 CFR 51. 308(d)(1)(i)(B).*

Currently, we are in the second planning period for national regional haze efforts. There are a few key distinctions from the processes that took place during the first planning period. Most notably, the second planning period analysis will distinguish between "natural" and "anthropogenic" sources. Using a Photochemical Grid Model (PGM), the Western Regional Air Partnership (WRAP) in coordination with the EPA will compare anthropogenic source contributions against natural background concentrations.

Pursuant to 40 CFR 51.308(d)(3)(iv), "The State must identify all anthropogenic sources of visibility impairment considered by the State in developing its long-term strategy. The State should consider major and minor stationary sources, mobile sources, and area sources." To accomplish this for major stationary sources, the New Mexico Environment Department (NMED) reviewed 2016 emission inventory data for Title V sources and screened each facility's potential impact on visibility in Class I areas using a "Q/d" analysis, where "Q" is the magnitude of emissions that could impact ambient visibility, and "d" is the distance of a facility to a Class I area. From this analysis, 24 facilities were identified by the NMED. On July 19, 2019 the NMED informed Targa Midstream Services LLC (Targa) that its Monument Gas Plant was identified as one of the sources potentially contributing to regional haze at the Carlsbad Caverns National Park Class I Area.



[1] Federal Register / Vol. 64, No. 126 /Thursday, July 1, 1999 (https://www.govinfo.gov/content/pkg/FR-1999-07-01/pdf/99-13941.pdf).

1.1. CONTRIBUTION TO VISIBILITY

1.1.1. Lack of Contribution to Visibility Impairment Due To Prevailing Winds

The NMED did not consider actual contribution to visibility impairment when selecting sources for the Four-Factor Analysis, but this is a critical factor in establishing realistic reasonable progress goals for Class I areas. In Figure 1-1 below, the prevailing wind from Hobbs, NM, can be used to estimate this facility's potential impact on the nearest Class I Area, Carlsbad Caverns National Park. Targa's Monument Gas Plant is located approximately 68.2 miles northeast at a wind vector of 65.9 degrees from the Carlsbad Caverns. The 2015 meteorological data from the NMED website at the Hobbs, NM meteorological station shows that wind blows from 56.3 to 78.8 degrees at a frequency of approximately 4.5%.[2] Based off this infrequent amount of time the wind blows from Targa's Monument Gas Plant toward Carlsbad Caverns, Targa believes that it is unlikely that the facility's potential emissions impact visibility at Carlsbad Caverns. Therefore, when balancing retrofit costs and visibility improvements, NMED should remain mindful that emissions from this facility are unlikely to contribute to regional haze at Carlsbad Caverns.

Figure 1-1. Hobbs, NM Meteorological Data, 2015 Wind rose

[2] https://www.env.nm.gov/air-quality/meteorological-data/

1.1.2. Lack of Contribution to Visibility Impairment Due to Already Effective SO_2 Controls

Further, with respect to SO_2 emissions, Targa controls H_2S emissions from the amine unit through operation of an acid gas injection (AGI) well and is in the process of adding redundant electric compression to the AGI well system to further reduce SO_2 emissions from the flare during SSM and malfunction events. The addition of the redundant electric compression is solely required by a Settlement Agreement and Stipulated Final Compliance Order between the Environmental Protection Division of the New Mexico Environment Department and Targa Midstream Services LLC. Targa expects this project to reduce flaring emissions at Monument Gas Plant by approximately 150-200 tons per year of SO_2. The installation of the redundant compression constitutes effective emission control technology to meet emission reductions required under the Settlement Agreement. This project will be complete by September 1, 2020; therefore, occurring during the 2nd Planning Period. There are no further SO_2 control options for the amine unit. Thus, the only equipment at this facility subject to this regional haze evaluation emit NOx.

Per 40 CFR 51.308(f)(2) of the Regional Haze rule, the NMED must determine emission reduction measures that are necessary to make reasonable further progress. The NMED, in an outreach webinar on Regional Haze Planning held on October 2, 2019, presented data on the most impaired days. This presentation identified ammonium sulfate as the largest contributor of visibility impairment in the National Parks of New Mexico. Ammonium sulfate is a byproduct of gaseous sulfur dioxide which becomes oxidized in the atmosphere to form sulfate particulate matter. This sulfate particulate matter is composed of sulfuric acid and corresponding salts such as ammonium sulfate. Since this information indicates the major contribution to regional haze is from sulfur dioxide emissions, not nitrogen dioxide emissions, the NMED should ensure that any required NOX reductions show significant contribution to improving visibility prior to requiring capital expenditures. Because emissions from Targa's Monument Gas Plant are not expected to impact visibility in the Carlsbad Caverns National Park Class I Area based on predominant wind direction (see Section 1.1), the NMED should find all technically feasible NO_X controls for the Monument Gas Plant economically unreasonable.

1.2. EQUIPMENT ANALYSIS

In coordination with guidance provided by WRAP, the NMED devised criteria to determine specific equipment that is subject to the four factor analysis. In the NMED's notification letter to Targa, they specify that any equipment with a potential to emit (PTE) greater than 10 pounds per hour (lb/hr) and 5 tons per year (tpy) of Nitrogen Oxides (NO_X) or Sulfur Dioxide (SO_2) shall be included in this analysis. The equipment at the facility that is subject to this analysis, the PTE associated with that equipment, and the applicability of a four-factor analysis for each pollutant, are reported in Table 1.

Table 1. Summary of equipment and applicability of the four-factor analysis.

Unit	Equipment	NO_X (lb/hr)	NO_X (tpy)	NO_X Subject to Analysis? (Yes/No)	SO_2 (lb/hr)	SO_2 (tpy)	SO_2 Subject to Analysis? (Yes/No)
C-01	Natural Gas Fired Two-Stroke Lean-Burn Engine	27.8	121.8	Yes	0.11	0.47	No
C-02	Natural Gas Fired Two-Stroke Lean-Burn Engine	27.8	121.8	Yes	0.11	0.47	No
C-04	Natural Gas Fired Two-Stroke Lean-Burn Engine	25.1	109.9	Yes	0.06	0.26	No
C-05	Natural Gas Fired Two-Stroke Lean-Burn Engine	25.1	109.9	Yes	0.06	0.26	No
C-06	Natural Gas Fired Two-Stroke Lean-Burn Engine	25.1	109.9	Yes	0.06	0.26	No
C-24	Natural Gas Fired Two-Stroke Lean-Burn Engine	41.9	183.5	Yes	0.17	0.76	No
C-28	Natural Gas Fired Two-Stroke Lean-Burn Engine	16.6	72.7	Yes	0.13	0.58	No
AM-01/ F-03	Amine Gas Treating Unit/Flare[a]	-	-	No	5817.5	872.6	Yes

[a] This unit is controlled by an acid gas injection well during normal operations and a flare during SSM or malfunction activities. Hydrogen sulfide emissions from this unit are combusted to form sulfur dioxide at flare F-03.

Once the applicability of process equipment and pollutants has been determined, potential retrofit control technologies must be identified in accordance with 40 CFR 51, Appendix Y. At the recommendation of the NMED,[3] this is primarily achieved by utilizing RACT/BACT/LAER Clearinghouse (RBLC) data. In order to determine the most relevant and current retrofit controls available, the RBLC was queried for the two-stroke lean-burn engines over the past 20 years. Summaries of the search results are provided and discussed in Section 2 of this report. The facility engineers then reviewed the list of available retrofit technologies and performed a technical feasibility assessment for each control option. The required four-factor analysis is then conducted for those controls that are technically feasible.

Targa conducted the required Four Factor Analysis for engines listed in Table 1 above. Based on a comprehensive review of the RBLC and engine control vendor's input of available control technologies for natural gas fired engines, Targa determined the only feasible additional control option is installation of clean burn technology for the 2SLB engines.

2. BACKGROUND INFORMATION & TECHNICAL FEASIBILITY

2.1. SO_2 EMISSIONS

Targa controls H_2S emissions from the amine unit through operation of an acid gas injection (AGI) well at the site and is in the process of adding redundant electric compression to the AGI well system to further reduce SO_2 emissions during SSM and malfunction flaring events. The addition of the redundant electric compression is solely required by a Settlement Agreement and Stipulated Final Compliance Order between the Environmental Protection Division of the New Mexico Environment Department and Targa Midstream Services LLC. Targa expects this project to reduce SO_2 flaring emissions at the Monument Gas Plant by approximately 150-200 tons per year. The installation of the redundant compression constitutes effective emission control technology to meet emission reductions required under the Settlement Agreement. This project will be complete by September 1, 2020 and therefore occurs during the 2nd Planning Period.

There are no further control options for the amine unit. No further analysis should be necessary to evaluate SO_2 emissions from the amine treater since no additional control equipment can be added to reduce SO_2 emissions at the site. Therefore, Targa will not assess any further control technology for this process unit.

2.2. NO_X EMISSIONS

Monument Gas Plant has seven (7) natural gas-fired two-stroke lean-burn engines. Units C-01, C-02, C-04, C-05, C-06, C-24, and C-28 that are subject to review under this analysis. The only pollutant subject to evaluation for these units is nitrogen oxides (NO_X). More detailed information on each engine is listed in Table 2 below:

Table 2. Summary of equipment and applicability of the four-factor analysis.

Unit	Make & Model	Date of Manufacture	Permitted Capacity
C-01	Clark RA-8	1956	800 hp
C-02	Clark RA-8	1956	800 hp
C-04	Clark RA-6	1956	600 hp
C-05	Clark RA-6	1956	600 hp
C-06	Clark RA-6	1956	600 hp
C-24	Clark HRA-8	1969	880 hp
C-28	Cooper Bessemer GMVA-8	1977	1100 hp

2.2.1. Two-Stroke Lean-Burn Engines

Table 3. Potential Control Equipment for Two-Stroke Lean-Burn RICE

Control Equipment	Technically Feasible?	NO_X Control Efficiency
Good Combustion Practices and Fuel Selection	**Yes**	**Base Case**
Clean Burn Technology	**Yes**	**70% to 90%**
Selective Catalytic Reduction	**No**	**N/A**
Non-Selective Catalytic Reduction	**No**	**N/A**

2.2.1.1. Two-Stroke Lean-Burn Engines Background

A reciprocating internal combustion engine (RICE) is a device that uses the combustion of fuel and air in an internal chamber to generate a reciprocating motion and convert heat energy into mechanical work. The units use a piston to draw air and fuel into the combustion chamber and compress it. The compressed air/fuel mixture is then ignited, generating combustion in the chamber. The energy of combustion pushes out the piston, turning a crankshaft and producing mechanical work. In the same cycle, the products of combustion remaining in the chamber are released and exhausted from the unit.

Natural gas-fired RICE are separated into multiple design classes, including 2-stroke lean-burn (2SLB), 4-stroke lean-burn (4SLB), and 4-stroke rich-burn (4SRB). The four-stroke design uses four strokes of the piston, or two turns of the crankshaft, to complete the power cycle. The two-stroke design completes the power cycle in a single revolution of the crankshaft. Rich-burn engines are designed to operate close to the stoichiometric, or chemically balanced, air-to-fuel ratio (around 16:1) with exhaust oxygen levels less than 4%, while lean-burn engines operate at significantly higher air-to-fuel ratios (ranging from 20:1 to 50:1), with exhaust oxygen levels of 12% or more.[4] .

NO_X is formed in reciprocating engines by the following mechanisms:

(1) Thermal NO_X - the thermal dissociation and subsequent reaction of nitrogen (N_2) and oxygen (O_2) molecules during combustion,
(2) Fuel NO_X - the evolution and reaction of fuel-bound nitrogen compounds with oxygen, and
(3) Prompt NO_X - the early reactions of nitrogen intermediaries and hydrocarbon radicals in fuel.

The Monument engines also use natural gas fuel; therefore, the formation of prompt NO_X and fuel NO_X will again be insignificant, and this analysis will focus on thermal NO_X. The rate of NO_X formation through the thermal NO_X mechanism is highly dependent upon the air-to-fuel ratio, combustion temperature, and residence time at the combustion temperature. Maximum thermal NO_X formation occurs near the stoichiometric air-to-fuel mixture ratio because combustion temperatures are greatest at this ratio[5].

NO_X reduction in natural gas-fired RICE can be accomplished by three general methods, as follows:[6]

(1) Operational control methods, such as adjusting the timing or other operating parameters.

[4] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[5] Ibid.
[6] Ibid.

(2) Combustion control techniques, for example reducing the peak flame temperature or introducing inerts that limit initial NO_X formation.
(3) Post-combustion NO_X control technologies, which employ various strategies to chemically reduce NO_X.

The potential to emit (PTE) from each engine is reported in the Monument Gas Plant's NSR (0110M9R3) and Title V (P110-R2M1) permits as well as summarized in Table 1. Additionally, the NO_X emission rates from the RICE are calculated using stack test data.

2.2.1.2. Potential NO_X Controls for 2SLB Engines

Retrofit control options identified for 2SLB RICE were identified via comprehensive review of the RBLC and available technical literature and are summarized in Table 3. A detailed description and discussion of the technical feasibility and anticipated performance of each control is provided below.

2.2.1.2.1 Good Combustion Practices and Fuel Selection

NO_X emissions are caused by oxidation of nitrogen gas in the combustion air during fuel combustion. This occurs due to high combustion temperatures and insufficiently mixed air and fuel in the cylinder where pockets of excess oxygen occur. By following concepts from engineering knowledge, experience, and manufacturer's recommendations, good combustion practices for operation of the units can be developed and maintained by training maintenance personnel on equipment maintenance, routinely scheduling inspections, conducting overhauls as appropriate for equipment involved, and using pipeline quality natural gas. By maintaining good combustion practices, the unit will operate as intended with the lowest NO_X emissions.

Utilizing good combustion practices and fuel selection was identified in this review of the RBLC for the control of NO_X emissions from large natural gas-fired lean-burn stationary internal combustion engines; therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Monument Gas Plant. However, these practices are currently in use at Monument Gas Plant. No further assessment of these control practices has been included in this report.

Monument Gas Plant conducts routine maintenance on all engines at the site per manufacture recommendations using trained maintenance personnel and using pipeline quality natural gas.

2.2.1.2.2 Clean Burn Technology

Clean Burn Technology (CBT) is another term for utilizing combustion mixtures in engines with fuel-lean air-to-fuel ratios. This method of reducing NO_X emissions involves reconfiguring the engines by adding an air-to-fuel ratio controller so that they are capable of operating at more desirable ratios.

As described in Section 2.1.1 of this report, lean-burn engines operate at air-to-fuel ratios ranging from 20:1 to 50:1. A combustion mixture with a higher air-to-fuel ratio results in reduced NO_X emissions, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. 2SLB engines are typically designed to operate at the high air-to-fuel ratios employed in CBT; however, further increasing the air-to-fuel ratio in lean-burn engines can decrease the NO_X emissions.[7]

[7] State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines, State of New Jersey Department of Environmental Protection, 2003.

In order to avoid derating the engine, combustion air must be increased at constant fuel flow. To achieve this, the engine would need to be retrofitted with a turbocharger, which forces additional air into the combustion chamber, as well as an automatic air-to-fuel ratio controller.

Many 2SLB engines, such as naturally aspirated engines, do not have identical air-to-fuel ratios in each cylinder, which can result in limited ability to vary the air-to-fuel ratio. To maintain acceptable engine performance at lean conditions, high energy ignition systems (HEIS) have been developed that promote flame stability at very lean conditions.[8]

2SLB engines are mechanically capable of being retrofit with more sensitive air-to-fuel ratio controllers and running on higher air-to-fuel ratio combustion to control NO_X emissions. Therefore, it has been determined that this method of NO_X control is feasible for the 2SLB engines at Monument. On 2SLB RICE, air-to-fuel ratio adjustment generally achieves a 5 to 30% reduction in NO_X emissions; however, this reduction is very specific to each engine and typical loading.[9]

Targa was able to request potential NO_X reduction options from their engine control vendor including Clean Burn technology. The Clean Burn technology will reduce NO_X emissions between 70% and 90%. The units could be modified to operate with pre-combustion chambers and pilot fuel systems with Jet Cells which are needed to significantly lean the combustion mixture with the required capacity air source. The 2SLB engines will also need turbochargers or externally driven blowers added as well. If a 2SLB engine does need an externally driven blower, this will be an electric blower and require electricity to operate. At this time, Monument Gas Plant would have to significantly upgrade the power substation at the plant to operate blowers associated with these controls. The cost provided in Section 3 of this report does not include the cost to upgrade the electrical substation at the facility. An engineering design assessment would need to be completed before a total cost for the upgrade can be provided but is estimated at $1 million to $3 million.

Even with the power concerns, Targa has determined that this method of NO_X control is feasible for the 2SLB engines at the facility.

2.2.1.2.3 Selective Catalytic Reduction

Selective Catalytic Reduction (SCR) is the process by which a nitrogen-based reagent, such as ammonia or urea, is injected into the exhaust of a combustion unit. Within a reactor vessel containing a metallic or ceramic catalyst, the injected reagent reacts selectively with the NO_X in the exhaust to produce molecular nitrogen (N_2) and water (H_2O).[10] The chemical reactions for this process are shown in the equations below.

$$4\ NO + 4\ NH_3 + O_2 \rightarrow 4\ N_2 + 6\ H_2O$$
$$2\ NO_2 + 4\ NH_3 + O_2 \rightarrow 3\ N_2 + 6\ H_2O$$

An SCR system includes the catalyst, catalyst housing, reagent storage tank, reagent injector, reagent pump, pressure regulator, and an electronic control system. The electronic controls regulate the quantity of reagent injected as a function of engine load, speed, and temperature, so NO_X emissions reductions can be achieved. The

[8] Ibid.
[9] Ibid.
[10] U.S. EPA, Office of Air Quality Planning and Standards, "Air Pollution Control Technology Fact Sheet (Selective Catalytic Reduction (SCR))," EPA-452/F-03-032.

catalyst effectiveness can reduce over time and ultimately become inactive. This inactivity can be caused by the following: [11]

- Poisoning of the active sites by flue gas constituents;
- Thermal sintering of active sites due to high temperatures within the catalyst reactor;
- Blinding/plugging/fouling of active sites by ammonia-sulfur salts and particulate matter; and
- Erosion due to high gas velocities.

Typically, a small amount of ammonia is not consumed in the reactions and is emitted in the exhaust stream. These ammonia emissions are referred to as ammonia slip. Unreacted ammonia in the exhaust can form ammonium sulfates which may plug or corrode downstream equipment. Particulate-laden streams can blind the catalyst and may necessitate the application of a soot blower.[12]

For an SCR system to function properly, the exhaust gas must be within a particular temperature range (typically between 450 and 850 °F), the material of the catalyst will affect the specific temperature range the exhaust must operate within. Exhaust gas temperatures greater than the upper limit will cause the NO_X and ammonia to pass through the catalyst unreacted.[13]

In order for the chemical reactions necessary for SCR to occur effectively, the exhaust streams injected with the reagent must be fairly oxygen rich. The exhaust oxygen levels for 2SLB engines are sufficient to support these reactions; therefore, this technology can be used on lean-burn engines. That said, the RBLC does not identify SCR as a control for these specific engine models.[14] This is likely because there is limited operating experience to date with the use of SCR on 2SLB RICE. Additionally, there is a historical precedent that installation of SCR on 2SLB engines can result in significant technical complications, including a necessity to derate the engines and unreliable operation post-retrofit.

The engine control vendors did not offer or suggest SCR as a suitable control option as there are significant challenges to install this equipment on the 2SLB units at Monument. The main challenge is most 2SLB engines have a poor air-to-fuel ratio that will not support the SCR control. The vendors provided CBT technology as the technically feasible option to control NO_X emissions from 2SLB engines. As SCR control technology is not listed in the RBLC tables for 2SLB engines, has not been a proven as an effective control of NO_X emissions for 2SLB engines and has significant operating challenges for 2SLB engines, Targa has determined this control is technically infeasible.

2.2.1.2.4 Non-Selective Catalytic Reduction

Non-Selective Catalytic Reduction (NSCR) is a control technique that uses residual hydrocarbons and carbon monoxide (CO) in engine exhaust as a reducing agent for NO_X. In an NSCR system, hydrocarbons and CO are oxidized by oxygen (O_2) and NO_X. The excess hydrocarbons, CO, and NO_X pass over a catalyst (usually a noble metal such as platinum, rhodium, or palladium) that oxidizes the excess hydrocarbons and CO to H_2O and CO_2, while reducing NO_X to N_2.[15] This technique does not require additional reagents to be injected because the

[11] Ibid.
[12] Ibid.
[13] U.S. EPA, AP-42, Section 3.2, "Natural Gas-fired Reciprocating Engines"
[14] Ibid.
[15] Ibid.

unburned hydrocarbons in the engine exhaust are used as the reductant. The chemical reactions for this process are shown in the equations below.[16]

Phase 1:
$$2CO + O_2 \rightarrow 2CO_2$$
$$2H_2 + O_2 \rightarrow 2H_2O$$
$$HC + O_2 \rightarrow CO_2 + H_2O$$

Phase 2:
$$NO_X + CO \rightarrow CO_2 + N_2$$
$$NO_X + H_2 \rightarrow H_2O + N_2$$
$$NO_X + HC \rightarrow CO_2 + H_2O + N_2$$

The reactions in Phase 1 of the chemical process above function to remove excess oxygen from the exhaust stream. This step is necessary because if the oxygen is not removed, it will react more readily with the CO and hydrocarbons than the NO_X, thus reducing the NO_X removal.

Despite this oxygen removal step in the chemical process, the engine exhaust gas stream must already have low levels of excess oxygen, or the oxygen will not be fully removed in Phase 1 and the NO_X removal will not be efficient. Consequently, application of the NSCR control technique is effectively limited to engines with normal exhaust oxygen levels of 4% or less. This includes naturally aspirated 4SRB engines and some turbocharged 4SRB engines. In order to achieve effective NO_X reduction performance, the engine may need to be run with a richer fuel adjustment than normal, resulting in an exhaust excess oxygen level closer to 1%.[17]

The exhaust oxygen levels for 2SLB engines are not sufficiently low to support the reactions described above; therefore, this technology is not a method used to control NO_X emissions from lean-burn engines. Furthermore, NSCR was not identified in the review of the RBLC as a potential control of NO_X emissions from large natural gas-fired lean-burn stationary RICE and AP-42 Section 3.2 does not list NSCR as an available control technique for 2SLB engines.[18] For these reasons, it has been determined that this method of NO_X control is infeasible for the 2SLB engines at Monument.

[17] U.S. EPA, AP-42, Section 3.2, "Natural Gas-Fired Reciprocating Engines"
[18] Ibid.

According to the EPA Control Cost Manual, there are five steps associated with evaluating the control cost effectiveness:

1. Obtain the facility parameters and regulatory options for a given facility;
2. Draft the control system design;
3. Size the control system components;
4. Estimate the costs of these individual components; and
5. Estimate the capital and annual costs of the entire system.

The cost effectiveness discussion and summary tables for the engines applicable to this analysis are provided in this section. Detailed cost control estimates are provided in Appendix B.

3.1. TWO-STROKE LEAN-BURN ENGINE CONTROLS

Table 4. Cost analysis summary of technically feasible controls for two-stroke lean-burn engines.

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)[a, b]	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Clean Burn Technology	C-01	**900,000[c]**	**175,311**	**20.58**	**8,519.78**
	C-02	**900,000[c]**	**175,311**	**27.99**	**6,263.84**
	C-04	**900,000[c]**	**175,311**	**5.17**	**33,892.19**
	C-05	**900,000[c]**	**175,311**	**16.67**	**10,517.35**
	C-06	**900,000[c]**	**175,311**	**12.65**	**13,857.01**
	C-24	**900,000[c]**	**175,311**	**103.87**	**1,687.77**
	C-28	**850,000[c]**	**171,127**	**2.99**	**57,280.51**

[a]Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.
[b] This cost does not include annual operating costs for upgrade to the electrical substation that would incur. A full engineering assessment would need to be completed in order to know the full annual cost of this upgrade.
[c] The Capital Cost does not include the $1 million to $3 million required to upgrade the electrical substation at the site needed to power blowers for the CTB technology. A full engineering assessment would need to be completed in order to know the full cost of this upgrade.

3.1.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. There is no further cost to assess for this control technology.

3.1.2. Clean Burn Technology

Targa has received an estimated direct capital costs for the equipment and vendor labor associated with implementing a CBT on the 2SLB models located at Monument from the engine control vendor. Based on prior knowledge of the equipment, Targa estimated the direct annual costs (maintenance, operating labor, reagent cost, electricity cost, and catalyst cost) and indirect annual costs associated with Targa's internal labor, overhead and capital recovery for the project. Please note that the cost in Table 4 does not include the significant upgrade to the power substation at the plant to operate the blowers associated with these CTB controls as discussed in Section 2.2.12.2. The upgrade to the substation would require a Capital Cost of at least $1 million to $3 million. A full engineering design assessment would need to be completed before a final full cost can be provided.

This cost estimate assumes that the CBT will reduce NO_X emissions to an outlet concentration of 2 g/hp-hr, based on information provided by the engine control vender. The cost effectiveness for each engine control option are summarized in Table 4. The full cost estimation for each unit is included in Appendix B of this report. To calculate the emission reductions, Targa used the 2016 Emission Inventory (EI) data. This was compared to the maximum PTE emission rate of the equipment post-control to get an Emission Reduction (tpy) value. The Total Annual Cost was then divided by the Emission Reduction to come up with a Cost Effectiveness ($/ton) amount.

4.1. TWO-STROKE LEAN-BURN ENGINE CONTROLS

4.1.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. There is no further time for compliance to assess for this control technology.

4.1.2. Clean Burn Technology

Targa estimates that approximately 7 years will be needed to budget, design, procure, permit and install the CBT equipment from the time the facility is required to add this control.

5.1. TWO-STROKE LEAN-BURN ENGINES

5.1.1. Good Combustion Practices and Fuel Selection

There are no anticipated unique or site-specific energy or non-air impacts imposed by continuing to use good combustion practices and fuel selection.

5.1.2. Clean Burn Technology

Clean burn technology control employs a combustion mixture with a higher air-to-fuel ratio, because using fuel-lean mixtures lowers the combustion temperature by diluting energy input. This will reduce NO_X emissions; however, a reduction in combustion temperature increases emissions of CO, due to incomplete combustion. The blowers associated with this control will require electrical power to operate. This additional power will cause additional strain on the electrical grid and require an upgrade to the electrical substation at the site.

6.1. TWO-STROKE LEAN-BURN ENGINE CONTROLS

6.1.1. Good Combustion Practices and Fuel Selection

Targa already employs good combustion practices and fuel selection. No further information needs to be assessed in this section.

6.1.2. Clean Burn Technology

The estimated useful life of the CTB equipment is 20 years, based on industry standards for life of the controls.

7. RESULTS & CONCLUSION

Based on a comprehensive review of the RBLC, and engine control vendor's input of available control technologies for the natural-gas fired engines located at Monument Gas Plant, Targa has determined that CBT and good combustion practices for the 2SLB engines are the only technically feasible NO_X control options for the engines being reviewed under this analysis. However, retrofitting these technologies would require Targa to spend significant amounts of time (for design and installation) and capital. In addition, based on the predominant wind direction and that SO_2, not NO_X, is the contaminant of interest for visibility impairment in Carlsbad Caverns, NO_X emissions from these pieces of equipment are inconsequential for regional haze purposes. Thus, retrofitting the Monument Gas Plant engines would be uneconomical and unnecessary for improving visibility.

APPENDIX B: COST ANALYSIS SUPPORTING INFORMATION

The cost analysis was based on information received from engine control vendors or knowledge on the particular equipment and is provided in Table B-1 below.

Table B-1. Engine Cost Information.

Equipment	Model	Control Type	Purchased Equipment Cost [a] ($)	Direct & Indirect Installation Cost [b] ($)	Capital Cost ($)
Clark	RA-8	CBT	800,000	100,000	900,000
Clark	RA-6	CBT	800,000	100,000	900,000
Clark	HRA-8	CBT	800,000	100,000	900,000
Cooper Bessemer	GMVA-8	CBT	750,000	100,000	850,000

[a] The cost in this column is based on a control vendor estimated quote. This cost does not include the $1 million to $3 million required to upgrade the electrical substation at the site needed to power blowers for the CTB technology. A full engineering assessment would need to be completed in order to know the full cost of this upgrade.

[b] The cost in this column is based on Targa's knowledge of the equipment but does not include the additional costs of operating the upgraded electrical substation.

REGIONAL HAZE FOUR-FACTOR ANALYSIS
SSM FLARING ADDENDUM

Targa Midstream Services LLC – Monument Gas Plant

SSM FLARING ADDENDUM

Targa appends the Four-Factor Analysis for Monument Gas Plant with the following additional information on process and SSM flaring at Monument Gas Plant as requested in Liz Bisbey-Kuehn's November 14, 2019 emailed letter titled "Submittal Requirements for Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring as part of the Regional Haze Four-Factor Analyses".

In Targa's original Four-Factor Analysis report submitted on October 31, 2019, flaring associated with F-03, Acid Gas Flare, was discussed in Section 1.1.2. As such, we do not intend to include additional information about this flaring. Targa maintains that the redundant compression unit to be installed by December 30, 2020 constitutes effective emission control technology to meet emission reductions required under the Settlement Agreement and therefore, does not require additional review.

Table 1A below shows the flare emission rates permitted in the current NSR permit for Monument Gas Plant.

Table 1A. Summary of Flaring Emissions at Monument Gas Plant.

Unit	Equipment	NO_X (lb/hr)	NO_X (tpy)	SO_2 (lb/hr)	SO_2 (tpy)
F-01	Plant Flare (Allowable Emissions)	0.083	0.36	0.004	0.018
F-01	Plant Flare (Allowable SSM Emissions)	522.4	5.1	0.004	0.02
F-02	Emergency Flare (Allowable Emissions)	0.083	0.36	0.004	0.018
F-02	Emergency Flare (Allowable SSM Emissions)	631.0	2.0	6,865.3	17.5
F-03	Acid Gas Flare (Allowable Emissions)	0.083	0.36	0.004	0.018
F-03	Acid Gas Flare (Allowable SSM Emissions)	68.4	10.7	5,817.5	899.1[1]

Targa does not have process streams that vent to flare during normal operations. Targa's authorized flaring is associated with startup, shutdown, and maintenance (SSM) events. As required under 20.2.7.14, Targa developed and implemented a plan to minimize emissions during routine and predictable startup, shutdown, and scheduled maintenance through work practice standards and good air pollution control practices. Targa has followed these requirements while continueing to look for ways to reduce and minimize emissions at the Monument Gas Plant.

Targa minimizes emissions during startups, shutdowns, and maintenance activities through the use of industry standards and/or manufacturer recommended operating practices. In addition, equipment at the facility is equipped with safety devices that will aid in minimizing excess emissions during non-routine operating conditions. The following summarizes Targa's operational plans for minimizing excess emissions.

[1] Permit amendment for redundant AGI compressor has not been submitted and will lower annual PTE for SSM emissions significantly from EPN F-03. See Section 1.1.2 of Monument's Four-Factor Analysis Report submitted 10/31/2019.

After reviewing options for minimizing emissions associated with flaring at Targa's Monument Gas Plant, Targa has not identified any new options to lower flared emission rates beyond what it is already doing. Below is a more detailed explanation of what Targa already does to minimize emissions at the gas plant.

1.1. MAINTENANCE

Targa takes a pro-active approach to facility and equipment maintenance. Operations personnel are aware of the importance of proper and efficient operation of equipment. Moreover, Targa recognizes the economic incentives to maintain and operate equipment efficiently. Malfunctioning equipment wastes resources and costs money.

Equipment at the facility is maintained in accordance with manufacturers' recommendations, industry best operating practices, and Targa's own practices designed to minimize downtime and non-routine operations. Procedures exist for maintenance of each major piece of equipment; personnel are trained in proper procedures; and Targa's own internal review processes ensure that procedures are followed. As a result, non-routine operational events and consequent excess emissions are minimized.

1.2. STARTUP AND SHUTDOWN

Targa's Monument Gas Plant is shutdown annually, in conjunction with required third party pipeline maintenance outages. During this downtime, Targa conducts annual inspections and maintenance of its equipment to minimize downtime. However, due to the nature of oil and natural gas production, natural gas production rates cannot be easily turned on and off when a gas plant needs to be offline for maintenance activities. When natural gas cannot be processed, the gas must be vented or combusted.

During startup of the gas plant some flaring is necessary and cannot be avoided. The first processing step at the plant involves removal of carbon dioxide (CO_2) and hydrogen sulfide (H_2S) followed by the removal of water from the gas. This processing is necessary because Monument utilizes a cryogenic process to split out methane from the heavier hydrocarbons found in raw natural gas. The cryogenic process operates at approximately -150°F. Due to this very cold temperature, the gas must meet very low specifications for water, CO2 and H2S content. Additionally, the natural gas, methane, produced from the cryogenic process must meet several specifications for BTU value as well as ethane content prior to the pipeline accepting the gas.

During startup, the gas will not initially meet the specifications required to go onto the next step in the process. Therefore, there is a period of time flaring of the gas prior to being able to introduce it into the next step of the process. Therefore, the gas must be flared initially until the stream reaches the specifications and can be routed to the next step in the process.

1.3. MINIMIZING EMISSIONS

To reduce emissions during equipment shutdowns for maintenance or operational outages, procedures are designed to minimize the duration of events. Such procedures include the following:

- Compression and other operational loads may be shifted to other units.
- Maintenance may be scheduled for periods of low load.
- Use of spare equipment to maintain operating rates during routine maintenance downtime of certain equipment, like natural gas fired engines.
- Multiple maintenance activities may be scheduled to occur simultaneously.
- Gas may be routed to other nearby gas plants.

- Producers may be asked to shut-in production to minimize gas flow to the plant.
- Startup is conducted with lower H_2S gas streams. Higher H_2S streams are not introduced to the gas plant inlet until the plant is operating normally.
- Compressors are first blown down to lower pressure process equipment prior to venting to reduce volume of process gas emitted (for example blowdown higher stage compressors to first stage suction at approximately 5 psig rather than venting from operating pressure that can be over 100 psig).
- Startup procedures for the turbines and engine are normally completed in less than five minutes, and shutdown procedures are normally completed in less than two minutes.

Targa believes the Monument Gas Plant already utilizes efficient processes and mitigation strategies to reduce flaring emissions through the use of an acid gas injection system as well as by the techniques explained in this addendum. Targa is not aware of control technology that could further reduce emissions from the gas plant.

Permitting Administrative Multi-Form

Use for NSR administrative permit revisions (including GCPs), TV administrative amendments, TV responsible official notifications, and other submittals required by a permit condition. Refer to Section 4 for instructions, acronyms, and mailing addresses.

Section 2-D: Closing a Facility, Removing Units from a Permit, or Canceling an NOI

(Administrative Revision)

Check the appropriate boxes and provide complete information in the table. Closing the permit does not relieve the permittee from any outstanding permit fees.

If any of the units being removed are emission control equipment explain how a permit, federal regulation, or state regulation will not be violated by removal of the control equipment.

☐ Cease operations of the entire facility and close the construction permit (20.2.72.219.A(1)(c) NMAC).

Date the facility ceased operating:

☒ Retire an emissions unit and remove it from the construction permit (20.2.72.219.A(1)(c) NMAC).

Date unit(s) retired: **01/01/2021**
List all retired unit numbers to be removed from the permit: **A-01, C-01, C-02, C-03, C-04, C-05, C-06, C-07, C-08, C-09, F-01, F-03, G-01, G-02, G-03, and I-01**

☐ Close a construction permit for a facility or remove an emissions unit that has not and will not be constructed (20.2.72.219.A(1)(d) NMAC).

☐ Facility (plant) will not be constructed, or	☐ The following units will not be constructed and should be removed from the permit:

☒ Retire an emissions unit and remove it from the TV permit (20.2.70.404.A(1)(c) NMAC).

Date unit(s) retired: **01/01/2021**
List all retired unit numbers to be removed from the permit: **A-01, C-01, C-02, C-03, C-04, C-05, C-06, C-07, C-08, C-09, F-01, F-03, G-01, G-02, G-03, and I-01**

☒ Voluntary Discontinuation of the TV permit (20.2.70.400.I NMAC).

Explanation: **With the retirement of the equipment specified above, Targa has determined that the facility will have a potential to emit and actual emissions below Title V Major source thresholds and will no longer require a Title V permit to operate.**

☐ Close a construction permit that is no longer required.

Explanation:

☐ Removal of minor NSR exempt equipment.

Explanation:

☐ Cancel a Notice of Intent (check one or explain):

☐ PER is now below 20.2.73.200 NMAC threshold.	☐ Date the facility ceased operating:

(505) 266-6611

February 2020

Project 193201.0194

Environmental solutions delivered uncommonly well

Targa Midstream Services LLC (Targa) appends the Four-Factor Analysis for Eunice Gas Plant, Monument Gas Plant and Saunders Gas Plant with the following information requested by Kerwin Singleton's December 23, 2019 emailed letter titled "Request for Additional Information on Four-Factor Analysis under the Regional Haze Program." In addition, this submittal includes the SSM Flaring Addendum that NMED requested for the Saunders Gas Plant.

INTRODUCTION

In supplementing, at NMED's request, Targa's original four-factor analysis reports submitted on October 31, 2019, Targa wishes to re-assert as an initial matter that emissions from its facilities are unlikely to impact Class I areas at all. The NMED did not consider actual contribution to visibility impairment when selecting sources for the Four-Factor Analysis, but this is a critical factor in establishing realistic reasonable progress goals for Class I areas. As demonstrated in Section 1.1.1 of Targa's original reports, the location of Targa's facilities and meteorology make it unlikely that potential emissions could impact Class I areas. Therefore, when balancing retrofit costs and visibility improvements, NMED should remain mindful that emissions reductions from Targa's facilities are unlikely to contribute to improvement in regional haze at Class I areas.

RESPONSE TO FOUR-FACTOR ANALYSIS QUESTIONS

Please find below Targa's response to questions from the NMED December 23, 2019 letter on the Four-Factor Analysis reports that Targa submitted on October 31, 2019 for the Monument, Eunice, and Saunders Gas Plants.

1. Overarching (for all 3 facilities)

a. Please provide the electronic spreadsheets used to determine the costs of control technologies for all three facilities for all sources subject to the four-factor analysis.

Targa has included a CD with copies of the Excel spreadsheets used in the Four Factor Analyses for the three plants.

b. Flaring: Please provide the following information for the flares at the Targa facilities with emission limits of NOX and/or SO2 greater than 10 pounds per hour (pph) and equal to or greater than 5 tons per year (tpy): Monument Gas Processing Plant F-01, F-02, F-03; Eunice Gas Processing Plant F-01 and F-02; Saunders Gas Processing Plant F-01.

i. If not already provided in the SSM Flaring Addendum submitted on December 13, 2019 from the Eunice and Monument gas plants, please provide a description of each flare and all of its purposes.

Facility	Flare Unit No.	Description
Monument Gas Plant	F-01	Process flare used during maintenance or upset events within the facility to control residue gas (pipeline quality natural gas). Flare meets 40 CFR 60.18 requirements with a 98 % destruction efficiency.
	F-02	Process flare used during maintenance or upset events within the facility to combust inlet gas. Flare meets 40 CFR 60.18 requirements with a 98 % destruction efficiency.
	F-03	Process flare used during AGI well maintenance or upset events within the facility to combust acid gas. Flare meets 40 CFR 60.18 requirements with a 98 % destruction efficiency.
Eunice Gas Plant	F-01	Process flare used during AGI well maintenance or upset events within the facility to combust acid gas. Flare meets 40 CFR 60.18 requirements with a 98 % destruction efficiency.
	F-02	Process flare used during maintenance or upset events within the facility to combust inlet and residue gas. Flare meets 40 CFR 60.18 requirements with a 98 % destruction efficiency.
Saunders Gas Plant	F-01	Process flare used during SRU maintenance or upset events when the SRU is not operating to combust acid gas. Flare meets 40 CFR 60.18 requirements with a 98 % destruction efficiency.

ii. Provide the startup, shutdown, and maintenance plan required by 20.2.7.14 NMAC that was mentioned as the existing and only method and that is currently implemented to reduce SSM flaring emissions, including any equipment maintenance and training plans used to prevent outages. According to the December 13, 2019 submittal, there are no other alternatives to reducing emissions other than that is required by 20.2.7.14 NMAC. If it is not possible to make any improvements to the facility or its processes to reduce SSM flaring events, then please explain why.

Targa is commercially and economically incentivized to minimize SSM downtime, and thereby SSM flaring. Further, the AQB's excess emissions reporting rules and enforcement process incentivize Targa to minimize SSM downtime and SSM flaring. Targa's existing O&M policies and SSM Plans were designed and are implemented accordingly. As explained in Targa's SSM Flaring Addendums (and in Section 4 of this submittal for the Saunders Gas Plant), Targa takes a number of steps to prevent and reduce SSM flaring, and Targa's practices comply with NMED's "minimize emissions" requirements in 20.2.7.14 NMAC. That said, it is infeasible to completely eliminate SSM downtime and SSM flaring emissions—indeed, Targa has represented expected SSM emissions in permit applications and the AQB authorized those emissions.

Targa's SSM plans are attached to this submittal in Appendix B.

iii. List and describe all of the reasons that trigger each type of flaring event. This is to identify and clarify the causes to help find potential solutions to reduce flaring emissions.

Please refer to Targa's SSM Flaring Addendums, Section 4 of this submittal (Saunders Gas Plant), and the table in Section b.i. above.

iv. Include a discussion of any potential alternative control options or operational changes that could reduce flaring NO_X and/or SO_2 emissions, including but not limited to:

a. infrastructure that allows recovering and re-routing or recirculating the gas within the facility or outside of the facility until an SSM event is over;

This option is outside the scope of the haze analysis. The regional haze planning process should result in establishment of emissions limitations or other limitations (40 C.F.R. 51.308(f)(2)) that may be met by applying retrofit technologies or practices to an existing source, not redefining a source. *See* 40 C.F.R. Part 51, App. Y ("We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis."). As demonstrated below, this option would completely redefine the gas processing plants.

Rerouting gas volumes to other facilities is currently in place when a facility has an SSM event. However, inlet gas to a facility cannot be diverted or routed directly to a sales meter or transmission pipeline (bypassing the facility) due to contaminants in the inlet gas such as water, CO2, H2S, and heavy liquids. Sales pipelines cannot and will not take inlet gas unless it meets certain specifications. Inlet gas cannot be recirculated back to the producer or field system. Producer gas continues flowing until high pressure limits of equipment and/or pipe is reached, resulting in flaring or physically shut-in gas at the well head.

As stated above and in the SSM flaring addendums, the current operating system will route gas to other nearby gas plants when possible during SSM or upset events.

b. sulfur absorbent technology used to remove sulfur from pipelines and other auxiliary equipment to reduce inlet or plant flaring SO_2 emissions;

Targa already utilizes sulfur absorbent technology, amine, to remove H_2S and CO_2 from the inlet gas. Targa's Four Factor Analysis did not include selective chemical absorption where the H_2S remains in the liquid and disposed as hazardous waste. Non regenerative chemical absorbent technology is not designed for high volumes (100 MMSCFD) or high H_2S concentrations. When there are both high volumes and high H_2S concentrations, the amount of chemical absorbent needed is extremely high and it is technically infeasible to store the amount of absorbent needed on a daily basis or the ability to replenish the spent chemical to remove H_2S from the stream. A gas plant is a gathering system of wells that all converge in a pipeline to the facility. This technology was designed to use on a much smaller scale than a gas plant.

c. Gas Capture Plans with facilities located downstream and upstream similar to those required for producers to better synchronize upstream and downstream services with the Targa facilities;

As the question implies, New Mexico's rules do not require midstream companies to maintain gas capture plans. Requiring Targa to maintain a gas capture plan would not reduce flaring at its

gas plants for at least three reasons. First, Targa already coordinates with upstream producers and downstream pipelines to plan for scheduled outages, and so further coordination requirements would be duplicative and not cost effective. Second, scheduled maintenance, unexpected equipment malfunctions, or third-party power outages are the typical cause of gas plant flaring—not upstream or downstream coordination problems. Third, gas capture plans are only required for producers and may reduce well site flaring. The outcome of the regional haze process, however, should be an enforceable emissions limitation or other limitation at the source under review, and gas capture plans can neither be converted into an enforceable limitation nor reduce flaring at the source under review (i.e. gas plants).

d. use of remote capture equipment;

A remote gas capture system is a small gas plant (produces NGLs). Targa is unaware of this technology ever being "proven" for use at a gas processing plant. For that reason alone, Targa considers this technology infeasible. 40 C.F.R. Part 51, App. Y (regarding how to identify available retrofit emission control technologies, stating "[t]echnologies which have not yet been applied to (or permitted for) full scale operations need not be considered as available; we do not expect the source owner to purchase or construct a process or control device that has not already been demonstrated in practice.").

For Targa's gas plants in particular, using this technology would be technically infeasible for 100 MMSCFD gas plants due to the size and H_2S content of the gas. In addition, when a downstream facility has a malfunction, Targa is unable to send gas or NGL liquids to the outlet pipelines. In these instances, especially, a gas capture system would not work since there would be no place to send the gas or liquids downstream.

Further, the regional haze analysis focuses on the source under review (Targa's gas plants), and not interconnected sources (upstream oil and gas wells). The NMED's Draft Methane Advisory Panel Report, for example, assesses the use of remote capture equipment only for upstream operators. As that report notes, well sites may have the space for this equipment as well pads designed for hydraulic fracturing will have additional space become available when well pad equipment is removed. Further, upstream operators may be able to deploy this technology knowing that there will be a reliable stream of "shut-in" gas to be captured, such as when buildout of a gathering system is delayed. This investment would be infeasible for a gas processing plant that goes to flare during limited SSM periods.

e. better infrastructure planning and changes to existing infrastructure that connects the downstream and upstream operations to ensure that there is adequately processing capacity to move produced gas to market.

Targa does not and cannot control upstream infrastructure planning. This process is largely driven by upstream operators and regulatory agencies such as the NMOCD, the N.M. State Land Office, and the Bureau of Land Management. For its part, Targa has adequate infrastructure for connecting and continues developing infrastructure to connect downstream and upstream operations in New Mexico. Thus, Targa already has the infrastructure in place to adequately process and move produced gas to market while mitigating flaring emissions as much as possible.

v. For any technically feasible solutions, provide a four-factor analysis. For additional information regarding potential alternative controls to flaring see the New Mexico Methane Strategy.

Targa has been involved in the development of the New Mexico Methane Strategy. For example, Targa's Director of Air Permitting gave a technical presentation to the Methane Advisory Panel on natural gas dehydration units. To date, that Panel has only produced a *draft* technical report that includes discussion of addressing flaring and venting in New Mexico. Targa reviewed the draft report and did not see any midstream-specific NOx or SO_2 solutions that should be considered technically feasible for a four-factor analysis.

c. Engines: Please provide the following information for all engines that were evaluated in the Four-Factor Analysis for NO_X:

Targa is providing the requested information below. However, as an initial matter, note that NMED has presented information identifying ammonium sulfate as the largest contributor to visibility impairment in New Mexico's National Parks. Ammonium sulfate is a byproduct of gaseous sulfur dioxide which becomes oxidized in the atmosphere to form sulfate particulate matter. This information indicates that the major contribution to regional haze is from sulfur dioxide emissions, not nitrogen dioxide emissions. Thus, NMED should ensure that any required NOx reductions show significant contribution to improving visibility prior to requiring capital expenditures. Because emissions from Targa's facilities are not expected to impact visibility in Class I areas, any technically feasible NOx controls are economically unreasonable.

i. Natural gas-fired two-stroke lean-burn (2SLB) engines from the three gas plants have widely varying emissions rates and control efficiencies. Please explain why there are such large differences for engines that are the same make, model, and horsepower.

The cost analyses submitted to the NMED on October 31, 2019 were based on 2016 actual emissions. Actual emissions were calculated based on 2016 hours of operation multiplied by the stack tested emission rate. With regards to the engine usage, Targa attempts to use its engines uniformly but this does not mean equally on a calendar year basis. The annual hours of operation will depend on various factors. The main reasons may be a unit's service availability (is it working or not), or if the unit requires scheduled maintenance (i.e. the unit may be scheduled to be swapped with an identical unit). As such, each year the engines will operate with different hours of operation and fuel usage. Since the NMED requested 2016 actual emissions be used in the cost analysis, the cost calculations for each unit will have varying emission totals which creates varying costs per ton for identical engines. Per AP-42 Section 3.2.3 "It is not unusual to test emissions from two identical engines in the same plant, operated by the same personnel, using the same fuel, and have the test results show significantly different emissions. This variability in the test data is evidenced in the high relative standard deviation reported in the data set." Stack tests are a snapshot in time and only provide potential emissions based on that snapshot. See the included Excel spreadsheets for details on the emission rate calculations.

ii. Targa states that some compressors that were previously powered by natural gas-fueled engines used at the Eunice Gas Processing Plant were replaced with compressors powered by commercial electric power. Please consider and include a discussion on the feasibility of replacing more natural gas-fueled engines with commercial electric powered compressors at Eunice and other facilities.

The regional haze planning process should result in establishment of emissions limitations or other limitations (40 C.F.R. 51.308(f)(2)) that may be met by applying retrofit technologies or practices to an

existing source, not redefining a source. *See* 40 C.F.R. Part 51, App. Y ("We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis."). Thus, replacement of one source (natural gas-fired engines) with another (electric compression) is beyond the scope of the regional haze analysis.

Further, Targa is unable to add additional electric driven compression to Monument or Eunice without significant investment in electrical infrastructure at the sites. Electrical substations would need to be built at the Eunice and Monument Gas Plants. In addition, the power to the plants would need to be upgraded by the electrical provider. Saunders Gas Plant currently generates power from on-site generators.

iii. Consider and include a discussion of variations of Clean Burn Technology (CBT) used to reduce NO_X emissions that may be less expensive than the full CBT packages proposed. Please include cost and efficiencies in the analysis.

Targa has provided an updated cost analysis for Clean Burn Technology on the Cooper Bessemer engines showing an optional NO_X reduction to 5 g/hp-hr as an alternative to the 2 g/hp-hr reduction provided in the original analysis. To meet 5 g/hp-hr the engines would need to add a pre-combustion chamber with power cylinder heads, modification to the fuel system, a turbocharger system, and combustion air intercoolers with jacket water. To meet 2 g/hp-hr, the same equipment would need to be installed to meet the base reduction plus an additional intercooler water circuit radiator and electric motor driven water pump to operate a lower temperature water system for air cooling.

Please note, some units tested below 5 g/hp-hr for 2016 and are not included in this updated control analysis. Also, unit C-03 at Eunice had incorrect emissions reported in the 2016 Emission Inventory. The correct emission rate should be based on 14.192 g/hp-hr, the 2015 performance test on the engine. See further discussion in 3.b. This cost analysis is attached to Appendix A.

iv. Please provide vendor quotes that include the cost information, recommendations, and equipment specifications for the engine control cost estimates.

Targa has included the requested vendor cost estimate, recommendations, and equipment specifications in Appendix B. This appendix has been marked confidential and included separately as vendor data is confidential.

v. Provide the technical basis for the "historical precedent that installation of SCR on two-stroke lean-burn (2SLB) engines can result in significant technical complications, require deration of engines, and unreliable operation post-retrofit" statement.

Selective catalytic reduction technology has not been applied successfully to 2SLB engines. After researching SCR controls on 2SLB engines, the EPA document titled "Technical Issues Related to the Potential Use of Selective Catalytic Reduction (SCR) to Reduce NOx Emissions from Natural Gas-Fired Lean Burn Engines" is the only document found with information on the application of SCR's on 2SLB engines. This documentation shows that many units did not perform properly after SCR was installed. Targa was unable to find any historical installation of SCR on 2SLB engines in the RLBC tables. The only proven technology to control NO_X for 2SLB engines is Clean Burn Technology. This is also the technology recommended by the engine control vendor to control NO_X for the units at Targa's three gas plants.

When completing BACT analyses and even in the BART requirements under 40 C.F.R. Part 51, App. Y, the EPA only requires analysis for technologies that have been proven. 40 C.F.R. Part 51, App. Y (regarding how to identify available retrofit emission control technologies, stating "[t]echnologies which have not yet been applied to (or permitted for) full scale operations need not be considered as available; we do not expect the source owner to purchase or construct a process or control device that has not already been demonstrated in practice."). As such, this is the definition Targa used to analyze equipment for this report.

vi. Provide the basis for the operational and maintenance (O&M) costs used in the cost analyses.

The O&M cost included in the analyses were based on Targa's experience operating similar control devices at other sites for expected maintenance and repair. Targa intends to conduct recommended maintenance per manufacturer.

vii. Explain why the air-to-fuel ratio adjustments for 2SLB engines varies so much depending on the specific engine and typical loading (e.g. 5% to 30% reduction).

The air-to-fuel ratio information was obtained in a document titled "State of the Art (SOTA) Manual for Reciprocating Internal Combustion Engines from the State of New Jersey."[1] This document contained the range for the air-to fuel-ratio used in the original submittal.

viii. Provide an explanation for the need to upgrade the power substations at the Monument Gas Processing Plant and the Eunice Gas Processing Plant to operate blowers for the proposed CBT.

Targa is unable to add any further high-power electrical equipment to the sites without significant modifications to the facilities' power substations. As stated in the original submittal, Eunice and Monument Gas Plants would need to add a substation in order to operate more electric units as well as contract more power from the power company. Not only is this expensive, but the power the facility currently receives has been unreliable at times, especially at Eunice Gas Plant. The electricity currently used to operate Eunice Gas Plant has voltage fluctuations and voltage spikes. This causes units to shutdown or malfunction when these conditions occur. A partial loss of power or voltage spike (voltage fluctuation) has the same effect as total loss in that it will cause high power electrical equipment to automatically shutdown to avoid equipment damage.

ix. Typically, under the Regional Haze process, a time period of two to five (2-5) years is assumed to be reasonable for the installation of controls; therefore, an estimate of seven (7) years to install CBT on the 2SLB engines at your facilities seems excessive. Please detail the reason for the long compliance times and whether there are ways to reduce compliance times and installation.

The time period Targa included to install controls on the facility's 2SLB engines was based on an estimate for installing controls for all 2SLB engines located at Eunice, Monument and Saunders Gas Plants. This would require installing CBT for a combined 30 units. The timeline of 7 years allows Targa 5 years to install 30 units plus 2 years to conduct engineering design work and obtain the air permits.

Below is a breakdown of our estimate for 7 years.

[1] https://www.state.nj.us/dep/aqpp/downloads/sota/sota13.pdf

- Engineering design work is estimated to take 3 months.

- An air quality permit will need to be obtained before installing the modifications. Typically, an air permit application takes 1-2 months to prepare and the permit application, once submitted, will take 9 to 12 months to receive.

- Concurrent to obtaining the air permit, Targa would also need to prepare an engineering schedule and complete final design work on the installations and order long lead-time equipment to install the controls on each unit.

- Targa would need to obtain a new contract with the electric company for the additional power. The electric company would need to build a substation and potentially run additional lines to the plant. This assumes the electrical company can provide the additional power needed within the required timeline. This is unknown at this time.

- Installation could begin once the air permit was issued and equipment was delivered. Installation of the substation would need to occur first so power would be available to run the CBT. This is estimated to take up to a year due to long lead time of equipment.

- Startup of the first set of CBT controls would take approximately 24-30 months. Assuming installation of up to 6 units a year would spread out installation over 5 years. In order to install the controls, once the control equipment is installed, the engines will have to be taken out of service for approximately 2 weeks to hook up the additional control equipment to the engine. Installing 6 units per year allows for the engineering construction crew to move from one engine to the next in an orderly fashion since there will be reduced gas processing rates through the plants during shutdown of the unit for control installation.

x. Please provide the details regarding Good Combustion Practices (GCP) and the routine maintenance schedule and procedures that are currently used to mitigate NO_X emissions and are proposed as a feasible control.

On all engines Targa operates, specific job plans are developed from the original equipment manufacturer (OEM) recommended maintenance procedures. They are done on OEM recommended intervals and are tracked in Targa's Maximo maintenance tracking system. The operators also make daily rounds and record exhaust temps. Temperatures are used to plan maintenance on the units.

2. Monument Gas Processing Plant

a. Sour Gas Amine Treating Units / Flare:

i. Describe why the Amine Treating Unit / Flare emissions for 2016-2017 are approximately 2,000 tons SO2. Was there a malfunction in the acid gas injection well (AGI) process? Describe the current emissions rate, current status of operations and why there are no further control options evaluated other than the AGI.

Targa's Monument AGI well failed an OCD required pressure test on July 27, 2016. Targa shut down the AGI well on August 8th to attempt to repair the well and began flaring acid gas. However, the well repair was unsuccessful and the well had to be plugged and abandoned. Targa drilled a new well immediately and the well became fully operational in March 2017. This was an unexpected failure of the AGI well after only 5 years of service. Since most of these emissions were caused by an upset condition, calendar year 2016 and 2017 actual emissions would not be a reasonable emission rate to use for Regional Haze

review. Targa maintains that no further review should be required for the amine unit at the Monument Gas Plant under the Four Factor Analysis as an AGI well with redundant compression constitutes effective emission control technology of H_2S and SO_2 emissions.

ii. Describe how the addition of a redundant compressor will increase the control efficiency of the AGI system.

The addition of the redundant compressor will reduce the number of hours that the AGI system is offline for maintenance and upset conditions, thus reducing the amount of SO_2 emitted during flaring of the acid gas. The AGI system currently must be taken offline for maintenance of the AGI compressor, which is used to increase the acid gas to the pressure necessary for injection into the AGI well.

iii. Are there additional ways of optimizing performance of the AGI system in addition to redundant compression?

Targa is spending approximately $7,000,000 to install redundant compression, and this was done to settle an AQB enforcement case, not as part of meeting BACT-based emission limits. Targa has not identified any technically feasible control alternatives to further optimize performance of the AGI system.

3. Eunice Gas Processing Plant

a. Amine Unit Controls: Include a discussion of alternative control methods, other than redundant acid gas injection (AGI) for amine units, such as sulfur recovery units (SRUs).

In Settlement Agreement Number AQCA 09-00(CO) issued by the NMED, Targa was required to shutdown the SRU and incinerator at the Eunice Gas Plant and install an AGI well. In addition, Targa believes that an AGI injection system with redundant compression as required under Settlement Agreement ABQ TAR-0610-1701(NOV) is effective emission control as defined in the Regional Haze rules. Targa has not identified any technically feasible control alternatives.

b. Engines: For Engine Unit C-03, provide the origin of the 5.13 g/hp-hr NOx emission factor used in baseline emissions calculations instead of the performance test results of 14.192 g/hp-hr.

This was an error in the 2016 emissions inventory. The 2015 performance test for C-03 was not used to calculate 2016 emissions on the engine. Targa has updated the emission rate calculations for this engine in our analysis and the cost effectiveness has been updated based on the performance test results of 14.192 g/hp-hr.

c. Steam Generating Boilers: Units B-01 and B-02.

i. Please provide details of the GCP and the associated routine maintenance schedule and procedures that are currently used to mitigate NO_X emissions and are proposed as a feasible control for the Boilers.

Specific job plans are developed from the original equipment manufacturer (OEM) recommended maintenance procedures. They are done on OEM recommended intervals and are tracked in Targa's Maximo maintenance tracking system. The operators also make daily rounds on the units.

As part of the maintenance program of these boilers, Targa conducts an efficiency study every 5 years per 40 CFR Part 63, Subpart DDDDD.

ii. Provide vendor specifications that include the cost information, recommendations, technical feasibility/infeasibility basis, and equipment specifications for the boiler control estimates.

Vendor information is provided in Appendix B. This information is business confidential information.

iii. Consider and include a discussion of the feasibility of staged combustion techniques, peak flame temperature reduction, water/steam injection, fuel-induced recirculation (FIR), and natural gas reburning (NGR) to reduce NOx emissions.

The option recommended by the boiler control vender to reduce NO_X emissions is to add flue gas recirculation (FGR) to the boilers. Other options, including the options listed above, will require major modifications to the boilers. FGR requires the least amount of modification to the boilers. These boilers were manufactured in the 1950's and not designed with add-on controls in mind. Installing controls on a unit never designed with controls in mind has a high potential to affect runtime, reliability, and will require increased maintenance. The boilers provide heat to the amine unit. With a higher amount of downtime on the units, this will cause associated flaring since sour gas cannot be processed without the amine system to remove CO_2 and H_2S. This will likely result in negatively offsetting the NO_X reductions from additional control technology.

Per our consultant, staged combustion is typical for burner types that are air staged, similar to the Eunice burners, or fuel staged. To do deeper air staging, the boiler sidewalls would need modification as the A frame style boilers to not lend themselves to deep air staging. Therefore, this is technically infeasible.

Peak flame temperature reduction is how NO_X emissions are reduced but is not a specific control technology. However, this is typically done through flue gas recirculation (FGR) or fuel induced recirculation (FIR). Per our consultant, FIR requires modification of the burners to accept the mixing of flue gas with the fuel. This method requires very precise method of mixing the flue gas with the fuel. If not designed well, burner acoustics will occur. This technology also requires higher fuel gas pressures. Due to the precise modifications that would need to be made to these 1950 vintage boilers and likelihood of burner acoustics, Targa determined this technology to be technically impractical. Targa has already provided information on FGR technology on the boilers. See original Four Factor Analysis.

Steam injection was determined to be technically impractical for a number of reasons including that the boiler furnaces were not designed for water and high purity water is not available. As a result, this technology would significantly increase maintenance downtime for cleaning and inspections due to scaling on the outside of the tube bundles. Additional NO_X emissions would be generated from the increased firing rate of the boiler to accommodate the additional steam requirement for injection. Scaling would decrease fuel efficiency of the boilers increasing the firing rate as well. This would result in higher NO_X emission from the boilers, offsetting the reductions from the control technology.

NGR was not considered for these units as it is applicable to boilers burning coal, wood or heavy oils. The Eunice boilers are natural gas fueled.

iv. Supplement the technical analysis that eliminated selective catalytic reduction (SCR) as technically infeasible as an add-on NO_X control for the boilers. The reasons given in the analysis for eliminating SCR are that retrofitting SCR controls on boilers is difficult and affects the reliability of the boilers and references the EPA SCR fact sheet. The fact sheet states that retrofitting is difficult but mentions nothing about boiler reliability. The other reason that SCR was eliminated for technical reasons is that SCR takes significant electrical power that would require a significant upgrade to the power system. The cost of upgrading the electric system is not considered at the technical feasibility step.

The boilers were manufactured in the 1950's and installing new technology on a unit never designed with controls in mind has a high potential to affect runtime, reliability, and will require increased maintenance downtime. With a higher potential for downtime on the units, this will cause associated flaring when the units are down and likely result in negatively offsetting NO_X reductions from the control technology. Targa believes installing SCR's on these boilers should be considered technically infeasible. However, Targa has provided the cost per ton to install SCR on the boilers at Eunice. Using the EPA Cost Control Manual estimates $134,021.21/ton for boiler B-01 and $139,853.11/ton for boiler B-02. This cost is not reasonable for this control. These calculations are provided in the electronic files.

v. Why was natural gas reburn (NGR) not included in the discussion?

NGR was never considered for these units as it is applicable to boilers burning coal, wood or heavy oils. These are natural gas fueled boilers.

vi. Provide a summary of the continuous emissions monitoring system (CEMS) data used to provide the emission factors for the boiler baseline calculations.

The boilers do not have CEMS installed and CEMS data was not used. Targa used the most recent stack test available (2008) as the baseline emission factor for the emission inventory. Targa also used this basis for the cost analysis.

vii. Please provide the basis for the total capital investment and annual O&M costs provided by Targa.

On all engines Targa operates, specific job plans are developed from the original equipment manufacturer (OEM) recommended maintenance procedures. They are done on OEM recommended intervals and are tracked in Targa's Maximo maintenance tracking system.

4. Saunders Gas Plant

a. Engines: The analysis states that the emission factors for the baseline emissions calculations for the engines were based on performance tests. Typically, a performance test refers to an initial compliance test using EPA Reference Methods. The Department's records show that this was a periodic portable analyzer test, not what would be called a performance test. Were these the only tests conducted on these units during 2016, or were additional periodic portable analyzer tests conducted? If so, please provide test results of all portable analyzer tests conducted on these engines in 2016.

The portable analyzer tests conducted on the engines that were used for the emission inventory calculations are attached to this addendum in Appendix A.

b. All Four-Stroke Rich-Burn (4SRB) Engines: Table 3., Potential Control Options for 4SRB Recirculating Internal Combustion Engines (RICE) indicates that CBT is technically feasible for these engines, with a NOX control efficiency of 10% - 40%; however, the narrative on the technical feasibility for this technology concludes that, for various reasons, Targa has determined that this method is infeasible for 4SRB engines. Please explain this discrepancy.

The 10% to 40% provided in the table of the original submittal was a typographical error. The table should have stated N/A for 4SRB engines as this technology was determined to be infeasible.

c. All Two-Stroke Lean-Burn (2SLB) Engines: The estimated cost effectiveness for the installation and operation of CBT on the six (6) Cooper Bessemer GMVA-10 engines at the facility varies drastically from

a low of $2,753.99/ton NO_X to a high of $277,724.45/ton NO_X based on performance tests (periodic portable analyzer tests) conducted in 2016. Has Targa conducted an evaluation of these units to determine why the emissions from these identical engines varies so greatly ((2.05 – 10.78 grams NO_X/hp-hr.)? If we assume that that the addition of CBT on unit C-01 is uneconomical at $277,724.45/ton NO_X reduced, the average the cost effectiveness of units C-02 through C-09 is $5,926.01 and would result in an estimated annual NO_X reduction of 279.65 tons. Would Targa be willing to reduce the allowable emission rate for unit C-01 to ensure continued low NO_X emissions from this unit?

The cost analyses submitted to the NMED on October 31, 2019 were based on 2016 actual emissions. The actual emissions were calculated from 2016 hours of operation multiplied by the emission rate from stack testing. With regards to the engine usage, Targa attempts to use its engines uniformly but this does not mean equally on a calendar year basis. The annual hours of operation will depend on various factors. The main reasons may be a unit's service availability (is it working or not), or if the unit requires scheduled maintenance (i.e. the unit may be scheduled to be swapped with an identical unit). As such, each year the engines will operate with different hours of operation and fuel usage. Since the NMED requested 2016 actual emissions be used in the cost analysis, the cost calculations for each unit will have a varying emission totals which will create varying costs per ton for identical engines. Per AP-42 Section 3.2.3 "It is not unusual to test emissions from two identical engines in the same plant, operated by the same personnel, using the same fuel, and have the test results show significantly different emissions. This variability in the test data is evidenced in the high relative standard deviation reported in the data set." Stack tests are a snapshot in time and only provide potential emissions based on that snapshot. See the included Excel spreadsheets for details on the emission rate calculations.

Targa believes it is unnecessary and unwarranted to reduce the allowable emission rate for unit C-01 to ensure continued low NO_X emissions.

d. Amine Treating Unit:

i. How efficient is the amine treating unit at removing H2S and CO2 from the gas stream? Is it technically feasible to add additional stages to the sulfur recovery unit to reduce the amount of sulfur compounds in the tail gas?

The current amine treating unit removes CO_2 and H_2S from the natural gas stream down to very low concentrations, as required to meet pipeline specifications and the low temperatures of the cryogenic unit used to split the methane from the natural gas liquids. The sulfur recovery unit (SRU) meets the NSPS LLL requirement of 74% efficiency in removing sulfur from the acid gas stream. The acid gas stream is the vent gas stream off the amine unit still vent. Additional SRU stages to control SO_2 emissions from the sulfur recovery unit are discussed in d.ii below.

ii. Similarly, as Targa had previously determined that the construction of an acid gas injection well is technically infeasible, is it feasible to have a redundant sulfur recovery unit in order to limit acid gas flaring during maintenance of the primary sulfur recovery unit?

Three different add-on control scenarios for the SRU are provided below to further reduce SO_2 emissions from the SRU and incinerator.

- Add a 3rd bed to current SRU, which would result in a 90% recovery of inlet sulfur. The current system reduces inlet sulfur by 74%.

- Add a redundant SRU, which would result in reducing flaring emissions when the current SRU is down for maintenance.

- Add a tail gas unit after the SRU, which would increase the sulfur recovery to 95% of inlet sulfur.

These scenarios are deemed technically feasible. The cost analysis for these scenarios are shown in the table below.

Control Equipment	Unit	Capital Cost ($)	Total Annual Cost ($)*	Emission Reduction (tpy)	Cost Effectiveness ($/ton)
Redundant SRU	I-01	**26,760,000**	**2,489,259**	**25.59**	**97,287.09**
3rd Bed to SRU	I-01	**8,590,000**	**818,805**	**242.97**	**3,369.96**
Tailgas Unit	I-01	**6,850,000**	**2,073,203**	**347.49**	**5,966.28**

*Total Annual Cost includes the annualized capital cost, as well as the direct and indirect annual operating costs.

Targa has received an estimated direct capital costs for the equipment and vendor labor associated with implementing the above changes to the amine system located at Saunders from a consultant who designs the equipment. Based on prior knowledge of the equipment, Targa estimated the direct annual costs (maintenance, operating labor, reagent cost, electricity cost, and catalyst cost) and indirect annual costs associated with Targa's internal labor, overhead and capital recovery for the project.

Cost effectiveness for each scenario are summarized in the Table above. To calculate the emission reductions, Targa used the 2016 Emission Inventory (EI) data. This was compared to the maximum PTE emission rate of the equipment post-control to get an Emission Reduction (tpy) value. The Total Annual Cost was then divided by the Emission Reduction to come up with a Cost Effectiveness ($/ton) amount. The full cost estimation for each unit is included in Appendix A of this report.

The Tailgas Unit would have negative environmental impacts due to the waste generated from the caustic chemical used to control the tail gas SO_2 emissions. This control would have 600 bbl/d of waste that would need to be trucked out and disposed.

Targa estimates that approximately 4 years will be needed to budget, design, procure, authorize, and install either of these types of control equipment if the facility is required to add these controls. The estimated useful life of the SRU equipment is 20 years, based on industry standards for life of the controls.

SAUNDERS SSM FLARING

Additional information on process and SSM flaring at Saunders Gas Plant is included below as requested in Liz Bisbey-Kuehn's November 14, 2019 emailed letter titled "Submittal Requirements for Process Flaring and Startup, Shutdown, and Maintenance (SSM) Flaring as part of the Regional Haze Four-Factor Analyses".

Targa does not have process streams that vent to flare during normal operations. Targa's authorized flaring is associated with startup, shutdown, and maintenance (SSM) events. As required under 20.2.7.14, Targa developed and implemented a plan to minimize emissions during routine and predictable startup, shutdown, and scheduled maintenance through work practice standards and good air pollution control practices. Targa has followed these requirements while continuing to look for ways to reduce and minimize emissions at the Saunders Gas Plant.

Targa minimizes emissions during startups, shutdowns, and maintenance activities through the use of industry standards and/or manufacturer recommended operating practices. In addition, equipment at the facility is equipped with safety devices that will aid in minimizing excess emissions during non-routine operating conditions. The following summarizes Targa's operational plans for minimizing excess emissions. After reviewing options for minimizing emissions associated with flaring at Targa's Saunders Gas Plant, Targa has not identified any new options to lower flared emission rates beyond what it is already doing. Below is a more detailed explanation of what Targa already does to minimize emissions at the gas plant.

MAINTENANCE

Targa takes a pro-active approach to facility and equipment maintenance. Operations personnel are aware of the importance of proper and efficient operation of equipment. Moreover, Targa recognizes the economic incentives to maintain and operate equipment efficiently. Malfunctioning equipment wastes resources and costs money.

Equipment at the facility is maintained in accordance with manufacturers' recommendations, industry best operating practices, and Targa's own practices designed to minimize downtime and non-routine operations. Procedures exist for maintenance of each major piece of equipment; personnel are trained in proper procedures; and Targa's own internal review processes ensure that procedures are followed. As a result, nonroutine operational events and consequent excess emissions are minimized.

STARTUP AND SHUTDOWN

Targa's Saunders Gas Plant is shutdown as needed, in conjunction with required third party pipeline maintenance outages. During this downtime, Targa conducts inspections and maintenance of its equipment to minimize other downtime. However, due to the nature of oil and natural gas production, natural gas production rates cannot be easily turned on and off when a gas plant needs to be offline for maintenance activities. When natural gas cannot be processed, the gas must be vented or combusted.

During startup of the gas plant some flaring is necessary and cannot be avoided. The first processing step at the plant involves removal of carbon dioxide (CO2) and hydrogen sulfide (H2S) followed by the removal of water from the gas. This processing is necessary because Saunders utilizes a cryogenic process to split out methane from the heavier hydrocarbons found in raw natural gas. The cryogenic process operates at approximately -150°F. Due to this very cold temperature, the gas must meet very low specifications for water, CO_2, and H_2S content. Additionally, the natural gas (methane) produced from the cryogenic process must meet several specifications including BTU value and ethane content prior to the outlet pipeline accepting the gas.

During startup, the gas will not initially meet the specifications required to go onto the next step in the process. Therefore, there is a period of time flaring of the gas is necessary prior to being able to introduce it into the next step of the process. Therefore, the gas must be flared initially until the stream reaches the specifications and can be routed to the next step in the process.

Additionally, the sulfur recovery unit (SRU) must be warmed prior to introducing acid gas to the unit. Targa minimizes emissions from SRU startup using hot nitrogen gas to warm up the SRU beds. This allows the recovery of sulfur to be higher once acid gas is introduced into the SRU.

MINIMIZING EMISSIONS

To reduce emissions during equipment shutdowns for maintenance or operational outages, procedures are designed to minimize the duration of events. Such procedures include the following:

- Compression and other operational loads may be shifted to other units.
- Maintenance may be scheduled for periods of low load.
- Use of spare equipment to maintain operating rates during routine maintenance downtime of certain equipment, like natural gas fired engines.
- Multiple maintenance activities may be scheduled to occur simultaneously.
- Gas may be routed to other nearby gas plants.
- Producers may be asked to shut-in production to minimize gas flow to the plant.
- Startup is conducted with lower H_2S gas streams. Higher H_2S streams are not introduced to the gas plant inlet until the plant is operating normally.
- Compressors are first blown down to lower pressure process equipment prior to venting to reduce volume of process gas emitted (for example blowdown higher stage compressors to first stage suction at approximately 5 psig rather than venting from operating pressure that can be over 100 psig).
- Startup procedures for the turbines and engine are normally completed in less than five minutes, and shutdown procedures are normally completed in less than two minutes.
- Using hot nitrogen gas to warm up the SRU bed prior to introducing acid gas.

Targa believes the Saunders Gas Plant already utilizes efficient processes and mitigation strategies to reduce flaring emissions through the use of an acid gas injection system as well as by the techniques explained in this addendum. Additional control technology to reduce SSM flaring is covered in response to 4.d.ii. above.

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the MW rating at full load capacity (Bmw)?	25	MMBtu/hr
What is the higher heating value (HHV) of the fuel?	1,000	Btu/scf
What is the estimated actual annual MWhs output?	219,500,000	scf/year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3400	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ○ Method 2
- ◉ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	73.59	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	14.72	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	700	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	16.67	ft^3/min-MMBtu/hour

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0361	$/kWh			* $0.0361/kWh is a default value for electicity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Interest Rate (Percent)	5.5	Default bank prime rate		Use known interest rate or use bank prime rate, available at https://www.federalreserve.gov/releases/h15/.

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	25	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	219,500,000	scf/year	
Actual Annual fuel consumption (Mactual) =		219,500,000	scf/year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	1.000	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8760	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	1.47	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	6.45	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	417.6	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	0.2	/hour	
Residence Time	1/V_{space}	5.4119	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.13		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.0	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^Y -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	2,260.11	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	0	ft^2

Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1,733	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	1	ft^2
Reactor length and width dimensions for a square reactor =	$(A_{SCR})^{0.5}$	0.7	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	6,968	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	573	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	1,977	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	264	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	88,800	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	$i (1+ i)^n/(1+ i)^n - 1$ = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage:			
Electricity Consumption (P) =	A x 1,000 x 0.0056 x $(CoalF \times HRF)^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	12.88	kW

Cost Estimate

Total Capital Investment (TCI)

1.13 ELEVF

TCI for Oil and Natural Gas Boilers

	New	Retrofit
For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW: $TCI = 86,380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$	$0	$0
For Oil and Natural Gas-Fired Utility Boilers >500 MW: $TCI = 62,680 \times B_{MW} \times ELEVF \times RF$	$0	$0
For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour : $TCI = 7,850 \times (2,200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$	$0	$0
For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour : $TCI = 10,530 \times (1,640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$	$0	$1,289,882
For Oil-Fired Industrial Boilers >5,500 MMBtu/hour: $TCI = 5,700 \times Q_B \times ELEVF \times RF$	$0	$0
For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour: $TCI = 7,640 \times Q_B \times ELEVF \times RF$	$0	$0
	$0	$1,289,882

Total Capital Investment (TCI) =	$1,436,087	in 2018 dollars

TCI for Coal-Fired Boilers

For Coal-Fired Boilers:

$$TCI = 1.3 \times (SCR_{cost} + RPC + APHC + BPC)$$

Capital costs for the SCR (SCR_{cost}) =	$0	in 2018 dollars
Reagent Preparation Cost (RPC) =	$0	in 2018 dollars
Air Pre-Heater Costs (APHC)* =	$0	in 2018 dollars
Balance of Plant Costs (BPC) =	$0	in 2018 dollars
Total Capital Investment (TCI) =	$0	in 2018 dollars

* Not applicable - This factor applies only to coal-fired boilers that burn bituminous coal and emits equal to or greater than 3lb/MMBtu of sulfur dioxide.

SCR Capital Costs (SCR_{cost})

For Coal-Fired Utility Boilers >25 MW: $SCR_{cost} = 310,000 \times (NRF)^{0.2} \times (B_{MW} \times HRF \times CoalF)^{0.92} \times ELEVF \times RF$	$0.00	$0.00
For Coal-Fired Industrial Boilers >250 MMBtu/hour: $SCR_{cost} = 310,000 \times (NRF)^{0.2} \times (0.1 \times Q_B \times CoalF)^{0.92} \times ELEVF \times RF$	0.00	0.00
	$0	$0

SCR Capital Costs (SCR_{cost}) =	$0 in 2018 dollars

Reagent Preparation Costs (RPC)

For Coal-Fired Utility Boilers >25 MW: $RPC = 564,000 \times (NOx_{in} \times B_{MW} \times NPHR \times EF)^{0.25} \times RF$	$0	$0
For Coal-Fired Industrial Boilers >250 MMBtu/hour: $RPC = 564,000 \times (NOx_{in} \times Q_B \times EF)^{0.25} \times RF$	$0	$0
	$0	$0

Reagent Preparation Costs (RPC) =	$0 in 2018 dollars

Air Pre-Heater Costs (APHC)*				
For Coal-Fired Utility Boilers >25MW:				
	$APHC = 69{,}000 \times (B_{MW} \times HRF \times CoalF)^{0.78} \times AHF \times RF$		$0	$0
For Coal-Fired Industrial Boilers >250 MMBtu/hour:				
	$APHC = 69{,}000 \times (0.1 \times Q_B \times CoalF)^{0.78} \times AHF \times RF$		$0	$0
Air Pre-Heater Costs (APH_{cost}) =		$0 in 2018 dollars	**$0**	**$0**

* Not applicable - This factor applies only to coal-fired boilers that burn bituminous coal and emit equal to or greater than 3lb/MMBtu of sulfur dioxide.

Balance of Plant Costs (BPC)				
For Coal-Fired Utility Boilers >25MW:				
	$BPC = 529{,}000 \times (B_{MW} \times HRF \times CoalF)^{0.42} \times ELEVF \times RF$		**$0**	**$0**
For Coal-Fired Industrial Boilers >250 MMBtu/hour:				
	$BPC = 529{,}000 \times (0.1 \times Q_B \times CoalF)^{0.42} ELEVF \times RF$		**$0**	**$0**
Balance of Plant Costs (BOP_{cost}) =		$0 in 2018 dollars	**$0**	**$0**

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$743,053 in 2018 dollars
Indirect Annual Costs (IDAC) =	$122,915 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$865,968 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$7,180 in 2018 dollars	
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$0	#REF!
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$677,809 in 2018 dollars	
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$4,074 in 2018 dollars	
Annual Catalyst Replacement Cost =		$53,989 in 2018 dollars	
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$		
Direct Annual Cost =		$743,053 in 2018 dollars	

	1
Method 1	$53,989
	9,794

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,714 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$120,200 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$122,915 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$865,968	per year in 2018 dollars
NOx Removed =	6.45	tons/year
Cost Effectiveness =	$134,314	per ton of NOx removed in 2018 dollars

Data Inputs

Enter the following data for your combustion unit:

Is the combustion unit a utility or industrial boiler? Industrial

What type of fuel does the unit burn? Natural Gas

Is the SCR for a new boiler or retrofit of an existing boiler? Retrofit

Please enter a retrofit factor between 0.8 and 1.5 based on the level of difficulty. Enter 1 for projects of average retrofit difficulty. 1

Complete all of the highlighted data fields:

What is the MW rating at full load capacity (Bmw)?	25	MMBtu/hr
What is the higher heating value (HHV) of the fuel?	1,000	Btu/scf
What is the estimated actual annual MWhs output?	219,500,000	scf/year
Enter the net plant heat input rate (NPHR)	8.2	MMBtu/MW

If the NPHR is not known, use the default NPHR value:

Fuel Type	Default NPHR
Coal	10 MMBtu/MW
Fuel Oil	11 MMBtu/MW
Natural Gas	8.2 MMBtu/MW

Plant Elevation	3400	Feet above sea level

Not applicable to units burning fuel oil or natural gas

Type of coal burned: Not Applicable

Enter the sulfur content (%S) = _____ percent by weight

Not applicable to units buring fuel oil or natural gas

Note: The table below is pre-populated with default values for HHV and %S. Please enter the actual values for these parameters in the table below. If the actual value for any parameter is not known, you may use the default values provided.

Coal Type	Fraction in Coal Blend	%S	HHV (Btu/lb)
Bituminous	0	1.84	11,841
Sub-Bituminous	0	0.41	8,826
Lignite	0	0.82	6,685

Please click the calculate button to calculate weighted average values based on the data in the table above.

For coal-fired boilers, you may use either Method 1 or Method 2 to calculate the catalyst replacement cost. The equations for both methods are shown on rows 85 and 86 on the ***Cost Estimate*** tab. Please select your preferred method:

- ○ Method 1
- ● Method 2
- ○ Not applicable

Enter the following design parameters for the proposed SCR:

Number of days the SCR operates (t_{SCR})	365	days
Number of days the boiler operates (t_{plant})	365	days
Inlet NO_x Emissions (NOx_{in}) to SCR	61.31	lb/MMBtu
Outlet NO_x Emissions (NOx_{out}) from SCR	12.26	lb/MMBtu
Stoichiometric Ratio Factor (SRF)	1.050	

*The SRF value of 1.05 is a default value. User should enter actual value, if known.

Number of SCR reactor chambers (n_{scr})	1	
Number of catalyst layers (R_{layer})	3	
Number of empty catalyst layers (R_{empty})	1	
Ammonia Slip (Slip) provided by vendor	2	ppm
Volume of the catalyst layers ($Vol_{catalyst}$) (Enter "UNK" if value is not known)	UNK	Cubic feet
Flue gas flow rate ($Q_{fluegas}$) (Enter "UNK" if value is not known)	UNK	acfm

Estimated operating life of the catalyst ($H_{catalyst}$)	24,000	hours
Estimated SCR equipment life	20	Years*

* For industrial boilers, the typical equipment life is between 20 and 25 years.

Gas temperature at the SCR inlet (T)	700	°F
Base case fuel gas volumetric flow rate factor (Q_{fuel})	16.67	ft^3/min-MMBtu/hour

Concentration of reagent as stored (C_{stored})	29	percent*
Density of reagent as stored (ρ_{stored})	56	lb/cubic feet*
Number of days reagent is stored ($t_{storage}$)	14	days

*The reagent concentration of 29% and density of 56 lbs/cft are default values for ammonia reagent. User should enter actual values for reagent, if different from the default values provided.

Densities of typical SCR reagents:

50% urea solution	71 lbs/ft^3
29.4% aqueous NH_3	56 lbs/ft^3

Select the reagent used: Ammonia

Enter the cost data for the proposed SCR:

Desired dollar-year	2018				
CEPCI for 2018	603.1	Enter the CEPCI value for 2018	541.7	2016 CEPCI	CEPCI = Chemical Engineering Plant Cost Index
Annual Interest Rate (i)	5.5	Percent*			* 5.5 percent is the default bank prime rate. User should enter current bank prime rate (available at https://www.federalreserve.gov/releases/h15/.)
Reagent ($Cost_{reag}$)	0.293	$/gallon for 29% ammonia*			* $0.293/gallon is a default value for 29% ammonia. User should enter actual value, if known.
Electricity ($Cost_{elect}$)	0.0361	$/kWh			* $0.0361/kWh is a default value for electicity cost. User should enter actual value, if known.
Catalyst cost ($CC_{replace}$)	227.00	$/cubic foot (includes removal and disposal/regeneration of existing catalyst and installation of new catalyst			* $227/cf is a default value for the catalyst cost based on 2016 prices. User should enter actual value, if known.
Operator Labor Rate	60.00	$/hour (including benefits)*			* $60/hour is a default value for the operator labor rate. User should enter actual value, if known.
Operator Hours/Day	4.00	hours/day*			* 4 hours/day is a default value for the operator labor. User should enter actual value, if known.

Note: The use of CEPCI in this spreadsheet is not an endorsement of the index, but is there merely to allow for availability of a well-known cost index to spreadsheet users. Use of other well-known cost indexes (e.g., M&S) is acceptable.

Maintenance and Administrative Charges Cost Factors:

Maintenance Cost Factor (MCF) =	0.005
Administrative Charges Factor (ACF) =	0.03

Data Sources for Default Values Used in Calculations:

Data Element	Default Value	Sources for Default Value	If you used your own site-specific values, please enter the value used and the reference source . . .	Recommended data sources for site-specific information
Reagent Cost ($/gallon)	-	U.S. Geological Survey, Minerals Commodity Summaries, January 2017 (https://minerals.usgs.gov/minerals/pubs/commodity/nitrogen/mcs-2017-nitro.pdf		Check with reagent vendors for current prices.
Electricity Cost ($/kWh)	-	U.S. Energy Information Administration. Electric Power Annual 2016. Table 8.4. Published December 2017. Available at: https://www.eia.gov/electricity/annual/pdf/epa.pdf.		Plant's utility bill or use U.S. Energy Information Administration (EIA) data for most recent year. Available at https://www.eia.gov/electricity/monthly/epm_table_grapher.php?t=epmt_5_6_a.
Percent sulfur content for Coal (% weight)		Not applicable to units burning fuel oil or natural gas		Check with fuel supplier or use U.S. Energy Information Administration (EIA) data for most recent year." Available at http://www.eia.gov/electricity/data/eia923/.
Higher Heating Value (HHV) (Btu/lb)	1,033	2016 natural gas data compiled by the Office of Oil, Gas, and Coal Supply Statistics, U.S. Energy Information Administration (EIA) from data reported on EIA Form EIA-923, Power Plant Operations Report. Available at http://www.eia.gov/electricity/data/eia923/.	1025	Fuel supplier or use U.S. Energy Information Administration (EIA) data for most recent year." Available at http://www.eia.gov/electricity/data/eia923/.
Catalyst Cost ($/cubic foot)	227	U.S. Environmental Protection Agency (EPA). Documentation for EPA's Power Sector Modeling Platform v6 Using the Integrated Planning Model. Office of Air and Radiation. May 2018. Available at: https://www.epa.gov/airmarkets/documentation-epas-power-sector-modeling-platform-v6.		Check with vendors for current prices.
Operator Labor Rate ($/hour)	$60.00	U.S. Environmental Protection Agency (EPA). Documentation for EPA's Power Sector Modeling Platform v6 Using the Integrated Planning Model. Office of Air and Radiation. May 2018. Available at: https://www.epa.gov/airmarkets/documentation-epas-power-sector-modeling-platform-v6.		Use payroll data, if available, or check current edition of the Bureau of Labor Statistics, National Occupational Employment and Wage Estimates – United States (https://www.bls.gov/oes/current/oes_nat.htm).
Interest Rate (Percent)	5.5	Default bank prime rate		Use known interest rate or use bank prime rate, available at https://www.federalreserve.gov/releases/h15/.

SCR Design Parameters

The following design parameters for the SCR were calculated based on the values entered on the *Data Inputs* tab. These values were used to prepare the costs shown on the *Cost Estimate* tab.

Parameter	Equation	Calculated Value	Units	
Maximum Annual Heat Input Rate (Q_B) =	HHV x Max. Fuel Rate =	25	MMBtu/hour	
Maximum Annual fuel consumption (mfuel) =	(QB x 1.0E6 x 8760)/HHV =	219,500,000	scf/year	
Actual Annual fuel consumption (Mactual) =		219,500,000	scf/year	
Heat Rate Factor (HRF) =	NPHR/10 =	0.82		
Total System Capacity Factor (CF_{total}) =	(Mactual/Mfuel) x (tscr/tplant) =	1.000	fraction	
Total operating time for the SCR (t_{op}) =	CF_{total} x 8760 =	8760	hours	
NOx Removal Efficiency (EF) =	(NOx_{in} - NOx_{out})/NOx_{in} =	80.0	percent	
NOx removed per hour =	NOx_{in} x EF x Q_B =	1.23	lb/hour	
Total NO_x removed per year =	(NOx_{in} x EF x Q_B x t_{op})/2000 =	5.38	tons/year	
NO_x removal factor (NRF) =	EF/80 =	1.00		
Volumetric flue gas flow rate ($q_{flue\ gas}$) =	Q_{fuel} x QB x (460 + T)/(460 + 700)n_{scr} =	417.6	acfm	
Space velocity (V_{space}) =	$q_{flue\ gas}$/$Vol_{catalyst}$ =	0.2	/hour	
Residence Time	1/V_{space}	5.4119	hour	
Coal Factor (CoalF) =	1 for oil and natural gas; 1 for bituminous; 1.05 for sub-bituminous; 1.07 for lignite (weighted average is used for coal blends)	1.00		
SO_2 Emission rate =	(%S/100)x(64/32)*1x10^6)/HHV =			Not applicable; factor applies only to coal-fired boilers
Elevation Factor (ELEVF) =	14.7 psia/P =	1.13		
Atmospheric pressure at sea level (P) =	2116 x [(59-(0.00356xh)+459.7)/518.6]$^{5.256}$ x (1/144)* =	13.0	psia	
Retrofit Factor (RF)	Retrofit to existing boiler	1.00		

* Equation is from the National Aeronautics and Space Administration (NASA), Earth Atmosphere Model. Available at https://spaceflightsystems.grc.nasa.gov/education/rocket/atmos.html.

Catalyst Data:

Parameter	Equation	Calculated Value	Units
Future worth factor (FWF) =	(interest rate)(1/((1+ interest rate)^{Y} -1) , where Y = $H_{catalyts}$/(t_{SCR} x 24 hours) rounded to the nearest integer	0.3157	Fraction
Catalyst volume ($Vol_{catalyst}$) =	2.81 x Q_B x EF_{adj} x Slipadj x NOx_{adj} x S_{adj} x (T_{adj}/N_{scr})	2,260.11	Cubic feet
Cross sectional area of the catalyst ($A_{catalyst}$) =	$q_{flue\ gas}$ /(16ft/sec x 60 sec/min)	0	ft^2
Height of each catalyst layer (H_{layer}) =	($Vol_{catalyst}$/(R_{layer} x $A_{catalyst}$)) + 1 (rounded to next highest integer)	1,733	feet

SCR Reactor Data:

Parameter	Equation	Calculated Value	Units
Cross sectional area of the reactor (A_{SCR}) =	1.15 x $A_{catalyst}$	1	ft^2
Reactor length and width dimensions for a square reactor =	(A_{SCR})$^{0.5}$	0.7	feet
Reactor height =	(R_{layer} + R_{empty}) x (7ft + h_{layer}) + 9ft	6,968	feet

Reagent Data:

Type of reagent used: Ammonia

Molecular Weight of Reagent (MW) = 17.03 g/mole

Density = 56 lb/ft^3

Parameter	Equation	Calculated Value	Units
Reagent consumption rate ($m_{reagent}$) =	(NOx_{in} x Q_B x EF x SRF x MW_R)/MW_{NOx} =	478	lb/hour
Reagent Usage Rate (m_{sol}) =	$m_{reagent}$/Csol =	1,647	lb/hour
	(m_{sol} x 7.4805)/Reagent Density	220	gal/hour
Estimated tank volume for reagent storage =	(m_{sol} x 7.4805 x $t_{storage}$ x 24)/Reagent Density =	74,000	gallons (storage needed to store a 14 day reagent supply rounded to t

Capital Recovery Factor:

Parameter	Equation	Calculated Value
Capital Recovery Factor (CRF) =	i (1+ i)^{n}/(1+ i)^{n} - 1 = Where n = Equipment Life and i= Interest Rate	0.0837

Other parameters	Equation	Calculated Value	Units
Electricity Usage: Electricity Consumption (P) =	A x 1,000 x 0.0056 x (CoalF x HRF)$^{0.43}$ = where A = (0.1 x QB) for industrial boilers.	12.88	kW

Cost Estimate

Total Capital Investment (TCI)

1.13 ELEVF

TCI for Oil and Natural Gas Boilers

	New	Retrofit
For Oil and Natural Gas-Fired Utility Boilers between 25MW and 500 MW: $TCI = 86,380 \times (200/B_{MW})^{0.35} \times B_{MW} \times ELEVF \times RF$	$0	$0
For Oil and Natural Gas-Fired Utility Boilers >500 MW: $TCI = 62,680 \times B_{MW} \times ELEVF \times RF$	$0	$0
For Oil-Fired Industrial Boilers between 275 and 5,500 MMBTU/hour : $TCI = 7,850 \times (2,200/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$	$0	$0
For Natural Gas-Fired Industrial Boilers between 205 and 4,100 MMBTU/hour : $TCI = 10,530 \times (1,640/Q_B)^{0.35} \times Q_B \times ELEVF \times RF$	$0	$1,289,882
For Oil-Fired Industrial Boilers >5,500 MMBtu/hour: $TCI = 5,700 \times Q_B \times ELEVF \times RF$	$0	$0
For Natural Gas-Fired Industrial Boilers >4,100 MMBtu/hour: $TCI = 7,640 \times Q_B \times ELEVF \times RF$	$0	$0
	$0	$1,289,882

Total Capital Investment (TCI) =	$1,436,087	in 2018 dollars

TCI for Coal-Fired Boilers

For Coal-Fired Boilers:

$$TCI = 1.3 \times (SCR_{cost} + RPC + APHC + BPC)$$

Capital costs for the SCR (SCR_{cost}) =	$0	in 2018 dollars
Reagent Preparation Cost (RPC) =	$0	in 2018 dollars
Air Pre-Heater Costs (APHC)* =	$0	in 2018 dollars
Balance of Plant Costs (BPC) =	$0	in 2018 dollars
Total Capital Investment (TCI) =	$0	in 2018 dollars

* Not applicable - This factor applies only to coal-fired boilers that burn bituminous coal and emits equal to or greater than 3lb/MMBtu of sulfur dioxide.

SCR Capital Costs (SCR_{cost})

For Coal-Fired Utility Boilers >25 MW: $SCR_{cost} = 310,000 \times (NRF)^{0.2} \times (B_{MW} \times HRF \times CoalF)^{0.92} \times ELEVF \times RF$	$0.00	$0.00
For Coal-Fired Industrial Boilers >250 MMBtu/hour: $SCR_{cost} = 310,000 \times (NRF)^{0.2} \times (0.1 \times Q_B \times CoalF)^{0.92} \times ELEVF \times RF$	0.00	0.00
	$0	$0

SCR Capital Costs (SCR_{cost}) =	$0 in 2018 dollars

Reagent Preparation Costs (RPC)

For Coal-Fired Utility Boilers >25 MW: $RPC = 564,000 \times (NOx_{in} \times B_{MW} \times NPHR \times EF)^{0.25} \times RF$	$0	$0
For Coal-Fired Industrial Boilers >250 MMBtu/hour: $RPC = 564,000 \times (NOx_{in} \times Q_B \times EF)^{0.25} \times RF$	$0	$0

Reagent Preparation Costs (RPC) =	$0 in 2018 dollars	**$0**	**$0**

Air Pre-Heater Costs (APHC)*

For Coal-Fired Utility Boilers >25MW:

$$APHC = 69{,}000 \times (B_{MW} \times HRF \times CoalF)^{0.78} \times AHF \times RF$$

	$0	$0

For Coal-Fired Industrial Boilers >250 MMBtu/hour:

$$APHC = 69{,}000 \times (0.1 \times Q_B \times CoalF)^{0.78} \times AHF \times RF$$

	$0	$0

Air Pre-Heater Costs (APH_{cost}) =	$0 in 2018 dollars	**$0**	**$0**

* Not applicable - This factor applies only to coal-fired boilers that burn bituminous coal and emit equal to or greater than 3lb/MMBtu of sulfur dioxide.

Balance of Plant Costs (BPC)

For Coal-Fired Utility Boilers >25MW:

$$BPC = 529{,}000 \times (B_{MW} \times HRF \times CoalF)^{0.42} \times ELEVF \times RF$$

	$0	**$0**

For Coal-Fired Industrial Boilers >250 MMBtu/hour:

$$BPC = 529{,}000 \times (0.1 \times Q_B \times CoalF)^{0.42} ELEVF \times RF$$

	$0	**$0**

Balance of Plant Costs (BOP_{cost}) =	$0 in 2018 dollars	**$0**	**$0**

Annual Costs

Total Annual Cost (TAC)

TAC = Direct Annual Costs + Indirect Annual Costs

Direct Annual Costs (DAC) =	$629,947 in 2018 dollars
Indirect Annual Costs (IDAC) =	$122,915 in 2018 dollars
Total annual costs (TAC) = DAC + IDAC	$752,862 in 2018 dollars

Direct Annual Costs (DAC)

DAC = (Annual Maintenance Cost) + (Annual Reagent Cost) + (Annual Electricity Cost) + (Annual Catalyst Cost)

Annual Maintenance Cost =	0.005 x TCI =	$7,180 in 2018 dollars	
Annual Operating Labor Cost =	Operator Labor Rate x Operator Hours/Day x Operating Days/Year =	$0	#REF!
Annual Reagent Cost =	$m_{sol} \times Cost_{reag} \times t_{op}$ =	$564,703 in 2018 dollars	
Annual Electricity Cost =	$P \times Cost_{elect} \times t_{op}$ =	$4,074 in 2018 dollars	
Annual Catalyst Replacement Cost =		$53,989 in 2018 dollars	
			1
	$n_{scr} \times Vol_{cat} \times (CC_{replace}/R_{layer}) \times FWF$		Method 1 $53,989
Direct Annual Cost =		$629,947 in 2018 dollars	9,794

Indirect Annual Cost (IDAC)

IDAC = Administrative Charges + Capital Recovery Costs

Administrative Charges (AC) =	0.03 x (Operator Cost + 0.4 x Annual Maintenance Cost) =	$2,714 in 2018 dollars
Capital Recovery Costs (CR)=	CRF x TCI =	$120,200 in 2018 dollars
Indirect Annual Cost (IDAC) =	AC + CR =	$122,915 in 2018 dollars

Cost Effectiveness

Cost Effectiveness = Total Annual Cost/ NOx Removed/year

Total Annual Cost (TAC) =	$752,862	per year in 2018 dollars
NOx Removed =	5.38	tons/year
Cost Effectiveness =	$139,859	per ton of NOx removed in 2018 dollars

Saunders Revised Cost Analyses Omitted for Brevity

CBI Attachment Omitted

From: Roberts, Melanie
To: Hardison, Cember, NMENV
Cc: Jane Romero-Kotovsky; Klein, Cindy S.
Subject: [EXT] RE: [EXTERNAL] question about Eunice four factor calculations
Date: Thursday, March 12, 2020 2:44:35 PM
Attachments: Eunice_Cost Analysis v0.6 2020-0311 Final.xlsx
Monument_CostAnalysis v0.5 2020-0311_Final.xlsx

Targa has reviewed and has the following clarification on the report. Please let me know if you have any further questions.

> *In the original 4FA submitted to the NMED on 10/31/2019, Targa was only able to acquire vendor information on the Cooper Bessemer 2SLB units located at their facilities. Targa used the estimates from the Cooper engines for the Clark 2SLB units located at Eunice and Monument emissions, as this was the only information that Targa was able to obtain by the November 1, 2019 deadline set by the NMED.*
>
> *When the NMED requested additional information including vendor specific information in the December 23, 2019 letter to Targa, Targa was able receive a quote on the Clark 2SLB engines. The lowest guarantee provided to Targa for the Clark 2SLB engine located at the Targa sites was 2 g/hp-hr. There was a calculation error in the spreadsheets showing 4 g/hp-hr for the Clark engines that should have been 2 g/hp-hr. The Cooper Bessemer engines should remain the same. Please see attached revised calculation sheets with the calculation correction.*

Subject: [EXTERNAL] question about Eunice four factor calculations

Hello Melanie and Rebecca,
I highlighted the parts of Targa's 2-17 submittal that we had questions about.
Page 7 of the pdf mentions that the vendor quote provided was for 5 and 2 g/hp-hr. The vendor quote in the confidential information reflects 2 and 5 g/hp-hr and the costs for those two emission factors correlate with what is used in the calculations.
Page 83 has the Eunice and Monument engine calculations. See the highlighted 4 g/hp-hr in the calculations. It appears that 2 g/hp-hr should have been used, rather than 4.
Compare the Eunice and Monument engine calculations to the Saunders engine calculations starting on page 114. If an engine already met 4 g/hp-hr, then only the 2 g/hp-hr calculation was included.

Please let us know if the 4 g/hp-hr used for Eunice and Monument gas plants should be changed to 2 g/hp-hr.
Thank you for your help.

Cember Hardison

RE: Targa Midstream Services LLC; Eunice, Monument, and Saunders Gas Plants
Four Factor Analysis NMED Follow-up Response

Dear Mr. Schooley:

On behalf of Targa Midstream Services LLC, we are submitting a response to the follow-up information request email received from the NMED September 14, 2020 regarding the Four Factor Analyses for the Eunice, Monument, and Saunders Gas Plants. Each question and response are included below.

Overarching:

1. *A technical feasibility analysis for electric compression is being requested from all facilities with compressors and turbines, and if feasible, then a four-factor analysis with cost estimations is required. Please provide some info on the compression that has already been converted to electric power as part of the discussion.*

   Targa has determined that installation of electric compression at the Eunice and Monument Gas Plants is technically feasible, provided sufficient time and resources. Saunders Gas Plant currently does not have third party electricity installed to handle operating the plant. Targa has not done an evaluation of bringing power into the Saunders Plant. Targa currently operates 4 natural gas fired generators (G-1, G-2, G-3, and G-4) to supply power to operate the Saunders plant.

   A four-factor analysis of the control is included below; however, Targa objects to the consideration of this change as the installation of electric compression would fundamentally redefine the sources subject to this analysis, the existing permitted engines. The EPA's policy since 1988 has been that control options which fundamentally redefine a proposed source can be excluded from consideration in BACT analyses. This policy derives from the understanding that the permit issuer must only consider control options that align with how the applicant, in proposing the facility, defines the purpose or basic design for the permitted facility. In initial development of the policy, the Administrator concluded that permit conditions defining the emissions control systems "are imposed on the source as the applicant has defined it" and that "the source itself is not a condition of the permit." [1]

   Furthermore, 40 CFR 51 Appendix Y states: "We do not consider BART as a requirement to redesign the source when considering available control alternatives. For example, where the source subject to BART is a coal-fired electric generator, we do not require the BART analysis to consider building a natural gas-fired electric turbine although the turbine may be inherently less polluting on a per unit basis." [2]

   Targa does not consider the replacement of existing permitted units with electric compression a reasonable option for emission reduction within the scope of the Regional Haze Rule.

[1] In re Pennsauken County, N.J., Res. Recovery Facility, 2 E.A.D. 667, 673 (Adm'r 1988)

[2] 40 CFR 51 Appendix Y: Guidelines for BART Determinations Under the Regional Haze Rule, Section IV.D.1.5.

a) **Cost of Compliance**

The cost estimates for electric compression at the Eunice and Monument Gas Plants are summarized below in Table 1 and Table 2, respectively. Calculations for the below estimates are provided in Appendix A. These costs include the capital cost of the electrical substations that would be necessary to be built, as well as the capital cost of environmental permitting for the facility changes, and the cost of the new compression equipment. Annual operating and maintenance costs are estimated for the electricity cost of the units, compressor maintenance cost, and cost of labor for maintaining the units.

Table 1: Cost analysis summary of electric compression at Eunice Gas Plant

Unit	Substation Capital Cost ($)	Permitting Capital Cost ($)	Compression Capital Cost ($)	Annual O&M Cost ($)	Total Annual Cost ($)	Emission Reduction (tpy)	Individual Cost Effectiveness ($/ton)	Cumulative Cost Effectiveness ($/ton)

Eunice Gas Plant

One (1) 3,250 hp electric compressor will be needed to replace approximately three (3) of the existing Clark engines. To replace all existing engines, a total of (5) 3,250 hp electric compressors will be needed. Targa has estimated the cost of compliance for this action using two methods in Table 1. The Individual Cost Effectiveness provided represents the cost to replace an individual permitted engine, dividing the Total Annual Cost of the upgrade by the anticipated Emission Reduction of a single unit. This allows Targa to estimate the cost effectiveness on a unit-by unit basis as is necessary for the Four Factor Analysis process. The Cumulative Cost Effectiveness represents the cost effectiveness of the replacement assuming that the single new electric compressor assumes its maximum potential load, or approximately three (3) existing permitted engines, and represents the Total Annual Cost divided by the emission reduction of all units that could potentially be replaced. It will be necessary to build a new electrical substation and re-permit the facility regardless of the number of replacements; therefore, those costs have been included for each batch of replacements. Annual O&M costs are detailed in the attached cost estimate spreadsheets.

The following Capital Costs have been applied in the Eunice assessments:

Table 3: Costs to Replace Eunice Clark BA-6 3rd stage; C-01, 02, 03, 04, 05, 06, 07, 13

Description	Estimated Costs
(5) 3250 hp compressor units installed	$ 20,833,333
Additional substation /power / MCC for needed power	$ 4,000,000
Permitting Cost	$ 40,000
Annual O&M Cost	$ 3,623,240
Total Cost	**$ 28,496,573**

Monument Gas Plant

Monument Clark 3rd stage; C-01, 02, 04, 05, 06

Three (3) 1,750 hp electric compressors will be necessary to replace existing 3rd stage engine units C-01, 02, 04, 05, and 06. It is approximated for this analysis that one of the new compressors would replace the existing Clark RA-8 engines (C-01 and C-02) and the second new compressor would replace the Clark RA-6 engines (C-04, C-05, and C-06).

The Individual Cost Effectiveness provided in cost analysis summary Table 2 represents the cost to replace an individual permitted engine, dividing the Total Annual Cost of electric compression by the anticipated Emission Reduction of a single unit. This allows Targa to estimate the cost effectiveness on a unit-by unit basis as is necessary for the Four Factor Analysis process. The Cumulative Cost Effectiveness represents the cost effectiveness of the replacement assuming that the single new electric compressor assumes its maximum potential load, taking on the load of all the existing Clark RA-8 or RA-6 engines. It will be necessary to build the electrical substation and re-permit the facility regardless of the number of replacements; therefore, those costs have been included for each batch of replacements. Annual O&M costs are detailed in the attached cost estimate spreadsheets.

The following Capital Costs have been applied in the Monument assessments for units C-01, 02, 04, 05, and 06:

Table 4: Costs to Replace Monument Clark 3rd stage; C-01, 02, 04, 05, 06

Description	Estimated Costs
(2) 1750HP 3rd stage units, VFDs, installed (based on Baesl estimate)	$ 8,250,000
Relocation / reconstruction of shop/storage	$ 200,000
Additional substation / power (for all conversions)	$ 4,000,000
Permitting cost	$ 60,000
Annual O&M Cost	$ 1,103,240
Total Cost	**$ 12,510,000**

Monument Clark HRA-8 1st & 2nd stages; C-24

One (1) 1,250 hp electric compressor unit will be necessary to replace the existing Clark HRA-8, unit C-24. The following Capital Costs have been applied in the Monument assessment for unit C-24:

Table 5: Costs to Replace Monument Clark HRA-8 1st & 2nd stages; C-24

Description	Estimated Costs
(1) 1250HP 1st & 2nd stage unit, VFD, installed	$ 3,500,000
Additional substation / power / MCC	$ 4,000,000
Additional wire trays / wire to C-24 location	$ 500,000
Removal and foundation work on C-24 for electric skid	$ 500,000
Permitting cost	$ 60,000
Annual O&M Cost	$ 463,240
Total Cost	**$ 9,023,240**

Monument Cooper GMVA-10 Refrigeration; C-28

One (1) 1,250 hp electric compressor unit will be necessary to replace existing Cooper GMVA-10, C-28. The following Capital Costs have been applied in the Monument assessment for unit C-28:

Table 6: Costs to Replace Monument Cooper GMVA-10 Refrigeration, C-28

Description	Estimated Costs
(1) 1250HP Refrig unit, VFD, installed	$ 7,000,000
Additional substation / power / MCC	$ 4,000,000
Additional wire trays / wire to C-28 location	$ 500,000
Header work to set unit outside C-28 location near propane scrubber	$ 200,000
Permitting cost (included above)	$ 60,000
Annual O&M Cost	$ 463,240
Total Cost	**$ 12,223,240**

b) **Time Necessary for Compliance**
Targa is unable to determine an exact time needed for compliance, as a large portion of the schedule for each project would be dependent on the availability of the power company to construct the required electrical substations. Targa would also like to note that their past experience with the power company

indicates that scheduling obligations may not be honored during construction of the substations. Considering those items, Targa conservatively estimates that 7-8 years would be needed to budget, design, procure, and construct all the equipment necessary at the substations and gas plants. This includes time for the power company to permit and construct the new electricity line to the plants, build the substation, and replace the units. Due to the extremely high costs, this would need to be split over several years.

c) **Energy and Non-Air Quality Environmental Impacts of Compliance**
This control will require a significant amount of electrical power to operate. This requirement will cause strain on the electrical grid and require new electrical substations to be built at each site. The physical footprint of the substation, powerlines, and access roads to be installed would have a detrimental impact on vegetation and wildlife in the area as well as exclude the land from the potential for future beneficial use. Furthermore, the EPA indicates that much of the equipment used in electricity transmission and distribution is insulated with sulfur hexafluoride, a powerful greenhouse gas which could be released during maintenance or as the facility ages.

d) Remaining Useful Life of Sources
The estimated useful life of the electric compressors is 20 years, based on industry standards for the life of these units.

2. *How were the annual O&M costs determined?*
Annual O&M costs are estimated by Targa using representative information from similar facilities and equipment. Targa estimated the direct annual costs (maintenance, operating labor, reagent cost, electricity cost, catalyst cost, etc.) and indirect annual costs associated with Targa's internal labor, overhead and capital recovery for the project. The costs associated with the 2SLB engines only included the maintenance and operating cost of the clean burn technology and not the costs for the existing engines. In our previous cost estimates provided we did not include the cost of electricity needed for the blowers that are required as part of the clean burn technology. Therefore, we have updated the cost estimates and they are provided in the attached cost estimate spreadsheet.

3. *Was the bank prime rate verified and/or documented during preparation of the analysis? The default rate of 5.5% was used in the analysis; however, it has been changed to the current bank prime rate of 3.25% in NMED's calculations.*
The bank prime rate used in the original analysis was verified as accurate during preparation of the analysis in October 2019. It has since dropped due to the national economic downturn. Targa has adjusted the rate to 3.25% for the costs provided above; however, Targa would like to note that 5.41% is a more realistic capitalized interest rate for the company, based on a review of the current company-specific economic status.

4. *Describe the potential issues with having enough power in existing substation and new substations for additional controls.*
Targa's Monument and Eunice Gas Plants have existing substations. However, an additional substation would need to be built to handle additional electricity load at both the Eunice and Monument Gas Plants, as the current substations are at or nearly at capacity. The amount of electricity needed for adding clean burn technology would require a new substation to be built at the site and additional electricity lines installed to the plants by the power company.

Targa Monument:

1. *In your 4FA you stated that installation of redundant electric compression for the AGI well system was required pursuant to a Settlement Agreement and Stipulated Final Compliance Order; and that installation should be complete by 9/1/20. Has this been completed?*
Targa's deadline to complete the agreed Supplemental Environmental Project (SEP) as part of the Settlement Agreement and Stipulated Final Compliance Order (SASFCO) TAR-0610-1701 was 24 months, or December 28, 2020 (II.B.17). However, Targa received an extension via email from Shannon Duran, dated 5/15/2020, extending

the SEP completion deadline to 3/31/2021. Targa has completed construction on the additional compression unit and expects the unit at Monument to start operation before the end of the year.

Targa Eunice:

1. *When were the LNB control installed on the boilers?*
   The exact date the LNB controls were installed is unknown. It is estimated that they were installed over 10 years ago.

2. *What is the new schedule on installation of redundant compression?*
   Targa's deadline to complete the agreed Supplemental Environmental Project (SEP) as part of the Settlement Agreement and Stipulated Final Compliance Order (SASFCO) TAR-0610-1701 was 24 months, or December 28, 2020 (II.B.17). However, Targa received an extension via email from Shannon Duran, dated 5/15/2020, extending the SEP completion deadline to 3/31/2021. Targa's permit amendment was issued on 9/17/2020. Targa intends to start construction at Eunice once the Monument unit is in service and expect to have the compressor operationally before the March 2021 deadline.

Targa Saunders:

1. *In the cost calculations for potential controls for the amine unit, the base case emissions for the acid gas emergency flare (F-01) indicate 29.5 tons SO2 for 2016. Reviewing the information pulled from the AEIR, we show 0.29 tons SO2 for 2016. Please verify the value submitted for this unit in 2016 in case this needs to be corrected. A rate of 29.5 tons in 2016 seems reasonable when compared to 2017 (29.9 tons) and 2018 (35.2 tons).*
   The 29.5 tons SO_2 for 2016 is the correct value for F-01. There was a typo in the EI. We are investigating what we need to do with the EI group on this error.

Please feel free to contact me at (480) 760-3860 or Melanie Roberts at (713) 584-1424 if you have any questions regarding this response.

Sincerely,

Subject: Follow-up clarifying questions Dec 18, 2020 / RE: [EXTERNAL] RE: Targa Four Factor Analyses

Thanks, Melanie, for the latest information submittal on Targa's Four Factor Analysis. We are nearing the end of wrapping up our Four Factor analyses and want to make sure our analyses are as accurate and representative as possible to then be evaluated in our long term strategy. In order to accomplish this, we have a few follow-up questions regarding your submittal:

1. Concerning the interest rate, Targa has stated that "The bank prime rate used in the original analysis was verified as accurate during preparation of the analysis in October 2019. It has since dropped due to the national economic downturn. Targa has adjusted the rate to 3.25% for the costs provided to the AQB; however, Targa would like to note that 5.41% is a more realistic capitalized interest rate for the company, based on a review of the current company-specific economic status." If Targa wants AQB to use a 5.41% interest rate in their calculations, then we will require that you provide documentation to support your proposed interest rate. This could be a letter from the chief financial officer for the institution that lends to your company, or from an official with your company (your company's CFO, for instance) that is in a position to know your company's costs of debt and equity.

   We are working on getting documentation on the interest rate but since we don't have it at this time please move ahead at the current 3.25%. We will continue to look into getting an official letter.

2. Electrification of engines at Monument and Eunice Gas Plants.

   a. The cost analysis you provided on 11/23/2020 is not clear as to whether the $4,000,000 capital costs for a substation and the $60,000 cost for permitting a particular engine should be applied to each individual engine or apportioned across all electrified compressors at that station. Can you clarify?

      The issue with the Four Factor Analysis is that you must look at each individual unit. If we are required to replace 1 unit with electric compression, we will need to build a substation expansion to bring in more electrical power. Therefore, we have included the cost for the substation with each engine cost calculation. However, the cost would only be incurred once

at the site even if we were required to replace multiple units. Splitting the cost across the units would unfairly reduce the cost per engine in the case that only 1 or 2 units required add-on controls.

b. At Monument Gas Plant, could the operating and maintenance costs of $1,103,240 also be apportioned over five engines; as well as dividing the O&M cost of $463,240 across the remaining two engines? Can this method be applied to the costs for Eunice Gas Plant?

Yes, the operating and maintenance cost of $1,103,240 was the total O&M costs for replacing the five 3rd stage engines. This cost should be divided out to the individual engines being replaced. However, it was hard to split it out since electric compression replacement would not be a 1:1 unit replacement.

3. In your calculations for the electrification of compressors operating and maintenance costs, of which the cost of electricity seems to be the overwhelming contributor, did you subtract the cost savings for the natural gas that would otherwise be combusted in the gas-fired engines?

No, we did not subtract any fuel charges for shutting down the gas fired units.

4. These questions of individual engine versus groupings of engines also apply to any revised costs that would be made for clean burn technology for Eunice and Monument Gas Plants. Appendix A is labelled, "Eunice and Monument Electric Compression Cost Effectiveness Calculations" but earlier in the text it refers to this section as having revised info for clean burn technology electrical substation capital costs and electrical O&M requirement costs. Please clarify and specify which costs need to be applied to single engines versus the entire group of engines being controlled. Is there an additional spreadsheet that was not attached?

Clean burn technology is the add-on control evaluated for the existing engines. So, it would be an individual emission calculation except for the substation capital cost. This would be the same explanation we provided in #2a for electric drive units. If we add clean burn controls to a single unit, we will need to upgrade the substation. But it would be a one-time cost even if controls are required on multiple units. However, since the analysis is on an individual unit basis, we included the capital cost of the substation to each unit being evaluated.

We inadvertently left out the revised Clean Burn Engine Control spreadsheet for Eunice. The spreadsheet is now attached. For the revised Clean Burn Control O&M cost at Eunice we have revised the costs to include electricity for the new blower plus costs for pressure and temperature sensor calibrations and replacement, increased spark plug replacements, blower required maintenance and replacement or refurbishment approximately every 5-8 years. This totaled $200,000 per unit. Monument engines with smaller blowers totaled $100,000 per unit, which is what was previously used. Annual electricity cost was estimated to be $164,000/unit for Eunice engines for the 400 hp blower and $58,000/unit for Monument engine 160 hp blower.

5. Regarding the Operation and Maintenance (O&M) costs for all facilities, do these values reflect the incremental cost of O&M, i.e., costs over and above those already realized for the units?

For the Clean Burn controls the O&M costs only include the incremental cost of O&M on the added controls. For the replacement units, there was no evaluation of current cost of the units evaluated since we would be installing new units.

We are willing to arrange a TEAMS call to discuss the questions and answers at your convenience,

but need to finalize our 4-factor analysis by early January so the earlier the better. These questions are key in our evaluation and the topics have also been discussed with us by EPA, FLMS, and other stakeholders in the regional haze process.

Thank you,

Mark Jones

Subject:	[EXTERNAL] Targa Regional Haze - Revised Cost Estimates
Date:	Friday, August 4, 2023 11:00:17 AM

CAUTION: This email originated outside of our organization. Exercise caution prior to clicking on links or opening attachments.

Thank you for allowing Targa to provide updated information on our previously submitted Four Factor Analyses for our Eunice, Monument, and Saunders Gas Plants. Our updates include equipment operational status changes and updated cost information, including vendor estimates as well as updates to our expected operation and maintenance costs. Vendor cost estimates have been included in a separate confidential submittal.

No changes were made to the Saunders Plant estimates. Targa continues to evaluate the long-term status of this plant. We don't have a schedule for when a final determination will be made.

Electrical Power Updates

Targa has evaluated the cost of adding additional power to the Eunice Gas Plant and has received cost estimates for upgrading the existing substation. The most recent cost estimate was for $7.8 MM in 2022 without any contingency. Our previous estimate was $3 MM. This is a huge increase in costs from what we had previously estimated and is based on actual quotes for expanding the Clark Substation located at Eunice Gas Plant. Targa has included price quotes for some of the equipment needed and a summary of the estimated costs. See confidential submittal for details of the cost estimate.

Other Cost Updates

Targa has made some operational changes to the plants since our last submittal. Eunice Gas Plant has permanently shutdown engines C-8 (previously disclosed), C-9, C-10, C-11, C-12, and C-13. These engines have been blinded off from the headers and can be removed from the air permits. The other engines subject to the 4FA at Eunice (C-01, C-02, C-03, C-04, C-05, C-06. C-07) are subject to NMAC 20.2.50 emission limitations of 3 g/hp-hr and are required to be in compliance by January 1, 2029, based on Targa's current engine inventory and percentage of engines already meeting the standard. At the Monument Plant, we do not have any recent changes to include. Only engine C-28 is subject to the emission limitations of NMAC 20.2.50. The other engines are below the 1,000 hp threshold for applicability.

Targa continues to evaluate the Alternative Compliance Plan (ACP) option in 20.2.50.113.B(10) for engines subject to the emission limitations in 20.2.50.113. Targa intends to submit an ACP for one or more engines at Eunice and/or Monument. A final decision has not yet been made on which engines to apply for the alternative standards. We continue to work to make a determination on which and how many engines we would submit this request for.

Additionally, Targa received updated cost estimates for upgrading the boilers based on the different control technology.

Targa has received updated cost estimates for the following controls or engine replacements:

- Clean-burn technology cost for controls and installation on engines,
- Electric driven compressor,
- Natural gas fired compressor, and
- Additional control modifications for the boilers.

See confidential submittal for details of the cost estimates. These will be sent in a separate email.

Re: Tri-State Generation and Transmission Association, Inc. Escalante Generating Station Closure

Dear Ms. Bisbey-Kuehn:

Tri-State Generation and Transmission Association, Inc. (Tri-State) owns and operates the Prewitt Escalante Generating Station (PEGS) in Prewitt, New Mexico. In a letter dated July 18, 2019, the New Mexico Environment Department (NMED) requested that Tri-State conduct a regional haze reasonable progress four-factor analysis for PEGS to comply with EPA's regional haze rule. Tri-State provided that analysis to NMED on December 6, 2019. On January 8, 2020, the Tri-State Board of Directors voted to close PEGS by no later than December 31, 2020.

Tri-State has been engaged with members of the local community in and around Prewitt and those near PEGS as it plans for closure of the facility. Tri-State is committed to supporting our employees and the communities we operate in that are affected by the transition. Tri-State is working with the local community to ease the impact of facility closure, as much as possible. Among other efforts, Tri-State is discussing options with the McKinley Paper Company, located adjacent to PEGS, to continue supplying steam to McKinley Paper through the ongoing operation of the PEGS auxiliary boiler. To date, no decisions have been made about this or other options and discussions are on-going.

Since the PEGS main, coal-fired boiler will not be operating beyond 2020, the Air Quality Bureau and Tri-State have agreed that it would not be appropriate or necessary for further analysis of PEGS under the regional haze rule. In the context of reasonable progress goals under regional haze, the "remaining useful life" referred to in 40 CFR 308(d)(1)(i)(A) will conclude for PEGS in 2020, prior to NMED's proposal of a State Implementation Plan in 2021.

Tri-State appreciates the opportunity to have worked with NMED and the Air Quality Bureau on the development of the reasonable progress four-factor analysis prescribed by the regional haze rule. Should you or your staff have any questions or need additional information please contact Doug Lempke of our staff at 303-254-3590.

Sincerely,

Barbara A. Walz

Subject: NSR Technical Revision Permit Application for Permit #PSD-0285-R4, Prewitt Escalante Generating Station (PEGS)

To Whom it May Concern:

Attached please find two (2) hardcopies and two (2) electronic (CD) copies of the 20.2.72 NMAC Technical Permit Application for Tri-State Generation and Transmission Association, Inc (Tri-State) Prewitt Escalante Generating Station (PEGS). This letter is attached to the application copy that has the original notarized signature page (Section 22), along with an application submittal fee of $500.

PEGS is a single unit coal-fired electric generating station owned and operated by Tri-State. With this technical revision permit application, Tri-State is permanently shutting down the coal-fired boiler, associated coal and limestone handling equipment, and the cooling tower on or before December 31, 2020. Additionally, Tri-State will be transferring ownership and operation of the existing auxiliary boiler and water treatment plant to McKinley Paper Company's Prewitt Mill. Transfer of ownership of the existing auxiliary boiler and water treatment plant to McKinley Paper Company's Prewitt Mill is scheduled for September 30, 2020. Tri-State will continue to operate the existing auxiliary boiler and water treatment plant under the revised PEGS permit until McKinley Paper Company is issued a minor NSR permit.

Please let me know if you have any questions or need additional information.

Sincerely,

Paul Wade
